# Outline

- Part I Statement of the guidance problem
- Part II Autonomous guidance law architecture
- Part III Flatness-based trajectory planning
- Part IV Fault-tolerant trajectory planning
- Part V Integration of aerologic disturbances
- Part VI Convexification methodology

Part I  
Guidance problem statement:  
TAEM and A&L phases

# US Space Shuttle Orbiter STS-1

Space transportation system

- Mission:

*Insertion in low-Earth orbit of payloads and crews*

- First flight: 04/12/1981,
- Total number of flights: 126 as of 05/11/2009,
- Mean cost per mission: from \$300M to \$400M (2006),
- 3 operational vehicles until 2010 (fleet retirement).

main features	symbol	value
reference area [ $m^2$ ]	$S$	249.9
overall mass at injection point [ $kg$ ]	$m$	89930
wingspan [ $m$ ]	$b$	23.8
chord length [ $m$ ]	$\bar{c}$	12
max. gliding ratio (for $M \leq 3$ )	$(L/D)_{\max}$	$\approx 4$
inertial moments [ $kg/m^2$ ]	$I_{xx}$	1213866
	$I_{yy}$	9378654
	$I_{zz}$	9759518
	$I_{xz}$	228209
inertial products [ $kg/m^2$ ]	$I_{xy}$	6136
	$I_{yz}$	2972
	$x_{mrc}$	17
moments reference center [ $m$ ]	$y_{mrc}$	0
	$z_{mrc}$	-1.2
	$x_{cg}$	27.3
center of gravity [ $m$ ]	$y_{cg}$	0
	$z_{cg}$	9.5

Orbiter STS-1 main features

# US Space Shuttle Orbiter STS-1

control surface	symbol	deflection limits		deflection rates (deg/s)
		min (deg)	max (deg)	
<b>elevons</b>				
pitching	$\delta_e$	-35	20	20
aileron	$\delta_a$	-35	20	20
<b>rudder</b>	$\delta_r$	-22.8	22.8	10
<b>speedbrake</b>	$\delta_{sb}$	0	87.2	5

*control surfaces deflections limits and rates*

# Atmospheric reentry mission

## 3 main phases:

- Hypersonic entry
- Terminal Area Energy Management (TAEM)
- Autoland phase (A&L)

*sketch of an atmospheric reentry mission*

# TAEM guidance problem

	$\alpha$	$\mu$	$\beta$
lower bound [deg]	0	-80	-3
upper bound [deg]	25	80	3
max. rate [deg/s]	2	5	2

*guidance inputs bounds and rates*

## Objectives:

- dissipate the total energy of the vehicle from entry point (TEP) down to nominal exit point (ALI)
- align the vehicle with the extended runway centerline to ensure a safe autoland

## requirements

### mechanical constraints

max. load factor $\Gamma_{max}$ [g]	< 2.5
max. dynamic pressure $\bar{q}_{max}$ [kPa]	< 16

### kinematic constraints at ALI

Mach number	0.5
altitude [km]	5
downrange [km]	10
crossrange [km]	0
final heading [deg]	headwind landing
flight path angle [deg]	-27

*TAEM guidance constraints*

## 2 kinds of constraints:

- *trajectory constraints:* dynamic pressure, load factor
- *mission constraints:* kinematic constraints at ALI

# TAEM guidance problem

- 3 dof model in flat Earth coordinates:

$$\begin{array}{l}
 \textit{position} \\
 \left\{ \begin{array}{l} \dot{x} = V \cos \chi \cos \gamma, \\ \dot{y} = V \sin \chi \cos \gamma, \\ \dot{h} = V \sin \gamma. \end{array} \right.
 \end{array}
 \qquad
 \begin{array}{l}
 \textit{velocity} \\
 \left\{ \begin{array}{l} \dot{V} = -\frac{D(\alpha, M)}{m} - g \sin \gamma, \\ \dot{\gamma} = \frac{1}{mV} (L(\alpha, M) \cos \mu - Y(\beta, M) \sin \mu) - \frac{g}{V} \cos \gamma, \\ \dot{\chi} = \frac{1}{mV \cos \gamma} (L(\alpha, M) \sin \mu + Y(\beta, M) \cos \mu). \end{array} \right.
 \end{array}$$

where  $L(\alpha, M) = \bar{q} SC_{L_0}(\alpha, M)$ , and  $\bar{q} = \frac{1}{2} \rho V^2$ : dynamic pressure,  
 $D(\alpha, M) = \bar{q} SC_{D_0}(\alpha, M)$ ,  $g$ : constant gravitational acceleration,  
 $Y(\beta, M) = \bar{q} SC_{Y_0}(\beta, M)$ .  $\rho = \rho_0 \exp(-h/H_0)$ : atmospheric density.

- the corresponding optimal control problem is given (in the state space) by:

$$\begin{array}{l}
 \min_{x(t), u(t)} \mathcal{C}_0(x(t_0), u(t_0)) + \int_{t_0}^{t_f} \mathcal{C}_t(x(t), u(t)) dt + \mathcal{C}_f(x(t_f), u(t_f)) \\
 \text{t.q.} \\
 \dot{x}(t) = f(x(t), u(t)), \quad t \in [t_0, t_f], \\
 x(t_0) = x_0, \\
 u(t_0) = u_0, \\
 0 \leq \Gamma(x(t), u(t)) \leq \Gamma_{\max}, \quad t \in [t_0, t_f], \\
 0 \leq \bar{q}(x(t)) \leq \bar{q}_{\max}, \quad t \in [t_0, t_f], \\
 u_{\min} \leq u(t) \leq u_{\max}, \quad t \in [t_0, t_f], \\
 x(t_f) = x_f, \\
 u(t_f) = u_f.
 \end{array}$$

# A&L guidance problem

## Objectives:

- bring the vehicle from ALI point down to wheels stop on the runway
- simpler problem than TAEM (longitudinal motion only)

## Constraints:

- similar to TAEM phase

	requirements
<b>mechanical constraints</b>	
max. load factor $\Gamma_{\max}$ [g]	< 2.5
max. dynamic pressure $\bar{q}_{\max}$ [kPa]	< 16
<b>kinematic constraints at touchdown</b>	
relative velocity [m/s]	90
altitude [km]	runway altitude
downrange [km]	0
flight path angle [deg]	-3

## A&L guidance constraints

# A&L guidance problem

- 3 dof equations of motion in flat Earth coordinates are given by

$$\begin{cases} \dot{x} = V \cos \gamma, \\ \dot{h} = V \sin \gamma, \\ \dot{V} = -\frac{D(\alpha, M)}{m} - g \sin \gamma, \\ \dot{\gamma} = \frac{L(\alpha, M)}{mV} - \frac{g}{V} \cos \gamma, \end{cases}$$

where  $\bar{q} = \frac{1}{2}\rho V^2$  and  $\Gamma = \frac{\sqrt{L^2(\alpha, M) + D^2(\alpha, M)}}{mg}$ : total load factor.

- the corresponding optimal control problem is given (in the state space) by:

$$\begin{aligned} & \min_{x(t), u(t)} \mathcal{C}_0(x(t_0), u(t_0)) + \int_{t_0}^{t_f} \mathcal{C}_t(x(t), u(t)) dt + \mathcal{C}_f(x(t_f), u(t_f)) \\ & \text{t.q.} \\ & \dot{x}(t) = f(x(t), u(t)), \quad t \in [t_0, t_f], \\ & x(t_0) = x_0, \\ & u(t_0) = u_0, \\ & 0 \leq \Gamma(x(t), u(t)) \leq \Gamma_{\max}, \quad t \in [t_0, t_f], \\ & 0 \leq \bar{q}(x(t)) \leq \bar{q}_{\max}, \quad t \in [t_0, t_f], \\ & u_{\min} \leq u(t) \leq u_{\max}, \quad t \in [t_0, t_f], \\ & x(t_f) = x_f, \\ & u(t_f) = u_f. \end{aligned}$$

# Part II

## Autonomous guidance law architecture

## Objectives:

- *Design of an autonomous guidance law for atmospheric reentry vehicles*
- provide a level of fault tolerance against severe aerodynamic control surfaces failures
- onboard processing to react quickly to manage a faulty situation
- provide high levels of performance and robustness

## Motivation:

- to improve in-service guidance schemes by locally assigning autonomy and responsibility to the vehicle, exempting the ground segment from “low level” operational tasks, so that it can ensure more efficiently its mission of global coordination

