## Monsieur Rémy Chrétien

Analyse automatique de propriétés d'équivalence pour les protocoles cryptographiques

Thèse soutenue à Cachan, le 11 janvier 2016 :
Composition du Jury :

M David Basin
M Bruno Blanchet
Mme Véronique Cortier
Mme Stéphanie Delaune
M Thomas Jensen M David Pointcheval M Géraud Sénizergues M Dominique Unruh

Professeur, ETH Zürich Rapporteur
Directeur de Recherche, INRIA Rapporteur
Directrice de Recherche, CNRS Directrice de thèse
Chargée de Recherche, CNRS Directrice de thèse
Directeur de Recherche, INRIA Président du Jury
Directeur de Recherche, CNRS Examinateur
Professeur, Université Bordeaux Examinateur
Professeur, University of Tartu Examinateur

## Résumé

À mesure que le nombre d'objets capables de communiquer croît, le besoin de sécuriser leurs interactions également. La conception des protocoles cryptographiques nécessaires pour cela est une tâche notoirement complexe et fréquemment sujette aux erreurs humaines. La vérification formelle de protocoles entend offrir des méthodes automatiques et exactes pour s'assurer de leur sécurité.

Nous nous intéressons en particulier aux méthodes de vérification automatique des propriétés d'équivalence pour de tels protocoles dans le modèle symbolique et pour un nombre non borné de sessions. Les propriétés d'équivalence sont naturellement employées pour s'assurer, par exemple, de l'anonymat du vote électronique ou de la non-traçabilité des passeports électroniques.

Parce que la vérification de propriétés d'équivalence est un problème complexe, nous proposons dans un premier temps deux méthodes pour en simplifier la vérification : tout d'abord une méthode pour supprimer l'utilisation des nonces dans un protocole tout en préservant la correction de la vérification automatique; puis nous démontrons un résultat de typage qui permet de restreindre l'espace de recherche d'attaques sans pour autant affecter le pouvoir de l'attaquant.

Dans un second temps nous exposons trois classes de protocoles pour lesquelles la vérification de l'équivalence dans le modèle symbolique est décidable. Ces classes bénéficient des méthodes de simplification présentées plus tôt et permettent d'étudier automatiquement des protocoles taggués, avec ou sans nonces, ou encore des protocoles ping-pong.

## Acknowledgements

I would first like to thank my advisors, Véronique Cortier and Stéphanie Delaune, for offering me such a wonderful opportunity. These years have been excellent and working with you was a real pleasure.

I am very grateful to David Basin and Bruno Blanchet who kindly accepted to review this manuscript. I also thank Thomas Jensen, David Pointcheval and Dominique Unruh and who accepted to be part of the jury. I would also like to thank Géraud Sénizergues for his collaboration and presence for my defense.

I also thank all the members of LSV for making this thesis such an enjoyable experience. Thank you for the stimulating discussions and the help throughout these years. Thank you in particular to the PhD students for making the laboratory far more than just a work place.

I want to give special thanks to all my family, who has always supported me and believed in me. Thank you for blessing me with such a nurturing home and helping me become a better person.

Finally, I would like to thank Marie for her unwavering support. Thank you for brightening up my days, even when your own plate was full too. Thank you so much.

## Chapter 1

## Introduction

### 1.1 Protocols and attacks

As technology becomes ubiquitous and software is embedded into each and every device around us, the amount of communication among connected objects and computers grows substantially. Communication protocols are designed to govern these communications. These are small programs whose goal is to allow a number of agents to transmit information between each other. They define sets of rules to properly communicate, such as for instance the format of messages that agents send and receive, their timings or error messages. Examples of protocols can be found within the Internet Protocol suite, with HTTP, TCP, UDP and many others. Protocols also appear when using RFID tags and readers to transmit data about the nature or price of a product. Cryptographic protocols consist of a subset of communication protocols using cryptography to achieve their objective. Cryptographic primitives like symmetric or asymmetric encryption, hash functions or zero-knowledge proofs can indeed enable properties such as secret data transmission or the establishment of secret keys for further applications. These cryptographic protocols can be found in a large number of applications. Credit cards, with or without contact, need to ensure that a payment can legitimately be made by checking the credentials and the account balance of its user. E-passports convey RFID chips which transmit to an authenticated reader, e.g. at a border checkpoint, the identification data (name, nationality, digitised picture) of its owner to facilitate the verification of her identity. Electronic voting, either over the internet or via electronic voting machines, make heavy use of cryptography to ensure the anonymity of voters and the validity of the ballot result.

As protocols, cryptographic or not, have to perform a large variety of tasks, we need to specify the properties they provide to their users. In the case of cryptographic protocols, we will be naturally interested in security properties. One of the simplest and most natural security property is the notion of secrecy: if two agents are transmitting data over some channel, can an attacker learn part or all of this data? In the credit card example, one can hope the banking account information is kept secret to avoid later frauds. Another property is authentication, describing the ability for agents to be convinced they are interacting with one another, and in the case of the credit card reader, that the card is an authentic one. For the e-passport, untraceability of a user, the impossibility for an attacker to relate two different sessions of the protocol to the same user, is often seen as desirable for the sake of privacy. In the case of electronic voting, anonymity of the voters and the verifiability of the results are two fundamental features of a good design. But to speak more precisely about security properties, we need both to make clear what our threat model is, i.e. what are the abilities of the attacker and the features of the network and agents, as well as explicitly state our definitions for such properties. The former will be considered in Section 1.2 and the latter in Section 1.3.

Unfortunately, even with appropriate definitions, the secure design of cryptographic protocols is a difficult task. The Needham-Schroeder protocol [58] is an authentication protocol between two agents using asymmetric cryptography and designed in 1978. Seventeen years later, Lowe discovered an attack [53] allowing a malicious agent on the network to impersonate an honest participant. More recently, an attack on the Google Single Sign-On protocol
was found by Armando et al. [7] in 2008. The original protocol can be schematically described in the following way, where $A$ denotes an agent willing to authenticate to an Identity Provider $I_{P}$ to gain access to the services offered by the Service Provider $S_{P}$ :

$$
\begin{array}{lllll}
A & \rightarrow & S_{P} & : & A, S_{P}, \text { url } \\
S_{P} & \rightarrow & A & : & A, I_{P}, \operatorname{AuthReq}\left(i d, S_{P}\right), \text { url } \\
A & \rightarrow & I_{P} & : & A, I_{P}, \operatorname{AuthReq}\left(i d, S_{P}\right), \text { url } \\
I_{P} & \rightarrow & A & : & \operatorname{sign}\left(A u t h A \operatorname{ssert}\left(A, I_{P}\right), \text { sk }_{I_{P}}\right), \text { url } \\
A & \rightarrow & S_{P} & : & \operatorname{sign}(A u t h A s s e r t \\
\left.\left(A, I_{P}\right), \text { sk }_{I_{P}}\right), \text { url }
\end{array}
$$

In this informal specification, url denotes the address of the resource $A$ is trying to access from $S_{P}$, id is a unique identifier generated by $S_{P}$. AuthReq builds an authentication request for $I_{P}$ to process, to which $I_{P}$ answers using the authentication assertion AuthAssert, itself signed with the private key sk $I_{P}$ of $I_{P}$. Note that the inner working of AuthReq and AuthAssert are not important to the attack itself, and one can just assume these to be secure primitives which guarantee authentication in a successful execution of the protocol. The core of the attack instead relies on the fact that the authentication assertion does not actually depend on url, $i d$ and $S_{P}$ : the target address from $A$, the unique identifier $i d$ generated by $S_{P}$ and the identity of the service provider $S_{P}$ are not taken into account when building the authentication token $\operatorname{sign}$ (AuthAssert $\left(A, I_{P}\right), \operatorname{sk}_{I_{P}}$ ) that $A$ sends to $S_{P}$ in her last message to gain access to her resources. Intuitively, if able to recover such a token $\operatorname{sign}\left(\right.$ AuthAssert $\left.\left(A, I_{P}\right), \operatorname{sk}_{I_{P}}\right)$ from $A$, an attacker could then use it to impersonate $A$ and gain access to any of her resources, for any service provider using the same identity provider. This design flaw naturally leads to a man-in-the-middle attack where an attacker $I$, posing as a service provider and able to make $A$ start a session with her, can gain access to this token, and hence authenticate as $A$ to any service provider.

$$
\begin{array}{llll}
I(A) & \rightarrow S_{P} & : A, S_{P}, \text { url } \\
S_{P} & \rightarrow I(A) & : A, I_{P}, \text { AuthReq }\left(i d, S_{P}\right), \text { url } \\
I(A) & \rightarrow S_{P} & : \operatorname{sign}\left(\text { AuthAssert }\left(A, I_{P}\right), \text { sk }_{I_{P}}\right), \text { url }
\end{array}
$$

Here $I(A)$ denotes the intruder when impersonating agent $A$. In this attack, we assume $I$ got a copy of the token $\operatorname{sign}\left(\right.$ AuthAssert $\left.\left(A, I_{P}\right), \mathrm{sk}_{I_{P}}\right)$ in a previous session, for instance by luring $A$ into connecting to a service she controls. Then $I$ starts a session with $S_{P}$ impersonating $A$ to gain access to authenticate and gain access to url. Instead of forwarding the authentication request of $S_{P}$ to $I_{P}$ (AuthReq $\left(i d, S_{P}\right)$ ), the attacker just uses the authentication token she already possess, along with the address of the new resource url.

This attack is actually reminiscent of the earlier attack on the Needham-Schroeder protocol, and other similar high-level attacks can also be found for other applications such as the French version of the electronic passport prior to 2010. These attacks on deployed systems highlight how error-prone the design and analysis of security protocols is. To address this difficulty, automated tools for the verification of security properties of cryptographic protocols can be designed to automatically find attacks on protocols or prove their security within a particular model.

### 1.2 Security and the symbolic model

In order to properly specify the security goals for our protocols, and hope to prevent attacks that would compromise these goals, we need to define a threat model. In particular, this model must explicit what are the precise capabilities of the attacker, what she can learn, what she controls and what are her objectives. The choice of this model is highly dependent on the nature of attacks we are interested in and the trust we have in the components of the system. A classical way of classifying attacks, and therefore the type of attacker, is the following one. We can first consider computational attacks on the cryptography itself: by finding flaws in the algorithms used by the cryptographic primitives, from the encryption algorithms to the pseudo-random number generators, an attacker could be able to, partially or totally, nullify the security brought by these primitives. In another type of attacks, focus is put on the low-level details of the security system. Errors or deviations from the specifications, for instance the seeding of a pseudo-random number generator
of the Debian OpenSSL package in May 2008, are found in the implementation of the protocol, leading to attacks on the program itself, rather than the specification of the protocol. A third way of modelling attacks, and the one we will be the most interested in, is to focus on the high-level specification of the protocol. In this case, the attacker is looking for logical flaws, related to the formats of the messages, leading for instance to man-in-the-middle attacks. Finally, we may consider side-channel attacks: the attacker then relies on information which was not modelled in any of the previous steps. From the power consumption of a device running the protocol to the timing used to compute some cryptographic primitives, the attacker can gain an advantage and ruin the security goals of the protocol.

In this thesis, we consider a high-level view of the cryptographic protocol. More specifically, we focus here on the symbolic Dolev-Yao model [43]. In this model, cryptographic primitives are modelled as abstract function symbols, and operations such as encryption or decryption as applications of rewriting rules or equalities modulo an equational theory. Messages are themselves built on a term algebra and exchanged on the network, which is under the control of the attacker. Even though it assumes perfect cryptography, this model gives a lot of power to the attacker and is effective in finding logical attacks in the specification of many cryptographic protocols. Flaws mentioned in Section 1.1 indeed fall into this category. This model is moreover expressive enough to express a large variety of security properties which we will classify in the next section.

### 1.3 Security properties

Symbolic models allow many security properties to be expressed. To do so, we can rely on the notion of knowledge of the attacker and her deduction powers. Intuitively, an attacker knowing both the encryption of a plaintext by some public key and the associated private key would be able to deduce the plaintext. Here we informally state a number of security properties.

- Secrecy of a message, a key or some secret data, can be stated as the inability for the attacker and for any execution of the protocol, to deduce this message.
- Authentication states that, for every execution of the protocol, any honest agent believing it is finishing a session with another honest agent should indeed be finishing a session with this agent. Or, in other words, no attacker is impersonating an honest agent.
- Temporary secrecy states that if an information is secret at some point in an execution, it will remain secret at any point in the future. In particular, all temporary secrets are permanent secrets.

Secrecy, temporary or not, and authentication all belong to a class of security properties that can be stated as follows: for any execution (also called trace) of the protocol, a property on the execution must hold. These properties are commonly referred as trace properties or reachability properties. But some properties cannot be expressed along this line. Consider the case of the anonymity of the user of some anonymous application. The possible values for the identity of the user may already be known to the attacker, as the list of user names may be public information. Unknown to her, on the other hand, are the identities of the users for a specific session.

- Anonymity of the said user identity can thus be modelled as the inability for the attacker to distinguish between a situation where an agent is using some identity $i d_{1}$ and a situation where the same agent would be using identity $i d_{2}$. Slightly more formally, if we let $P$ be a formal specification of the anonymous application under investigation, $P\left[{ }^{i d_{1}} /{ }_{i d}\right]$ the variant of $P$ where our agent's identity is $i d_{1}$ and $P\left[{ }^{i d_{2}} / i d\right]$ when the value is $i d_{2}$, the anonymity of the identity can be stated as $P\left[{ }^{i d_{1}} /{ }_{i d}\right] \approx P\left[{ }^{i d_{2}} /{ }_{i d}\right]$ where $\approx$ denotes some equivalence relation between protocols, representing the inability for the attacker to distinguish between two protocols.
- Untraceability is another property related to the ability for an attacker to link together messages from the same execution of a protocol. It models an attacker trying to trace an agent by trying to recognise the sessions which generated particular messages. It is a desirable property in the case of e-passports, where an attacker should not
be able to link messages together and thus track the movements of its bearer. More formally, for untraceability to hold, an attacker should think than each session she observes has been generated by a new distinct e-passport. If $P_{\text {multi }}$ is the original version of the e-passport protocol where each passport can take part into any number of sessions, and $P_{\text {single }}$ is an ideal version where each passport can only execute one session, then the equivalence $P_{\text {multi }} \approx P_{\text {single }}$ should hold.

An alternative interpretation of these equivalences is the inability for an attacker, given two protocols, to accurately guess for any execution (or trace) of one of those two, which protocol produced it. Properties which can be expressed as such are usually referred as equivalence properties. Most properties relevant to privacy are actually modelled as equivalences, e.g. in voting protocols, as well as more exotic properties, for example in mobile ad-hoc routing [28].

### 1.4 Automation of security proofs

Abstraction of the messages and the underlying cryptography in the symbolic models opens up the possibility of efficiently automating the process of attack discovery and, conversely, the verification of the system security. This formalisation indeed allows to benefit from classical models and techniques in theoretical computer science, ranging from model-checking to resolution and rewriting systems. Tools, as further described in Section 1.5, are for instance able to catch the attacks mentioned in Section 1.1. Still, automatically verifying a security property remains a difficult task, whose complexity is directly related to the power which is given to the attacker as well as the intricacy of the security property considered. In the following sections, we give a panorama of these difficulties and the techniques employed to deal with different kind of properties.

### 1.4.1 (Un)decidability of reachability properties

We first consider reachability properties, such as secrecy and authentication, and the existing decidability or undecidability results associated. In the most general setting, reachability properties can already be shown to be undecidable [45,57] with minimal cryptographic primitives such as symmetric encryption and pairs. A simple encoding relies on the arbitrary size of messages to store the words needed to encode the Post Correspondence Problem, encrypted to avoid unwanted alterations by the attackers. But even if the unbounded size of messages can be seen as an undesirable property, undecidability of secrecy can still be proven with messages of bounded size [4], by using nonces, fresh values generated by the protocol and attacker, as pointers to encode, once again, an instance of the Post Correspondence Problem.

For this reason, in order to achieve decidability, one needs to consider restrictions, either on the protocols or on the power given to the attacker when verifying a security property. One of the most classical ones consists in bounding the number of sessions in the verification. This limitation practically forbids any agent to execute a protocol more than a fixed number of times, number set a priori. Although this restriction manages to achieve decidability for reachability properties [55, 11, 35], it fails to be entirely acceptable. The bound on the number of sessions being arbitrary, it provides no guarantee on the security of the protocol if no attack were to be found for a given number of sessions. Moreover, existing tools are only able to handle a low number of sessions, barring the practical verification of a protocol for an increasing large number of sessions.

These obstacles are thus incentive to focus on verification for an unbounded number of sessions. Another line of restrictions in that direction is to restrict the ability of the agents to blindly copy portions of messages they received. More formally, by limiting the amount of information an agent can forward, secrecy can again be proven decidable [31]. Another way of achieving decidability is to consider tagged protocols. Tagging can be first considered from a practical implementation perspective as a way of making messages unambiguous, a good practice in protocol design [54]. By adding a specific constant, the tag, to the beginning of any encrypted plaintext, an agent can easily deduce from which stage of the protocol this message originate. For this reason, it prevents a number of type-flaw
attacks where a message being parsed as another resulted in unwanted behaviours, for instance in the Otway-Rees protocol [59]. On top of that, tagging schemes can also lead to decidability for secrecy [60] or temporary secrecy [47].

### 1.4.2 Proof techniques for reachability properties

As we have seen earlier, reachability properties are undecidable in general without tight restrictions. But some techniques can still be used to reduce the difficulty of the verification of reachability properties. Tagging schemes, as mentioned previously in Section 1.4.1, are also able to greatly reduce the space of traces to consider when checking for secrecy thanks to typing results [6]. Well-typed traces indeed constrain the size and shape of the messages which can be exchanged by both the honest agents and the attacker.

Another way of easing verification is to prevent agents from generating new nonces. The infinite number of nonces to consider is a difficult point to address as it leads to consider infinitely many messages of any size and causes undecidability [4] as already discussed. Fortunately, when checking for secrecy, removing nonce generation from the specification of a protocol without else branches is sound. Which is to say that if $\bar{P}$ is a version of a protocol $P$ with its nonce generation removed and $\bar{P}$ preserves the secret of some value $s$, then $P$ also preserves the secrecy of $s$. Even if the converse is not true in general, it still provides a safe way to prove secrecy properties for protocols with nonces when using only procedures designed for protocols without nonces. More generally, approximations on nonces enable tools such as ProVerif [13] to soundly prove security properties.

### 1.4.3 The case of equivalence

Verifying trace equivalence is, unfortunately, more difficult in general than verifying reachability properties. A property like secrecy can for instance very easily be encoded as an equivalence between two processes which differ only if the secret data is disclosed. Indeed, on top of the existing difficulties for reachability properties, equivalence itself adds a new layer of complexity as even when considering substantially simpler process algebra without terms to model protocols, such as CCS or the $\pi$-calculus, equivalence is known to be very hard and in most cases an undecidable problem [48].

Specific to the verification of equivalence properties, there is actually some leeway in the precise definition of the equivalence of protocols we consider. Several notions have been described in the literature, such as trace equivalence, may-testing equivalence or observational equivalence [17, 2, 1]. In this thesis we consider trace equivalence as our core notion of equivalence. Other notions still coexist and can provide alternate methods for checking equivalence. Labeled bisimilarity for instance offers a tighter notion of equivalence between processes, and differ from trace equivalence in the same way as for process algebra without terms, which is in particular helpful in providing proofs of equivalence [65], instead of providing attacks i.e. witnesses of non-equivalence, as is usually done by tools. Diff-equivalence [14] offers another example of a tighter notion of equivalence whose verification can be encoded within the tool ProVerif and leads to a sound non-terminating procedure for checking equivalence, albeit prone to false negatives. Nevertheless, when dealing with "deterministic protocols" such as determinate protocols, a number of these equivalences actually collapse [19].

As mentioned before, verifying equivalence is a difficult problem and there exist very few decidability results. In particular, they all consider equivalence for a bounded number of sessions [12,35] and are thus subject to the same limitations as discussed in Section 1.4.1. One way to limit the number of traces that can be produced in response to the actions of the attacker is to restrict the branching behaviour of protocols. The use of if/then conditional statements is invaluable for providing agents with the ability to test values, such as signatures or keys, before proceeding to the remaining of the protocol. Unfortunately, else branches in these conditional statements tend to make equivalence checking much more difficult as they require to analyse any path that can be taken through all the conditionals in an execution. For this reason, removing else is often used as a restriction. A common restriction on protocols for proving equivalence is to consider "deterministic protocols". During an execution, a protocol can be presented with non-deterministic choices. In most process algebras, when presented with a message from the network which can be
received by two agents, e.g. when the same channel is used, a choice must be made to decide which of the two agents should capture the message and proceed. More directly, some algebras contain a non-deterministic choice operator (usually " + ") which can force an agent to make such a choice. These choices impact the number of interleavings of actions to consider, and similarly to the else branches, it is a natural hypothesis to remove any occurrences of such choices. This leads to notions of determinism, for which only one behaviour is possible in response to the given actions of the attacker. This determinism can take the form of determinate protocols [19] or simple protocols [33].

### 1.5 Existing tools

To fill the need for the automated verification of protocols, a number of tools were developed to find attacks and prove security properties about cryptographic protocols. Each of them relies on a number of assumptions on the protocols, properties and equivalence to consider in order to obtain sound verification procedures. In what follows, we focus on tools which are either devoted or contain features to prove the equivalence of protocols. Some are full decision procedures whereas other do not always provide termination in every case.

- Spec [65]: Implemented on top of the Bedwyr logical framework [9], Spec verifies open bisimulation for protocols modelled in a version of the spi-calculus. It relies on a fixed set of cryptographic primitives and only handles a bounded number of sessions, while guaranteeing termination. Thanks to the open bisimulation, the tool is able to provide proofs of equivalence, in the form of the bisimulation relation.
- Akiss [19]: Akiss is another tool which verifies equivalence for a bounded number of sessions. It uses an encoding as Horn clauses and focuses on trace equivalence. It does not support else branches and may not terminate but it can deal with large number of primitives and equational theories, as well as provide witness of non-equivalence.
- Apte [20]: Apte deals with the verification of trace equivalence for a bounded number of sessions and for standard primitives. It guarantees termination and supports both else branches and private channels.
- ProVerif [13]: Initially developed for reachability properties, it was extended to prove a stronger notion of equivalence: the diff-equivalence of bi-processes [14]. Like the original version, termination is not guaranteed when proving equivalence. ProVerif uses an encoding as Horn clauses and supports private channels and a large number of equational theories. Contrary to the previous tools, ProVerif consider an unbounded number of sessions but can produces false negatives, despite recent improvements [21, 40].
- Maude-NPA [61]: Maude-NPA is an analysis tool based on multiset-rewriting. As ProVerif, it handles an unbounded number of sessions and proves a tighter version of protocol equivalence. It also puts an emphasis on algebraic properties of primitives to deal, in particular, with Associative-Commutative equational theories, even though it currently handles rather simple protocols.
- Tamarin [10]: As ProVerif and Maude-NPA, Tamarin deals with an equivalence stronger than trace equivalence and can handle an unbounded number of sessions. It also uses multiset rewriting and can either produce attacks or prove equivalence, at the cost of potential non-termination, for a large number of primitives and theories. It moreover provides an interactive mode for proving properties.

### 1.6 Contributions

The main objective of my thesis is to prove decidability results for checking trace equivalence of protocols, as well as to provide new proof methods to ease the automated verification of protocol equivalence. My contributions can be split into five main points, which are summarised here. The two first aspects are related to ways of making equivalence
checking easier, by soundly removing some of its complexity or by sharply restricting the search spaces to consider. The last three consists of new classes of protocols such that trace equivalence are decidable. Combined with the facilitating methods described earlier, they further enlarge the classes of protocols for which equivalence properties can be proven.

### 1.6.1 Simplifying equivalence checking

Sound removal of nonces for checking protocol equivalence As mentioned in Section 1.4, the existence of an unbounded number of nonces that the agents and the attacker can use is an important source of complexity for the verification of security properties for an unbounded number of sessions. In the case of secrecy, this difficulty can be partially avoided by the soundness of direct removal of any nonce generation in the specification of the protocol (see Section 1.4.2), i.e. if no attack is found when nonces are removed, then no attack whatsoever can be found. This implication is unfortunately false in the case of equivalence. Our first contribution, presented in Chapter 3, consists then in a new transformation defined on protocols which removes nonce generation while remaining a sound abstraction for the equivalence with a unbounded number of sessions. Hence, if $P$ and $Q$ are two protocols, with arbitrary name generation, we algorithmically define two transformed versions of these, $\bar{P}$ and $\bar{Q}$ without nonces, such that $\bar{P} \approx \bar{Q} \Rightarrow P \approx Q$. This transformation works for a large number of cryptographic primitives and rewriting systems, namely adequate theories, which encompass traditional symmetric or asymmetric encryption, signatures or zero-knowledge proofs and simple protocols. Compared to the naive nonce deletion used to deal with secrecy, this transformation considers an additional copy of each nonce before deleting it. This result allows to directly turn a decision procedure for trace equivalence of protocols without nonces but for an unbounded number of sessions, such as the one presented in Chapter 5, into a terminating and sound procedure to verify trace equivalence of protocols with nonces and for an unbounded number of sessions.

Search space restriction through typing Section 1.4 described the use of tagging as a good and reasonable design practice. It also introduced the role of typing in the decidability results obtained for the weak secrecy within tagged protocols. Our second contribution, presented in Chapter 4 offers a generalisation of both tagging and typing to the case of trace equivalence for determinate protocols and an unbounded number of sessions. While focusing on the theory of symmetric encryption, it offers an important reduction in the set of traces searched for proving equivalence. It happens to be instrumental for the decidability results presented in Chapters 5 and 6 . Intuitively, the notion of typecompliance, introduced to generalise the idea of tagging, constrains protocols to avoid ambiguity in the interpretation of the origin of any message sent on the network and therefore drastically limit the shape and size of messages which can be exchanged between honest agents. The typing result ensures that limiting the attacker to abide by these constrained shapes and sizes of messages does not reduce her power at all. More formally, we prove that if an attacker is able to produce a witness of non-equivalence between two type-compliant protocols, then she is also able to produce a well-typed witness of non-equivalence between those two protocols, i.e. an attack such that any message sent on the network by the agents and the attacker fits a particular format defined by the specification of the protocol. To achieve this result, we designed a decision procedure for trace equivalence with a bounded number of sessions which produces, in case of non-equivalence, only well-typed witnesses.

### 1.6.2 Decidable classes

Decidability of equivalence for simple protocols without nonces Decidability results for equivalence for an unbounded number of sessions are difficult to obtain, due to the inherent complexity of protocol equivalence as discussed in Section 1.4. Chapter 5 presents one of the first decidability results for trace equivalence between simple type-compliant protocols without nonces. This result deeply relies on the typing theorem from Chapter 4 to bound the search space for attacks with such protocols. The additional restriction on nonces allows us to further bound the total number of messages which can be exchanged on the network, either by honest agents or the attacker. This bound can
then be translated into an upper bound on the length of any minimal witness of non-equivalence, if it exists. Moreover, even though it does not deal directly with nonces, this class is compatible with the abstraction presented in Chapter 3 to produce a sound procedure for checking equivalence for simple type-compliant protocols with nonces.

Decidability of equivalence for tagged protocols with nonces Chapter 6 introduces the first result of decidability for an unbounded number of sessions and tagged protocols with nonces. The typing result introduced in Chapter 4 offered a reduction in the search space when proving equivalence. This work pursues it by refining the typing systems considered to obtain structure-preserving typing systems, a notion closely related to tagging schemes in the literature. It also develops the notion, independently presented in [47] for the restricted case of temporary secrecy, of dependency graph which formally abstracts the dependencies between the actions in a protocol specification. It allows to define acyclic protocols, intuitively related to protocols without loops in their natural executions. Focusing on simple acyclic type-compliant protocols using symmetric encryption, we provide a decidability result for an unbounded number of sessions as well as an unbounded number of nonces. This result also provides a computable upper bound on the length of any potential minimal witness of non-equivalence between such protocols.

Decidability of equivalence for ping-pong protocols The last contribution of this thesis, detailed in Chapter 7, presents another decidability result for trace equivalence of protocols for an unbounded number of sessions. It focuses on a class of ping-pong protocols, reminiscent of the class studied in the seminal work of Dolev and Yao [43] with cryptographic primitives such as symmetric and asymmetric encryption, signature and hash functions, but without pairing or nonces. It provides a two-way reduction between trace equivalence of ping-pong protocols and language equivalence of deterministic pushdown automata [63] as well as a decidability result for ping-pong protocols for an unbounded number of sessions. As a side result, it also produces a new undecidability result for trace equivalence with very elementary protocols too, further highlighting the difficulty of this task. Based on the complexity of the reductions between protocols and deterministic pushdown automata [62, 64], it also sheds some light on the inherent complexity of trace equivalence. Focusing on trace equivalence for an unbounded number of sessions without nonces, this result appears to be a prime candidate for the application of the abstraction discussed in Chapter 3.

### 1.7 Outline

The remainder of this thesis is articulated into two main parts, focusing first on easing the verification of trace equivalence mainly through nonce removal and typing and then on describing classes of protocols for which trace equivalence is decidable.

Part I is made of three chapters. Chapter 2 aims at defining a unified formal model for protocols and equivalence checking which will be used throughout this thesis, facilitating the application of the subsequent results. Following that, Chapter 3 proposes a first method to simplify equivalence checking by removing nonces and effectively reducing the equivalence checking of protocols with an unbounded number of nonces to protocols with a bounded number of nonces. Chapter 4 then proposes a new practical restriction on protocols and executions in order to reduce equivalence checking to the verification of well-typed equivalence.

Part II compiles three classes of protocols for which trace equivalence can be proven decidable with an unbounded number of sessions. Chapter 5 describes a decidable class of protocols with a bounded number of nonces naturally formed from the restrictions introduced in Chapter 4 and which easily interfaces itself with the result from Chapter 3. Then Chapter 6 introduces a novel notion of acyclic protocols and dependency graph to define a practical class of protocols with an unbounded number of nonces and sessions for which equivalence is decidable. Finally, Chapter 7 describes a final class of protocols, ping-pong protocols, whose equivalence is reduced to the equivalence of language between deterministic pushdown automata and hence decidable.

Appendix A and B ultimately contain proofs from Chapters 4 and 7, respectively, which were not included into the body of this thesis.

### 1.8 Publications

- The results from Chapter 3 led to a conference article presented at the 20th European Symposium On Research In Computer Science (ESORICS) in 2015 [25].
- The results from Chapter 4 and 5 led to a conference article presented at the 25 th Conference on Concurrency Theory (CONCUR) in 2014 [24].
- The results from Chapter 7 led to a conference article presented at the 40 th International Colloquium on Automata, Languages and Programming (ICALP) in 2013 [23], as well as a journal version in Transactions on Computational Logic in 2015 [27].
- The results from Chapter 6 finally led to a conference article presented at the 28th IEEE Computer Security Foundations Symposium (CSF) in 2015 [26].

## Model for general protocols

In this chapter, we present the model we will use through this thesis to model protocols and their properties. Security protocols are modelled through a process algebra inspired from the applied pi-caculus [1] that manipulates terms. Still, we consider a variant with several differences: we do not consider else branches in conditional expressions, nor do we allow private channels. We also introduce several classes of protocols which convey the idea of determinism as mentioned in introduction: determinate and simple protocols. Section 2.5 finally describes the core notion of type-compliant protocols, related to the tagging introduced in [15]. This idea on protocols will constitute the central hypothesis of the results of Chapters 4 and 6.

### 2.1 Term algebra

We assume an infinite set $\mathcal{N}$ of names, which are used to represent keys and nonces and an infinite set $\mathcal{X}$ of variables. We assume a signature $\Sigma$, i.e. a set of function symbols together with their arity, and we make a distinction between constructor symbols and destructor symbols: $\Sigma=\Sigma_{c} \uplus \Sigma_{d}$. Given a signature $\Sigma$, we denote by $\mathcal{T}(\Sigma, \mathrm{A})$ the set of terms built from symbols in $\Sigma$ and atomic data in A . Terms without variables are called ground. The set $\mathcal{T}\left(\Sigma_{c}, \mathcal{X} \cup \mathcal{N}\right)$ is the set of constructor terms. Then among the terms in $\mathcal{T}\left(\Sigma_{c}, \mathcal{N}\right)$ we distinguish a special subset of terms called messages and noted $\mathcal{M}_{\Sigma}$, and that is stable under renaming of names: a message does not contain any destructor symbol, and $m \in \mathcal{M}_{\Sigma}$ implies that $m \rho \in \mathcal{M}_{\Sigma}$ for any renaming $\rho$ (not necessarily a bijective one).

In addition to the set of variables $\mathcal{X}$, we consider an infinite disjoint set of variables $\mathcal{W}$. Variables in $\mathcal{W}$ intuitively refer to variables used to store messages learnt by the attacker. We denote vars $(u)$ the set of variables that occur in a term $u$. The application of a substitution $\sigma$ to a term $u$ is written $u \sigma$, and we denote $\operatorname{dom}(\sigma)$ its domain. The positions of a term are defined as usual. Two terms $u$ and $v$ are unifiable if there is a substitution $\sigma$ such that $u \sigma=v \sigma$.

The properties of the primitives are expressed using rewriting rules of the form $\mathrm{g}\left(t_{1}, \ldots, t_{n}\right) \rightarrow t$ where g is a destructor, that is $\mathrm{g} \in \Sigma_{d}$, and $t_{1}, \ldots, t_{n}, t$ are constructor terms. A rewriting rule can only be applied to constructor terms. Formally, we say that $u$ can be rewritten into $v$ if there is a position $p$ and a rule $\mathrm{g}\left(t_{1}, \ldots, t_{n}\right) \rightarrow t$ such that $u$ at position $p$ is equal to $\mathrm{g}\left(t_{1}, \ldots, t_{n}\right) \theta$ and $v=u[t \theta]_{p}$ (that is $u$ where the term at position $p$ has been replaced by $t \theta$ ) for some substitution $\theta$ such that $t_{1} \theta, \ldots, t_{n} \theta, t \theta$ are messages. We only consider sets of rewriting rules that yield convergent rewrite systems. We denote by $u \downarrow$ the normal form of a given term $u$. We refer the reader to [42] for the precise definitions of rewriting systems, convergence, and normal forms.

Example 2.1.1. A typical signature for representing symmetric encryption and pair is

$$
\Sigma=\left\{\text { senc, sdec, }\langle \rangle, \operatorname{proj}_{1}, \operatorname{proj}_{2}\right\} \uplus \Sigma_{0}
$$

where $\Sigma_{0}$ is a set of atomic data. The set $\Sigma_{0}$ typically contains the public constants known to the attacker (e.g. agent names $a, b, \ldots$ ). The symbols senc and sdec of arity 2 represent symmetric encryption and decryption. Pairing
is modelled using $\left\rangle\right.$ of arity 2 , whereas projection functions are denoted $\operatorname{proj}_{1}$ and $\operatorname{proj}_{2}$ (both of arity 1 ). The relations between encryption/decryption and pairing/projections are represented through the following convergent rewrite system:

$$
\operatorname{sdec}(\operatorname{senc}(x, y), y) \rightarrow x, \quad \text { and } \operatorname{proj}_{i}\left(\left\langle x_{1}, x_{2}\right\rangle\right) \rightarrow x_{i} \text { with } i \in\{1,2\} .
$$

We have that $\operatorname{proj}_{1}\left(\operatorname{sdec}\left(\operatorname{senc}\left(\left\langle s_{1}, s_{2}\right\rangle, k\right), k\right)\right) \downarrow=s_{1}$. Note that, since a destructor can only be applied on messages, no rewriting rule can be applied on the term $\operatorname{sdec}\left(\operatorname{senc}\left(s, \operatorname{proj}_{1}(s)\right), \operatorname{proj}_{1}(s)\right)$ which is thus in normal form (but not a message). This signature $\Sigma$ is split into two parts as follows: $\Sigma_{c}=\{$ senc, $\langle \rangle\} \uplus \Sigma_{0}$ and $\Sigma_{d}=$ $\left\{\mathrm{sdec}, \operatorname{proj}_{1}, \operatorname{proj}_{2}\right\}$. Then, we may consider $\mathcal{M}_{\Sigma}$ to be $\mathcal{M}_{c}=\mathcal{T}\left(\Sigma_{c}, \mathcal{N}\right)$ the set of all ground constructor terms. We may also restrict $\mathcal{M}_{\Sigma}$ to be $\mathcal{M}_{\text {atomic }}$, the set of ground constructor terms that only use atomic data in key position.

Finally, we assume $\Sigma$ to be split into two parts, and this distinction is orthogonal the one made between destructor and constructor symbols. We denote by $\Sigma_{\text {pub }}$ the set of function symbols that are public, i.e. available to the attacker, and $\Sigma_{\text {priv }}$ for those that are private. Actually, an attacker builds his own messages by applying public function symbols to terms he already knows. Formally, a computation done by the attacker is modelled by a term in $\mathcal{T}\left(\Sigma_{\text {pub }}, \Sigma_{0} \cup \mathcal{W}\right)$, called a recipe. Note that such a term does not contain any name. Indeed, all names are initially unknown to the attacker.

### 2.2 Process algebra

Let $\mathcal{C} h$ be an infinite set of channels. We consider processes built using the grammar below where $u \in \mathcal{T}\left(\Sigma_{c}, \mathcal{N} \cup \mathcal{X}\right)$, $v \in \mathcal{T}(\Sigma, \mathcal{N} \cup \mathcal{X}), n \in \mathcal{N}$, and $c, c^{\prime} \in \mathcal{C} h$ :

| $P, Q \quad:=$ | $\begin{aligned} & 0 \\ & \text { in }(c, u) \cdot P \\ & \text { out }(c, u) \cdot P \\ & \text { let } x=v \text { in } P \\ & (P \mid Q) \\ & !P \\ & \text { new } n . P \\ & \text { new } c^{\prime} . \text { out }\left(c, c^{\prime}\right) \cdot P \end{aligned}$ | null <br> input <br> output <br> evaluation <br> parallel <br> replication <br> restriction <br> channel generation |
| :---: | :---: | :---: |

The process 0 does nothing. The process "in $(c, u) . P$ " expects a message $m$ of the form $u$ on channel $c$ and then behaves like $P \sigma$ where $\sigma$ is a substitution such that $m=u \sigma$. The process "out $(c, u) . P$ " emits $u$ on channel $c$, and then behaves like $P$. The variables that occur in $u$ are instantiated when the evaluation takes place. The process "let $x=v$ in $P$ " tries to evaluate $v$ and in case of success the process $P$ is executed; otherwise the process is blocked. The process " $P \mid Q$ " runs $P$ and $Q$ in parallel. The process " $P$ " executes $P$ some arbitrary number of times. The restriction "new $n$ " is used to model the creation of a fresh random number (e.g., a nonce or a key) whereas channel generation "new $c^{\prime}$.out $\left(c, c^{\prime}\right) . P$ " is used to model the creation of a fresh channel name that shall immediately be made public. Note that we consider only public channels. It is still useful to generate fresh channel names to let the attacker identify the different sessions (as it is often the case in practice through sessions identifiers).

Note that our calculus allows both message filtering as well as explicit application of destructor symbols. For example, to represent a process that waits for a message, decrypts it with a key $k$, and sends the plaintext in clear, we may write $P=\operatorname{in}(c, \operatorname{senc}(x, k))$.out $(c, x)$ as well as $Q=\operatorname{in}(c, y)$.let $x=\operatorname{sdec}(y, k)$ in out $(c, x)$. However, the choice of filtering or let yields a slightly different behaviour since a message will be received in $P$ only if it matches the expected format while any message will be received in $Q$ (and then the format is checked).

We write $f v(P)$ for the set of free variables that occur in $P$, i.e. the set of variables that are not in the scope of an input or a let construction. We assume $\mathcal{C} h=\mathcal{C} h_{0} \uplus \mathcal{C} h^{\text {fresh }}$ where $\mathcal{C} h_{0}$ and $\mathcal{C} h^{\text {fresh }}$ are two infinite sets of channels. Intuitively, channels of $\mathcal{C} h^{\text {fresh }}$, denoted $c h_{1}, \ldots, c h_{i}, \ldots$ will be used in the semantics to instantiate the channels generated during the execution of a protocol. They shall not be part of its specification.

Definition 2.2.1. A protocol $P$ is a process such that $P$ is ground, i.e. $f v(P)=\emptyset$; and $P$ does not use channel names from $\mathcal{C} h^{\text {fresh }}$.

Example 2.2.1. The Denning Sacco protocol [30] (without timestamps) is a key distribution protocol using symmetric encryption and a trusted server. It can be described informally as follows:

$$
\begin{aligned}
& \text { 1. } A \rightarrow S: A, B \\
& \text { 2. } S \rightarrow A:\left\{B, K_{a b},\left\{K_{a b}, A\right\}_{K_{b s}}\right\}_{K_{a s}} \\
& \text { 3. } A \rightarrow B:\left\{K_{a b}, A\right\}_{K_{b s}}
\end{aligned}
$$

where $\{m\}_{k}$ denotes the symmetric encryption of a message $m$ with key $k$. The agents $A$ and $B$ aim at authenticating each other and establishing a session key $K_{a b}$ through a trusted server $S$. The key $K_{a s}$ (resp. $K_{b s}$ ) is a long term key shared between $A$ and $S$ (resp. $B$ and $S$ ).

We model the Denning Sacco protocol in our formalism. Below, $k_{a s}, k_{b s}, k_{a b}$ are names, whereas a and b are constants from $\Sigma_{0}$. We denote by $\left\langle x_{1}, \ldots, x_{n-1}, x_{n}\right\rangle$ the term $\left\langle x_{1},\left\langle\ldots\left\langle x_{n-1}, x_{n}\right\rangle\right\rangle\right\rangle$. The protocol is modelled by the parallel composition of three processes $P_{A}, P_{B}$, and $P_{S}$, corresponding to the roles of $A, B$, and $S$.

$$
\begin{aligned}
& P_{\mathrm{DS}}= \text { !new } c_{1} \text {.out }\left(c_{A}, c_{1}\right) \cdot P_{A} \mid \text { !new } c_{2} \text {.out }\left(c_{B}, c_{2}\right) \cdot P_{B} \\
& \mid \text { !new } c_{3} \text {.out }\left(c_{S}, c_{3}\right) \cdot P_{S}
\end{aligned}
$$

The processes $P_{A}, P_{B}$, and $P_{S}$ are given below.

$$
\begin{aligned}
P_{A}= & \operatorname{out}\left(c_{1},\langle\mathrm{a}, \mathrm{~b}\rangle\right) . \\
& \operatorname{in}\left(c_{1}, \operatorname{enc}\left(\left\langle\mathrm{~b}, x_{A B}, x_{B}\right\rangle, k_{a s}\right)\right) . \\
& \operatorname{out}\left(c_{1}, x_{B}\right) \\
P_{B}= & \operatorname{in}\left(c_{2}, \operatorname{enc}\left(\left\langle y_{A B}, \mathrm{a}\right\rangle, k_{b s}\right)\right) \\
P_{S}= & \operatorname{in}\left(c_{3},\langle\mathrm{a}, \mathrm{~b}\rangle\right) . \text { new } k_{a b} . \\
& \operatorname{out}\left(c_{3}, \operatorname{enc}\left(\left\langle\mathrm{~b}, k_{a b}, \operatorname{enc}\left(\left\langle k_{a b}, \mathrm{a}\right\rangle, k_{b s}\right)\right\rangle, k_{a s}\right)\right)
\end{aligned}
$$

### 2.3 Semantics

The operational semantics of a process is defined using a relation over configurations. A configuration is a pair $(\mathcal{P} ; \phi)$ where:

- $\mathcal{P}$ is a multiset of ground processes.
- $\phi=\left\{\mathrm{w}_{1} \triangleright m_{1}, \ldots, \mathrm{w}_{n} \triangleright m_{n}\right\}$ is a frame, i.e. a substitution where $\mathrm{w}_{1}, \ldots, \mathrm{w}_{n}$ are variables in $\mathcal{W}$, and $m_{1}, \ldots, m_{n}$ are messages, i.e. terms in $\mathcal{M}_{\Sigma}$.

We often write $P$ instead of $(\{P\} ; \emptyset)$, and $P \cup \mathcal{P}$ or $P \mid \mathcal{P}$ instead of $\{P\} \cup \mathcal{P}$. The terms in $\phi$ represent the messages that are known by the attacker.

The frame $\phi$ represents the messages the attacker has learnt so far. He may deduce new messages from his knowledge. This is formalised through the deducibility notion.

Definition 2.3.1. A message $u$ is deducible from a frame $\phi$, denoted $\phi \vdash u$, if there exists a recipe $R$ such that $R \phi \downarrow=u$.

The operational semantics of a process is induced by the relation $\xrightarrow{\alpha}$ as defined in Figure 2.1.
The first rule allows the attacker to send to some process a term built from publicly available terms and symbols. The second rule corresponds to the output of a term: the corresponding term is added to the frame of the current configuration, which means that the attacker can now access the sent term. Note that the term is outputted provided

$$
\begin{aligned}
& \text { (in }(c, u) . P \cup \mathcal{P} ; \phi) \xrightarrow{\text { in }(c, R)}(P \sigma \cup \mathcal{P} ; \phi) \quad \text { where } R \text { is a recipe such that } R \phi \downarrow \\
& \text { is a message and } R \phi \downarrow=u \sigma \text { for some } \sigma \text { with } \operatorname{dom}(\sigma)=\operatorname{vars}(u) \\
& \text { (out }(c, u) . P \cup \mathcal{P} ; \phi) \xrightarrow{\text { out }\left(c, w_{i+1}\right)}\left(P \cup \mathcal{P} ; \phi \cup\left\{\mathrm{w}_{i+1} \triangleright u\right\}\right) \\
& \text { where } u \text { is a message and } i \text { is the number of elements in } \phi \\
& \text { (new } \left.c^{\prime} . \operatorname{out}\left(c, c^{\prime}\right) . P \cup \mathcal{P} ; \phi\right) \xrightarrow{\text { out }\left(c, c h_{i}\right)}\left(P\left\{c c_{i} / c^{\prime}\right\} \cup \mathcal{P} ; \phi\right) \\
& \text { where } c h_{i} \text { is the "next" fresh channel name available in } \mathcal{C} h^{\text {fresh }} \\
& \text { (let } x=v \text { in } P \cup \mathcal{P} ; \phi) \xrightarrow{\tau}(P\{v \downarrow / x\} \cup \mathcal{P} \phi) \quad \text { where } v \downarrow \text { is a message } \\
& \text { (new } n . P \cup \mathcal{P} ; \phi) \xrightarrow{\tau}\left(P\left\{n^{\left.n^{\prime} / n\right\}} \cup \mathcal{P} ; \phi\right) \quad \text { where } n^{\prime} \text { is a fresh name in } \mathcal{N}\right. \\
& (!P \cup \mathcal{P} ; \phi) \xrightarrow{\tau}(P \cup!P \cup \mathcal{P} ; \phi)
\end{aligned}
$$

Figure 2.1: Semantics of protocols
that it is a message. The third rule corresponds to the special case of an output of a freshly generated channel name. In such a case, the channel is not added to the frame but it is implicitly assumed known to the attacker, as all the channel names. These three rules are the only observable actions. The fourth rule corresponds to the evaluation of the term $v$; if this succeeds, i.e. if $v \downarrow$ is a message then $x$ is bound to the result and $P$ is executed; otherwise the process is blocked. The two remaining rules are quite standard and are unobservable by the attacker.