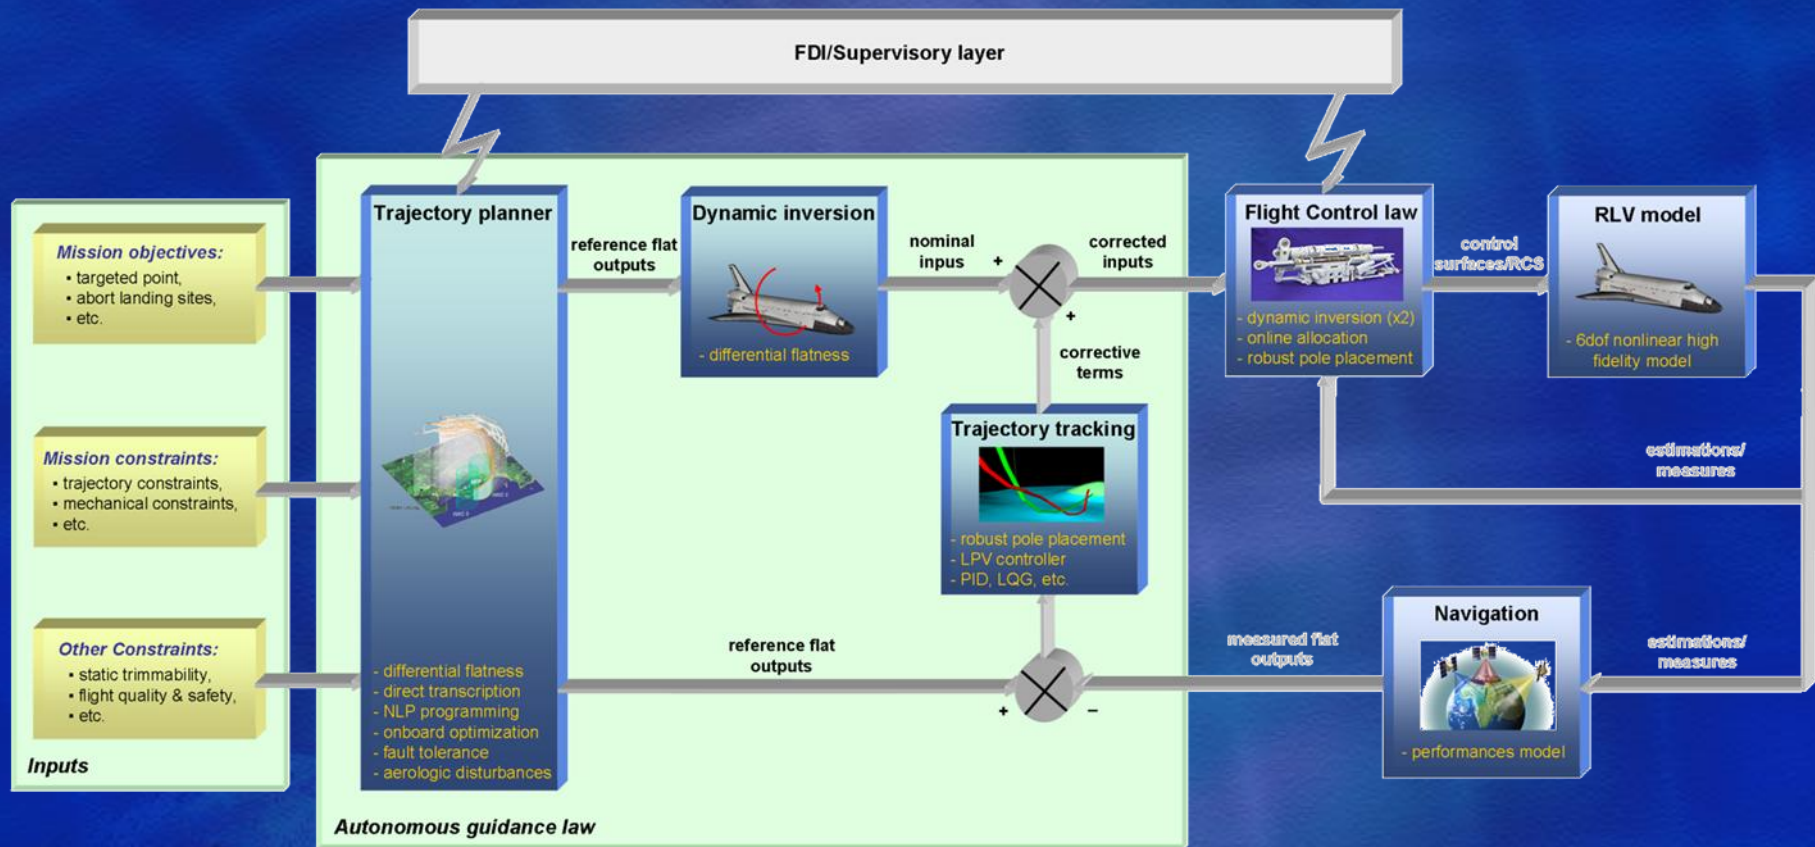

## Methodological approach:

- use *flatness approach* as the baseline tool to perform onboard processing
- atmospheric reentry trajectory planning/reshaping in faulty situations
- integration of static aerologic disturbances
- convexification of the optimal control problem to guarantee convergence

## Constraints:

- reliable FDI indicators

# Autonomous guidance law: functional architecture

*functional architecture of the autonomous guidance law*

The proposed autonomous guidance law consists of:

- a Fault-Tolerant Onboard Path Planner (FTOPP)
- a Nonlinear Dynamic Inversion block based on flatness approach
- a trajectory tracking controller (LPV controller, not presented)

*This presentation focus on the design of the FTOPP and the NDI functions*

# Part III

## Flatness-based trajectory planning

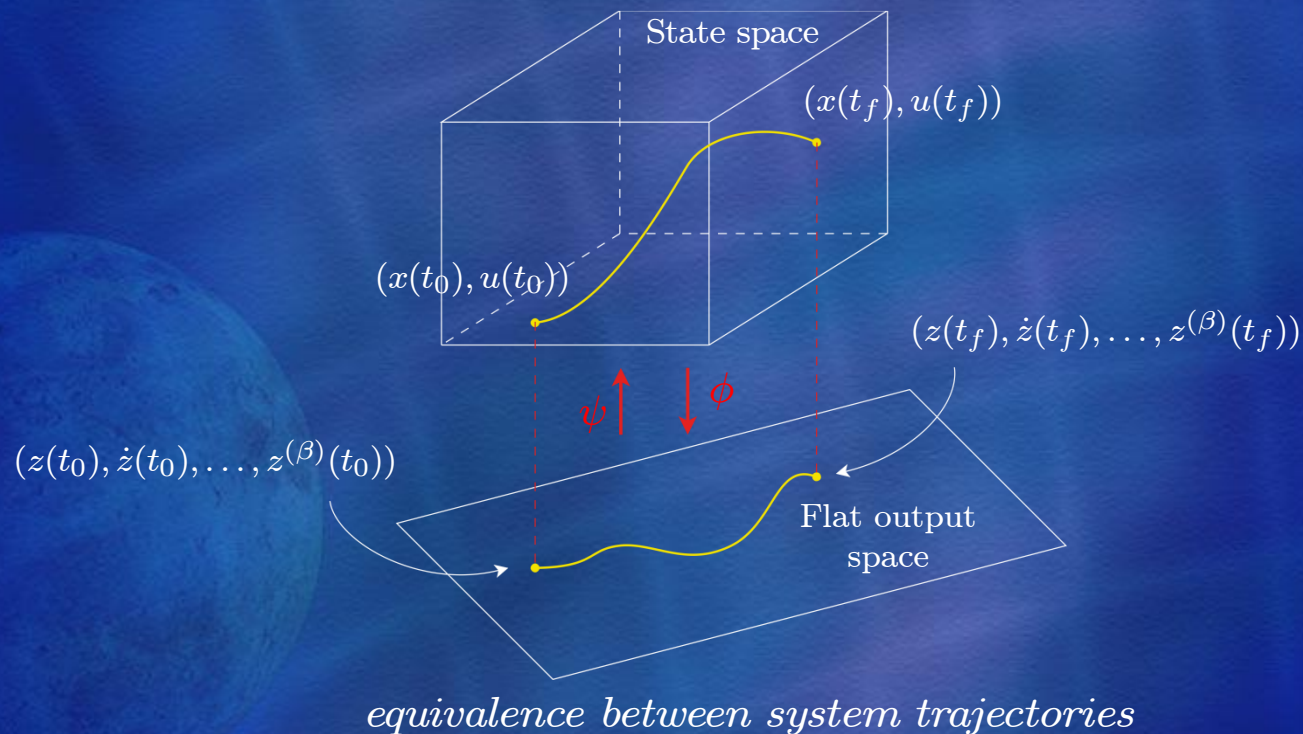

# Flatness-based trajectory planning

## Advantages of flatness approach for trajectory planning applications

- *minimum number of decision variables in the OCP*: the optimization variables become the flat output of the system
- *integration-free optimization problem*: the system dynamics is intrinsically satisfied
- avoid emergence of *unobservable dynamics* (which may be potentially unstable)

## Main drawback:

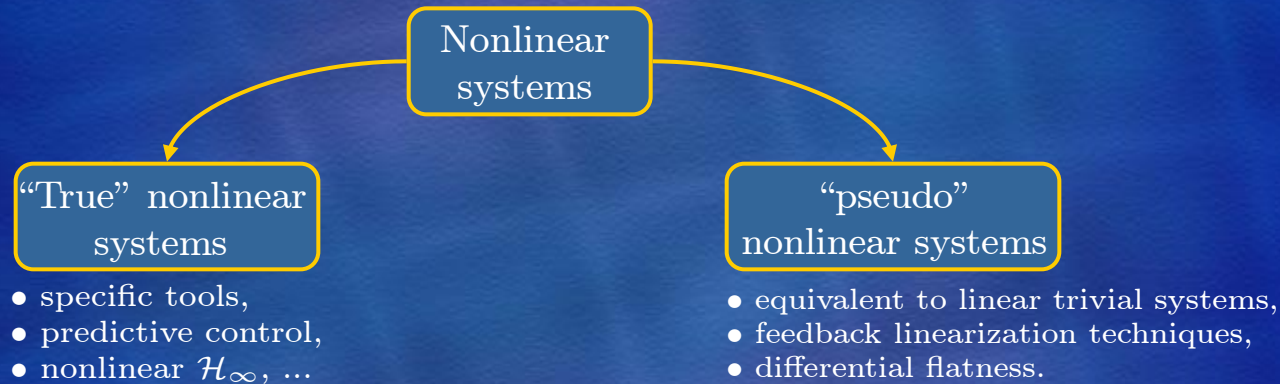

- often highly nonlinear and nonconvex OCP in the flat output space

# Differential flatness: a brief overview

- *Differential flatness* concept introduced in 1991 by Fliess, Lévine, Martin and Rouchon: deals with “pseudo” nonlinear systems

**Definition** (Differential flatness (Fliess *et al.*, 1995)). *The nonlinear system  $\dot{x} = f(x, u)$  is differentially flat (or, shortly flat) if and only if there exists a collection  $z$  of  $m$  variables, whose elements are differentially independant, defined by:*

$$z = \phi \left( x, u, \dot{u}, \dots, u^{(\alpha)} \right),$$

*such that*

$$\begin{cases} x = \psi_x \left( z, \dot{z}, \dots, z^{(\beta-1)} \right) \\ u = \psi_u \left( z, \dot{z}, \dots, z^{(\beta)} \right) \end{cases}$$

*where  $\psi_x$  and  $\psi_u$  are smooth applications over the manifold  $X$ , and  $\alpha = (\alpha_1, \dots, \alpha_m)$ ,  $\beta = (\beta_1, \dots, \beta_m)$  are finite  $m$ -tuples of integers.*

*The collection  $z \in \mathbb{R}^m$  is called a flat output (or linearizing output).*

# Differential flatness: a brief overview

## A simple example

- kinematic equations:

$$\begin{cases} \dot{x} = u \cos \theta \\ \dot{y} = u \sin \theta \\ \dot{\theta} = \frac{u}{l} \tan \varphi \end{cases}$$

- implicit form:

$$\dot{x} \sin \theta - \dot{y} \cos \theta = 0$$

- candidate flat output:  $(x, y)$

- state and inputs wrt the flat output and its derivatives:

$$\theta = \arctan \left( \frac{\dot{y}}{\dot{x}} \right), u = \sqrt{\dot{x}^2 + \dot{y}^2}, \varphi = \arctan \left( \frac{l(\ddot{y}\dot{x} - \dot{y}\ddot{x})}{(\dot{x}^2 + \dot{y}^2)^{\frac{3}{2}}} \right)$$

## Flatness necessary and sufficient conditions

- General formulations of flatness necessary and sufficient conditions are now well-established for linear and nonlinear systems governed by ordinary differential equations (Lévine and Nguyen (2003), Lévine (2006))
- Based on classical tools coming from linear polynomial algebra: *Smith decompositions*
- Cartan's generalized *moving frame structure equations* are used to find an integrable basis

- Theoretical contribution to flatness theory
- Joint work with Prof. Jean Lévine at the Centre Automatique et Systèmes (CAS), École des Mines de Paris, France.
- Extension of the results obtained for linear systems governed by ordinary differential equations
- Development of a simple constructive algorithm to check if a linear system is  $\delta$ -flat and, if so, to compute a candidate  $\delta$ -flat output:
  - Based on classical concepts coming from linear polynomial algebra: *Smith decompositions*
  - The system is considered in *implicit form* to account for its natural property of invariance by endogenous dynamic feedback
- See PhD dissertation for more details
- A journal paper under preparation

- Consider a nonlinear system defined on a differentiable manifold by

$$\dot{x}(t) = f(x(t), u(t)),$$

where  $x : [t_0, t_f] \mapsto \mathbb{R}^n$ : state of size  $n$  and  $u : [t_0, t_f] \mapsto \mathbb{R}^m$ : control inputs vector of size  $m$ .