The relation $\xrightarrow{\alpha_{1} \ldots \alpha_{n}}$ between configurations (where $\alpha_{1} \ldots \alpha_{n}$ is a sequence of actions) is defined as the transitive closure of $\xrightarrow{\alpha}$. Given a sequence of observable actions tr, we write $K \stackrel{\mathrm{tr}}{\Longrightarrow} K^{\prime}$ when there exists a sequence $\alpha_{1} \ldots \alpha_{n}$ such that $K \xrightarrow{\alpha_{1} \ldots \alpha_{n}} K^{\prime}$ and $\operatorname{tr}$ is obtained from $\alpha_{1} \ldots \alpha_{n}$ by erasing all occurrences of $\tau$. For every protocol $P$, we define its set of traces as follows:

$$
\operatorname{trace}(P)=\{(\operatorname{tr}, \phi) \mid P \stackrel{\operatorname{tr}}{\Longrightarrow}(\mathcal{P} ; \phi) \text { for some configuration }(\mathcal{P} ; \phi)\}
$$

Example 2.3.1. From Example 2.2.1, consider the following sequence tr :

$$
\begin{aligned}
\operatorname{tr}= & \operatorname{out}\left(c_{A}, c h_{1}\right) \cdot \operatorname{out}\left(c_{B}, c h_{2}\right) \cdot \operatorname{out}\left(c_{S}, c h_{3}\right) . \\
& \operatorname{out}\left(c h_{1}, \mathrm{w}_{1}\right) \cdot \operatorname{in}\left(c h_{3}, \mathrm{w}_{1}\right) \cdot \operatorname{out}\left(c h_{3}, \mathrm{w}_{2}\right) . \\
& \operatorname{in}\left(c h_{1}, \mathrm{w}_{2}\right) \cdot \operatorname{out}\left(c h_{1}, \mathrm{w}_{3}\right) \cdot \operatorname{in}\left(c h_{2}, \mathrm{w}_{3}\right)
\end{aligned}
$$

This sequence tr allows one to reach the frame:

$$
\phi=\left\{\mathrm{w}_{1} \triangleright\langle\mathrm{a}, \mathrm{~b}\rangle, \mathrm{w}_{2} \triangleright \operatorname{enc}\left(\left\langle\mathrm{~b}, k_{a b}, \operatorname{enc}\left(\left\langle k_{a b}, \mathrm{a}\right\rangle, k_{b s}\right)\right\rangle, k_{a s}\right), \mathrm{w}_{3} \triangleright \operatorname{enc}\left(\left\langle k_{a b}, \mathrm{a}\right\rangle, k_{b s}\right)\right\} .
$$

We have that $(\operatorname{tr}, \phi) \in \operatorname{trace}\left(P_{\mathrm{DS}}\right)$. This trace corresponds to a normal execution of the protocol. Moreover we have that, for instance, a is deducible, as $\operatorname{proj}_{1}\left(\mathrm{w}_{1}\right) \phi \downarrow=\mathrm{a}$.

### 2.4 Trace equivalence

Intuitively, two protocols are equivalent if they cannot be distinguished by any attacker. Trace equivalence can be used to formalise many interesting security properties, in particular privacy-type properties, such as those studied for instance in $[18,39]$. We first define indistinguishability of sequences of messages, called static equivalence.

Definition 2.4.1. Two frames $\phi_{1}$ and $\phi_{2}$ are statically equivalent, $\phi_{1} \sim \phi_{2}$, when we have that $\operatorname{dom}\left(\phi_{1}\right)=\operatorname{dom}\left(\phi_{2}\right)$, and:

- for any recipe $R, R \phi_{1} \downarrow \in \mathcal{M}_{\Sigma}$ if, and only if, $R \phi_{2} \downarrow \in \mathcal{M}_{\Sigma}$; and
- for all recipes $R_{1}$ and $R_{2}$ such that $R_{1} \phi_{1} \downarrow, R_{2} \phi_{1} \downarrow \in \mathcal{M}_{\Sigma}$, we have that

$$
R_{1} \phi_{1} \downarrow=R_{2} \phi_{1} \downarrow \text { if, and only if, } R_{1} \phi_{2} \downarrow=R_{2} \phi_{2} \downarrow .
$$

Intuitively, two frames are equivalent if an attacker cannot see the difference between the two situations they represent. If some computation fails in $\phi_{1}$ for some recipe $R$, i.e. $R \phi_{1} \downarrow$ is not a message, it should fail in $\phi_{2}$ as well. Moreover, the frames $\phi_{1}$ and $\phi_{2}$ should satisfy the same equalities. In other words, the ability of the attacker to distinguish whether a recipe $R$ produces a message, or whether two recipes $R_{1}, R_{2}$ produce the same message should not depend on the frame.
Example 2.4.1. Consider $\phi_{1}=\left\{\mathrm{w}_{1} \triangleright \operatorname{senc}\left(\mathrm{~m}_{1}, \mathrm{k}_{i}\right)\right\}$, and $\phi_{2}=\left\{\mathrm{w}_{1} \triangleright \operatorname{senc}\left(\mathrm{~m}_{2}, \mathrm{k}_{i}\right)\right\}$. Assuming that $\mathrm{m}_{1}, \mathrm{~m}_{2}$ and $\mathrm{k}_{i}$ are public constants from $\Sigma_{0}$, we have that $\phi_{1} \nsim \phi_{2}$. An attacker can observe that decrypting the message of $\phi_{1}$ with the public constant $\mathrm{k}_{i}$ leads to the public constant $\mathrm{m}_{1}$. This is not the case in $\phi_{2}$. Consider the recipes $R_{1}=\operatorname{sdec}\left(\mathrm{w}_{1}, \mathrm{k}_{i}\right)$ and $R_{2}=\mathrm{m}_{1}$. We have that $R_{1} \phi_{1} \downarrow=R_{2} \phi_{1} \downarrow$ whereas $R_{1} \phi_{2} \downarrow \neq R_{2} \phi_{2} \downarrow$.

Intuitively, two protocols are trace equivalent if, however they behave, the resulting sequences of messages observed by the attacker are in static equivalence.
Definition 2.4.2. Let $P$ and $Q$ be two protocols. We have that $P \sqsubseteq Q$ if for every $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$, there exists $\left(\operatorname{tr}^{\prime}, \phi^{\prime}\right) \in \operatorname{trace}(Q)$ such that $\operatorname{tr}=\operatorname{tr}^{\prime}$ and $\phi \sim \phi^{\prime}$. They are in trace equivalence, written $P \approx Q$, if $P \sqsubseteq Q$ and $Q \sqsubseteq P$.

The choice of $\mathcal{M}_{\Sigma}$ as well as the choice of public symbols allow to fine-tune what an attacker can observe. The set of public function symbols tell exactly which functions the attacker may use. Then the choice $\mathcal{M}_{\Sigma}$ defines when computations fail. For example, if $\mathcal{M}_{\Sigma}$ represents the set of terms with atomic keys only, then an attacker may potentially observe that some computation fails because he was able to inject a non atomic key.
Example 2.4.2. Let $n, k \in \mathcal{N}$ and consider the protocol $P=\operatorname{in}(c, x) . \operatorname{out}(c, \operatorname{enc}(n, k))$ as well as the protocol $Q=\operatorname{in}(c, x)$.out $(c, \operatorname{enc}(\operatorname{enc}(n, x), k))$. An attacker may distinguish between $P$ and $Q$ by sending a non atomic data and observing whether the process can emit. $Q$ will not be able to emit since its first encryption will fail. This attack would not have been detected if arbitrary terms were allowed in key position.

Example 2.4.3. The process $P_{\mathrm{DS}}$ presented in Example 2.2 .1 models the Denning Sacco protocol. Assume now that we wish to check strong secrecy of the exchanged key, as received by the agent $B$. As discussed in Introduction, this can be expressed by checking whether $P_{\mathrm{DS}}^{1} \approx P_{\mathrm{DS}}^{2}$ where:

- $P_{\mathrm{DS}}^{1}$ is as $P_{\mathrm{DS}}$ but we add " $\beta_{2}: \operatorname{out}\left(c_{2}, \operatorname{enc}\left(\mathrm{~m}_{1}, y_{A B}\right)\right)$ " at the end of the process $P_{B}$;
- $P_{\mathrm{DS}}^{2}$ is as the protocol $P_{\mathrm{DS}}$ but we add at the end of $P_{B}$ the instruction
"new $k$. $\beta_{2}$ : out $\left(c_{2}, \operatorname{enc}\left(\mathrm{~m}_{2}, k\right)\right.$ )".
The terms $m_{1}$ and $m_{2}$ are two public constants from $\Sigma_{0}$.
While the key received by $B$ cannot be learnt by an attacker, strong secrecy of this key is not guaranteed. Indeed, due to the lack of freshness, the same key can be sent several times to $B$, and this can be observed by an attacker. Formally, the attack is as follows. Consider the sequence

$$
\operatorname{tr}^{\prime}=\operatorname{tr} . \mathrm{out}\left(c h_{2}, \mathrm{w}_{4}\right) \cdot \operatorname{out}\left(c_{B}, c h_{4}\right) \cdot \operatorname{in}\left(c h_{4}, \mathrm{w}_{3}\right) \cdot \operatorname{out}\left(c h_{4}, \mathrm{w}_{5}\right)
$$

where tr has been defined in Example 2.3.1. The attacker simply replays an old session. The resulting (unique) frames are

- $\phi_{1}^{\prime}=\phi \cup\left\{\mathrm{w}_{4} \triangleright \mathrm{enc}\left(\mathrm{m}_{1}, k_{a b}\right), \mathrm{w}_{5} \triangleright \mathrm{enc}\left(\mathrm{m}_{1}, k_{a b}\right)\right\}$; and
- $\phi_{2}^{\prime}=\phi \cup\left\{\mathrm{w}_{4} \triangleright \mathrm{enc}\left(\mathrm{m}_{2}, k\right), \mathrm{w}_{5} \triangleright \mathrm{enc}\left(\mathrm{m}_{2}, k^{\prime}\right)\right\}$.

Then $\left(\operatorname{tr}^{\prime}, \phi_{1}^{\prime}\right) \in \operatorname{trace}\left(P_{\mathrm{DS}}^{1}\right)$ and $\left(\operatorname{tr}^{\prime}, \phi_{2}^{\prime}\right) \in \operatorname{trace}\left(P_{\mathrm{DS}}^{2}\right)$. However, we have that $\phi_{1}^{\prime} \nsim \phi_{2}^{\prime}$ since $\mathrm{w}_{4}=\mathrm{w}_{5}$ in $\phi_{1}^{\prime}$ but not in $\phi_{2}^{\prime}$. Thus $P_{\mathrm{DS}}^{1}$ and $P_{\mathrm{DS}}^{2}$ are not in trace equivalence. To avoid this attack, the messages of the Denning-Sacco protocol shall include timestamps.

### 2.4.1 Determinate protocols

We consider determinate protocols as defined in [19], i.e., we consider protocols in which the attacker knowledge is completely determined (up to static equivalence) by its past interaction with the protocol participants.
Definition 2.4.3. A protocol $P$ is determinate if for any $\operatorname{tr}$, and for any $\left(\mathcal{P}_{1}, \phi_{1}\right),\left(\mathcal{P}_{2}, \phi_{2}\right)$ such that $P \xlongequal{\mathrm{tr}}\left(\mathcal{P}_{1}, \phi_{1}\right)$, and $P \stackrel{\mathrm{tr}}{\Longrightarrow}\left(\mathcal{P}_{2}, \phi_{2}\right)$, we have that $\phi_{1} \sim \phi_{2}$.

Determinate protocols are useful for the analysis of trace equivalence. Definition 2.4.2 can indeed be equivalently rewritten (see [19]) as:

Definition 2.4.4. Let $P$ and $Q$ be two determinate protocols. We have that $P \sqsubseteq Q$ if:

- for every $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ and for every recipe $R$ such that $R \phi \downarrow$ is a message, there exists $\left(\operatorname{tr}^{\prime}, \phi^{\prime}\right) \in \operatorname{trace}(Q)$ such that $\operatorname{tr}=\operatorname{tr}^{\prime}$ and $R \phi^{\prime} \downarrow$ is a message.
- for every $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ and for every recipes $R$ and $R^{\prime}$ such that $R \phi \downarrow, R^{\prime} \phi \downarrow$ are messages and $R \phi \downarrow=$ $R^{\prime} \phi \downarrow$, there exists $\left(\operatorname{tr}^{\prime}, \phi^{\prime}\right) \in \operatorname{trace}(Q)$ such that $\operatorname{tr}=\operatorname{tr}^{\prime}$ and $R \phi^{\prime} \downarrow=R \phi^{\prime} \downarrow$.

They are in trace equivalence, written $P \approx Q$, if $P \sqsubseteq Q$ and $Q \sqsubseteq P$.
This allows us to get rid of an alternation between quantifiers in the original definitions and makes possible the algorithms and proofs we describe in the next chapters.

### 2.4.2 Simple protocols

We then introduce the class of simple protocols, similar to the one introduced e.g. in [33].
Definition 2.4.5. A simple protocol $P$ is a protocol of the form:

$$
\text { !new } c_{1}^{\prime} \text {.out }\left(c_{1}, c_{1}^{\prime}\right) \cdot B_{1}|\ldots| \text { !new } c_{m}^{\prime} \cdot \text { out }\left(c_{m}, c_{m}^{\prime}\right) \cdot B_{m}\left|B_{m+1}\right| \ldots \mid B_{m+p}
$$

where each $B_{i}$ with $1 \leq i \leq m+p$ is a basic process on $c_{i}$, that is a ground process built using the following grammar:

$$
B:=0\left|\operatorname{in}\left(c_{i}, u\right) \cdot B\right| \text { out }\left(c_{i}, u\right) \cdot B \mid \text { let } x=v \text { in } B \mid \text { new } n . B
$$

where $u \in \mathcal{T}\left(\Sigma_{c}, \mathcal{N} \cup \mathcal{X}\right), v \in \mathcal{T}(\Sigma, \mathcal{N} \cup \mathcal{X})$, and $n \in \mathcal{N}$. Moreover, we assume that $c_{1}, \ldots, c_{m}, c_{m+1}, \ldots, c_{m+p}$ are pairwise distinct.

Even if considering simple processes may seem to be restricted, in practice it is often the case that an attacker may identify processes through e.g. IP addresses and even sessions using sessions identifiers. Therefore, encoding protocols in such a class may be considered as a good practice since it allows to potentially discover more flaws. Indeed, it gives more power to the attacker and allows him to know from which agent he receives a message.

Lemma 2.4.1. A simple protocol is determinate.
Intuitively, as simple protocols use fresh channels on each of their branches, given a trace of that simple protocol, only one execution is possible, which then leads to a uniquely defined frame, up to renamings of nonces.

### 2.5 Type-compliant protocols

We describe several classes of protocols which will be used for our later results. They introduce the notion of typing system and type-compliance. These ideas are at the core of the results from Chapter 4 onward.

### 2.5.1 Typing systems

We now introduce the notion of type-compliance for protocols w.r.t. typing systems. In these protocols, terms are given a particular type and we require that types are preserved by unification and application of substitutions. These operations are indeed routinely used in decision procedures.

The type given to any term is defined by a typing system whose definition we give below.
Definition 2.5.1. A typing system is a pair $(\mathcal{T}, \delta)$ where $\mathcal{T}$ is a set of elements called types, and $\delta$ is a function mapping terms $t \in \mathcal{T}\left(\Sigma_{c}, \Sigma_{0} \cup \mathcal{N} \cup \mathcal{X}\right)$ to types $\tau$ in $\mathcal{T}$ such that:

- if $t$ is a term of type $\tau$ and $\sigma$ is a well-typed substitution, i.e. $\forall x \in \operatorname{dom}(\sigma), \delta(x)=\delta(x \sigma)$, then $t \sigma$ is of type $\tau$,
- for any terms $t$ and $t^{\prime}$ with the same type, i.e. $\delta(t)=\delta\left(t^{\prime}\right)$ and which are unifiable, their most general unifier ( $m g u\left(t, t^{\prime}\right)$ ) is well-typed.

We further assume the existence of an infinite number of constants in $\Sigma_{0}$ (resp. variables in $\mathcal{X}$, names in $\mathcal{N}$ ) of any type.

A straightforward typing system is when all terms are of a unique type, say Msg. Of course, our typing result would then be useless to reduce the search space for attacks. Which typing system shall be used typically depends on the protocols under study.

Structure-preserving typing systems are example of useful typing systems, as it will be demonstrated in depth in Chapter 6. These more precise typing systems preserve the structure of terms and are defined as follows:

Definition 2.5.2. A structure-preserving typing system is a pair $\left(\mathcal{T}_{0}, \delta_{0}\right)$ where $\mathcal{T}_{0}$ is a set of elements called atomic types, and $\delta_{0}$ is a function mapping atomic terms in $\Sigma_{0} \cup \mathcal{N} \cup \mathcal{X}$ to types $\tau$ generated using the following grammar:

$$
\tau, \tau_{1}, \ldots, \tau_{n}=\begin{array}{ll}
\tau_{0} & \text { with } \tau_{0} \in \mathcal{T}_{0} \\
\mid \mathrm{f}\left(\tau_{1}, \ldots, \tau_{n}\right) & \text { with } \mathrm{f} \in \Sigma_{\mathrm{c}}
\end{array}
$$

We further assume the existence of an infinite number of constants in $\Sigma_{0}$ (resp. variables in $\mathcal{X}$, names in $\mathcal{N}$ ) of any type. Then, $\delta_{0}$ is extended to constructor terms as follows:

$$
\delta_{0}\left(\mathrm{f}\left(t_{1}, \ldots, t_{n}\right)\right)=\mathrm{f}\left(\delta_{0}\left(t_{1}\right), \ldots, \delta_{0}\left(t_{n}\right)\right) \text { with } \mathrm{f} \in \Sigma_{\mathrm{c}} .
$$

Note that a structure-preserving typing system is a special case of typing system, whose types are defined only slightly differently. Lemma 2.5.1 formally links the two definitions.

Lemma 2.5.1. If $\left(\mathcal{T}_{0}, \delta_{0}\right)$ is a structure-preserving typing system, $\left(\operatorname{img}\left(\delta_{0}\right), \delta_{0}\right)$ is a typing system, where $\operatorname{img}\left(\delta_{0}\right)$ is the image of the extension of $\delta_{0}$ to arbitrary constructor terms.

Proof. Note that in Definition 2.5.1, $\mathcal{T}$ is the set of all types, whereas $\mathcal{T}_{0}$, as defined in Definition 2.5.2, only contains atomic types. The set of all types from $\mathcal{T}_{0}$ is obtained by looking at the image of the typing function extended to arbitrary types by induction on their structure: we set $\mathcal{T}=\operatorname{img}\left(\delta_{0}\right)$ and $\delta=\delta_{0}$. Let us then verify that the two items of Definition 2.5.1 apply to $(\mathcal{T}, \delta)$ :

- if $t$ is a term, $\delta_{P}(t)=\tau$ and $\sigma$ a well-typed substitution: let us reason by induction on $t$ :
- if $t$ is a constant, name or variable such that $t \notin \operatorname{dom}(\sigma), t=t \sigma$, and then $\delta(t \sigma)=\tau$,
- if $t$ is a variable and $t \in \operatorname{dom}(\sigma)$ : as $\sigma$ is well-typed, $\delta_{P}(x)=\delta_{P}(x \sigma)$ which amounts to $\delta_{P}(t)=$ $\delta_{P}(t \sigma)=\tau$,
- if $t=\mathrm{f}\left(t_{1}, \ldots, t_{n}\right)$ and for any $i, \delta_{P}\left(t_{i}\right)=\delta_{P}\left(t_{i} \sigma\right)$, then $\delta_{P}\left(\mathrm{f}\left(t_{1}, \ldots, t_{n}\right)\right)=\mathrm{f}\left(\delta_{P}\left(t_{1}\right), \ldots, \delta_{P}\left(t_{n}\right)\right)$ by Definition 2.5.2, which is equal to, by induction hypothesis, $f\left(\delta_{P}\left(t_{1} \sigma\right), \ldots, \delta_{P}\left(t_{n} \sigma\right)\right)$ and the same as $\delta_{P}\left(\mathrm{f}\left(t_{1} \sigma, \ldots, t_{n} \sigma\right)\right)$, by Definition 2.5.2 once again, leading to the result, $\delta_{P}(t)=\delta_{P}(t \sigma)$.
- for any terms $t, t^{\prime}$ such that $\delta_{P}(t)=\delta_{P}\left(t^{\prime}\right), \operatorname{mgu}\left(t, t^{\prime}\right)$ is well-typed: there again we prove the result by induction on the computation of the $m g u\left(t, t^{\prime}\right)$, as done e.g. in [6, Lemma 1].

### 2.5.2 Type compliance

The class of protocols we consider here is the class of protocols type-compliant w.r.t. some typing system. Their defining characteristic is that any two unifiable encrypted subterms are of the same type. The goal of this part is to state this hypothesis formally.

Due to the presence of replication, we need to consider two copies of protocols in order to consider different instances of the variables. Given a protocol $P$ with replication, we define its 2 -unfolding unfold ${ }^{2}(P)$ to be the protocol such that every occurrence of a process $!R$ in $P$ is replaced by $R \mid R$, and some $\alpha$-renaming is performed on one copy to ensure names and variables distinctness of the resulting process. Note that if $P$ is a protocol that does not contain any replication, we have that $\operatorname{unfold}^{2}(P)=P$.

Example 2.5.1. Let $P_{1}=\operatorname{in}(c, x)$.!new $k$. in $(c, \operatorname{enc}(\langle x, y\rangle, k))$. We have that:
$\operatorname{unfold}^{2}\left(P_{1}\right)=\operatorname{in}(c, x) \cdot\left(\right.$ new $k_{1} \cdot \operatorname{in}\left(c, \operatorname{enc}\left(\left\langle x, y_{1}\right\rangle, k_{1}\right)\right) \mid$ new $\left.k_{2} \cdot \operatorname{in}\left(c, \operatorname{enc}\left(\left\langle x, y_{2}\right\rangle, k_{2}\right)\right)\right)$
We write $S t(t)$ for the set of (syntactic) subterms of a term $t$, and $E S t(t)$ the set of its encrypted subterms, i.e. $\operatorname{ESt}(t)=\left\{u \in S t(t) \mid u\right.$ is of the form enc $\left.\left(u_{1}, u_{2}\right)\right\}$. We extend this notion to sets/sequences of terms, and to protocols as expected.
Definition 2.5.3. A protocol $P$ is type-compliant w.r.t. a typing system $(\mathcal{T}, \delta)$ if for every $t, t^{\prime} \in E S t\left(\operatorname{unfold}^{2}(P)\right)$ we have that: $t$ and $t^{\prime}$ unifiable implies that $\delta(t)=\delta\left(t^{\prime}\right)$.

Example 2.5.2. Going back to the protocols of Example 2.2.1 and 2.4.3, we consider the structure-preserving typing system generated from the set of atomic types

$$
\mathcal{T}_{\mathrm{DS}}=\left\{\tau_{\mathrm{a}}, \tau_{\mathrm{b}}, \tau_{\mathrm{m}}, \tau_{k a s}, \tau_{k b s}, \tau_{k a b}\right\}
$$

and the function $\delta_{\mathrm{DS}}$ that associates the expected type to each constant/name, and the following type to variables:

- $\delta_{\mathrm{DS}}\left(x_{A B}\right)=\delta_{\mathrm{DS}}\left(y_{A B}\right)=\tau_{k a b}$; and
- $\delta_{\mathrm{DS}}\left(x_{B}\right)=\operatorname{enc}\left(\left\langle\tau_{k a b}, \tau_{\mathrm{a}}\right\rangle, \tau_{k b s}\right)$.

Example 2.5.3. The protocol $P_{\mathrm{DS}}^{1}$ (resp. $P_{\mathrm{DS}}^{2}$ ) is type-compliant w.r.t. the typing system given in Example 2.5.2. Indeed, the encrypted subterms of unfold ${ }^{2}\left(P_{\mathrm{DS}}^{1}\right)$ are:

1. $t_{A}=\operatorname{enc}\left(\left\langle\mathrm{b}, x_{A B}, x_{B}\right\rangle, k_{a s}\right)$;
2. $t_{B 1}=\operatorname{enc}\left(\left\langle y_{A B}, \mathrm{a}\right\rangle, k_{b s}\right)$;
3. $t_{B 2}=\mathrm{enc}\left(\mathrm{m}_{1}, y_{A B}\right)$;
4. $t_{S 1}=\operatorname{enc}\left(\left\langle\mathrm{b}, k_{a b}, \operatorname{enc}\left(\left\langle k_{a b}, \mathrm{a}\right\rangle, k_{b s}\right)\right\rangle, k_{a s}\right)$; and
5. $t_{S 2}=\operatorname{enc}\left(\left\langle k_{a b}, a\right\rangle, k_{b s}\right)$
as well as the renaming of these terms obtained by replacing $k_{a b}, x_{A B}, y_{A B}$, and $x_{B}$ with fresh names/variables of the same type.