- We consider that all the the trajectory planning objectives, defined either at the “mission” level or at the “vehicle” level, may be classically formulated as a constrained optimal control problem (OCP)

$$\min_{x(t), u(t)} \mathcal{C}_0(x(t_0), u(t_0, t_0)) + \int_{t_0}^{t_f} \mathcal{C}_t(x(t), u(t), t) dt + \mathcal{C}_f(x(t_f), u(t_f), t_f)$$

s.t.

$$\begin{aligned} \dot{x}(t) &= f(x(t), u(t)), & t \in [t_0, t_f], \\ l_0 &\leq A_0 x(t_0) + B_0 u(t_0) \leq u_0, \\ l_t &\leq A_t x(t) + B_t u(t) \leq u_t, & t \in [t_0, t_f], \\ l_f &\leq A_f x(t_f) + B_f u(t_f) \leq u_f, \\ L_0 &\leq c_0(x(t_0), u(t_0)) \leq U_0, \\ L_t &\leq c_t(x(t), u(t)) \leq U_t, & t \in [t_0, t_f], \\ L_f &\leq c_f(x(t_f), u(t_f)) \leq U_f. \end{aligned}$$

# Flatness-based trajectory planning

- the *equivalent* optimal control problem in the flat output space is given by

$$\min_{\bar{z}(t)} \mathcal{C}_0(\psi_x(\bar{z}(t_0)), \psi_u(\bar{z}(t_0)), t_0) + \int_{t_0}^{t_f} \mathcal{C}_t(\psi_x(\bar{z}(t)), \psi_u(\bar{z}(t)), t) dt$$

$$+ \mathcal{C}_f(\psi_x(\bar{z}(t_f)), \psi_u(\bar{z}(t_f)), t_f)$$

s.t.

$$\begin{aligned} l_0 &\leq A_0 \bar{z}(t_0) \leq u_0, \\ l_t &\leq A_t \bar{z}(t) \leq u_t, & t \in [t_0, t_f], \\ l_f &\leq A_f \bar{z}(t_f) \leq u_f, \\ L_0 &\leq c_0(\psi_x(\bar{z}(t_0)), \psi_u(\bar{z}(t_0))) \leq U_0, \\ L_t &\leq c_t(\psi_x(\bar{z}(t)), \psi_u(\bar{z}(t))) \leq U_t, & t \in [t_0, t_f], \\ L_f &\leq c_f(\psi_x(\bar{z}(t_f)), \psi_u(\bar{z}(t_f))) \leq U_f. \end{aligned}$$

where the flat output

$$z = \phi(x, u, \dot{u}, \dots, u^{(\alpha)})$$

satisfies

$$\begin{cases} x = \psi_x(z, \dot{z}, \dots, z^{(\beta-1)}), \\ u = \psi_u(z, \dot{z}, \dots, z^{(\beta)}). \end{cases}$$

- OCP decision variables:  $\bar{z} = (z_1, \dots, z_m, \dot{z}_1, \dots, \dot{z}_m, \dots, z_1^{(2)}, \dots, z_m^{(2)}, \dots)$

# Direct transcription into an NLP problem

1) parametrization of the OCP decision variables by means of B-spline curves

$$\begin{aligned} z_1(t, p^1) &= \sum_{i=0}^{q_1} c_i^1 \mathcal{B}_{i,k_1}(t) && \text{for the knot breakpoint sequence } \eta_1, \\ z_2(t, p^2) &= \sum_{i=0}^{q_2} c_i^2 \mathcal{B}_{i,k_2}(t) && \text{for the knot breakpoint sequence } \eta_2, \\ &\vdots && \\ z_m(t, p^m) &= \sum_{i=0}^{q_m} c_i^m \mathcal{B}_{i,k_m}(t) && \text{for the knot breakpoint sequence } \eta_m, \end{aligned}$$

where  $\mathcal{B}_{i,k_j}(t)$  is the zero order derivative of the  $i$ -th function associated to the B-spline basis of order  $k_j$ , built on the knot breakpoint sequence  $\eta_j$ , and  $c_i^j$  is the corresponding vector of control points.

2) discretization of the optimal control problem over the time partition

$$t_0 = \tau_1 < \tau_2 < \dots < \tau_N = t_f,$$

where  $N$  is a predefined number of collocation points.

The cost functional is approximated by means of a quadrature rule.

# Direct transcription into an NLP problem

- by setting  $u_i \triangleq (c_1^i, c_2^i, \dots, c_{l_i(k_i - s_i) + s_i}^i) \in \mathbb{R}^{l_i(k_i - s_i) + s_i}$ , the set of all control points of the B-splines can be defined by

$$u \triangleq (u_1, \dots, u_m).$$

- the OCP constraints, evaluated at every collocation points are given by

$$\Lambda(u) = \left( \Lambda_{li}(u), \Lambda_{nli}(u), \Lambda_{lt}^1(u), \dots, \Lambda_{lt}^N(u), \Lambda_{nlt}^1(u), \dots, \Lambda_{nlt}^N(u), \Lambda_{lf}(u), \Lambda_{nlf}(u) \right),$$

$$\left\{ \begin{array}{ll} \Lambda_{lt}^j(u) & = A_t \bar{z}(t_j), & j = 1, \dots, N, \\ \Lambda_{nlt}^j(u) & = c_t(\psi_x(\bar{z}(t_j)), \psi_u(\bar{z}(t_j))), & j = 1, \dots, N, \\ \Lambda_{li}(u) & = A_0 \bar{z}(t_0), \\ \Lambda_{lf}(u) & = A_f \bar{z}(t_f), \\ \Lambda_{nli}(u) & = c_0(\psi_x(\bar{z}(t_0)), \psi_u(\bar{z}(t_0))), \\ \Lambda_{nlf}(u) & = c_f(\psi_x(\bar{z}(t_f)), \psi_u(\bar{z}(t_f))). \end{array} \right.$$

- the B-splines control points become the new decision variables of the nonlinear programming (NLP) problem

$$\begin{array}{ll} \min_{u \in \mathbb{R}^M} & J(u) \\ \text{s.t.} & L_b \leq \Lambda(u) \leq U_b, \\ & \text{where } M = \sum_{i=1}^m l_i(k_i - s_i) + s_i. \end{array}$$

- the NLP problem can be solved onboard by using NPSOL, SNOPT, KNITRO, ...

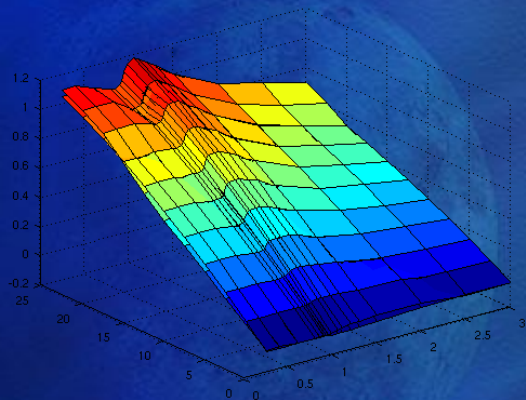

# Flatness-based TAEM trajectory planning

## Assumptions:

- flat Earth: coriolis and centrifugal forces neglected,
- symmetric flight:  $\beta = 0$  (typical guidance assumption),
- no cost functional considered: feasibility problem only

Tabulated aerodynamic force coefficients in clean configuration are approximated by means of:

- principal component analysis (PCA): *results in a decoupling of angle-of-attack and Mach number variables,*
- analytical neural networks (ANN): *parsimonious approximators of smooth multivariate functions*

lift coefficient  $C_{L_0}$

gliding ratio  $C_{L_0}/C_{D_0}$

drag coefficient  $C_{D_0}$

# Flatness-based TAEM trajectory planning

- time being not a relevant parameter during atmospheric reentry, the 3 dof model is reparameterized wrt. free trajectory duration parameter  $\lambda$

$$\tau = \frac{t}{\lambda}, \text{ with } 0 \cdot \tau \cdot 1: \text{ normalized time} \quad \longrightarrow \quad (\cdot)' = \frac{d(\cdot)}{d\tau} = \lambda \frac{d(\cdot)}{dt},$$

- the new point-mass model is given by

<i>position</i>	<i>velocity</i>
$\begin{cases} x' = \lambda V \cos \chi \cos \gamma, \\ y' = \lambda V \sin \chi \cos \gamma, \\ h' = \lambda V \sin \gamma. \end{cases}$	$\begin{cases} V' = \lambda \left( -\frac{D}{m} - g \sin \gamma \right), \\ \gamma' = \lambda \left( \frac{L \cos \mu}{mV} - \frac{g}{V} \cos \gamma \right), \\ \chi' = \lambda \frac{L \sin \mu}{mV \cos \gamma}. \end{cases}$

- this model is not flat since  $\beta = 0$ , but the autonomous observable may be parameterized wrt.  $z_1 = x$ ,  $z_2 = y$  and  $z_3 = h$  and the parameter  $\lambda$

<u>states:</u>	$V = \frac{\sqrt{z_1'^2 + z_2'^2 + z_3'^2}}{\lambda},$	$V' = \frac{z_1' z_1'' + z_2' z_2'' + z_3' z_3''}{\lambda \sqrt{z_1'^2 + z_2'^2 + z_3'^2}},$
$\gamma$	$= \arctan \left( \frac{z_3'}{\sqrt{z_1'^2 + z_2'^2}} \right),$	$\gamma' = \frac{z_3'' (z_1'^2 + z_2'^2) - z_3' (z_1' z_1'' + z_2' z_2'')}{(z_1'^2 + z_2'^2 + z_3'^2) \sqrt{z_1'^2 + z_2'^2}},$
$\chi$	$= \arctan \left( \frac{z_2'}{z_1'} \right),$	$\chi' = \frac{z_2'' z_1' - z_2' z_1''}{z_1'^2 + z_2'^2}.$

inputs:  $\mu = \arctan \left( \frac{\chi' \cos \gamma}{\gamma' + \frac{g \cos \gamma}{V} \lambda} \right), \alpha = \frac{2m}{a_1 f_{C_{L_0}}(M) \rho S V \cos \mu} \left( \frac{\gamma'}{\lambda} + \frac{g \cos \gamma}{V} \right) - \frac{a_0}{a_1},$

where  $C_{L_0}(\alpha, M) = (a_0 + a_1 \alpha) f_{C_{L_0}}(M),$

equality constraint:  $\Lambda_\tau(x, u) = \frac{V'}{\lambda} + g \sin \gamma + \frac{1}{2} \frac{\rho S V^2 C_{D_0}(\alpha, M)}{m} = 0,$

The corresponding optimal control problem in the flat output space is given by

find  $(\bar{z}(t), \lambda)$

s.t.

$$\begin{aligned}
 & \psi_x(\bar{z}(\tau_0), \lambda) = x_0, \\
 & \psi_u(\bar{z}(\tau_0), \lambda) = u_0, \\
 & \Lambda_\tau(\psi_x(\bar{z}(\tau), \lambda), \psi_u(\bar{z}(\tau), \lambda)) = 0, \quad \tau \in [\tau_0, \tau_f], \\
 & 0 \leq \Gamma(\psi_x(\bar{z}(\tau), \lambda), \psi_u(\bar{z}(\tau), \lambda)) \leq \Gamma_{\max}, \quad \tau \in [\tau_0, \tau_f], \\
 & 0 \leq \bar{q}(\psi_x(\bar{z}(\tau), \lambda)) \leq \bar{q}_{\max}, \quad \tau \in [\tau_0, \tau_f], \\
 & u_{\min} \leq \psi_u(\bar{z}(\tau), \lambda) \leq u_{\max}, \quad \tau \in [\tau_0, \tau_f], \\
 & \psi_x(\bar{z}(\tau_f), \lambda) = x_f, \\
 & \psi_u(\bar{z}(\tau_f), \lambda) = u_f,
 \end{aligned}$$

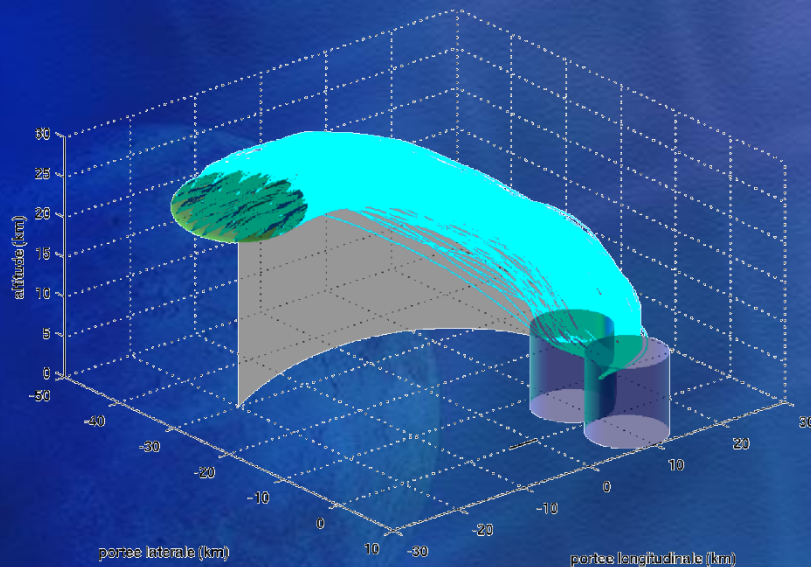

where  $\bar{z} = (z_1, z_2, z_3, \dot{z}_1, \dot{z}_2, \dot{z}_3, \ddot{z}_1, \ddot{z}_2, \ddot{z}_3), \tau_0 = 0$  and  $\tau_f = 1.$

# Flatness-based TAEM trajectory planning

Part IV  
Fault-tolerant trajectory planning

## Main objective:

*Design of a fault-tolerant trajectory planner by flatness approach*

## Motivations:

- flight control law reconfiguration and/or guidance controller adaptation may not be sufficient to recover the vehicle from strong faulty situations,
- aerodynamic forces may change significantly in case of multiple actuators faults

## How?

- prediction of surface failure effects at every flight conditions: *trimmability maps*
- *1st solution:* explicit integration of flight quality constraints in the optimal control problem
- *2nd solution:* controlled replanning with exogenous reconfiguration signals (off-line modeling of the trimmability maps)

## Trimmability maps:

- Introduced in trajectory planning applications by Air Force Research Lab. (Oppenheimer, 2004)
- Used to obtain the Mach- $\alpha$  regions over which the vehicle can be statically trimmed along the trajectory

**Problem** (static trimmability problem (Oppenheimer, 2004)). *Let  $\delta$  be the control surfaces deflection vector associated to rolling, pitching and yawing moments defined respectively by  $C_{l_\delta}(\alpha, M, \delta)$ ,  $C_{m_\delta}(\alpha, M, \delta)$  and  $C_{n_\delta}(\alpha, M, \delta)$ . The pitching moment coefficient in clean configuration is denoted by  $C_{m_0}(\alpha, M)$ . The static trimmability problem is then defined by the feasibility problem*

$$\min_{\delta} J_D = \min_{\delta} \left\| \begin{bmatrix} C_{l_\delta}(\alpha_i, M_j, \delta) \\ C_{m_\delta}(\alpha_i, M_j, \delta) \\ C_{n_\delta}(\alpha_i, M_j, \delta) \end{bmatrix} - \begin{bmatrix} 0 \\ -C_{m_0}(\alpha_i, M_j) \\ 0 \end{bmatrix} \right\|_l$$

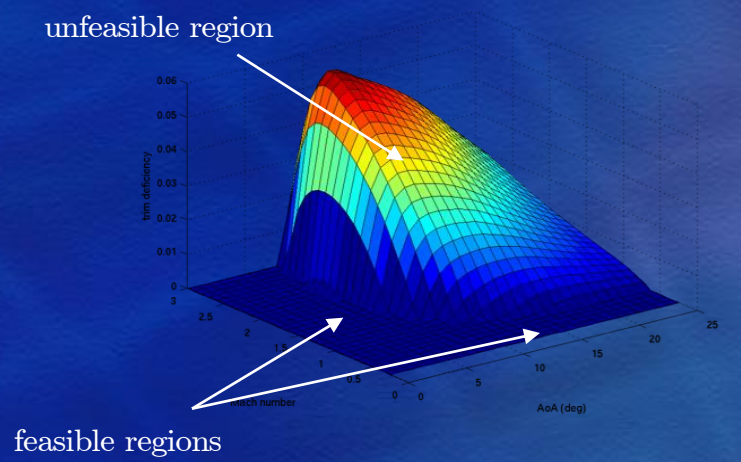

*s.t.*

$$\underline{\delta} \cdot \delta \cdot \bar{\delta},$$

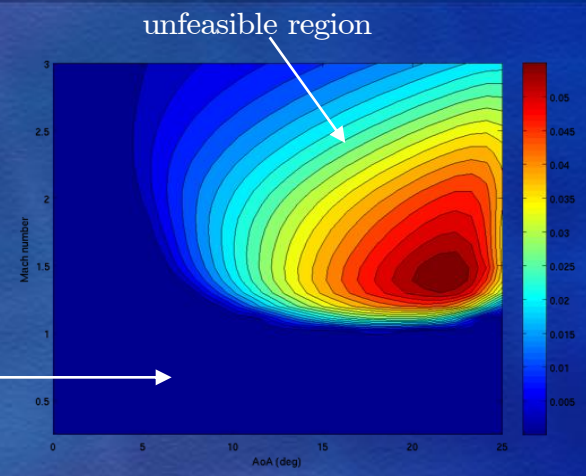

*at each point  $(\alpha_i, M_j)$  of the aerodynamic database, where  $l$  is a norm.*

# Fault-tolerant trajectory planning

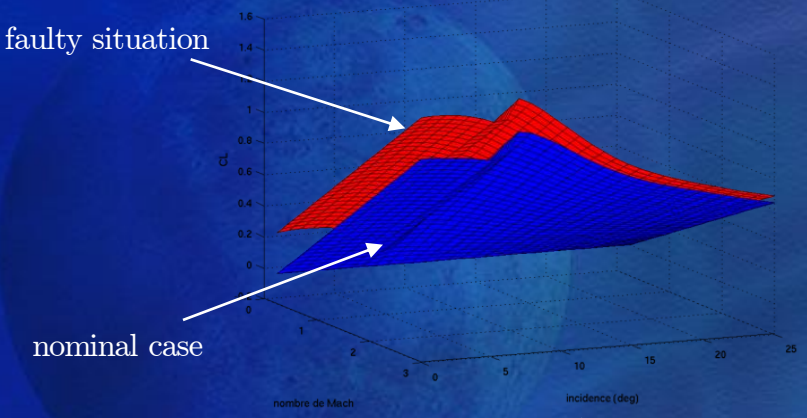

*example of 3D trimmability map*

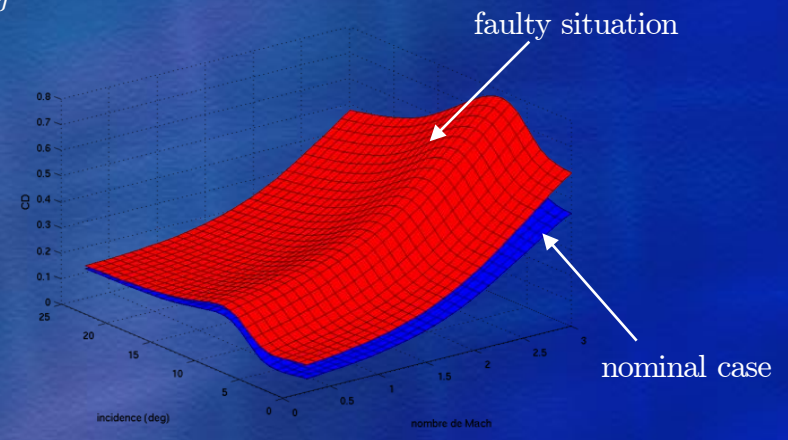

*projection in the Mach- $\alpha$  space*

- Control surfaces failures effects on the lift and drag coefficients at the point  $(\alpha_i, M_j)$  and for  $\delta_{i,j}^*$ :

$$\begin{cases} C_L(\alpha_i, M_j) = C_{L0}(\alpha_i, M_j) + C_{L\delta_{i,j}^*}(\alpha_i, M_j, \delta_{i,j}^*), \\ C_D(\alpha_i, M_j) = C_{D0}(\alpha_i, M_j) + C_{D\delta_{i,j}^*}(\alpha_i, M_j, \delta_{i,j}^*). \end{cases}$$