It is easy to check that the type-compliance condition is satisfied for any pair of terms. For instance, we have that $t_{A}$ and $t_{S 1}$ are unifiable, and they have indeed the same type:

$$
\begin{aligned}
\delta_{\mathrm{DS}}\left(t_{A}\right) & =\operatorname{enc}\left(\left\langle\tau_{\mathrm{b}}, \tau_{k a b}, \operatorname{enc}\left(\left\langle\tau_{k a b}, \tau_{\mathrm{a}}\right\rangle, \tau_{k b s}\right)\right\rangle, \tau_{k a s}\right) \\
& =\delta_{\mathrm{DS}}\left(t_{S 1}\right) .
\end{aligned}
$$

As shown in the following example, not all protocols are type-compliant w.r.t. a structure-preserving typing system.
Example 2.5.4. For instance, consider the following protocol:

$$
P=!\text { new } c . \text { out }\left(c, c^{\prime}\right) \cdot \operatorname{in}\left(c^{\prime}, \operatorname{enc}(x, k)\right) . \text { out }\left(c^{\prime}, \operatorname{enc}(\langle x, x\rangle, k)\right.
$$

We have that $t_{1}=\operatorname{enc}(x, k)$ and $t_{2}=\operatorname{enc}(\langle x, x\rangle, k)$ are both in $E S t\left(\operatorname{unfold}^{2}(P)\right)$ as well as the terms $t_{1}^{\prime}$ and $t_{2}^{\prime}$ obtained from $t_{1}$ and $t_{2}$ by simply renaming $x$ with another variable, say $x^{\prime}$, having the same type as $x$. The two terms $t_{1}$ and $t_{2}^{\prime}$ are unifiable, and thus should receive the same type, but this would imply that $\delta(x)=\left\langle\delta\left(x^{\prime}\right), \delta\left(x^{\prime}\right)\right\rangle$, and thus $x$ can not receive the same type as $x^{\prime}$.

### 2.5.3 Tagged protocols

Finally, as an instance of our definitions, we consider tagged protocols, for a notion of tagging similar to one introduced by Blanchet and Podelski [15]. They form an interesting particular case of type-compliant protocols. Assume given a protocol $P$ and an unfolding $P^{\prime}$ of it (remember that when computing unfold ${ }^{2}(P)$ names and variables are renamed to avoid clashes). Let $u$ be a term in $\mathcal{T}\left(\Sigma_{c}, \Sigma_{P} \cup \mathcal{N}_{P}^{\prime} \cup \mathcal{X}_{P}^{\prime}\right)$ where $\Sigma_{P}, \mathcal{N}_{P}^{\prime}, \mathcal{X}_{P}^{\prime}$ are the constants, names, and variables occurring in $P^{\prime}$, we denote by $\bar{u}$ the transformation that replaces any name and variable occurring in $u$ by its antecedent in $\mathcal{N}_{P}$ and $\mathcal{X}_{P}$ where $\mathcal{N}_{P}$ and $\mathcal{X}_{P}$ are the names and variables occurring in $P$.
Definition 2.5.4. A protocol $P$ is tagged if there exists a substitution $\sigma_{P}$ such that for any $s_{1}, s_{2} \in E S t\left(\operatorname{unfold}^{2}(P)\right)$ with $s_{1}$ and $s_{2}$ unifiable, we have that $\overline{s_{1} \sigma_{P}}=\overline{s_{2} \sigma_{P}}$.

The protocols introduced in Example 2.4.3 are example of tagged protocols. If a protocol is not naturally tagged, tagging can easily be enforced by labelling encrypted terms, as proposed in [15].

Definition 2.5.5. A protocol $P$ is strongly tagged if:

1. any term in $\operatorname{ESt}(P)$ is of the form enc $(\langle\mathrm{c}, m\rangle, k)$ for some $\mathrm{c} \in \Sigma_{0}$; and
2. there exists $\sigma_{P}$ such that for any $s, t \in E S t(P)$ with $s=\operatorname{enc}\left(\left\langle\mathrm{c}_{0}, s_{1}\right\rangle, s_{2}\right)$ and $t=\operatorname{enc}\left(\left\langle\mathrm{c}_{0}, t_{1}\right\rangle, t_{2}\right)$ for some $\mathrm{c}_{0} \in \Sigma_{0}$, we have that $s \sigma_{P}=t \sigma_{P}$.

The second condition requires that there is a substitution that unifies any two tagged terms unless their tags differ. This condition is easy to achieve for executable protocols. More precisely, assume a protocol admits an execution where each protocol step (in and out) is executed once (i.e. there is one honest execution). This protocol can be easily strongly tagged by adding a distinct tag in each encrypted term.

Lemma 2.5.2. Let $P$ be a protocol. If $P$ is strongly tagged then $P$ is tagged.
Proof. Let us assume $P$ is a strongly tagged protocol and $\sigma_{P}$ be the substitution as in Definition 2.5.5. Let $s_{1}, s_{2} \in$ $E S t\left(\right.$ unfold $\left.^{2}(P)\right)$ such that there exists $\sigma$ with $s_{1} \sigma=s_{2} \sigma$. As both terms are of the form enc $\left(\left\langle\mathrm{c}, u_{i}\right\rangle, v_{i}\right)$ for some $u_{i}$ and $v_{i}$ and are unifiable, they share the same tagging constant c . Then $s_{1} \sigma_{P}=s_{2} \sigma_{P}$ by Definition 2.5.5, and thus, $a$ fortiori, $\overline{s_{1} \sigma_{1}}=\overline{s_{2} \sigma_{2}}$.

Example 2.5.5. The Otway-Rees protocol [30] is a key distribution protocol using symmetric encryption and a trusted server. It can be described informally as follows:

1. $A \rightarrow B: M, A, B,\left\{N_{a}, M, A, B\right\}_{K_{a s}}$
2. $B \rightarrow S: M, A, B,\left\{N_{a}, M, A, B\right\}_{K_{a s}},\left\{N_{b}, M, A, B\right\}_{K_{b s}}$
3. $S \rightarrow B: M,\left\{N_{a}, K_{a b}\right\}_{K_{a s}},\left\{N_{b}, K_{a b}\right\}_{K_{b s}}$
4. $B \rightarrow A: M,\left\{N_{a}, K_{a b}\right\}_{K_{a s}}$
where $\{m\}_{k}$ denotes the symmetric encryption of a message $m$ with key $k, A$ and $B$ are agents trying to authenticate each other, $S$ is a trusted server, $K_{a s}$ (resp. $K_{b s}$ ) is a long term key shared between $A$ and $S$ (resp. $B$ and $S$ ), $N_{a}$ and $N_{b}$ are nonces generated by $A$ and $B, K_{a b}$ is a session key generated by $S$, and $M$ is a session identifier.

We propose a modelling of the Otway-Rees protocol in our formalism. We use restricted channels to model the use of unique session identifiers used along an execution of the protocol. Below, $k_{a s}, k_{b s}, m, n_{a}, n_{b}, k_{a b}$ are names, whereas a and b are constants from $\Sigma_{0}$. We denote by $\left\langle x_{1}, \ldots, x_{n-1}, x_{n}\right\rangle$ the term $\left\langle x_{1},\left\langle\ldots\left\langle x_{n-1}, x_{n}\right\rangle\right\rangle\right\rangle$.

$$
P_{\mathrm{OR}}=\text { ! new } c_{1} \text {.out }\left(c_{A}, c_{1}\right) . P_{A} \mid \text { !new } c_{2} \text {.out }\left(c_{B}, c_{2}\right) . P_{B} \mid \text { !new } c_{3} \text {.out }\left(c_{S}, c_{3}\right) . P_{S}
$$

where the processes $P_{A}, P_{B}$ are given below, and $P_{S}$ can be defined in a similar way.

$$
\begin{aligned}
P_{A}= & \text { new } m . \text { new } n_{a} \cdot \operatorname{out}\left(c_{1},\left\langle m, \mathrm{a}, \mathrm{~b}, \operatorname{enc}\left(\left\langle n_{a}, m, \mathrm{a}, \mathrm{~b}\right\rangle, k_{a s}\right)\right\rangle\right) \\
& \operatorname{in}\left(c_{1},\left\langle m, \operatorname{enc}\left(\left\langle n_{a}, x_{a b}\right\rangle, k_{a s}\right)\right\rangle\right) ; \\
P_{B}= & \operatorname{in}\left(c_{2},\left\langle y_{m}, \mathrm{a}, \mathrm{~b}, y_{a s}\right\rangle\right) \cdot \operatorname{new} n_{b} . \text { out }\left(c_{2},\left\langle y_{m}, \mathrm{a}, \mathrm{~b}, y_{a s}, \operatorname{enc}\left(\left\langle n_{b}, y_{m}, \mathrm{a}, \mathrm{~b}\right\rangle, k_{b s}\right)\right\rangle\right) . \\
& \operatorname{in}\left(c_{2},\left\langle y_{m}, z_{a s}, \operatorname{enc}\left(\left\langle n_{b}, y_{a b}\right\rangle, k_{b s}\right)\right\rangle\right) \cdot \text { out }\left(c_{2},\left\langle y_{m}, z_{a s}\right\rangle\right)
\end{aligned}
$$

In our modelling, $P_{\mathrm{OR}}$ is not tagged. For instance, let us consider the two terms $s_{1}=\operatorname{enc}\left(\left\langle n_{a}, m, \mathrm{a}, \mathrm{b}\right\rangle, k_{a s}\right)$ and $s_{2}=\operatorname{enc}\left(\left\langle n_{a}, x_{a b}\right\rangle, k_{a s}\right)$. Both are encrypted subterms of $P_{A}$ (and thus of unfold $\left.{ }^{2}\left(P_{\mathrm{OR}}\right)\right)$ and $s_{1}$ and $s_{2}$ are unifiable. Now, consider $s_{3}=\operatorname{enc}\left(\left\langle z_{a}, k_{a b}\right\rangle, k_{a s}\right)$. Actually, $s_{3}$ is an encrypted subterm of $P_{S}$ which is unifiable with $s_{2}$. However, there exists no substitution $\sigma$ such that $\overline{s_{1} \sigma}=\overline{s_{2} \sigma}=\overline{s_{3} \sigma}$.

We can consider a strongly tagged, and safer, version of the Otway-Rees protocol by introducing 4 different tags, denoted 1,2,3 and 4, that are modelled using constants from $\Sigma_{0}$.

$$
\begin{aligned}
& P_{\mathrm{OR}}^{\prime}=\text { ! new } c_{1} \text {.out }\left(c_{A}, c_{1}\right) . P_{A}^{\prime} \mid \text { !new } c_{2} \text {.out }\left(c_{B}, c_{2}\right) \cdot P_{B}^{\prime} \mid \text { ! new } c_{3} \text {.out }\left(c_{S}, c_{3}\right) \cdot P_{S}^{\prime} \\
& P_{A}^{\prime}=\text { new } m \text {.new } n_{a} \text {. out }\left(c_{1},\left\langle m, \mathrm{a}, \mathrm{~b}, \operatorname{enc}\left(\left\langle 1, n_{a}, m, \mathrm{a}, \mathrm{~b}\right\rangle, k_{a s}\right)\right\rangle\right) \text {. } \\
& \operatorname{in}\left(c_{1},\left\langle m, \operatorname{enc}\left(\left\langle 2, n_{a}, x_{a b}\right\rangle, k_{a s}\right)\right\rangle\right) \\
& P_{B}^{\prime}=\operatorname{in}\left(c_{2},\left\langle y_{m}, \mathrm{a}, \mathrm{~b}, y_{a s}\right\rangle\right) . \\
& \text { new } n_{b} \text {. out }\left(c_{2},\left\langle y_{m}, \mathrm{a}, \mathrm{~b}, y_{a s}, \operatorname{enc}\left(\left\langle 3, n_{b}, y_{m}, \mathrm{a}, \mathrm{~b}\right\rangle, k_{b s}\right)\right\rangle\right) \text {. } \\
& \operatorname{in}\left(c_{2},\left\langle y_{m}, z_{a s}, \operatorname{enc}\left(\left\langle 4, n_{b}, y_{a b}\right\rangle, k_{b s}\right)\right\rangle\right) \text {.out }\left(c_{2},\left\langle y_{m}, z_{a s}\right\rangle\right) \\
& P_{S}^{\prime}=\operatorname{in}\left(c_{3},\left\langle z_{m}, \mathrm{a}, \mathrm{~b}, \operatorname{enc}\left(\left\langle 1, z_{a}, z_{m}, \mathrm{a}, \mathrm{~b}\right\rangle, k_{a s}\right), \operatorname{enc}\left(\left\langle 3, z_{b}, z_{m}, \mathrm{a}, \mathrm{~b}\right\rangle, k_{b s}\right)\right\rangle\right) . \\
& \text { new } k_{a b} \text {. out }\left(c_{3},\left\langle z_{m}, \operatorname{enc}\left(\left\langle 2, z_{a}, k_{a b}\right\rangle, k_{a s}\right) \text {, enc }\left(\left\langle 4, z_{b}, k_{a b}\right\rangle, k_{b s}\right)\right\rangle\right)
\end{aligned}
$$

We can show that $P_{\mathrm{OR}}^{\prime}$ is strongly tagged: consider the natural execution of $P_{\mathrm{OR}}^{\prime}$, matching inputs and outputs as intended. From this execution we can define:

$$
\begin{aligned}
\sigma_{P}=\left\{x_{a b} \triangleright k_{a b},\right. & \left.y_{m} \triangleright m, y_{a s} \triangleright \operatorname{enc}\left(\left\langle 1, n_{a}, m, \mathrm{a}, \mathrm{~b}\right\rangle, k_{a s}\right)\right\rangle, \\
& \left.z_{a s} \triangleright \operatorname{enc}\left(\left\langle 2, n_{a}, k_{a b}\right\rangle, k_{a s}\right), z_{m} \triangleright m, z_{a} \triangleright n_{a}, z_{b} \triangleright n_{b}\right\} .
\end{aligned}
$$

It is then easy to check that for any two terms $s_{1}$ and $s_{2}$ that are unifiable, their instances by $\sigma_{P}$ are actually identical.
For any tagged protocol, we can infer a finite typing system, and show the type-compliance of the tagged protocol w.r.t. this typing system.

Definition 2.5.6. Let $P$ be a tagged protocol, and $\sigma_{P}$ the substitution witnessing this fact. Let $\Sigma_{P}, \mathcal{N}_{P}, \mathcal{X}_{P}$ be respectively the constants, names, and variables occurring in $P$. We consider the function $\delta_{P}$, inductively defined on $\mathcal{T}\left(\Sigma_{\mathrm{c}}, \Sigma_{P} \cup \mathcal{N}_{P} \cup \mathcal{X}_{P}\right)$ as follows:

- $\delta_{P}(x)=\overline{x \sigma_{P}}$ for any variable that occurs in $P$;
- $\delta_{P}(a)=a$ for any name, constant that occurs in $P$.
- $\delta\left(\mathrm{f}\left(t_{1}, t_{2}\right)\right)=\mathrm{f}\left(\delta\left(t_{1}\right), \delta\left(t_{2}\right)\right)$ for $\mathrm{f} \in\{$ enc, $\rangle\}$.

The image of $\delta_{P}$ is a set of types, denoted $\mathcal{T}_{p}$. The function $\delta_{P}$ is then extended arbitrarily to the remaining names, variables, constants such that there is an infinite set of names, variables, constants of each type in $\mathcal{T}_{p}$. This extends $\delta_{P}$ on $\mathcal{T}\left(\Sigma_{\mathrm{c}}, \Sigma_{0} \cup \mathcal{N} \cup \mathcal{X}\right)$ using the recursive definition: $\delta\left(\mathrm{f}\left(t_{1}, t_{2}\right)\right)=\mathrm{f}\left(\delta\left(t_{1}\right), \delta\left(t_{2}\right)\right)$ when $\mathrm{f} \in\{$ enc, $\rangle\}$.

Any tagged protocol is actually type-compliant w.r.t. its induced typing system.
Proposition 2.5.1. Let $P$ be a tagged protocol and let $\left(\mathcal{T}_{P}, \delta_{P}\right)$ as defined in Definition 2.5.6.

1. $\left(\mathcal{T}_{P}, \delta_{P}\right)$ is a typing system. We say that it is the typing system induced by $P$.
2. $P$ is type-compliant w.r.t. $\left(\mathcal{T}_{P}, \delta_{P}\right)$.

Proof. First we prove by induction on terms $t$ and $t^{\prime}$ in Definition 2.5.1 that $\left(T_{P}, \delta_{P}\right)$ as introduced in Definition 2.5.6 is a typing system. Then we prove that if $P$ is tagged then $P$ is type-compliant w.r.t. $\left(T_{P}, \delta_{P}\right)$. Indeed, let $s, t \in$ $E S t\left(\right.$ unfold $\left.^{2}(P)\right)$ and a substitution $\sigma$ such that $s \sigma=t \sigma$. We need to prove that $\delta_{P}(s)=\delta_{P}(t)$. Because $P$ is tagged, $\overline{s \sigma_{P}}=\overline{t \sigma_{P}}$. Moreover, $\delta_{P}(s)=\delta_{P}\left(\overline{s \sigma_{P}}\right)$ and $\delta_{P}(t)=\delta_{1}\left(\overline{t \sigma_{P}}\right)$. Hence $\delta_{P}(s)=\delta_{P}\left(\overline{s \sigma_{P}}\right)=\delta_{P}\left(\overline{t \sigma_{P}}\right)=\delta_{P}(t)$.

### 2.6 Conclusion

This chapter presented the general model needed to efficiently state the results from the following chapters. It also introduces the general classes of protocols, determinate, simple and type-compliant protocols, which are needed hypotheses to prove our main results. Determinate and simple protocols are both incarnations of the intuitive need for "deterministic" protocols explained in introduction as they limit, up to some equivalence, the number of executions for a given trace and thus constrain the branching nature of the search space when hoping to check trace equivalence. Type-compliant protocols on the other hand are related to tagging schemes, of which they form a generalisation and will allow us in Chapter 4 to state our typing result to greatly reduce the said search space.

## Chapter 3

## How to get rid of nonces

When proving security properties, it is important to obtain guarantees for an unlimited number of sessions. Unfortunately, it is well known that even secrecy is undecidable [44] in this context. Therefore, a standard restriction consists in bounding the number of nonces (and keys). Under this assumption, several decidability results have been established for secrecy $[44,15,31]$, and other will be for trace equivalence in Chapters 5 and 7.

Replacing nonces by constants is sound in the context of secrecy properties. More precisely, assuming that $\bar{P}$ is obtained from the security protocol $P$ by replacing nonces (and keys) by constants, whenever $\bar{P}$ is secure (w.r.t. a trace property such as secrecy) then $P$ is secure as well. Indeed, replacing nonces by constants may only introduce more attacks, since it may only create more equalities, as long as the protocol $P$ under study does not have else branches. Therefore, the decidability results developed for secrecy (e.g. [44, 15, 31]) may be seen as proof techniques: if $\bar{P}$ falls in a decidable class and can be shown to be secure then the protocol $P$ is secure as well. Unfortunately, such an approach is no longer valid in the context of equivalence properties. Indeed, consider the processes:

$$
P=!\text { new } n . \text { out }\left(c,\{n\}_{k}\right) \text { and } Q=!\text { out }\left(c,\{n\}_{k}\right)
$$

Intuitively, both processes send out an arbitrary number of messages on the public channel $c$. The process $P$ sends out each time a fresh nonce $n$ encrypted by a (secret) key $k$ while $Q$ always sends the same message. We assume here that encryption is not randomised. Clearly, the processes $P$ and $Q$ are not in equivalence (denoted $P \not \approx Q$ ) since an attacker can easily notice that $P$ sends distinct messages while $Q$ sends identical messages. However, abstracting away fresh names with constants, the resulting equivalence holds (denoted $\bar{P} \approx \bar{Q}$ ). Indeed, the two resulting processes are actually identical: $\bar{P}=\bar{Q}=$ ! out $\left(c,\{n\}_{k}\right)$. This illustrates that $\bar{P} \approx \bar{Q} \nRightarrow P \approx Q$.

In this chapter, we identify a technique to (soundly) get rid of freshly generated data (e.g. nonces, keys). The main idea consists in introducing an additional copy of each replicated nonce. More precisely, we show that:

$$
!\bar{P}\left|P^{\star} \approx!\bar{Q}\right| Q^{\star} \Rightarrow!P \approx!Q
$$

where $P^{\star}$ is obtained from $P$ by renaming all fresh nonces and keys to distinct (fresh) constants. Our result holds for simple processes, a notion described in Section 2.4.2. We consider a large family of primitives, provided that they can be described by a destructor/constructor theory with no critical pair. In particular, our technique allows one to deal with standard primitives (asymmetric and symmetric encryption, hash, signatures, MACs) as well as e.g. blind signatures and zero-knowledge proofs. In Chapters 5 and 7 we will present decidability results developed for protocols without nonces which could be applied to study the security of protocols with nonces thanks to this result.

Related work. Abstracting nonces and keys by constants is known to be sound for secrecy properties as part of the "folklore". We did not find a precise reference for this result. A related result is a reduction to two agents [32] for trace properties. Reducing the number of nonces can be obtained in a similar way.

The tool ProVerif $[13,14]$ also makes use of an abstraction for fresh data. In case of secrecy, nonces are abstracted by functions applied to the process inputs. In case of equivalence properties, nonces are additionally given a counter
(termination is of course not guaranteed). The abstraction technique is therefore more precise than using only constants but seems dedicated to the internal behaviour of the ProVerif tool.

### 3.1 Our hypotheses

Our technique soundly abstracts nonces and keys for trace equivalence, for simple protocols and for a large family of security primitives, namely adequate theories, that we define in this section.

In order to establish our result, we have to ensure that considering two distinct constants instead of fresh nonces is sufficient. We need this property to hold on terms first. Intuitively, when a term cannot be reduced further, it should be possible to isolate two nonces that cause the reduction to fail. This is indeed the case for a large class of primitives. We formalise this notion as follows:

Definition 3.1.1. Given a signature $\Sigma=\Sigma_{c} \uplus \Sigma_{d}$, a convergent rewriting system $\mathcal{R}$, and a set of messages $\mathcal{M}_{\Sigma}$, we say that the theory $(\Sigma, \mathcal{R})$ is adequate w.r.t. $\mathcal{M}_{\Sigma}$ when for any term $t \in \mathcal{T}(\Sigma, \mathcal{N}) \backslash \mathcal{M}_{\Sigma}$ in normal form, there exist $n_{1}, n_{2} \in \mathcal{N}$ such that for any renaming $\rho$ with $\rho\left(n_{1}\right) \neq \rho\left(n_{2}\right)$ then $t \rho \downarrow \notin \mathcal{M}_{\Sigma}$.

Intuitively, we require that whenever a term $t$ is not a message, it is possible to fix two names of $t$ such that any renaming of $t$ (preserving these two names) is still not a message. We could generalise our criterion to $n$-adequate theories where the number of names that need to fixed is bounded by $n$ but two names are actually sufficient to deal with most of the theories.

Example 3.1.1. The theory described in Example 2.1 .1 is adequate w.r.t. to the two notions of messages $\mathcal{M}_{c}$ and $\mathcal{M}_{\text {atomic }}$ that have been introduced. Intuitively, when a term is not a message, either this property is actually stable for any renaming $(e . g . \operatorname{sdec}(n, k))$ or is due to the failure of a decryption $\left(e . g . \operatorname{sdec}\left(\operatorname{senc}(n, k), k^{\prime}\right)\right)$. In such a case, maintaining the disequality between the terms modelling the encryption and the decryption keys is sufficient to ensure that the resulting term will not become a message.

Since the adequacy hypothesis might be cumbersome to prove by hand for each theory, we exhibit a simple criterion that ensures adequacy: the absence of critical pair.

Definition 3.1.2. Given a signature $\Sigma=\Sigma_{c} \uplus \Sigma_{d}$, and a rewriting system $\mathcal{R}$, we say that the theory $(\Sigma, \mathcal{R})$ has no critical pair if $\ell_{1}$ and $\ell_{2}$ are not unifiable for any distinct rules $\ell_{1} \rightarrow r_{1}$, and $\ell_{2} \rightarrow r_{2}$ in $\mathcal{R}$.

Our notion of critical pairs actually coincide with the usual one for the theories we consider. Indeed, rewrite rules are all of the form $\ell \rightarrow r$ such that the head symbol of $\ell$ is a destructor symbol and destructors may not appear anywhere else in $\ell$ nor $r$. Theories without critical pairs are convergent and adequate.

Lemma 3.1.1. Given a signature $\Sigma=\Sigma_{c} \uplus \Sigma_{d}$, a rewriting system $\mathcal{R}$, and a set of messages $\mathcal{M}_{\Sigma}$ such that $\mathcal{T}\left(\Sigma_{c}, \mathcal{N}\right) \backslash$ $\mathcal{M}_{\Sigma}$ is stable by renaming. If the theory $(\Sigma, \mathcal{R})$ has no critical pair, then $(\Sigma, \mathcal{R})$ is convergent and adequate w.r.t. $\mathcal{M}_{\Sigma}$.