*lift coefficient w/o faults*

*drag coefficient w/o faults*

# Fault-tolerant trajectory planning

- 1st solution:

*explicit integration of trimmability constraints in the optimal control problem, expressed in the flat output space*

$$\min_{\bar{z}(t), \delta(t)} \mathcal{C}_0(\psi_x(\bar{z}(t_0)), \psi_u(\bar{z}(t_0), \delta(t_0)), t_0) + \int_{t_0}^{t_f} \mathcal{C}_t(\psi_x(\bar{z}(t)), \psi_u(\bar{z}(t), \delta(t)), t) dt + \mathcal{C}_f(\psi_x(\bar{z}(t_f)), \psi_u(\bar{z}(t_f), \delta(t_f)), t_f)$$

s.t.

$$\begin{aligned} l_0 &\leq A_0 \bar{z}(t_0) \leq u_0, \\ l_t &\leq A_t \bar{z}(t) \leq u_t, \quad t \in [t_0, t_f], \\ l_f &\leq A_f \bar{z}(t_f) \leq u_f, \\ L_0 &\leq c_0(\psi_x(\bar{z}(t_0)), \psi_u(\bar{z}(t_0), \delta(t_0))) \leq U_0, \\ L_t &\leq c_t(\psi_x(\bar{z}(t)), \psi_u(\bar{z}(t), \delta(t))) \leq U_t, \quad t \in [t_0, t_f], \\ L_f &\leq c_f(\psi_x(\bar{z}(t_f)), \psi_u(\bar{z}(t_f), \delta(t_f))) \leq U_f, \end{aligned}$$

and

$$\underline{\delta} \leq \delta(t) \leq \bar{\delta}, \quad t \in [t_0, t_f].$$

- Advantages: the small number of assumptions about faults types and magnitudes provides a good level of autonomy to the trajectory replanning algorithm.
- Drawbacks: due to the additional number of optimization variables  $p$  corresponding to aerodynamic control surfaces, the total number of decision variables of the optimal control problem increases from  $n_{\bar{z}}$  to  $n_{\bar{z}} + p$ , which directly affects the CPU time.

# Fault-tolerant trajectory planning

- 2nd solution:

*Off-line computation/modelling of trimmability maps, and online interpolation wrt. the faulty situation*

$$\min_{\bar{z}(t)} \quad \mathcal{C}_0(\psi_x(\bar{z}(t_0)), \psi_u(\bar{z}(t_0), \delta_g), t_0) + \int_{t_0}^{t_f} \mathcal{C}_t(\psi_x(\bar{z}(t)), \psi_u(\bar{z}(t), \delta_g), t) dt$$

$$+ \mathcal{C}_f(\psi_x(\bar{z}(t_f)), \psi_u(\bar{z}(t_f), \delta_g), t_f)$$

s.t.

$$\begin{array}{llllll} l_0 & \leq & A_0 \bar{z}(t_0) & \leq & u_0, & \\ l_t & \leq & A_t \bar{z}(t) & \leq & u_t, & t \in [t_0, t_f], \\ l_f & \leq & A_f \bar{z}(t_f) & \leq & u_f, & \\ L_0 & \leq & c_0(\psi_x(\bar{z}(t_0)), \psi_u(\bar{z}(t_0), \delta_g)) & \leq & U_0, & \\ L_t & \leq & c_t(\psi_x(\bar{z}(t)), \psi_u(\bar{z}(t), \delta_g)) & \leq & U_t, & t \in [t_0, t_f], \\ L_f & \leq & c_f(\psi_x(\bar{z}(t_f)), \psi_u(\bar{z}(t_f), \delta_g)) & \leq & U_f. & \end{array}$$

where  $\delta_g \in \Delta \triangleq \{\delta_{g_1}, \delta_{g_2}, \dots, \delta_{g_K}\}$  is a control surface deflection vector in faulty situation used to drive the optimal control problem.

- Advantages: no additional decision variables enter in the optimal control problem (optimization of flat outputs only): same CPU load as for the initial optimal control problem.

- Drawbacks: the off-line computation and modeling of feasible Mach- $\alpha$  corridors and aerodynamic coefficients in faulty situations requires to predefine a set of representative faulty scenarios, and a great amount of time.

projection in the  $(x, h)$  plane

Part VI  
Optimal control problem convexification

# Optimal control problem convexification

## Main objective:

*Convexification of the optimal control problem by deformable shapes.*

## Motivations:

- the OCP described in the flat output space is often highly nonlinear and nonconvex (Ross, 2006)
- to guarantee global convergence of NLP solvers

## How?

- the convexification problem is solved by a genetic algorithm in order to get a global solution
- development of a Matlab software library (by the author): OCEANS (Optimal Convexification by Evolutionary Algorithm aNd Superquadrics)

# Superquadric shapes

## Superquadrics:

- generalization in 3 dimensions of the superellipses (Barr, 1981)
- used to perform a trade-off between the complexity of the shapes and the numerical tractability in high order flat output spaces

*examples of 3D superquadrics*

## Advantages:

- compactness of the representation
- an explicit parametrization exists

## Drawbacks:

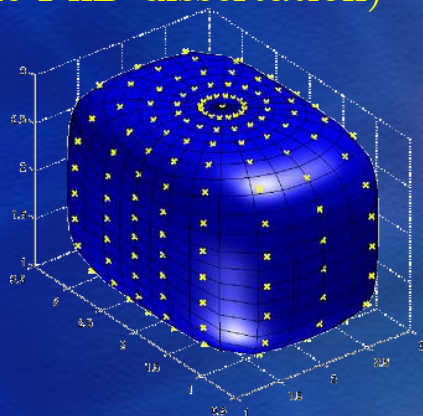

- limited number of shapes
- symmetric shapes only

*Necessity to obtain new mathematical results about  $n$ -D superquadrics and to introduce additional convexity-preserving geometric transformations*

# Superquadric shapes

Introduction of  $n$ -D transformations: rotation, translation and linear pinching (defined in the PhD dissertation)

*initial 3D superquadric*

Rotation

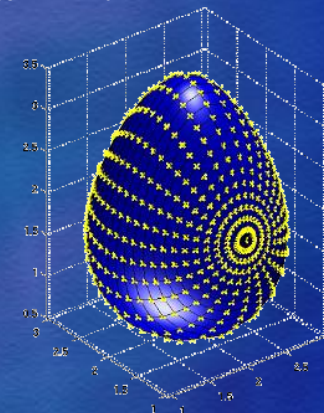

*effect of a 3D rotation*

*initial 3D superquadric*

Pinching

*effect of a linear pinching along z axis*

The set  $\Psi$  contains the sizing parameters needed to obtain a positioned, oriented and bended superquadric shape

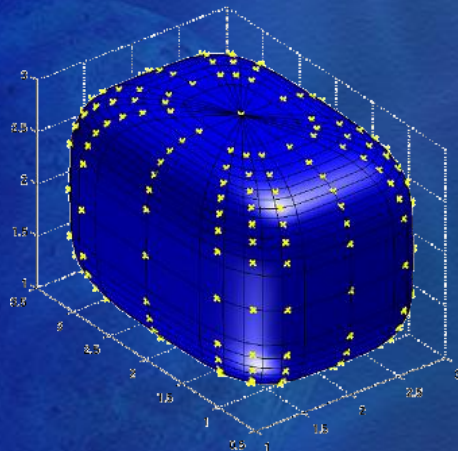

$$\Psi = \left\{ \underbrace{a_1, \dots, a_n}_{\text{semi-major axes}}, \underbrace{\varepsilon_1, \dots, \varepsilon_{n-1}}_{\text{roundness par.}}, \underbrace{\Phi_1, \dots, \Phi_{n(n+1)/2}}_{\text{rotation par.}}, \underbrace{d_1, \dots, d_n}_{\text{translation par.}}, \underbrace{v_1, \dots, v_{n-1}}_{\text{pinching par.}} \right\}$$

# Superquadric shapes

**Proposition** (trigonometric parametrization of a bended  $n$ -D superellipsoid (Morio,2008)).  
 Let  $\mathcal{S}$  a superquadric ellipsoid of size  $n$ , described by the vector  $\Psi$ . Then, the corresponding trigonometric parametrization, with cartesian coordinates  $x_i$ ,  $i = 1, \dots, n$ , is defined by

$$x_i = \begin{cases} a_1 (v_1 \sin^{\varepsilon_p - 1} \theta_{p-1} \prod_{j=p}^{n-1} \cos^{\varepsilon_j} \theta_j + 1) \prod_{k=1}^{n-1} \cos^{\varepsilon_k} \theta_k, & i = 1, \\ a_i (v_i \sin^{\varepsilon_p - 1} \theta_{p-1} \prod_{j=p}^{n-1} \cos^{\varepsilon_j} \theta_j + 1) \sin^{\varepsilon_{i-1}} \theta_{i-1} \prod_{k=i}^{n-1} \cos^{\varepsilon_k} \theta_k, & i = 2, \dots, n-1, \quad i \neq p, \\ a_p \sin^{\varepsilon_p - 1} \theta_{p-1} \prod_{j=p}^{n-1} \cos^{\varepsilon_j} \theta_j, & i = p, \\ a_n (v_n \sin^{\varepsilon_p - 1} \theta_{p-1} \prod_{j=p}^{n-1} \cos^{\varepsilon_j} \theta_j + 1) \sin^{\varepsilon_{n-1}} \theta_{n-1}, & i = n, \end{cases}$$

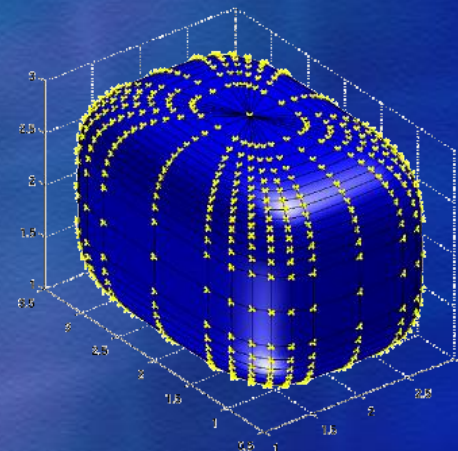

where  $p$  is the pinching direction ( $v_p = 0$ ). In addition, the vector of anomalies  $\theta$  satisfies  $\theta_i \in [-\pi, \pi[$  if  $i = 1$  and  $\theta_i \in [-\frac{\pi}{2}, \frac{\pi}{2}]$  if  $i = 2, \dots, n-1$ .

3D trigonometric parametrization

No. of anomalies

variation of the number of anomalies

**Proposition** (angle-center parametrization of a bended  $n$ -D superellipsoid (Morio,2008)).  
 Let  $\mathcal{S}$  be a superquadric ellipsoid of size  $n$ , described by the vector  $\Psi$ . Then, the corresponding angle-center parametrization, with cartesian coordinates  $x_i$ ,  $i = 1, \dots, n$ , is defined by

$$x_i = \begin{cases} r(\theta) \left( \frac{v_1}{a_p} r(\theta) \sin \theta_{p-1} \prod_{j=p}^{n-1} \cos \theta_j + 1 \right) \prod_{k=1}^{n-1} \cos \theta_k, & i = 1, \\ r(\theta) \left( \frac{v_i}{a_p} r(\theta) \sin \theta_{p-1} \prod_{j=p}^{n-1} \cos \theta_j + 1 \right) \sin \theta_{i-1} \prod_{k=i}^{n-1} \cos \theta_k, & i = 2, \dots, n-1, i \neq p, \\ r(\theta) \sin \theta_{p-1} \prod_{j=p}^{n-1} \cos \theta_j, & i = p, \\ r(\theta) \left( \frac{v_n}{a_p} r(\theta) \sin \theta_{p-1} \prod_{j=p}^{n-1} \cos \theta_j + 1 \right) \sin \theta_{n-1}, & i = n, \end{cases}$$

where  $p$  is the pinching direction ( $v_p = 0$ ). The radius  $r(\theta) = \frac{1}{\chi_{n,n}}$  is given by

$$\begin{cases} \chi_{n,2} = \left[ \left( \frac{\prod_{k=1}^{n-1} \cos \theta_k}{a_1} \right)^{\frac{2}{\varepsilon_1}} + \left( \frac{\sin \theta_1 \prod_{k=2}^{n-1} \cos \theta_k}{a_2} \right)^{\frac{2}{\varepsilon_1}} \right]^{\frac{\varepsilon_1}{2}}, & j = 2, \\ \chi_{n,j} = \left[ (\chi_{n,j-1})^{\frac{2}{\varepsilon_{j-1}}} + \left( \frac{\sin \theta_{j-1} \prod_{k=j}^{n-1} \cos \theta_k}{a_j} \right)^{\frac{2}{\varepsilon_{j-1}}} \right]^{\frac{\varepsilon_{j-1}}{2}}, & j = 3, \dots, n, \end{cases}$$

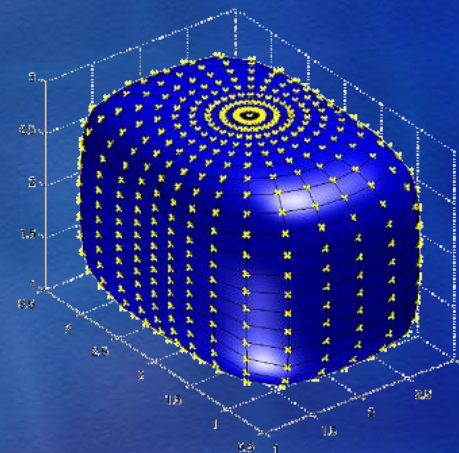

with  $\theta_i \in [-\pi, \pi[$  if  $i = 1$  and  $\theta_i \in [-\frac{\pi}{2}, \frac{\pi}{2}]$  if  $i = 2, \dots, n-1$ .

# Superquadric shapes

3D angle-center parametrization

→  
No. of anomalies

variation of the number of anomalies

The angle-center parametrization results in a better sampling of the superquadric surface for smooth convex shapes

**Proposition** (inside-outside function of a bended  $n$ -D superellipsoid (Morio,2008)). Let  $\mathcal{S}$  be a superellipsoid of size  $n$ , described by the vector  $\Psi$ . Then, the corresponding (implicit) inside-outside function  $\mathcal{F}_n(\Psi, x) = \Lambda_{n,n}(\Psi, x)$ , is defined by the recursive expression

$$\begin{cases} \Lambda_{n,2}(\Psi, x) = \left( \frac{x_1}{a_1 \left( \frac{v_1}{a_p} x_p + 1 \right)} \right)^{\frac{2}{\varepsilon_1}} + \left( \frac{x_2}{a_2 \left( \frac{v_2}{a_p} x_p + 1 \right)} \right)^{\frac{2}{\varepsilon_1}}, \\ \Lambda_{n,k}(\Psi, x) = \left( \Lambda_{n,k-1}(\Psi, x) \right)^{\frac{\varepsilon_{k-2}}{\varepsilon_{k-1}}} + \left( \frac{x_k}{a_k \left( \frac{v_k}{a_p} x_p + 1 \right)} \right)^{\frac{2}{\varepsilon_{k-1}}}, \end{cases}$$

where  $v_p = 0$  in the pinching direction  $p$ .

# Superquadric shapes

**Proposition** (*n*-D euclidean radial distance (Morio,2008)). *The euclidean radial distance  $d(\Psi, x_0)$  is defined as being the distance between a point  $Q$  with coordinates  $x_0$ , and a point  $P$  with coordinates  $x_s$ , corresponding to the projection of  $Q$  onto the superellipsoid, along the direction defined by the point  $Q$  and the center of the geometric shape. For an arbitrary *n*-D superellipsoid, described by the vector  $\Psi$ , the expression of the radial euclidean distance  $d(\Psi, x_0) = |x_0 - x_s|$  is given by*

$$d(\Psi, x_0) = |x_0| \cdot \left| 1 - (\mathcal{F}_n(\Psi, x_0))^{-\frac{\varepsilon_{n-1}}{2}} \right|,$$

**Proposition** (volume of a bended *n*-D superellipsoid (Morio,2008)). *Let  $\mathcal{S}$  be a bended superellipsoid of size *n*, described by the vector  $\Psi$ . The volume  $V_n(\Psi)$  of  $\mathcal{S}$  is defined by*

$$V_n(\Psi) = 2a_n \left[ \prod_{\substack{i=1 \\ i \neq p-1}}^{n-1} a_i \varepsilon_i B\left(\frac{\varepsilon_i}{2}, i \frac{\varepsilon_i}{2} + 1\right) \right] \cdot \left[ a_{p-1} \varepsilon_{p-1} \sum_{|\alpha|=0}^{n-1} v^\alpha B\left(\frac{|\alpha|+1}{2} \varepsilon_{p-1}, \frac{p-1}{2} \varepsilon_{p-1} + 1\right) \right],$$

where the multi-index  $\alpha = (\alpha_1, \dots, \alpha_{p-1}, 0, \alpha_{p+1}, \dots, \alpha_n)$  satisfies

$$v^\alpha = \prod_{k=1}^n v_k^{\alpha_k}, \quad |\alpha| = \sum_{j=1}^n \alpha_j, \quad \alpha_i \in \{0, 1\}, \quad i = 1, \dots, n,$$

In addition, the Beta function  $B(x, y)$  is linked to the Gamma function by

$$B(x, y) = 2 \int_0^{\pi/2} \sin^{2x-1} \phi \cos^{2y-1} \phi d\phi = \frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)},$$

the Gamma being typically defined by

$$\Gamma(x) = \int_0^\infty \exp^{-t} t^{x-1} dt,$$

# Superellipsoidal annexion problem

We assume that the nonconvex domain may be described by means of one or more analytical expressions defined by

$$f_{min} \leq f_{nc}(x) \leq f_{max},$$

where  $x$  is a set of variables of size  $n$ .

**Problem** (superellipsoidal annexion problem (Morio,2008)). Let  $\mathcal{S}$  be a superellipsoid of size  $n$ , described by the vector  $\Psi$ . The superellipsoidal annexion problem (or convexification problem) consists then in finding the optimal parameters  $\Psi^*$  associated to the biggest superellipsoid  $\mathcal{S}_{opt}$  contained inside the feasible domain (supposed to be nonconvex) defined by the analytical expression  $f_{nc}$ , such that