Proof. To prove the convergence of $\mathcal{R}$, we need to show $\mathcal{R}$ is both terminating and confluent. Because each rewrite rule strictly decreases the number of destructors in a term, the termination is trivial. Confluence then stems from local confluence (Newman's lemma), which comes from the fact that, at any given position in a term, only one rule of $\mathcal{R}$ can be applied (as $\mathcal{R}$ has no critical pair) and reductions have to follow an innermost strategy (because rules can only be applied on arguments without destructors).

Let $t \in \mathcal{T}(\Sigma, \mathcal{N}) \backslash \mathcal{M}_{\Sigma}$ be a term in normal form. We want to prove there exist $n_{1}, n_{2} \in \mathcal{N}$ such that for any renaming $\rho$ with $\rho\left(n_{1}\right) \neq \rho\left(n_{2}\right)$, $t \rho \downarrow \notin \mathcal{M}_{\Sigma}$. If $t \in \mathcal{T}\left(\Sigma_{c}, \mathcal{N}\right) \backslash \mathcal{M}_{\Sigma}$, then the result directly holds as $\mathcal{T}\left(\Sigma_{c}, \mathcal{N}\right) \backslash \mathcal{M}_{\Sigma}$ is stable by renaming. Now, $t$ must then contain at least one destructor. Let $p$ be one of the lowest positions such that $t=C\left[\mathrm{~g}\left(t_{1}, \ldots, t_{k}\right)\right]_{p}$ where $\mathrm{g} \in \Sigma_{d}$ and for any position $q>p$ (we note $q>p$ when $p$ is a prefix of $q$ ), the symbol at position $q$ in $t$ is a constructor. In particular, $t_{1}, \ldots, t_{k} \in \mathcal{T}\left(\Sigma_{c}, \mathcal{N}\right)$.

We consider the case where there exists a renaming $\rho$ such that $\mathrm{g}\left(t_{1}, \ldots, t_{k}\right) \rho \rightarrow s$ using some linear rule $R \in \mathcal{R}$. Because rules in $\mathcal{R}$ start with a destructor, this rewrite rule can only be applied at position $\epsilon$ in $g\left(t_{1}, \ldots, t_{k}\right) \rho$. Because $R$ is linear, we also have that $\mathrm{g}\left(t_{1}, \ldots, t_{k}\right) \rightarrow s^{\prime}$ using the same rule $R$ and $s=s^{\prime} \rho$, and thus $t$ would not be in normal form. Hence we can assume that for any renaming $\rho$, no linear rule can be applied on $\mathrm{g}\left(t_{1}, \ldots, t_{n}\right) \rho$.

Let $n_{0} \in \mathcal{N}$ and $\rho_{n_{0}}$ the renaming such that $\rho_{n_{0}}(n)=n_{0}$ for any $n \in \mathcal{N}$. Let $\rho_{n}$ (resp. $\rho_{m}$ ) be a renaming such that there exists $n_{1}, n_{2} \in \mathcal{N}$ (resp. $\left.m_{1}, m_{2} \in \mathcal{N}\right)$ such that $\rho_{n}\left(n_{1}\right) \neq \rho_{n}\left(n_{2}\right)$ (resp. $\rho_{m}\left(m_{1}\right) \neq \rho_{m}\left(m_{2}\right)$ ). Let us further assume there exists some non-linear rule $R_{n} \in \mathcal{R}$ such that $\mathrm{g}\left(t_{1}, \ldots, t_{k}\right) \rho_{n} \rightarrow s_{n}$ (resp. some non-linear rule $R_{m} \in \mathcal{R}$ such that $\left.\mathrm{g}\left(t_{1}, \ldots, t_{k}\right) \rho_{m} \rightarrow s_{m}\right)$. We want to prove first that $R_{n}=R_{m}$. By definition of $\rho_{n_{0}}$ and $\rho_{n}$ (resp. $\rho_{m}$ ), there exists a renaming $\delta_{n}\left(\right.$ resp. $\left.\delta_{m}\right)$ such that $\rho_{n} \delta_{n}=\rho_{n_{0}}$ (resp. $\rho_{m} \delta_{m}=\rho_{n_{0}}$ ) and $\mathrm{g}\left(t_{1}, \ldots, t_{k}\right) \rho_{n} \delta_{n} \rightarrow s_{n} \delta_{n}$ using $R_{n}$ (resp. $\mathrm{g}\left(t_{1}, \ldots, t_{k}\right) \rho_{m} \delta_{m} \rightarrow_{R_{m}} s_{m} \delta_{m}$ using $R_{m}$ ). So we get that $\mathrm{g}\left(t_{1}, \ldots, t_{k}\right) \rho_{n_{0}} \rightarrow s_{n} \delta_{n}$ using $R_{n}$ and $\mathrm{g}\left(t_{1}, \ldots, t_{k}\right) \rho_{n_{0}} \rightarrow s_{m} \delta_{m}$ using $R_{m}$. Thus, this means that the left-hand side of $R_{n}$ and $R_{m}$ are unifiable. Because $\mathcal{R}$ contains no critical pair, we necessarily have that $R_{n}=R_{m}$. Thus there exist exactly one (non-linear) rule $R$ which can reduce $\mathrm{g}\left(t_{1}, \ldots, t_{k}\right) \rho_{n}$ for any such $\rho_{n}$. Let $R=\mathrm{g}\left(u_{1}, \ldots, u_{k}\right) \rightarrow r$ that rule. As $\mathrm{g}\left(t_{1}, \ldots, t_{k}\right)$ is in normal form (and thus $R$ cannot be applied) while $\mathrm{g}\left(t_{1}, \ldots, t_{k}\right) \rho_{n} \rightarrow s_{n}$ using $R$ for every $\rho_{n}$, we know that there exist two positions $p_{1}$ and $p_{2}$, two indices $i$ and $j$, and a variable $x$ such that $\left.u_{i}\right|_{p_{1}}=\left.u_{j}\right|_{p_{2}}=x$. Actually, we can even assume there exist two leaf positions $q_{1}>p_{1}$ and $q_{2}>p_{2}$ such that $\left.t_{i}\right|_{q_{1}} \neq\left. t_{j}\right|_{q_{2}}$ but $\left.t_{i} \rho_{n}\right|_{q_{1}}=\left.t_{j} \rho_{n}\right|_{q_{2}}$. Note that $t_{i}$ and $t_{i} \rho_{n}$ (resp. $t_{j}$ and $t_{j} \rho_{n}$ ) share the same leaf positions. Necessarily $\left.t_{i}\right|_{q_{1}},\left.t_{j}\right|_{q_{2}} \in \mathcal{N}$, as otherwise $\left.t_{i} \rho_{n}\right|_{q_{1}} \neq\left. t_{j} \rho_{n}\right|_{q_{2}}$. We have that $\left.t_{i}\right|_{q_{1}} \neq\left. t_{j}\right|_{q_{2}}$ and both are names. Let $\rho_{r}$ be a renaming such that $\rho_{r}\left(\left.t_{i}\right|_{q_{1}}\right) \neq \rho_{r}\left(\left.t_{j}\right|_{q_{2}}\right)$. We have that $\left.t_{i}\right|_{q_{1}} \rho_{r}=\left.t_{i}\right|_{q_{1}}$ and $\left.t_{i}\right|_{q_{1}} \rho_{r} \neq\left. t_{j}\right|_{q_{2}} \rho_{r}$. The latter implies that $\left.t_{i}\right|_{p_{1}} \rho_{r} \neq\left. t_{j}\right|_{p_{2}} \rho_{r}$, and as such $\mathrm{g}\left(t_{1}, \ldots, t_{k}\right) \rho_{r}$ cannot reduce with rule $R$, and consequently cannot reduce with any rule of $\mathcal{R}$. Thereby, $\mathrm{g}\left(t_{1}, \ldots, t_{k}\right) \downarrow=\mathrm{g}\left(t_{1}, \ldots, t_{k}\right) \notin \mathcal{T}\left(\Sigma_{c}, \mathcal{N}\right)$.

Finally $\mathrm{g}\left(t_{1}, \ldots, t_{k}\right)$ is in normal form and not a message, which ensures for any position $q<p,\left.t\right|_{q} \notin \mathcal{M}_{\Sigma}$ (because $t_{q}$ would contain the destructor g ) and $\left.t\right|_{q}$ cannot reduce with any rule of $\mathcal{R}$, as reduction requires that any variable must be instantiated with a message and one of its subterm is not a message (the rules themselves contain exactly one destructor in top-level position).

This lemma allows us to conclude that many theories used in practice to model security protocols are actually adequate. This is the case of the theory given in Example 2.1.1, and the theories that are presented below.

Standard cryptographic primitives. We may enrich the theory described in Example 2.1.1 with function symbols to model asymmetric encryption, and digital signatures.

$$
\Sigma^{+}=\Sigma \cup\{\text { aenc, adec, sign, checksign, getmsg, pub, priv, ok }\} .
$$

Symbols adec/aenc and sign/checksign of arity 2 are used to model asymmetric encryption and signature, whereas pub/priv of arity 1 will be used to model key pairs, and the symbol priv will be part of the signature $\Sigma_{\text {priv }}$. The symbol getmsg may be used in case we want to consider a signature algorithm that does not protect the signed message. The corresponding rewrite rules are defined as follows:

$$
\begin{aligned}
\operatorname{checksign}(\operatorname{sign}(x, \operatorname{priv}(y)), \operatorname{pub}(y)) & \rightarrow \text { ok } \\
\operatorname{getmsg}(\operatorname{sign}(x, \operatorname{priv}(y)) & \rightarrow x \\
\operatorname{adec}(\operatorname{aenc}(x, \operatorname{pub}(y)), \operatorname{priv}(y)) & \rightarrow x
\end{aligned}
$$

Regarding the notion of messages, a reasonable choice for $\mathcal{M}_{\Sigma^{+}}$is to consider $\mathcal{M}_{c}^{+}=\mathcal{T}\left(\Sigma_{c} \uplus\{\right.$ aenc, sign, pub, priv, ok $\left.\}, \mathcal{N}\right)$ the set of all ground constructor terms. We may also restrict $\mathcal{M}_{\Sigma_{+}}$in various ways to only allow some specific terms in key positions.

Blind signatures. The following theory is often used to model blind signatures (see e.g. [39]), checksign and unblind are the only destructor symbols.

$$
\begin{aligned}
\text { checksign }(\operatorname{sign}(x, \operatorname{priv}(y)), \operatorname{pub}(y)) & \rightarrow x \\
\text { unblind }(\operatorname{blind}(x, y), y) & \rightarrow x \\
\text { unblind }(\operatorname{sign}(\operatorname{blind}(x, y), \operatorname{priv}(z)), y) & \rightarrow \operatorname{sign}(x, \operatorname{priv}(z))
\end{aligned}
$$

Zero-knowledge proofs. A typical signature for representing zero-knowledge proofs is $\Sigma_{\text {ZKP }}=\{$ Verify, ZKP, ok $\}$ where ZKP represents a zero-knowledge proof and Verify models the verification of the proof. To ease the presentation, we present how to model the proof of a particular statement, namely the fact that a ciphertext is the encryption of either 0 or 1 . Such proofs are thoroughly used for example in the context of e-voting protocols such as Helios. In particular, the theory we consider here has been introduced in [37]. Specifically, let $\Sigma_{\text {ZKP }}^{+}=\Sigma_{\text {ZKP }} \uplus\{$ raenc, radec, pub, priv, 0,1$\}$ and consider the following rewrite rules.

$$
\begin{aligned}
\operatorname{radec}(\operatorname{raenc}(x, z, \operatorname{pub}(y)), \operatorname{priv}(y)) & \rightarrow x \\
\operatorname{Verify}(\operatorname{ZKP}(x, \operatorname{raenc}(0, x, \operatorname{pub}(y)), \operatorname{pub}(y)), \operatorname{raenc}(0, x, \operatorname{pub}(y)), \operatorname{pub}(y)) & \rightarrow \text { ok } \\
\operatorname{Verify}(\operatorname{ZKP}(x, \operatorname{raenc}(1, x, \operatorname{pub}(y)), \operatorname{pub}(y)), \operatorname{raenc}(1, x, \operatorname{pub}(y)), \operatorname{pub}(y)) & \rightarrow \text { ok }
\end{aligned}
$$

The symbol raenc represents randomised asymmetric encryption as reflected by the first rewrite rule. The two last rules ensure that a proof is valid only if the corresponding ciphertext contains either 0 or 1 and nothing else. Many variants of zero-knowledge proofs can be modelled in a very similar way.

### 3.2 Getting rid of nonces

As explained in introduction, our main contribution is to provide a transformation that soundly abstracts nonces. Informally, we prove an implication of the following form:

$$
!\bar{P}\left|P^{\star} \approx!\bar{Q}\right| Q^{\star} \Rightarrow!P \approx!Q
$$

where $\bar{P}$ is obtained from $P$ by replacing nonces by constants, and $P^{\star}$ is a copy of $P$. Before defining formally this transformation in Section 3.2.1, we introduce in Section 3.1 which hypotheses are required for the soundness of our transformation.

### 3.2.1 Our transformation

We now explain how to formally get rid of nonces. Our transformation is actually modular w.r.t. which nonces shall be abstracted. Let $P$ be a simple process in which any name is bound at most once. This means that any name that does not occur explicitly in the scope of a restriction is distinct from those introduced by the new operator. Moreover, a same name can not be introduced twice by the operator new. Our transformation is parametrised by a set of names N which correspond to the new instructions that we want to remove (typically those under a replication).

We denote by $\bar{P}^{N}$ (or simply $\bar{P}$ when N is clear from the context) the process obtained from $P$ by removing every instruction new $n$ for any $n \in \mathrm{~N}$. Given $B(c)$ a basic process built on channel $c$, we denote by $B^{\star}\left(c^{\star}\right)$ the process obtained from $B$ by applying a bijective alpha-renaming on each name bound by a new instruction and replacing each occurrence of the channel $c$ with the channel $c^{\star}$ (that is assumed to be fresh).

Example 3.2.1. Consider the process $P=$ !new $c^{\prime}$.out $\left(c, c^{\prime}\right) . B$ where $B$ is a basic process built on channel $c^{\prime}$. Let $B=$ new $n$.out $\left(c^{\prime}, \operatorname{senc}(n, k)\right)$, and $\mathrm{N}=\{n\}$. We have that:

1. $\bar{P}=$ !new $c^{\prime}$.out $\left(c, c^{\prime}\right)$.out $\left(c^{\prime}, \operatorname{senc}(n, k)\right)$, and
2. $B^{\star}\left(c^{\star}\right)=\operatorname{new} n^{\star} \cdot \operatorname{out}\left(c^{\star}, \operatorname{senc}\left(n^{\star}, k\right)\right)$.

Note that $B$ and $B^{\star}\left(c^{\star}\right)$ are identical up to the fact that they proceed on different channel. The transformation $\star$ applied on the basic process is just here to emphasise the fact that bound names are renamed to avoid some confusion due to name clashes.

Now, our transformation consists of combining these two building blocks. When removing fresh names from a process $P$, we keep a copy of one of the replicated basic processes of $P$, identified by its channel $c$. More formally, given a simple process $P$ of the form $P=!$ new $c^{\prime}$.out $\left(c, c^{\prime}\right) . B \mid P^{\prime}$, and a set of names N , the resulting process $\bar{P}^{\mathrm{N}, c}$ is defined as follows:

$$
\bar{P}^{\mathrm{N}, c} \stackrel{\text { def }}{=} \bar{P}^{\mathrm{N}} \mid B^{\star}\left(c^{\star}\right)
$$

Sometimes we simply write $\bar{P}^{c}$ instead of $\bar{P}^{\mathrm{N}, c}$ when N is clear from the context.
Example 3.2.2. Continuing Example 3.2.1, we have that:

$$
\bar{P}^{\mathrm{N}, c}=!\text { new } c^{\prime} . \text { out }\left(c, c^{\prime}\right) . \operatorname{out}\left(c^{\prime}, \operatorname{senc}(n, k)\right) \mid \operatorname{new} n^{\star} . \operatorname{out}\left(c^{\star}, \operatorname{senc}\left(n^{\star}, k\right)\right)
$$

### 3.2.2 Main result

We are now able to state our main result. We consider a signature $\Sigma=\Sigma_{c} \uplus \Sigma_{d}$ together with a convergent rewriting system $\mathcal{R}$, and a notion of messages $\mathcal{M}_{\Sigma}$ such that the theory $(\Sigma, \mathcal{R})$ is adequate w.r.t. $\mathcal{M}_{\Sigma}$. Given a simple process $P$, we note $\mathrm{Ch}(P)$ the set of public channel names occurring under a replication in $P$.

Theorem 3.2.1. Let $P$ and $Q$ be two simple protocols such that $\mathrm{Ch}(P)=\mathrm{Ch}(Q)$, and N be a set of names (intuitively those that we want to abstract away). We have that:

$$
\left[\forall c \in \operatorname{Ch}(P) \cdot \bar{P}^{\mathrm{N}, c} \approx \bar{Q}^{\mathrm{N}, c}\right] \Rightarrow P \approx Q
$$

Note that, in case $\operatorname{Ch}(P) \neq \mathrm{Ch}(Q)$, we trivially have that $P \not \approx Q$ since one process is able to emit on a channel whereas the other is not.

This theorem shows that whenever two processes are not in trace equivalence, then it is possible to find a witness of non-equivalence when nonces are replaced by constants provided that one basic process under a replication has been duplicated.

Example 3.2.3. Continuing the example developed in introduction of this chapter and pursued in Section 3.2.1, we consider

1. $P=$ !new $c^{\prime}$.out $\left(c, c^{\prime}\right)$.new $n_{P}$.out $\left(c^{\prime}, \operatorname{senc}\left(n_{P}, k\right)\right)$, and
2. $Q=$ !new $c^{\prime}$.out $\left(c, c^{\prime}\right)$.out $\left(c^{\prime}, \operatorname{senc}\left(n_{Q}, k\right)\right)$.

Let $\mathrm{N}=\left\{n_{P}\right\}$. We have that:

1. $\bar{P}^{c}=$ !new $c^{\prime}$.out $\left(c, c^{\prime}\right)$.out $\left(c^{\prime}, \operatorname{senc}\left(n_{P}, k\right)\right) \mid \operatorname{new} n_{P}^{\star}$.out $\left(c^{\star}, \operatorname{senc}\left(n_{P}^{\star}, k\right)\right)$, and
2. $\bar{Q}^{c}=$ !new $c^{\prime}$.out $\left(c, c^{\prime}\right)$.out $\left(c^{\prime}, \operatorname{senc}\left(n_{Q}, k\right)\right) \mid \operatorname{out}\left(c^{\star}, \operatorname{senc}\left(n_{Q}, k\right)\right)$.

Clearly $\bar{P}^{c} \not \approx \bar{Q}^{c}$ since an attacker can observe that $\bar{P}^{c}$ may send two distinct messages while $\bar{Q}^{c}$ cannot. Intuitively, the attack reflecting that $P \not \approx Q$ can be reflected in $\bar{P}^{c} \not \approx \bar{Q}^{c}$. Another choice for N is to consider the set $\left\{n_{P}, n_{Q}\right\}$ but this would lead exactly to the same result.

### 3.2.3 Proof

To establish our result, we first establish how to map traces from $P$ to $\bar{P}^{N}$. Given a simple process $P$, and a trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$, we denote by $\rho_{(\operatorname{tr}, \phi)}^{P, N}$ the replacement that associates to each name $r \in \mathcal{N}$ generated during the execution under study and occurring in the frame $\phi$, the name $n \in \mathrm{~N}$ that occurs in the instruction new $n$ of $P$ and that is responsible of the generation of this fresh name. This amounts in losing freshness of all the new $n$ instructions with $n \in \mathbf{N}$. Indeed all nonces induced by such an instruction are collapsed into a single nonce $n$. Our transformation is parametric in N : we may replace all new instructions or simply part of them. Note that, for simple processes, once $(\operatorname{tr}, \phi)$ is fixed, this replacement is uniquely defined.

Lemma 3.2.1. Let $P$ be a simple protocol, N be a set of names, and $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$. We have that $\left(\operatorname{tr}, \phi \rho_{(\operatorname{tr}, \phi)}^{P, N}\right) \in$ $\operatorname{trace}\left(\bar{P}^{\mathrm{N}}\right)$.

Lemma 3.2.1 is a direct corollary of Lemma 3.2.2 which we state below. In the following, we will only consider theories adequate w.r.t. $\mathcal{M}_{\Sigma}$. Given a frame $\phi$ (resp. $\psi$ ) and a name $r$ in $\phi$ (resp. $\psi$ ), let $n(r)$ be the nonce in $P$ (resp. $Q$ ) such that $r$ is an instance of $n(r)$ and let $c(r)$ be the channel of the protocol's branch which generated it. Actually, it can be computed as the channel on which $r$ appeared first in $\operatorname{tr} \phi \downarrow$ (resp. $\operatorname{tr} \psi \downarrow$ ). We note $\mathcal{D}_{\phi}=\{r \in \phi \mid n(r) \in \mathbf{N}\}$ and, by extension, $n(A)=\{r \mapsto n(r) \mid r \in A\}$ for any $A \subseteq \mathcal{D}_{\phi}$. To each nonce $n \in \mathbb{N}$, we can associate a new name $n^{\star}$ : we can then define the function $n^{\star}(\cdot)$ to be the function mapping any $r \in \mathcal{D}_{\phi}$ to $(n(r))^{\star}$. Similarly, $n^{\star}(A)=\left\{r \mapsto(n(r))^{\star} \mid r \in A\right\}$ for $A \subseteq \mathcal{D}_{\phi}$.

Lemma 3.2.2. We have the two following properties.

1. Let $(\operatorname{tr}, \phi) \in \operatorname{trace}(P), \mathcal{D}_{\phi}=\{r \in \phi \mid n(r) \in \mathrm{N}\}$ and $\rho_{0}=n\left(D_{\phi}\right)$. Then $\left(\operatorname{tr}, \phi \rho_{0}\right) \in \operatorname{trace}\left(\bar{P}^{\mathrm{N}}\right)$.
2. Moreover, let $c h$ be a channel such that $\operatorname{tr}=\operatorname{tr}_{1}$. out $(c, c h) \cdot \operatorname{tr}_{2}, \tilde{\mathcal{D}}_{\phi}=\{r \in \phi \mid n(r) \in \mathrm{N} \wedge c(r)=c h\}$ and $\rho=n\left(\mathcal{D}_{\phi} \backslash \tilde{\mathcal{D}}_{\phi}\right) \cup n^{\star}\left(\tilde{\mathcal{D}}_{\phi}\right)$. Then $\left(\operatorname{tr}^{\star}, \phi \rho\right) \in \operatorname{trace}\left(\bar{P}^{\mathrm{N}, c}\right)$, where $\operatorname{tr}^{\star}=\operatorname{tr}_{1} \cdot \operatorname{tr}_{2}\left\{c^{\star} / c h\right\}$.

Proof. We first prove the second item. For any trace $\operatorname{tr}=\operatorname{tr}_{1}$.out $(c, c h) \cdot \operatorname{tr}_{2}$, we note $\operatorname{tr}^{\star}=\operatorname{tr}_{1} \cdot \operatorname{tr}_{2}\left\{c^{\star} / c h\right\}$. We define $\rho^{\prime}$ as:

$$
\rho^{\prime}=\left\{n \mapsto n^{\star} \mid n \in \mathrm{~N} \wedge " \text { new } n " \text { occurs in } B\right\}
$$

where $B$ is described in the definition of the transformation. We want to prove that if $P \xrightarrow{\tau . s}(\mathcal{P} \cup M, \phi)$ then $\bar{P}^{\mathrm{N}, c} \xrightarrow{\bar{s}}\left(\overline{\mathcal{P}} \rho \cup \bar{M}^{\star} \rho \rho^{\prime}, \phi \rho\right)$ where $s$ is a sequence of actions (visible and invisible), $\bar{s}$ is a subsequence of $s$ with the same visible actions (i.e. only $\tau$-actions can be deleted) except for one action out $(c, c h)$ deleted and $c h$ is substituted by $c^{\star}, \overline{\mathcal{P}}$ is $\mathcal{P}$ expurgated of the new $n$ elements for $n \in \mathrm{~N}, M$ is either new $c^{\prime}$.out $\left(c, c^{\prime}\right) . B$, a process on channel $c h$ (which results from the execution of new $c^{\prime}$.out $\left(c, c^{\prime}\right) . B$ ) or the 0 process; and $\bar{M}^{\star}$ is $M$ expurgated of the new $n$ elements for $n \in \mathrm{~N}$; and $c h$ replaced by $c^{\star}$. We proceed by induction on $s$.