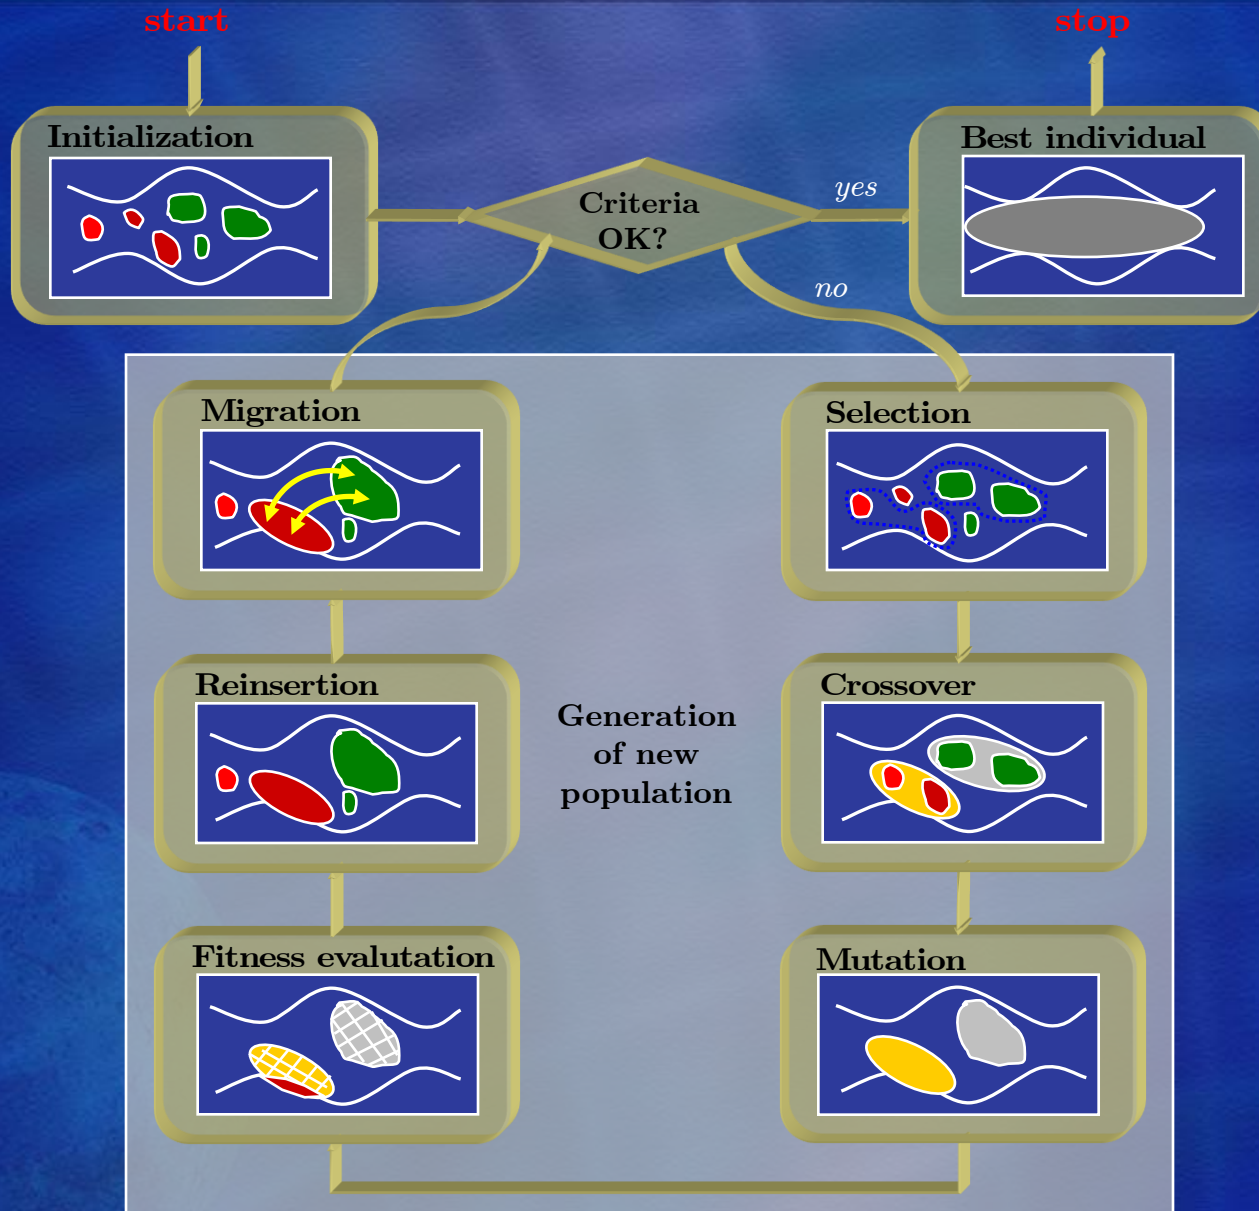

$$\begin{aligned} \max_{\Psi} \quad & \tilde{V}_n(\Psi) \\ \text{s.t.} \quad & \begin{cases} \mathcal{F}_n(\Psi, x) \leq 1, \\ f_{min} \leq f_{nc}(x) \leq f_{max}, \\ x_i^l \leq x_i \leq x_i^u, \quad i = 1, \dots, n. \end{cases} \end{aligned}$$

where the normalized superquadric volume  $\tilde{V}_n(\Psi)$  is defined by  $\tilde{V}_n(\Psi) = V_n(\Psi)^{\frac{1}{n}}$ , and  $\mathcal{F}_n(\Psi, x)$  is the inside-outside function. The variables  $x$  are the cartesian coordinates associated to a predefined number of sampling points at the superquadric surface.

# Resolution of the convexification problem

*Multi-population extended genetic algorithm adapted to the problem at hand*

# Convex optimal control problem

- the *convex* optimal control problem in the flat output space is given by

$$\min_{\bar{z}(t)} \mathcal{C}_0(\psi_x(\bar{z}(t_0)), \psi_u(\bar{z}(t_0)), t_0) + \int_{t_0}^{t_f} \mathcal{C}_t(\psi_x(\bar{z}(t)), \psi_u(\bar{z}(t)), t) dt + \mathcal{C}_f(\psi_x(\bar{z}(t_f)), \psi_u(\bar{z}(t_f)), t_f)$$

s.t.

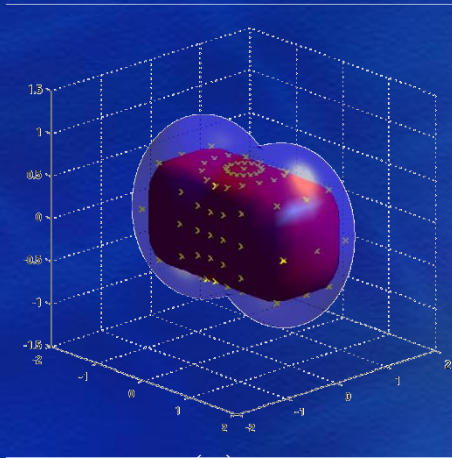

$$\begin{aligned} l_0 &\leq A_0 \bar{z}(t_0) \leq u_0, \\ l_t &\leq A_t \bar{z}(t) \leq u_t, \quad t \in [t_0, t_f], \\ l_f &\leq A_f \bar{z}(t_f) \leq u_f, \\ L_0 &\leq c_0(\psi_x(\bar{z}(t_0)), \psi_u(\bar{z}(t_0))) \leq U_0, \\ \mathbf{0} &\leq \mathcal{F}_n^i(\Psi^*, \bar{z}(t)) \leq \mathbf{1}, \quad t \in [t_0, t_f], \\ L_f &\leq c_f(\psi_x(\bar{z}(t_f)), \psi_u(\bar{z}(t_f))) \leq U_f. \end{aligned}$$

where  $\mathcal{F}_n^i(\Psi^*, \bar{z}(t))$ ,  $i = 1, \dots, n_s$ , are the inside-outside functions associated to the optimized convex shapes.

- boundary constraints must be met:  $\mathcal{F}_n(\Psi^*, \bar{z}(t_0)) \cdot \mathbf{1}$  and  $\mathcal{F}_n(\Psi^*, \bar{z}(t_f)) \cdot \mathbf{1}$ . It is possible to check if the extremal points of the trajectory are lying inside the convex envelopes by computing the associated  $n$ -D radial euclidean distances
- a convex cost functional may be obtained by using the same process.

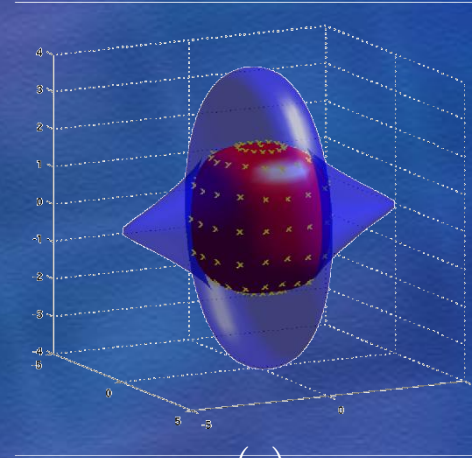

## *Some simple examples in 3 dimensions*

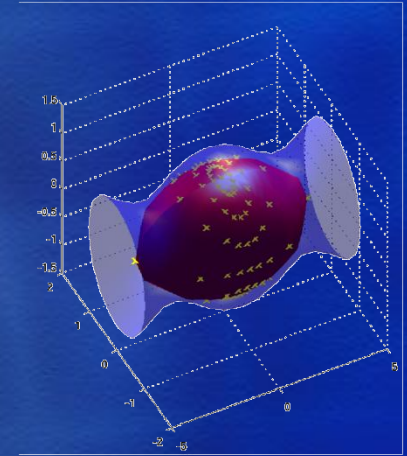

(a)

(b)

(c)

(d)

The initial nonconvex domains are defined by

$$(a) \quad D_1 = \{x | x \in \mathbb{R}^3, ((x_1 - 0.9)^2 + x_2^2 + x_3^2 - 1) ((x_1 + 0.9)^2 + x_2^2 + x_3^2 - 1) - 0.3 \cdot 0\},$$

$$(b) \quad D_2 = \{x | x \in \mathbb{R}^3, 4x_1^2 (x_1^2 + x_2^2 + x_3^2 + x_3) + x_2^2 (x_2^2 + x_3^2 - 1) \cdot 0\},$$

$$(c) \quad D_3 = \{x | x \in \mathbb{R}^3, (\sqrt{x_1^2 + x_3^2} - 3)^3 + x_2^2 - 1 \cdot 0\},$$

$$(d) \quad D_4 = \{x | x \in \mathbb{R}^3, x_2^2 + x_3^2 - 0.5 \cos x_1 \cos x_2 - 1 \cdot 0\}.$$

# Convexification of the optimal control problem

- example: dynamic pressure constraint along the TAEM trajectory, expressed wrt. flat outputs

$$0 \leq \frac{1}{2} \rho_0 \exp\left(-\frac{z_3}{H_0}\right) S \frac{\sqrt{z_1'^2 + z_2'^2 + z_3'^2}}{\lambda} \leq \bar{q}_{max}.$$

- nonconvex constraint: exponentially decreasing spherical shape
- Inner approximation by a 5-D superellipsoid described by

$$\Psi = \left\{ \underbrace{a_1, \dots, a_5}_{\text{semi-major axes}}, \underbrace{\varepsilon_1, \dots, \varepsilon_4}_{\text{roundness par.}}, \underbrace{\Phi_1, \dots, \Phi_{15}}_{\text{rotation par.}}, \underbrace{d_1, \dots, d_5}_{\text{translation par.}}, \underbrace{v_1, \dots, v_4}_{\text{pinching par.}} \right\}.$$