Base case: if $s=\epsilon$ : it holds by definition of $\bar{P}^{\mathrm{N}, c}$ and $\rho^{\prime}(\phi=\emptyset$ and nonces are not instantiated yet). We require one $\tau$-action to unfold the branch !new $c^{\prime}$.out $\left(c, c^{\prime}\right) . B$ once in $P$.

Induction cases: now we consider the cases where $s=s^{\prime}$. $a$ for some action $a$. We have that

$$
P \xrightarrow{\tau \cdot s^{\prime}}\left(\mathcal{P}^{\prime} \cup M^{\prime}, \phi^{\prime}\right) \xrightarrow{a}(\mathcal{P} \cup M, \phi)
$$

By induction hypothesis, $\bar{P}^{\mathrm{N}, c} \xrightarrow{\bar{s}^{\prime}}\left(\overline{\mathcal{P}}^{\prime} \rho \cup \bar{M}^{\prime \star} \rho \rho^{\prime}, \phi^{\prime} \rho\right)$. We want to prove that in $\bar{P}^{\mathrm{N}, c}$ :

$$
\left(\overline{\mathcal{P}}^{\prime} \rho \cup \bar{M}^{\prime \star} \rho \rho^{\prime}, \phi^{\prime} \rho\right) \xrightarrow{\bar{a}}\left(\overline{\mathcal{P}} \rho \cup \bar{M}^{\star} \rho \rho^{\prime}, \phi \rho\right) .
$$

- If $a=\tau$ and $a$ corresponds to a replication: if there exists a process ! $R$ in $\mathcal{P}^{\prime}$ on which to apply the replication unfolding, then $!\bar{R} \rho \in \overline{\mathcal{P}}^{\prime} \rho$, which directly leads to $\left(\overline{\mathcal{P}}^{\prime} \rho \cup \bar{M}^{\prime \star} \rho \rho^{\prime}, \phi^{\prime} \rho\right) \xrightarrow{\tau}\left(\overline{\mathcal{P}} \rho \cup \bar{M}^{\star} \rho \rho^{\prime}, \phi \rho\right)$.
- If $a=\tau$ and $a$ corresponds to the restriction of a name $n \in \mathrm{~N}$ which does not occur in $M^{\prime}$ : then there exists $Q$ such that new $n . Q \in \mathcal{P}^{\prime}$ and thus $\bar{Q} \rho \in \overline{\mathcal{P}}^{\prime} \rho$ as $n \in \mathrm{~N}$ and there exists $r$ such that $n$ is replaced by $r$ in $Q$. As $r \in \mathcal{D}_{\phi} \backslash \tilde{\mathcal{D}}_{\phi}$ (new $n$ does not occur in $M^{\prime}$ and thus $c(r) \neq c h$ ), $r \rho=n$ and thus $\overline{\mathcal{P}}^{\prime} \rho=\overline{\mathcal{P}} \rho$. Hence we get that $\left(\overline{\mathcal{P}}^{\prime} \rho \cup \bar{M}^{\prime \star} \rho \rho^{\prime}, \phi^{\prime} \rho\right) \xrightarrow{\epsilon}\left(\overline{\mathcal{P}} \rho \cup \bar{M}^{\star} \rho \rho^{\prime}, \phi \rho\right)$.
- If $a=\tau$ and $a$ corresponds to the restriction of a name $n \in \mathrm{~N}$ which occurs in $M^{\prime}$ : then there exists $Q$ such that new $n \cdot Q=M^{\prime}$ and thus $\bar{Q}^{\star} \rho \rho^{\prime}=\bar{M}^{\prime \star} \rho \rho^{\prime}$ as $n \in \mathrm{~N}$ and there exists $r$ such that $n$ is replaced by $r$ in $Q$. As $r \in \tilde{\mathcal{D}}_{\phi}$ (new $n$ occurs in $M^{\prime}$ and thus $c(r)=c h$ ), $r \rho=n^{\star}$. Then $\mathcal{P}^{\prime}=\mathcal{P}$ and $\bar{M}^{\prime \star} \rho \rho^{\prime}=\bar{M}^{\star} \rho \rho^{\prime}$ (as $\left.\bar{M}^{\prime \star} \rho=\bar{M}^{\star} \rho\right)$. Hence we get that $\left(\overline{\mathcal{P}}^{\prime} \rho \cup \bar{M}^{\prime \star} \rho \rho^{\prime}, \phi^{\prime} \rho\right) \xrightarrow{\epsilon}\left(\overline{\mathcal{P}} \rho \cup \bar{M}^{\star} \rho \rho^{\prime}, \phi \rho\right)$.
- If $a=\tau$ and $a$ corresponds to the restriction of a name $n \notin \mathrm{~N}$ : in this case, new $n$ appears in both $\mathcal{P}^{\prime}$ and $\overline{\mathcal{P}}^{\prime} \rho$ (or both $M^{\prime}$ and $\bar{M}^{\prime \star} \rho$ ) and is replaced by a nonce $r \notin \mathcal{D}_{\phi}$, leading to ( $\left.\overline{\mathcal{P}}^{\prime} \rho \cup \bar{M}^{\prime \star} \rho \rho^{\prime}, \phi^{\prime} \rho\right) \xrightarrow{\tau}\left(\overline{\mathcal{P}} \rho \cup \bar{M}^{\star} \rho \rho^{\prime}, \phi \rho\right)$.
- If $a=\operatorname{out}\left(c h^{\prime}, \mathrm{w}\right)$ for some $c h^{\prime} \neq c h$ : out $\left(c h^{\prime}, u\right) . Q \in \mathcal{P}^{\prime}$ for some term $u$ and process $Q \operatorname{implies}$ out $\left(c h^{\prime}, u \rho\right) . \bar{Q} \rho \in$ $\overline{\mathcal{P}}^{\prime} \rho$ which ensures that $\left(\overline{\mathcal{P}}^{\prime} \rho \cup \bar{M}^{\prime \star} \rho \rho^{\prime}, \phi^{\prime} \rho\right) \xrightarrow{\text { out }\left(c h^{\prime}, w\right)}\left(\overline{\mathcal{P}} \rho \cup \bar{M}^{\star} \rho \rho^{\prime}, \phi \rho\right)$.
- If $a=\operatorname{out}(c h, \mathrm{w}): M^{\prime}=\operatorname{out}(c h, u) \cdot Q$ for some term $u$ and process $Q$ implies $\bar{M}^{\prime \star} \rho \rho^{\prime}=\operatorname{out}\left(c^{\star}, u \rho \rho^{\prime}\right) \cdot \bar{Q}^{\star} \rho \rho^{\prime}$ (as communications occur on $c^{\star}$ instead of $c h$ in $\bar{M}^{\prime \star}$ ). As $u$ cannot contain any non-instantiated nonce, $u \rho^{\prime}=u$ and $u \rho \rho^{\prime}=u \rho$ (as $\rho$ and $\rho^{\prime}$ commute). Which leads us to ( $\left.\overline{\mathcal{P}}^{\prime} \rho \cup \bar{M}^{\prime \star} \rho \rho^{\prime}, \phi^{\prime} \rho\right) \xrightarrow{\text { out }\left(c^{\star}, \mathrm{w}\right)}\left(\overline{\mathcal{P}} \rho \cup \bar{M}^{\star} \rho \rho^{\prime}, \phi \rho\right)$.
- If $a=\operatorname{in}\left(c h^{\prime}, R\right)$ for some $c h^{\prime} \neq c h$ and recipe $R$. Note that $\left(R \phi^{\prime} \downarrow\right) \rho=R\left(\phi^{\prime} \rho\right) \downarrow$ as $R \phi^{\prime} \downarrow$ reduces to a message and thus contains no destructors. Then $\operatorname{in}\left(c h^{\prime}, u\right) . Q \in \mathcal{P}^{\prime}$, for some term $u$ and process $Q$, implies in $\left(c h^{\prime}, u \rho\right) . \bar{Q} \rho \in \overline{\mathcal{P}}^{\prime} \rho$ which ensures that, because there exists $\sigma$ such that $R \phi^{\prime} \downarrow=u \sigma, R \psi^{\prime} \downarrow \rho=R(\psi \rho) \downarrow=$ $(u \sigma)(\sigma \rho)=(u \sigma) \rho$ and thus the pattern matching is successful in $\mathcal{P}^{\prime}$. Then, as in the case where $a=$ out $\left(c h^{\prime}, \mathrm{w}\right)$ for some $c h^{\prime} \neq c h$, we get that $\left(\overline{\mathcal{P}}^{\prime} \rho \cup \bar{M}^{\prime \star} \rho \rho^{\prime}, \phi^{\prime} \rho\right) \xrightarrow{\text { in }\left(c h^{\prime}, R\right)}\left(\overline{\mathcal{P}} \rho \cup \bar{M}^{\star} \rho \rho^{\prime}, \phi \rho\right)$.
- If $a=\operatorname{in}(c h, R)$ for some recipe $R$. Here note that $\left(R \phi^{\prime} \downarrow\right) \rho \rho^{\prime}=R\left(\phi^{\prime} \rho \rho^{\prime}\right) \downarrow$ as $R \phi^{\prime} \downarrow$ reduces to a message and thus contains no destructors. Then, as in the case where $a=\operatorname{out}(c h, \mathrm{w})$, we get that $\left(\overline{\mathcal{P}}^{\prime} \rho \cup\right.$ $\left.\bar{M}^{\prime \star} \rho \rho^{\prime}, \phi^{\prime} \rho\right) \xrightarrow{\operatorname{in}\left(c^{\star}, R\right)}\left(\overline{\mathcal{P}} \rho \cup \bar{M}^{\star} \rho \rho^{\prime}, \phi \rho\right)$.
- If $a=\operatorname{out}(c, c h): M^{\prime}=$ new $c^{\prime}$.out $\left(c, c^{\prime}\right) . Q$ for some process $Q$ implies $\bar{M}^{\prime \star} \rho \rho^{\prime}=\bar{Q}^{\star} \rho \rho^{\prime}$ and then $\bar{M}^{\star} \rho \rho^{\prime}=$ $\bar{Q}^{\star} \rho \rho^{\prime}$. Hence $\left(\overline{\mathcal{P}}^{\prime} \rho \cup \bar{M}^{\prime \star} \rho \rho^{\prime}, \phi^{\prime} \rho\right) \xrightarrow{\epsilon}\left(\overline{\mathcal{P}} \rho \cup \bar{M}^{\star} \rho \rho^{\prime}, \phi \rho\right)$. Note that this action can only occur once in $s$, as channels are freshly generated and $c h$ is thus unique.
- If $a=\operatorname{out}\left(c, c h^{\prime}\right)$ for some $c h^{\prime} \neq c h$ : new $c^{\prime}$.out $\left(c, c^{\prime}\right) \cdot Q \in \mathcal{P}^{\prime}$ for some process $Q$ implies new $c^{\prime}$.out $\left(c, c^{\prime}\right) \cdot \bar{Q} \rho \in$ $\overline{\mathcal{P}}^{\prime} \rho$, which leads us to
$\left(\overline{\mathcal{P}}^{\prime} \rho \cup \bar{M}^{\prime \star} \rho \rho^{\prime}, \phi^{\prime} \rho\right) \xrightarrow{\text { out }(c, c h)}\left(\overline{\mathcal{P}} \rho \cup \bar{M}^{\star} \rho \rho^{\prime}, \phi \rho\right)$.
- If $a=\operatorname{out}\left(c^{\prime \prime}, c h^{\prime}\right)$ for some $c^{\prime \prime} \neq c$ and some $c h^{\prime}$ (necessarily $c h^{\prime} \neq c h$ as generated channels are fresh): this case is treated as the previous one.
- If $a=\tau$ and $a$ corresponds to a term evaluation let $x=v$ in $P$, whether in a process in $\mathcal{P}^{\prime}$ or in $M^{\prime}$, as messages are stable by renaming, we get the result, in the same way as for the inputs.

Thus we managed to prove that $\bar{P}^{\mathbf{N}, c} \xrightarrow{\bar{s}}\left(\overline{\mathcal{P}} \rho \cup \bar{M}^{\star} \rho \rho^{\prime}, \phi \rho\right)$, which, by definition of $\bar{s}$ translate to $\bar{P}^{\mathbf{N}, c} \stackrel{\operatorname{tr}^{\star}}{\Longrightarrow}(\overline{\mathcal{P}} \rho \cup$ $\left.\bar{M}^{\star} \rho \rho^{\prime}, \phi \rho\right)$ and proves that $\left(\operatorname{tr}^{\star}, \phi \rho\right) \in \operatorname{trace}\left(\bar{P}^{\mathrm{N}, c}\right)$.

The first item of the lemma can be seen as a special case of the previous proof where no action out $(c, c h)$ ever occurs and we do not need to split the multiset of processes between $\mathcal{P}$ and $M$. Hence the lemma.

Now, it remains to ensure that the disequality that is needed to witness the non-equivalence still remains, and this is the purpose of considering a fresh copy, namely $B^{\star}\left(c^{\star}\right)$.

The idea is to show that a witness of non-equivalence for $P \not \approx Q$ can be converted into a witness of non-equivalence for $\bar{P}^{c} \not \approx \bar{Q}^{c}$ for at least one $c \in \mathrm{Ch}(P)=\mathrm{Ch}(Q)$. Due to the fact that we consider simple processes, three main cases may occur (the three other symmetric cases can be handled similarly). We have that $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$, and

1. there exists $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ and two recipes $R_{1}, R_{2}$ such that $R_{1} \phi \downarrow, R_{2} \phi \downarrow, R_{1} \psi \downarrow$ and $R_{2} \psi \downarrow$ are messages; $R_{1} \phi \downarrow=R_{2} \phi \downarrow$ and $R_{1} \psi \downarrow \neq R_{2} \psi \downarrow$; or
2. there exists $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ and a recipe $R$ such that $R \phi \downarrow$ is a message but $R \psi \downarrow$ is not; or
3. there exists no frame $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$.

Each case is proved separately, following the same lines. First, we easily conclude thanks to Lemma 3.2.1, in case $\left(\operatorname{tr}, \phi \rho_{(\operatorname{tr}, \phi)}^{P, \mathrm{~N}}\right)$ is still a witness of non-equivalence. This roughly means that we do not even need the fresh copy to exhibit the non-equivalence. Otherwise, we need to maintain a disequality to ensure that the distinguishing test will not hold on the $Q$ side. Since we consider adequate theories, we know that this disequality can be maintained through the use of two distinct names. This is exactly why a fresh copy is needed. The other cases can be handled similarly.

Theorem 3.2.1. Let $P$ and $Q$ be two simple protocols such that $\mathrm{Ch}(P)=\mathrm{Ch}(Q)$, and N be a set of names (intuitively those that we want to abstract away). We have that:

$$
\left[\forall c \in \operatorname{Ch}(P) \cdot \bar{P}^{\mathrm{N}, c} \approx \bar{Q}^{\mathrm{N}, c}\right] \Rightarrow P \approx Q
$$

Proof. Let us assume there exists a witness of non-equivalence $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$. Three main cases can occur:

1. there exists $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ and two recipes $R_{1}, R_{2}$ such that $R_{1} \phi \downarrow, R_{2} \phi \downarrow, R_{1} \psi \downarrow$ and $R_{2} \psi \downarrow$ are messages; $R_{1} \phi \downarrow=R_{2} \phi \downarrow$ and $R_{1} \psi \downarrow \neq R_{2} \psi \downarrow ;$
2. or there exists $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ and a recipe $R$ such that $R \phi \downarrow$ is a message but $R \psi \downarrow$ is not;
3. or, finally, there exists no frame $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$.

Note that the remaining symmetric cases are handled by considering a witness $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ instead, as $P$ and $Q$ are both simple. We will deal with each case separately, with the same intermediate goal: define a renaming $\rho$ on $D_{\psi}$ such that any test failing in $\psi$ still fails $\psi \rho$ while the successful tests in $\phi$ remain so; then translate it into a valid trace of $\bar{P}^{\mathrm{N}, c}$ for some $c \in \mathrm{Ch}(P)$.

Case 1: Let us examine $R_{1} \psi \downarrow$ and $R_{2} \psi \downarrow$. If the two terms do not share the same constructors, then for any renaming $\rho, R_{1}(\psi \rho) \downarrow \neq R_{2}(\psi \rho) \downarrow$, while for any renaming $\rho^{\prime}, R_{1}\left(\phi \rho^{\prime}\right) \downarrow=R_{2}\left(\phi \rho^{\prime}\right) \downarrow$ (as the constructors are left unchanged, because every term is a message). Now, if the two terms share the same constructors, there must exist a leaf position $p$ in them such that $\left.R_{1} \psi \downarrow\right|_{p} \neq\left. R_{2} \psi \downarrow\right|_{p}$. Let us call $t$ and $s$ these terms respectively. If $s$ or $t$ is not an element of $\mathcal{D}_{\psi}$, then $s \rho \neq t \rho$ for any $\rho$ with $\operatorname{dom}(\rho)=\mathcal{D}_{\psi}$. As in the previous case, we get that $R_{1}(\psi \rho) \downarrow \neq R_{2}(\psi \rho) \downarrow$, while $R_{1}\left(\phi \rho^{\prime}\right) \downarrow=R_{2}\left(\phi \rho^{\prime}\right) \downarrow$ for any renaming $\rho^{\prime}$. Else, assume $s=r_{1}$ and $t=r_{2}$ are two nonces of $\mathcal{D}_{\psi}$ such that $n\left(r_{1}\right)=n_{1} \in \mathrm{~N}$ (resp. $n\left(r_{2}\right)=n_{2} \in \mathrm{~N}$ ). If $n_{1} \neq n_{2}$, consider the renaming $\rho_{0}^{Q}=\left\{r \mapsto n(r) \mid r \in \mathcal{D}_{\psi}\right\}$. Then $s \rho_{0}^{Q} \neq t \rho_{0}^{Q}$ and we get that $R_{1}\left(\psi \rho_{0}^{Q}\right) \downarrow \neq R_{2}\left(\psi \rho_{0}^{Q}\right) \downarrow$. By Lemma 3.2.2, $\left(\operatorname{tr}, \psi \rho_{0}^{Q}\right) \in \operatorname{trace}\left(\bar{Q}^{\mathrm{N}}\right)$. Similarly, by defining $\rho_{0}^{P}=\left\{r \mapsto n(r) \mid r \in \mathcal{D}_{\phi}\right\}$, $\left(\operatorname{tr}, \phi \rho_{0}^{P}\right) \in \operatorname{trace}\left(\bar{P}^{\mathrm{N}}\right)$. and $R_{1}\left(\phi \rho_{0}^{P}\right) \downarrow=R_{2}\left(\phi \rho_{0}^{P}\right) \downarrow$. Hence we get a witness of non-equivalence between $\bar{P}^{\mathrm{N}}$ and $\bar{Q}^{\mathrm{N}}$, which can translate into a witness between $\bar{P}^{\mathrm{N}, c}$ and $\bar{Q}^{\mathrm{N}, c}$ for any $c \in \operatorname{Ch}(P)$.

Else, if $n\left(r_{1}\right)=n\left(r_{2}\right)=n$, we need to be more precise to define a proper $\rho$. Let out $(c, c h)$ be the action of $\operatorname{tr}$ such that $\operatorname{tr}=\operatorname{tr}_{1}$.out $(c, c h) \cdot \operatorname{tr}_{2}$ and $c\left(r_{2}\right)=c h$. Let $\tilde{\mathcal{D}}_{\psi}=\{r \in \psi \mid n(r) \in \mathrm{N} \wedge c(r)=c h\}$ and $\tilde{\mathcal{D}}_{\phi}=$ $\{r \in \phi \mid n(r) \in \mathrm{N} \wedge c(r)=c h\} . r_{1} \in \mathcal{D}_{\psi} \backslash \tilde{\mathcal{D}}_{\psi}$ but $r_{2} \in \tilde{\mathcal{D}}_{\psi}$ Consider now $\rho_{Q}=n\left(\mathcal{D}_{\psi} \backslash \tilde{\mathcal{D}}_{\psi}\right) \cup n^{\star}\left(\tilde{\mathcal{D}}_{\psi}\right)$. In particular, $r_{1} \rho_{Q}=n$ while $r_{2} \rho_{Q}=n^{\star}$. Then $s \rho_{Q} \neq t \rho_{Q}$ and we get that $R_{1}\left(\psi \rho_{Q}\right) \downarrow \neq R_{2}\left(\psi \rho_{Q}\right) \downarrow$ and Lemma 3.2.2 ensures $\left(\operatorname{tr}^{\star}, \psi \rho_{Q}\right) \in \operatorname{trace}\left(\bar{Q}^{\mathrm{N}, c}\right)$. Similarly, by defining $\rho_{P}=n\left(\mathcal{D}_{\phi} \backslash \tilde{\mathcal{D}}_{\phi}\right) \cup n^{\star}\left(\tilde{\mathcal{D}}_{\phi}\right)$, Lemma 3.2.2 ensures $\left(\operatorname{tr}^{\star}, \phi \rho_{P}\right) \in \operatorname{trace}\left(\bar{P}^{\mathrm{N}, c}\right.$ ) and $R_{1}\left(\phi \rho_{P}\right) \downarrow=R_{2}\left(\phi \rho_{P}\right) \downarrow$ (only equalities have been introduced by removing the name restriction in $P$ ). Hence we get a witness of non-equivalence between $\bar{P}^{\mathrm{N}, c}$ and $\bar{Q}^{\mathrm{N}, c}$

Case 2: Because $R \psi \downarrow$ is not a message and our signature is adequate (see Definition 3.1.1), there must exist $a, b \in \mathcal{N}$ such that $a \neq b$ and for any renaming $\sigma: \mathcal{N} \rightarrow \mathcal{N}, a \sigma \neq b \sigma \Rightarrow t \sigma \downarrow \notin \mathcal{M}_{\Sigma}$. If $a \notin \mathcal{D}_{\psi}$ or $b \notin \mathcal{D}_{\psi}$, consider the renaming $\rho_{0}^{Q}=\left\{r \mapsto n(r) \mid r \in \mathcal{D}_{\psi}\right\}$ : as $a \rho_{0}^{Q}=a$ and $n(r) \neq a$ for any $r \in \mathcal{D}_{\psi}, R\left(\psi \rho_{0}^{Q}\right) \downarrow$ is still not a message. On the other hand, if $\rho_{0}^{P}=\left\{r \mapsto n(r) \mid r \in \mathcal{D}_{\phi}\right\}$, as $R \phi \downarrow$ is a message, $R \phi \downarrow \rho_{0}^{P}=R\left(\phi \rho_{0}^{P}\right) \downarrow$ is a message. Hence, Lemma 3.2.2 ensures $\left(\operatorname{tr}, \phi \rho_{0}^{P}\right) \in \operatorname{trace}\left(\bar{P}^{\mathrm{N}}\right)$ while $\left(\operatorname{tr}, \psi \rho_{0}^{Q}\right) \notin \operatorname{trace}\left(\bar{Q}^{\mathrm{N}}\right)$, leading to a witness of non-equivalence between $\bar{P}^{\mathrm{N}}$ and $\bar{Q}^{\mathrm{N}}$.

Else, assume $a=r_{1}$ and $b=r_{2}$ are two nonces in $\mathcal{D}_{\psi}$. If $n\left(r_{1}\right) \neq n\left(r_{2}\right), r_{1} \rho_{0}^{Q} \neq r_{2} \rho_{0}^{Q}$ and we can apply the same exact reasoning as before. So let us consider the case where $n\left(r_{1}\right)=n\left(r_{2}\right)=n$. Let out $(c, c h)$ be the action of $\operatorname{tr}$ such that $\operatorname{tr}=\operatorname{tr}_{1}$.out $(c, c h) \cdot \operatorname{tr}_{2}$ and $c\left(r_{2}\right)=c h$. Let $\tilde{\mathcal{D}}_{\psi}=\{r \in \psi \mid n(r) \in \mathrm{N} \wedge c(r)=c h\}$ and $\tilde{\mathcal{D}}_{\phi}=\{r \in \phi \mid n(r) \in \mathrm{N} \wedge c(r)=c h\} . r_{1} \in \mathcal{D}_{\psi} \backslash \tilde{\mathcal{D}}_{\psi}$ but $r_{2} \in \tilde{\mathcal{D}}_{\psi}$ Consider now $\rho_{Q}=n\left(\mathcal{D}_{\psi} \backslash \tilde{\mathcal{D}}_{\psi}\right) \cup n^{\star}\left(\tilde{\mathcal{D}}_{\psi}\right)$. In particular, $r_{1} \rho_{Q}=n$ while $r_{2} \rho_{Q}=n^{\star}$. Definition 3.1.1 ensures $R\left(\psi \rho_{0}^{Q}\right) \downarrow$ is still not a message. On the other hand, if $\rho_{P}=n\left(\mathcal{D}_{\phi} \backslash \tilde{\mathcal{D}}_{\phi}\right) \cup n^{\star}\left(\tilde{\mathcal{D}}_{\phi}\right)$, as $R \phi \downarrow$ is a message, $R \phi \downarrow \rho_{P}=R\left(\phi \rho_{P}\right) \downarrow$ is a message. Hence, Lemma 3.2.2 ensures $\left(\operatorname{tr}^{\star}, \phi \rho_{P}\right) \in \operatorname{trace}\left(\bar{P}^{\mathrm{N}, c}\right)$ while $\left(\operatorname{tr}^{\star}, \psi \rho_{Q}\right) \in \operatorname{trace}\left(\bar{Q}^{\mathrm{N}, c}\right)$, leading to a witness of non-equivalence between $\bar{P}^{\mathrm{N}, c}$ and $\bar{Q}^{\mathrm{N}, c}$.

Case 3: if tr ends with an output out $(c, \mathrm{w})$ such that $\mathrm{w} \psi$ is not a message, we can define $\rho_{Q}$ and $\rho_{P}$ as in case 2 and obtain a witness of non-equivalence. Similarly, if tr ends with an input or output out $(c, \mathrm{w})$ which cannot be executed in $Q$ because a let action did not reduce to a message, we can define $\rho_{Q}$ and $\rho_{P}$ as in case 2 and obtain a witness of non-equivalence. Consider now the subcase where $\operatorname{tr}=\operatorname{tr}^{\prime} . \operatorname{in}(c, R)$ for some $\operatorname{tr}^{\prime}$ such that $\left(\operatorname{tr}^{\prime}, \phi\right) \in \operatorname{trace}(P)$ and $\left(\operatorname{tr}^{\prime}, \psi\right) \in \operatorname{trace}(Q)$ for some frame $\psi$. Because $P$ and $Q$ are both simple protocols, there exists a unique term $u_{P}$ (resp. at most one term $u_{Q}$ ) in the multiset $\mathcal{P}$ (resp. $\mathcal{Q}$ ) of processes from the execution of $\operatorname{tr}^{\prime}$ in $P$ (resp. in $Q$ ) such that $\operatorname{in}\left(c, u_{P}\right) . M \in \mathcal{P}$ for some $M$ (resp. in $\left(c, u_{Q}\right) . N \in \mathcal{Q}$ for some $N$ ). Moreover, there exists $\sigma_{P}$ such that $R \phi \downarrow=u_{P} \sigma_{P}$ while there is no $\sigma$ such that $R \psi \downarrow=u_{Q} \sigma$. As before, we consider the renamings $\rho_{0}^{Q}=n\left(\mathcal{D}_{\psi}\right)$ and $\rho_{0}^{P}=n\left(\mathcal{D}_{\phi}\right)$. As $\left(\operatorname{tr}, \phi \rho_{0}^{P}\right) \in \operatorname{trace}\left(\bar{P}^{\mathrm{N}}\right)$ and $\left(\operatorname{tr}, \psi \rho_{0}^{Q}\right) \in \operatorname{trace}\left(\bar{Q}^{\mathrm{N}}\right)$ by Lemma 3.2.2, if there exists no $\sigma$ such that $u_{Q} \rho_{0}^{Q} \sigma=R \psi \downarrow \rho_{0}^{Q}$, tr is a witness of non-equivalence between $\bar{P}^{N}$ and $\bar{Q}^{N}$ and we are done. So let us then assume there exists $\sigma_{0}$ such that $u_{Q} \rho_{0}^{Q} \sigma_{0}=R \psi \downarrow \rho_{0}^{Q}$ while $u_{Q} \sigma \neq R \psi \downarrow$ for every $\sigma$. There exist two leaves with positions $p_{1}$ and $p_{2}$ in $R \psi \downarrow$ which correspond to positions below variables in $u_{Q}$ such that $\left.R \psi \downarrow\right|_{p_{1}} \neq\left. R \psi \downarrow\right|_{p_{2}}$ but $\left.R\left(\psi \rho_{0}^{Q}\right) \downarrow\right|_{p_{1}}=\left.R\left(\psi \rho_{0}^{Q}\right) \downarrow\right|_{p_{2}}$ and $\left.R \psi \downarrow\right|_{p_{1}}=r_{1}$ and $\left.R \psi \downarrow\right|_{p_{2}}=r_{2}$ such that $n\left(r_{1}\right)=n\left(r_{2}\right)=n \in \mathrm{~N}$. As repeatedly before, let out $(c, c h)$ be the action of tr such that $\operatorname{tr}=\operatorname{tr}_{1}$.out $(c, c h) \cdot \operatorname{tr}_{2}$ and $c\left(r_{2}\right)=c h$. Let $\tilde{\mathcal{D}}_{\psi}=\{r \in \psi \mid n(r) \in \mathrm{N} \wedge c(r)=c h\}$ and $\tilde{\mathcal{D}}_{\phi}=\{r \in \phi \mid n(r) \in \mathrm{N} \wedge c(r)=c h\} . r_{1} \in \mathcal{D}_{\psi} \backslash \tilde{\mathcal{D}}_{\psi}$ but $r_{2} \in \tilde{\mathcal{D}}_{\psi}$ Consider now $\rho_{Q}=n\left(\mathcal{D}_{\psi} \backslash \tilde{\mathcal{D}}_{\psi}\right) \cup n^{\star}\left(\tilde{\mathcal{D}}_{\psi}\right)$. In particular, $r_{1} \rho_{Q}=n$ while $r_{2} \rho_{Q}=n^{\star}$. As $R \psi \downarrow$ is a message (by virtue of our semantics), $R \psi \downarrow \rho_{Q}=R\left(\psi \rho_{Q}\right) \downarrow$ and now $\left.R\left(\psi \rho_{Q}\right) \downarrow\right|_{p_{1}} \neq\left. R\left(\psi \rho_{Q}\right) \downarrow\right|_{p_{2}}$. As such, $u_{Q} \rho_{Q} \sigma \neq R \psi \rho_{Q} \downarrow$ for any $\sigma$. By defining $\rho_{P}=n\left(\mathcal{D}_{\phi} \backslash \tilde{\mathcal{D}}_{\phi}\right) \cup n^{\star}\left(\tilde{\mathcal{D}}_{\phi}\right)$, as $R \phi \downarrow$ is a message, $R \phi \downarrow \rho_{P}=R\left(\phi \rho_{P}\right) \downarrow$ is a message. Hence, Lemma 3.2.2 ensures $\left(\operatorname{tr}^{\star}, \phi \rho_{P}\right) \in \operatorname{trace}\left(\bar{P}^{\mathrm{N}, c}\right)$ while $\left(\operatorname{tr}^{\star}, \psi\right) \notin \operatorname{trace}\left(\bar{Q}^{\mathrm{N}, c}\right)$ for any $\psi$, leading to a witness of non-equivalence between $\bar{P}^{\mathrm{N}, c}$ and $\bar{Q}^{\mathrm{N}, c}$.

### 3.3 Scope of our result

In this section, we explain why we need to assume simple processes and adequate theories and we discuss which class of protocols and primitives can be covered.

### 3.3.1 Simple processes

Simple processes are really necessary for our simplification result to hold. We provide below a small counter example to our result for non simple processes.

Example 3.3.1. We consider symmetric encryption and pairs as in Example 2.1 .1 with ok $\in \Sigma_{0}$. We define the two following processes.

```
P= !new c.out ( }\mp@subsup{c}{1}{},c)\mathrm{ .new n.out (c, senc}(n,k)
    | !new c.out ( c c, c).in( }c,\langle\operatorname{senc}(x,k),\operatorname{senc}(x,k),\operatorname{senc}(y,k)\rangle).out(c,ok
    | !new c.out ( }\mp@subsup{c}{2}{},c).\operatorname{in}(c,\langle\operatorname{senc}(x,k),\operatorname{senc}(y,k),\operatorname{senc}(x,k)\rangle).out(c,ok
    | !new c.out ( }\mp@subsup{c}{2}{},c).\operatorname{in}(c,\langle\operatorname{senc}(y,k),\operatorname{senc}(x,k),\operatorname{senc}(x,k)\rangle).out(c,ok
Q = !new c.out ( }\mp@subsup{c}{1}{},c).\mathrm{ new n.out (c, senc}(n,k)
    | !new c.out ( cc, c).in(c,\langle\operatorname{senc}(x,k),\operatorname{senc}(y,k),\operatorname{senc}(z,k)\rangle).out(c,ok).
\(Q=\) ! new \(c\).out \(\left(c_{1}, c\right)\).new \(n\).out \((c, \operatorname{senc}(n, k))\)
| ! new \(c\).out \(\left(c_{2}, c\right) \cdot \operatorname{in}(c,\langle\operatorname{senc}(x, k), \operatorname{senc}(y, k), \operatorname{senc}(z, k)\rangle)\).out \((c\), ok \()\).
```

Intuitively $P$ expects a list of three ciphertexts among which two must be identical, while $Q$ expects any three ciphertexts. The process $Q$ is simple but $P$ is not since several processes in parallel proceed on channel $c_{2}$. We have that $P \not \approx Q$ : it is possible using (1) to generate distinct ciphertexts, concatenate them, and send the resulting message on $c_{2}$. This message will not be accepted in $P$, but it will be accepted in $Q$.

Now, consider the process $\bar{P}^{c_{1}}$ and $\bar{Q}^{c_{1}}$ with $\mathrm{N}=\{n\}$, that is the processes obtained by applying our transformation on channel $c_{1}$ (the only branch that contains nonce generation) with the goal of getting rid of the instruction new $n$ on both sides. We obtain:

$$
\begin{aligned}
& \bar{P}^{c_{1}}=\text { !new } c . \text { out }\left(c_{1}, c\right) \text {.out }(c, \operatorname{senc}(n, k)) \\
& \text { | new } n^{\star} \text {. out }\left(c^{\star}, \operatorname{senc}\left(n^{\star}, k\right)\right) \\
& \text { | !new } c \text {.out }\left(c_{2}, c\right) \cdot \operatorname{in}(c,\langle\operatorname{senc}(x, k), \operatorname{senc}(x, k), \operatorname{senc}(y, k)\rangle) \text {.out }(c, \text { ok }) \\
& \text { | ! new } c \text {.out }\left(c_{2}, c\right) \cdot \operatorname{in}(c,\langle\operatorname{senc}(x, k), \operatorname{senc}(y, k), \operatorname{senc}(x, k)\rangle) \text {.out }(c, \text { ok }) \\
& \text { | ! new } c \text {.out }\left(c_{2}, c\right) \cdot \operatorname{in}(c,\langle\operatorname{senc}(y, k), \operatorname{senc}(x, k), \operatorname{senc}(x, k)\rangle) \text {.out }(c, \text { ok) } \\
& \bar{Q}^{c_{1}}=\text { !new } c \text {.out }\left(c_{1}, c\right) \text {.out }(c, \operatorname{senc}(n, k)) \\
& \text { | new } n^{\star} \text {.out }\left(c^{\star}, \operatorname{senc}\left(n^{\star}, k\right)\right) \\
& \text { ! new } c \text {.out }\left(c_{2}, c\right) \cdot \operatorname{in}(c,\langle\operatorname{senc}(x, k), \operatorname{senc}(y, k), \operatorname{senc}(z, k)\rangle) \text {.out }(c, \text { ok). }
\end{aligned}
$$

It is quite easy to see that the witness of non-equivalence given above is not a valid one anymore. Actually, we have that $\bar{P}^{c_{1}}$ and $\bar{Q}^{c_{1}}$ are in trace equivalence since only two distinct ciphertexts may be produced.

Note that it is easy to express standard protocols as simple processes. As explained previously, encoding security protocols as simple processes is a good practice, and gives power to the attacker. However, it prevents the modelling of unlinkability properties.

### 3.3.2 Adequate theories

The fact that we consider adequate theories may seem to be a proof artefact. We could probably go beyond adequate theories, but this would be at the price of considering a more complex transformation, and in particular additional constants. We provide below an example of a theory that reflects the same kind of issues as the ones illustrated by the processes presented in Example 3.3.1.
Example 3.3.2. In addition to the signature introduced in Example 2.1.1, we consider an additional destructor symbol g together with the following rewriting rules:

$$
\begin{array}{lll}
\mathrm{g}(\langle\operatorname{senc}(x, z), \operatorname{senc}(x, z), \operatorname{senc}(y, z)\rangle) & \rightarrow & \text { ok } \\
\mathrm{g}(\langle\operatorname{senc}(x, z), \operatorname{senc}(y, z), \operatorname{senc}(x, z)\rangle) & \rightarrow & \text { ok } \\
\mathrm{g}(\langle\operatorname{senc}(y, z), \operatorname{senc}(x, z), \operatorname{senc}(x, z)\rangle) & \rightarrow & \text { ok }
\end{array}
$$

Assume for instance that $\mathcal{M}_{\Sigma}$ is $\mathcal{M}_{c}=\mathcal{T}\left(\Sigma_{c}, \mathcal{N}\right)$ the set of all ground constructor terms. The resulting theory is not adequate. For instance, we have that the term $t=\mathrm{g}\left(\left\langle\operatorname{senc}\left(n_{1}, k\right), \operatorname{senc}\left(n_{2}, k\right), \operatorname{senc}\left(n_{3}, k\right)\right\rangle\right)$ is in normal form and not a message. However, any renaming $\rho$ that preserves distinctness between only two names among $n_{1}, n_{2}, n_{3}$, will be such that $t \rho \downarrow \in \mathcal{M}_{\Sigma}$. This yields a counter-example to our result, illustrated by the two following processes.

$$
\begin{aligned}
P^{\prime}= & !\text { new } c . \text { out }\left(c_{1}, c\right) \text {.new } n . \text { out }(c, \operatorname{senc}(n, k)) \\
& \mid \quad \operatorname{in}\left(c_{2},\left\langle\operatorname{senc}\left(x_{1}, k\right), \operatorname{senc}\left(x_{2}, k\right), \operatorname{senc}\left(x_{3}, k\right)\right\rangle\right) . \\
& \text { let } y=\mathrm{g}\left(\left\langle\operatorname{senc}\left(x_{1}, k\right), \operatorname{senc}\left(x_{2}, k\right), \operatorname{senc}\left(x_{3}, k\right)\right\rangle\right) \text { in out }\left(c_{2}, y\right) . \\
Q^{\prime}= & !\text { new } c . \text { out }\left(c_{1}, c\right) . \text { new } n . \text { out }(c, \operatorname{senc}(n, k)) \\
& \mid \quad \operatorname{in}\left(c_{2},\left\langle\operatorname{senc}\left(x_{1}, k\right), \operatorname{senc}\left(x_{2}, k\right), \operatorname{senc}\left(x_{3}, k\right)\right\rangle\right) . \text { out }\left(c_{2}, \text { ok }\right) .
\end{aligned}
$$

The process $P^{\prime}$ expects three ciphertexts and returns the result of applying g to them while $Q^{\prime}$ directly returns ok. For the same reasons as those explained in Example 3.3.1, we have that $P^{\prime} \not \approx Q^{\prime}$ whereas ${\overline{P^{\prime}}}^{c_{1}} \approx{\overline{Q^{\prime}}}^{c_{1}}$.

The equational theory above is contrived, and actually most of the equational theories useful to model cryptographic protocols can be shown to be adequate. An example of a non-adequate theory is tdcommit as described in [39] for modeling trapdoor commitment schemes, which does not fit the structure of our rules.

### 3.3.3 Is our abstraction precise enough?

Abstracting nonces with constants (as done in Theorem 3.2.1) may introduce false attacks. A typical case is when protocols make use of temporary secrets.

Example 3.3.3. Consider the signature described in Example 2.1.1. Let $P$ and $Q$ be:

$$
\begin{aligned}
& P=!\text { new } c^{\prime} . \text { out }\left(c, c^{\prime}\right) \cdot \operatorname{in}\left(c^{\prime}, x\right) \cdot \text { new } n \cdot \operatorname{out}\left(c^{\prime}, \operatorname{senc}(\text { ok, } n)\right) \\
& \text { let } y=\operatorname{sdec}(x, n) \text { in out }\left(c^{\prime}, y\right) ; \\
& Q=!\text { new } c^{\prime} . \text { out }\left(c, c^{\prime}\right) \cdot \operatorname{in}\left(c^{\prime}, x\right) \cdot \text { new } n \cdot o u t\left(c^{\prime}, n\right) .
\end{aligned}
$$

The two processes are in equivalence: $P \approx Q$. Now, consider the processes $\bar{P}^{c}$ and $\bar{Q}^{c}$ with $\mathrm{N}=\{n\}$, that is, the processes obtained by applying our transformation on channel $c$ to get rid of the fresh nonces.

$$
\begin{aligned}
\bar{P}^{c}= & !\text { new } c^{\prime} \cdot \operatorname{out}\left(c, c^{\prime}\right) \cdot \operatorname{in}\left(c^{\prime}, x\right) \cdot \operatorname{out}\left(c^{\prime}, \operatorname{senc}(\text { ok }, n)\right) . \\
& \text { let } y=\operatorname{sdec}(x, n) \operatorname{in} \operatorname{out}\left(c^{\prime}, y\right) \\
& \mid \operatorname{in}\left(c^{\star}, x\right) \cdot \operatorname{out}\left(c^{\star}, \operatorname{senc}\left(\text { ok, } n^{\star}\right)\right) \cdot \operatorname{let} y=\operatorname{sdec}\left(x, n^{\star}\right) \operatorname{in} \operatorname{out}\left(c^{\star}, y\right)
\end{aligned}
$$

$\bar{Q}^{c}$ is defined similarly. It is easy to notice that the output of the constant ok is now reachable, yielding $\bar{P}^{c} \not \approx \bar{Q}^{c}$.
Our transformation may in theory also introduce false attacks for protocols without temporary secrets. In this section, we review several (secure) protocols of the literature and study whether a false attack is introduced by our transformation. To perform this analysis we rely on the ProVerif tool. For each protocol, we first consider a scenario with honest agents only as for the Denning-Sacco protocol (Chapter 2). We then consider a richer scenario where honest agents are also willing to engage communications with a dishonest agent. In each case, we check whether ProVerif is able to establish:

1. the equivalence between the original processes (left column);
2. all the equivalences obtained after getting rid of all the nonces using our transformation (right column).

The results are reported on the table below: a $\checkmark$ means that ProVerif succeeded and a $\boldsymbol{X}$ means that it failed. Actually, on most of the protocols/scenarios we have considered, our abstraction does not introduce any false attack. ProVerif models of our experiments are available online at http://www.lsv.ens-cachan.fr/~chretien/prot.tar.

| Protocol name | original <br> (with nonces) | our transformation <br> (no nonce) |
| :--- | :---: | :---: |
| YAHALOM (corrected version) <br> - simple scenario <br> - with a dishonest agent | $\checkmark$ |  |
| OTwAY-REES | $\checkmark$ | $\checkmark$ |
| - simple scenario |  |  |
| - with a dishonest agent | $\checkmark$ | $\checkmark$ |
| KAO-CHOW (tagged version) | $\checkmark$ | $\checkmark$ |
| - simple scenario | $\checkmark$ |  |
| - with a dishonest agent | $\checkmark$ | $\checkmark$ |
| NEEDHAM-SchroEDER-LowE |  | $\checkmark$ |
| - simple scenario (secrecy of $N_{a}$ ) | $\checkmark$ |  |
| - simple scenario (secrecy of $N_{b}$ ) | $\checkmark$ | $\checkmark$ |
| - with a dishonest agent (secrecy of $N_{b}$ ) | $\checkmark$ | $\checkmark$ |
| DENNING-SACco (asymmetric) | $\checkmark$ | $\checkmark$ |
| - simple scenario |  |  |
| - with a dishonest agent | $\checkmark$ | $\checkmark$ |

Needham Schroeder Lowe protocol. We briefly comment on the false attack introduced by our transformation on the Needham Schroeder Lowe protocol.

$$
\begin{array}{llll}
\text { 1. } A \rightarrow B: & \left\{A, N_{a}\right\}_{\operatorname{pub}(B)} & \text { 1. } I(A) \rightarrow B: & \left\{A, N_{i}\right\}_{\operatorname{pub}(B)} \\
\text { 2. } B \rightarrow A: & \left\{N_{a}, N_{b}, B\right\}_{\operatorname{pub}(A)} & \text { 2. } B \rightarrow I(A): & \left\{N_{i}, N_{b}, B\right\}_{\operatorname{pub}(A)} \\
\text { 3. } A \rightarrow B: & \left\{N_{b}\right\}_{\operatorname{pub}(B)} & \text { 3.I(A) } \rightarrow B: & \left\{N_{b}\right\}_{\operatorname{pub}(B)}
\end{array}
$$

The protocol is given on the left, and the (false) attack depicted on the right. This attack scenario (and more precisely step 3 of this scenario) is only possible when nonces are abstracted away with constants. Indeed, the attacker will not be able to decrypt the message $\left\{N_{i}, N_{b}, B\right\}_{\operatorname{pub}(A)}$ he has received to retrieve the nonce $N_{b}$. Instead he will simply replay an old message coming from a previous honest session between $A$ and $B$. Since nonces have been replaced by constants, $B$ will accept this old message, and will assume that $N_{i}$ is a secret shared between $A$ and $B$, while $N_{i}$ is known by the attacker. Unfortunately, this abstraction does not seem to help ProVerif prove the security of new protocols. Nonetheless it can still be used as a proof technique to prove the security of protocols in classes defined in [23] and [24].

### 3.4 Conclusion

Our simplification result allows to soundly reduce the equivalence of processes with nonces to the equivalence of processes without nonces. This can be seen as a proof technique which removes a source of unboundedness problematic when trying to automatically check for trace equivalence. For example for tagged simple protocols with symmetric encryption, the resulting protocols fall in the decidable class of Chapter 4. Similarly, we could use the decidability result of Chapter 7 for ping-pong protocols with one variable per transition.

Our result assumes protocols to be simple processes. Otherwise, to prevent some transition, it could be necessary to maintain several disequalities. We plan to go slightly beyond simple processes and simply require some form of determinacy. More generally, we plan to study whether such a reduction result can be obtained for more general processes which include else branches to output errors messages, that is, study whether it is possible to compute a bound on the number of fresh copies from the structure of the processes.

Regarding adequate theories, we believe that our criterion is general enough to capture even more theories like exclusive or, or other theories with an associative and commutative operator. This would however require to extend our formalism to arbitrary terms (not just destructor/constructor theories).

## Chapter 4

## Well-typed executions

The subject of this chapter is a simplification result, that reduces the search space for attacks: if there is an attack, then there exists a well-typed attack. More formally, we show that if there is a witness (i.e. a trace) that $P \not \approx Q$ then there exists a witness which is well-typed w.r.t. $P$ or $Q$, provided that $P$ and $Q$ are determinate processes (see Definition 2.4.3). This typing result holds for an unbounded number of sessions and an unbounded number of nonces, that is, it holds even if $P$ and $Q$ contain arbitrary replications and NEW operations. It holds for any typing system provided that any two unifiable encrypted subterms of $P($ or $Q)$ are of the same type. It is then up to the user to adjust the typing system such that this hypothesis holds for the protocols under consideration.

As an application, we consider the class of tagged protocols introduced by Blanchet and Podelski [15] and defined in Chapter 2. An easy way to achieve this in practice is by labelling encryption and is actually a good protocol design principle [3, 49].

Interestingly, the proof of our main typing result involves providing a new decision procedure for trace equivalence in the case of a bounded number of sessions. This is a key intermediate result of our proof. Trace equivalence was already shown to be decidable for a bounded number of sessions (e.g. [65, 22]) but we propose a novel decision procedure that further provides a well-typed witness whenever the two processes are not in trace equivalence.