*geometric interpretation*

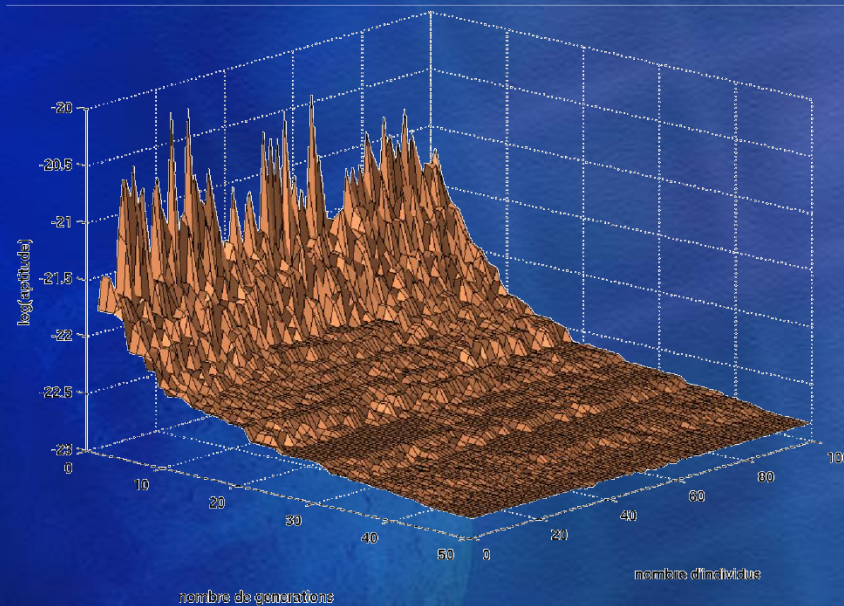

# Convexification of the optimal control problem

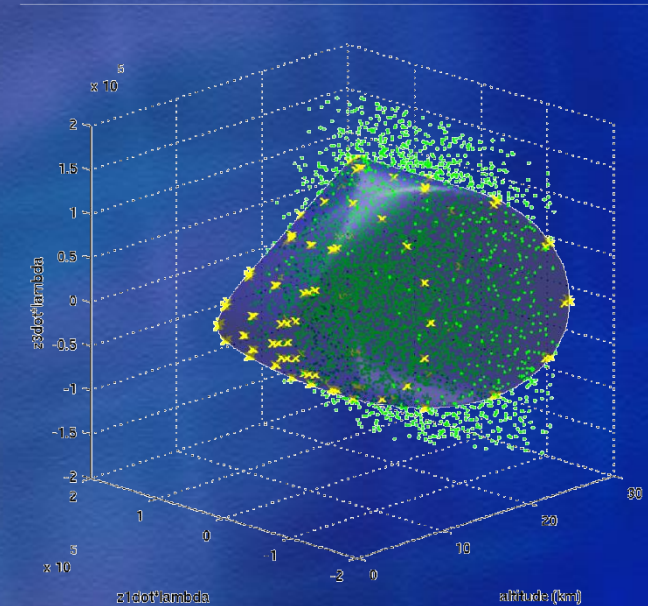

- simple genetic algorithm tuning parameters provide good results
- the inside-outside function  $\mathcal{F}_{\bar{q}}(\Psi^*, \bar{z})$  is given by

$$\mathcal{F}_{\bar{q}}(\Psi^*, \bar{z}) = \left[ (0.8 \cdot 10^{-4} z_3 - 1.2)^{20} + \left( \frac{z'_1}{3.2 \cdot 10^4 + 5.3 z_3} \right)^{20} \right]^{0.1} + \left( \frac{z'_2}{3.5 \cdot 10^4 + 5.9 z_3} \right)^2 + \left( \frac{z'_3}{3.1 \cdot 10^4 + 5.3 z_3} \right)^2 + \left( \frac{\lambda}{45.7 + 0.76 \cdot 10^{-2} z_3} \right)^2,$$

where  $\Psi^*$  are optimal defining parameters and  $\bar{z} = (z_3, z'_1, z'_2, z'_3, \lambda)$ .

*individuals fitnesses wrt. generations*

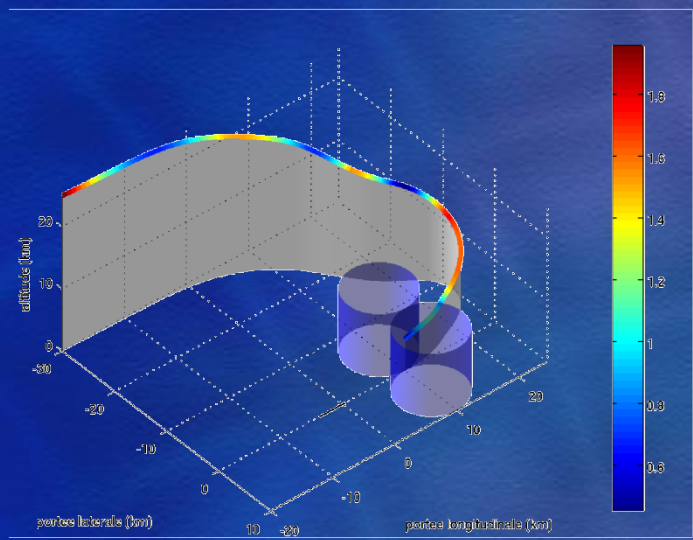

*approximating convex shape*

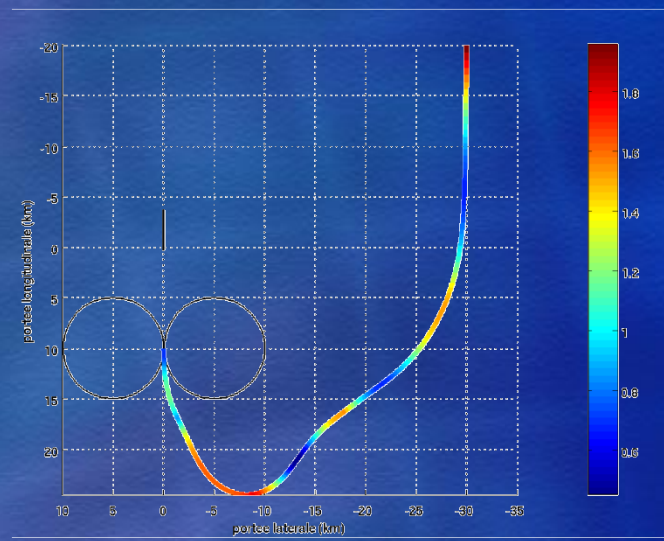

- other nonconvex trajectory constraints convexified by using the same process

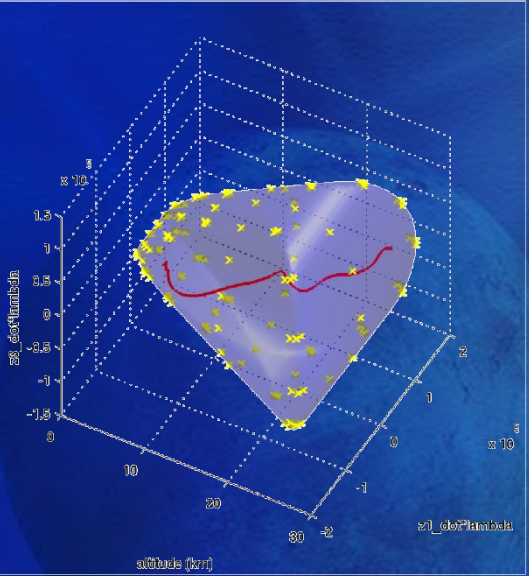

# Convexification of the optimal control problem

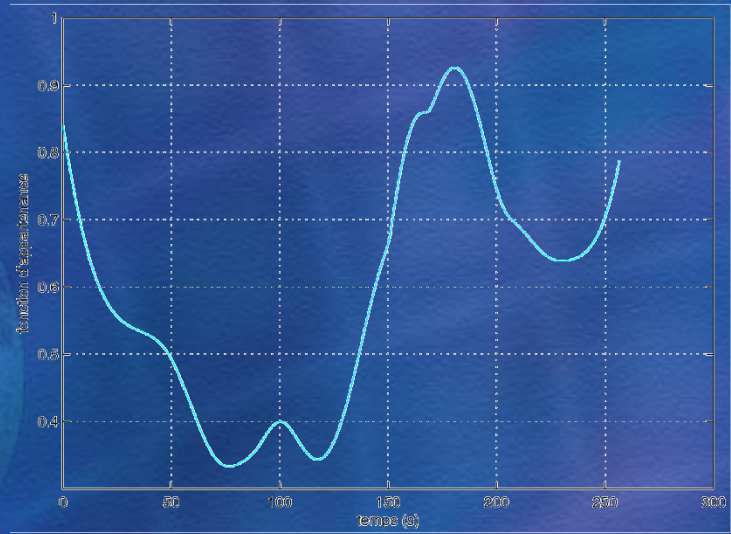

*3D reference trajectory*

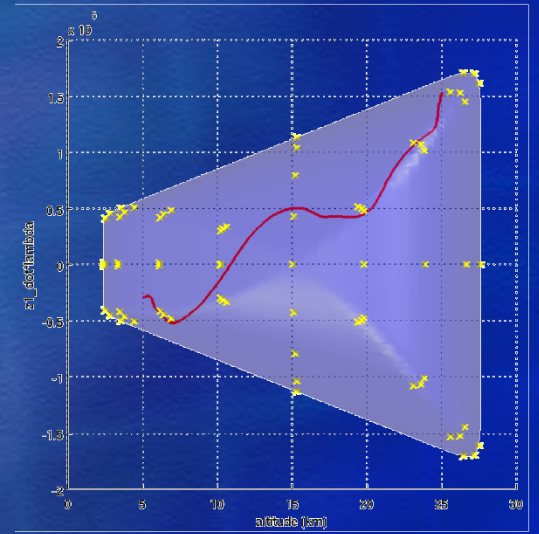

*projection in the horizontal plane*

*optimized superellipsoid*

*superellipsoid inside-outside function*

*optimized superellipsoid*

Research work includes contributions in 3 directions:

- ➔ Theoretical: necessary and sufficient conditions of  $\delta$ -flatness for linear delay systems (not presented)
- ➔ Methodological: design of an autonomous guidance law
  - modelling, problem formulation and onboard solving using flatness theory
  - convexification by superquadric shapes
  - fault-tolerant trajectory planning by integration of trimmability constraints
  - integration of aerologic disturbances
- ➔ Application to an atmospheric reentry mission:
  - Terminal Area Energy Management (TAEM) and Auto-Landing (A&L) phases of Shuttle orbiter STS-1 vehicle

- ➔ Application of the autonomous guidance law to other space missions: unmanned aerial vehicles, satellite orbital maneuvers, autonomous missile guidance, ...
- ➔ Onboard generation of fully constrained 6 dof trajectories (integration of flight control equations): may be used to bound the guidance inputs rates ( $\dot{\alpha}$ ,  $\dot{\beta}$ ,  $\dot{\mu}$ ) in presence of a faulty situation
- ➔ Adequately manage the transient regime between the occurrence of a fault and the integration of the reshaped trajectory in the GNC system
- ➔ Transform the convex optimal control problem into a semi-definite programming problem: requires to describe superquadric shapes as linear matrix inequalities