Our proof technique is inspired from the approach developed by Arapinis et al [6] for bounding the size of messages of an attack for the reachability case. Specifically, they show for some class of tagged protocols, that whenever there is an attack, there is a well-typed attack (for a particular typing system). We somehow extend their approach to trace equivalence and more general typing systems for symmetric encryption only, but without asymmetric encryption, signatures or hash functions.

### 4.1 Existence of a well-typed witness of non-equivalence

We consider the formal model defined in Chapter 2 with a restricted signature. More precisely, from this chapter onward, we will consider the signature

$$
\Sigma=\left\{\text { senc, sdec, }\langle \rangle, \operatorname{proj}_{1}, \operatorname{proj}_{2}\right\} \uplus \Sigma_{0}
$$

where $\Sigma_{0}$ is a set of atomic data, representing pairing and symmetric encryption as defined in Example 2.1.1. We also do not use evaluation in our processes, i.e. no let, and instead rely only on input filtering to model decryption operations. Moreover, we will consider only encryption with atomic keys, meaning that the set $\mathcal{M}$ of messages will be defined by $\mathcal{M}=\mathcal{M}_{\text {atomic }}$. Note that this decision increases the power of the attacker as it lets her distinguish between situations she could not before, as described in Example 2.4.2.

We can now present our first main contribution: a typing result that reduces the search space for attacks. We first explain these hypotheses and then we state our general simplification result (see Theorem 4.1.1). The proof of

$$
\begin{aligned}
& \operatorname{in}(c, u) . P \cup \mathcal{P} \xrightarrow[l_{s}]{\text { in }(c, u)} P \cup \mathcal{P}!P \cup \mathcal{P} \xrightarrow{\tau}_{s} P^{\prime} \cup!P \cup \mathcal{P} \\
& \operatorname{out}(c, u) . P \cup \mathcal{P} \xrightarrow{\text { out }(c, u)}{ }_{s} P \cup \mathcal{P} \quad \begin{array}{l}
\text { new } n . P \cup \mathcal{P} \xrightarrow{\tau}_{s} P\left\{n^{\prime} / n\right\} \cup \mathcal{P} \\
\text { new } c^{\prime} . \operatorname{out}\left(c, c^{\prime}\right) . P \cup \mathcal{P} \xrightarrow{\text { out }\left(c, c h_{i}\right)}{ }_{s} P\left\{{ }^{\left.c h_{i} / c^{\prime}\right\}} \cup \mathcal{P}\right.
\end{array}
\end{aligned}
$$

Figure 4.1: Symbolic semantics of protocols
this simplification result involves providing a novel decision procedure for trace equivalence in the case of a bounded number of sessions. The novelty of this decision procedure, in comparison to the existing ones, is to provide a well-typed witness whenever the two processes are not in trace equivalence. This key intermediate result is stated in Proposition 4.1.1.

### 4.1.1 Well-typed trace

Whether or not a trace is well-typed is defined w.r.t. the set of symbolic traces of a protocol. Formally, we define $\xrightarrow{\operatorname{tr}_{s}}{ }_{s}$ to be the transitive closure of the relation ${ }^{\alpha_{s}}$ s defined between processes in Figure 4.1.1: where $P^{\prime}$ is equal to $P$ up to renaming of variables that do not occur yet in the trace with fresh ones (of the same type), $n^{\prime}$ is a fresh name (of the same type as $n$ ), and $c h_{i}$ is the "next" fresh channel name available in $\mathcal{C} h^{\text {fresh }}$.

Then, the set of symbolic traces $\operatorname{trace}_{s}(P)$ of a protocol $P$ is defined as follows:

$$
\operatorname{trace}_{s}(P)=\left\{\operatorname{tr}_{s} \mid P{\xrightarrow{\operatorname{tr}_{s}}}_{s} Q \text { for some } Q\right\} .
$$

Intuitively, the symbolic traces are simply all possible traces before instantiation of the variables, with some renaming to avoid unwanted captures.

Example 4.1.1. Let $P_{1}=\operatorname{in}(c, x) .!$ new $k$. in $(c, \operatorname{enc}(\langle x, y\rangle, k))$. We have that:

$$
\operatorname{tr}_{s}=\operatorname{in}(c, x) \cdot \operatorname{in}\left(c, \operatorname{enc}\left(\left\langle x, y_{1}\right\rangle, k_{1}\right)\right) \cdot \operatorname{in}\left(c, \operatorname{enc}\left(\left\langle x, y_{2}\right\rangle\right), k_{2}\right) \in \operatorname{trace}_{s}\left(P_{1}\right)
$$

Indeed, the variable $x$ is bound before replication.
As stated in the lemma below, any concrete trace is the instance of a symbolic trace.
Lemma 4.1.1. Let $P$ be a protocol and $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$. We have that $\operatorname{tr} \phi \downarrow=\operatorname{tr}_{s} \sigma$ for some $\operatorname{tr}_{s} \in \operatorname{trace}_{s}(P)$ and some substitution $\sigma$.

A well-typed trace is simply a trace that is well-typed w.r.t. one of the symbolic traces. Since keys are atomic, some executions may fail when a protocol is about to output a term that contains an encryption with a non atomic key. To detect these behaviours, we need to consider slightly ill-typed traces. Formally, we consider a special constant $\omega \in \Sigma_{0}$. Its usefulness is illustrated in Example 4.1.2.

Definition 4.1.1. A first-order trace of $P$ is a sequence $\operatorname{tr}=\operatorname{tr}_{s} \sigma$ where $\operatorname{tr}_{s} \in \operatorname{trace}_{s}(P)$ and $\sigma$ is a substitution such that for any io $(c, u)$ that occurs in $\operatorname{tr}_{s}$ with io $\in\{$ in, out $\}$ and $u$ not a channel, then $u \sigma \in \mathcal{T}_{0}\left(\Sigma_{c}, \Sigma_{0} \cup \mathcal{N} \cup \mathcal{X}\right)$. The trace $t r$ is said to be:

- well-typed w.r.t. a typing system $(\mathcal{T}, \delta)$ if there exists such a $\sigma$ that is well-typed;
- pseudo-well-typed w.r.t. a typing system $(\mathcal{T}, \delta)$ if there exists such $\sigma$, as well as $\mathrm{c}_{0} \in \Sigma_{0}$ and $\sigma^{\prime}$ such that $\sigma=\sigma^{\prime}\left\{\langle\omega, \omega\rangle / c_{0}\right\}$ with $\sigma^{\prime}$ well-typed.

Then a trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ is well-typed (resp. pseudo-well-typed) if $\operatorname{tr} \phi \downarrow$ is well-typed (resp. pseudo-welltyped).

Note that Lemma 4.1.1 ensures that $\operatorname{tr} \phi \downarrow$ is a first-order trace of $P$, and a well-typed trace is also pseudo-welltyped.
Example 4.1.2. Going back to Example 2.4.2, let $\operatorname{tr}=\operatorname{in}(c,\langle\omega, \omega\rangle)$.out $\left(c, \mathrm{w}_{1}\right)$. We have that $\left(\operatorname{tr},\left\{\mathrm{w}_{1} \triangleright \mathrm{enc}(n, k)\right\}\right) \in$ $\operatorname{trace}(P)$ while there exists no frame $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$. Consider the typing system $(\mathcal{T}, \delta)$ such that $\delta(t)=$ atom for any atom or variable $t$ and $\delta(t)=\neg$ atom if $t$ is not an atom. We can see there exists no welltyped witness of $P \not \approx Q$ (while $P$ and $Q$ are type-compliant as defined in Definition 2.5.3). However, the witness ( $\left.\operatorname{tr},\left\{\mathrm{w}_{1} \triangleright \mathrm{enc}(n, k)\right\}\right)$ of $P \nsubseteq Q$ is pseudo-well-typed (note that $\langle\omega, \omega\rangle$ occurs in tr). Intuitively, pseudo-well-typed traces harness the ability for the attacker to use the protocol as an oracle to test if some terms (when used in a key position) are atomic.

### 4.1.2 Main result

We are now ready to state our first main contribution: if there is an attack, then there is a pseudo-well-typed attack. This result holds for protocols with replications and nonces.

Theorem 4.1.1. Let $P$ and $Q$ be two determinate protocols type-compliant w.r.t. $\left(\mathcal{T}_{1}, \delta_{1}\right)$ and $\left(\mathcal{T}_{2}, \delta_{2}\right)$ respectively. We have that $P \not \approx Q$ if, and only if, there exists a witness of non-equivalence tr such that:

- either $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ for some $\phi$ and $(\operatorname{tr}, \phi)$ is pseudo-well-typed w.r.t. $\left(\mathcal{T}_{1}, \delta_{1}\right)$;
- or $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ for some $\psi$ and $(\operatorname{tr}, \psi)$ is pseudo-well-typed w.r.t. $\left(\mathcal{T}_{2}, \delta_{2}\right)$.

The key step for proving Theorem 4.1.1 is to provide a decision procedure, in the bounded case (i.e. processes without replication), that returns a pseudo-well-typed witness of non-equivalence.

Proposition 4.1.1. Let $P$ and $Q$ be two determinate protocols without replication. There exists an algorithm that decides whether $P \approx Q$ and if not, returns a witness tr of non-equivalence. Moreover, if $P$ and $Q$ are type-compliant w.r.t. $\left(\mathcal{T}_{1}, \delta_{1}\right)$ and $\left(\mathcal{T}_{2}, \delta_{2}\right)$ respectively, the witness tr of non-equivalence returned by the algorithm is such that:

- either $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ for some $\phi$ and $(\operatorname{tr}, \phi)$ is pseudo-well-typed w.r.t. $\left(\mathcal{T}_{1}, \delta_{1}\right)$;
- or $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ for some $\psi$ and $(\operatorname{tr}, \psi)$ is pseudo-well-typed w.r.t. $\left(\mathcal{T}_{2}, \delta_{2}\right)$.

The main idea is to assume given a decision procedure (for a bounded number of sessions) for reachability properties such as those proposed in $[56,34,66]$ and to built on top of it a decision procedure for trace equivalence. Our procedure is carefully designed to only allow unification between encrypted subterms. To achieve this,

1. we use as a reachability blackbox one that satisfies this requirement. Most of the existing algorithms (e.g. [56, $34,66]$ ) were not designed with such a goal in mind. However, in the case of the algorithm given in [34], it has already been shown how it can be turned into one that satisfies this requirement [36].
2. we design carefully the remaining of our algorithm to only consider unification between encrypted subterms.

This design allows us to provide a pseudo-well-typed witness when the protocols under study are type-compliant and not trace equivalent.

Then, relying on Proposition 4.1.1, the proof of Theorem 4.1.1 is almost immediate. Indeed, whenever two determinate type-compliant protocols $P$ and $Q$ are not in trace equivalence, there exists a witness of non-inclusion for $P \sqsubseteq Q$ (or $Q \sqsubseteq P$ ) for a bounded version of $P$ and $Q$ (unfolding the replications).

### 4.2 A type preserving decision algorithm for bounded processes

In this section, we provide a new decision procedure for trace equivalence in the case of a bounded number of sessions to prove Proposition 4.1.1, and is thus pivotal in proving Theorem 4.1.1. The novelty of this procedure is to provide a well-typed witness whenever the two protocols are not in trace equivalence. A bounded number of sessions means formally that we consider the case of bounded protocols, namely determinate protocols without replication and thus without name restriction.

### 4.2.1 Reachability blackbox

The main idea is to assume given a decision procedure (for a bounded number of sessions) for reachability properties. Several decision procedures have already been proposed [56, 34, 66]. They are based on constraint solving techniques and even if they differ on the way the constraints are solved, the basic ideas are actually the same. These decision procedures actually do not simply say whether some state is reachable or not. They also provide a finite representation of all possible executions. More precisely, these algorithms compute a finite set of first-order (symbolic) traces that are in solved form, i.e. such that these traces are actually valid first-order traces when the variables are interpreted as constants.

Definition 4.2.1. Let $\operatorname{tr}_{s}=\mathrm{io}_{1}\left(c_{1}, u_{1}\right) \ldots \mathrm{io}_{n}\left(c_{n}, u_{n}\right)$ be a first-order trace of $P$ (see Definition 4.1.1). Its associated frame is

$$
\phi_{s}=\left\{\mathrm{w}_{1} \triangleright u_{i_{1}}, \ldots, \mathrm{w}_{\ell} \triangleright u_{i_{\ell}}\right\} .
$$

where $i_{1} \ldots i_{\ell}$ is the increasing sequence of indices that captures all the outputs of terms of the trace $\operatorname{tr}_{s}$, i.e. such that $\left\{i_{1}, \ldots, i_{\ell}\right\}=\left\{j \mid\right.$ io $_{j}=$ out and $u_{j}$ is not a channel $\}$

Definition 4.2.2. A first-order trace $\operatorname{tr}_{s}=i o_{1}, \ldots, i o_{n}$ is valid if for all $1 \leq i \leq n$, whenever, $i o_{i}=\operatorname{in}\left(c_{i}, u_{i}\right)$, we have that $R \phi_{s} \downarrow=u_{i}$ for some $R \in \mathcal{T}\left(\Sigma, \Sigma_{0} \cup \mathcal{W} \cup \mathcal{X}\right)$ where $\phi_{s}$ is the frame associated to the first-order trace $i o_{1} \ldots i o_{i}\left(\right.$ i.e. $\operatorname{tr}_{s}$ up to the index $i$ ).

Executions, i.e. traces of trace $(P)$, are exactly valid instances of symbolic traces (i.e., valid instances of trace $(P)$ ).
Lemma 4.2.1. Let $P$ be a bounded protocol. We have that:

$$
\begin{gathered}
\left\{\operatorname{tr}_{s} \sigma \mid \operatorname{tr}_{s} \in \operatorname{trace}_{s}(P), \sigma \text { ground and } \operatorname{tr}_{s} \sigma \text { is valid }\right\} \\
\{\operatorname{tr} \phi \downarrow \mid(\operatorname{tr}, \phi) \in \operatorname{trace}(P)\}
\end{gathered}
$$

Proof. The inclusion

$$
\{\operatorname{tr} \phi \downarrow \mid(\operatorname{tr}, \phi) \in \operatorname{trace}(P)\} \subseteq\left\{\operatorname{tr} \sigma \mid \operatorname{tr}_{s} \in \operatorname{trace}_{s}(P), \sigma \text { ground and } \operatorname{tr}_{s} \sigma \text { is valid }\right\}
$$

comes from Lemma 4.1.1 which is recalled and proven below. We need to prove that $\sigma$ is ground, which can be seen in its proof, as $\theta$ is ground; and moreover $\operatorname{tr}_{s} \sigma$ is valid as $\operatorname{tr} \sigma=\operatorname{tr} \phi \downarrow$.

Next, we need to show that $\left\{\operatorname{tr}_{s} \sigma \mid \operatorname{tr}_{s} \in \operatorname{trace}_{s}(P), \sigma\right.$ ground and $\operatorname{tr}_{s} \sigma$ is valid $\} \subseteq\{\operatorname{tr} \phi \downarrow \mid(\operatorname{tr}, \phi) \in \operatorname{trace}(P)\}$. Once again a similar induction as the one performed in the proof of Lemma 4.1.1 defines a trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$, the validity hypothesis ensuring that each transition in the concrete semantics is indeed possible.

Lemma 4.1.1. Let $P$ be a protocol and $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$. We have that $\operatorname{tr} \phi \downarrow=\operatorname{tr}_{s} \sigma$ for some $\operatorname{tr}_{s} \in \operatorname{trace}_{s}(P)$ and some substitution $\sigma$.

Proof. To prove this result, we consider a concrete execution $(P ; \emptyset){ }^{u^{1} \ldots u^{n}}\left(\mathcal{P}^{n} ; \phi^{n}\right)$ of $P$ and prove there exists an execution $(P ; \emptyset) \xrightarrow[s]{u_{s}^{1} \ldots u_{s}^{n}}\left(\mathcal{P}_{s}^{n} ; \phi_{s}^{n}\right)$ where $u_{s}^{1} \ldots u_{s}^{n}$ is a sequence of symbolic transition and such that there exists a substitution $\sigma_{n}$ with $\left(\mathcal{P}^{n} ; \phi^{n}\right)=\left(\mathcal{P}_{s}^{n} ; \phi_{s}^{n}\right) \sigma_{n}$. To do so, we proceed by induction on $u=u^{1} \ldots u^{n}$ and first note that if $u$ is the empty sequence, the result trivially holds.

Assuming we defined $u_{s}^{1} \ldots u_{s}^{n}$ and $\sigma_{n}$, we define $u_{s}^{n+1}$ and $\sigma_{n+1}$ as follows:

- if $u^{n+1}$ is a $\tau$-action (replication or name restriction), the rules, concrete and symbolic, are identical. Note that $\tau$-transitions in this setting (without let) only depend on the structure of the protocol, ensuring that this transition is enabled in $\mathcal{P}_{s}^{n}$ : we can fire $u_{s}^{n+1}=\tau$ (either a replication or a name restriction, like $u^{n+1}$ ). We can then define $\sigma_{n+1}=\sigma_{n}$ and still $\left(\mathcal{P}^{n+1} ; \phi^{n+1}\right)=\left(\mathcal{P}_{s}^{n+1} ; \phi_{s}^{n+1}\right) \sigma_{n+1}$.
- if $u^{n+1}$ is out $\left(c, c h_{i}\right), \mathcal{P}_{s}^{n}$ can fire with $u_{s}^{n+1}=\operatorname{out}\left(c, c h_{i}\right)$ : then $\sigma_{n+1}=\sigma_{n}$, as both rules, concrete and symbolic, are identical as in the previous case. Still $\left(\mathcal{P}^{n+1} ; \phi^{n+1}\right)=\left(\mathcal{P}_{s}^{n+1} ; \phi_{s}^{n+1}\right) \sigma_{n+1}$.
- if $u^{n+1}$ is $\operatorname{in}(c, R)$, we can set $u_{s}^{n+1}=\operatorname{in}(c, v)$ where in $(c, v)$ is the action in $P$ which was executed as in $(c, R)$ in $u$ (which can be fired, as $\mathcal{P}_{s}^{n} \sigma_{n}=\mathcal{P}^{n}$ implies there exists such a process in $(c, v) . Q$ in $\mathcal{P}_{s}^{n}$ for some process $Q)$ : there exists a substitution $\theta$ such that $R \phi \downarrow=v \sigma_{n} \theta$ as $\mathcal{P}^{n}=\mathcal{P}_{s}^{n} \sigma_{n}$ and $u_{1} \ldots u_{n}$ is a valid execution of $P$. Then $\sigma_{n+1}=\sigma_{n} \cup \theta$ and $\mathcal{P}^{n+1}=\mathcal{P}_{s}^{n+1} \sigma_{n+1}$. As the frames are left unchanged, $\phi^{n+1}=\phi_{s}^{n+1} \sigma_{n+1}$. Note that because variables are always assumed to be independently renamed, if $v$ binds a variable $x$ for the first time in $P, x \notin \operatorname{dom}\left(\sigma_{n}\right)$. We moreover have that $R \phi \downarrow=v \sigma_{n+1}$.
- if $u^{n+1}$ is out $(c, \mathrm{w})$, we can set $u_{s}^{n+1}=\operatorname{out}(c, v)$ where out $(c, v)$ is the action in $P$ which was executed as out $\left(c, \mathrm{w}\right.$ ) in $u$ (which can be fired, as $\mathcal{P}_{s}^{n} \sigma_{n}=\mathcal{P}^{n}$ implies there exists such a process out $(c, v) . Q$ in $\mathcal{P}_{s}^{n}$ for some process $Q$ ): then $\sigma_{n+1}=\sigma_{n}$. $\mathrm{w} \phi^{n}=v \sigma_{n}$ is a consequence of $\mathcal{P}^{n}=\mathcal{P}_{s}^{n} \sigma_{n}$; which leads to $\phi^{n} \uplus\left\{\mathrm{w} \triangleright v \sigma_{n+1}\right\}=\left(\phi_{s}^{n} \uplus\{\mathrm{w} \triangleright v\}\right) \sigma_{n+1}$ and $\mathcal{P}^{n+1}=\mathcal{P}_{s}^{n+1} \sigma_{n+1}$.

The result then holds by considering only observable action in $u$ and $u_{s}$.
Definition 4.2.3. An algorithm $\mathcal{B}$ is a reachability blackbox if it takes as input a first-order trace $t r$ (issued from a bounded protocol $P$ ), and returns as output a finite set of substitutions $\sigma_{1}, \ldots, \sigma_{n}$ (with $\operatorname{dom}\left(\sigma_{i}\right) \subseteq \operatorname{vars}(\operatorname{tr})$ ) such that:

- for each $i$, the first-order trace $\operatorname{tr} \sigma_{i}$ is valid; and
- if $\sigma$ is such that $\operatorname{tr} \sigma$ is a valid first-order trace of $P$ then there exists $i$, and a substitution $\tau$ such that $(i) \operatorname{tr} \sigma=$ $\operatorname{tr} \sigma_{i} \tau$, and (ii) for every $x \in \operatorname{vars}\left(\operatorname{tr} \sigma_{i}\right)$ there exists $R_{x} \in \mathcal{T}\left(\Sigma, \Sigma_{0} \cup\left\{\mathrm{w}_{1}, \ldots, \mathrm{w}_{\text {ind }_{x}}\right\}\right)$ such that $R_{x} \phi \downarrow=x \tau$ where $\phi$ is the frame associated to $\operatorname{tr} \sigma$ and ind $_{x}$ is the number of outputs that occur in $\operatorname{tr}_{s} \sigma_{i}$ before the first occurrence of an input that contains the variable $x$.

All the three decision procedures proposed in $[56,34,66]$ are actually reachability blackboxes.

### 4.2.2 Our algorithm for trace equivalence

Our algorithm $\mathcal{A}_{\mathcal{B}}$ makes use of a reachability blackbox $\mathcal{B}$. It takes as input two bounded protocols $P$ and $Q$ and returns yes when $P \approx Q$; and a minimal (in term of number of actions) witness tr of non-equivalence otherwise.

Our algorithm $\mathcal{A}_{\mathcal{B}}(P, Q)$ It consists of the following steps starting at level 1 until $\ell$ where $\ell$ denotes the maximal length (i.e. number of actions) of a trace in $\operatorname{trace}_{s}(P)$ or $\operatorname{trace}_{s}(Q)$. Note that since $P$ and $Q$ are bounded, $\operatorname{trace}_{s}(P)$ and $\operatorname{trace}_{s}(Q)$ are finite. If nothing has been returned yet (i.e. when the iteration steps for level $\ell$ has been done), then it returns yes, i.e. $P$ and $Q$ are trace equivalent.
Iteration steps for level $n$ :

1. Consider every symbolic trace $\operatorname{tr}_{0}$ in $\operatorname{trace}_{s}(P)$ of length $n$ and apply $\mathcal{B}$ to it. Consider any substitution $\sigma_{0}$ returned by $\mathcal{B}$. We have that $\operatorname{tr}_{1}=\operatorname{tr}_{0} \sigma_{0}$ is a valid first-order trace.
2. For any $s, t \in E S t\left(\operatorname{tr}_{1}\right)$ that are unifiable and such that $\operatorname{tr}_{1} \sigma_{1}$ is a first-order trace of $P$ where $\sigma_{1}=m g u(s, t)$, apply $\mathcal{B}$ to $\operatorname{tr}_{2}=\operatorname{tr}_{1} \sigma_{1}$. Consider any substitution $\sigma_{2}$ returned by $\mathcal{B}: \operatorname{tr}_{2} \sigma_{2}$ is a valid first-order trace.
3. Consider a bijective renaming $\rho$ from vars $\left(\operatorname{tr}_{2} \sigma_{2}\right)$ towards "fresh" public constants. Build a trace $(\operatorname{tr}, \phi) \in$ $\operatorname{trace}(P)$ such that $\operatorname{tr} \phi \downarrow=\left(\operatorname{tr}_{2} \sigma_{2}\right) \rho$. Its existence is ensured by Lemma 4.2.1
4. Check whether there exists $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$. If such a frame does not exist, then return tr. Otherwise, let $\psi$ be a resulting frame.
5. Let $K_{\phi}$ (resp. $K_{\psi}$ ) be the subset of $\operatorname{img}(\rho)$ of constants occurring in key position in $\phi$ (resp. $\psi$ ). Check whether $K_{\psi} \subseteq K_{\phi}$. If there exists $\mathrm{c}_{0} \in K_{\psi} \backslash K_{\phi}$ then return $\operatorname{tr}\left\{\langle\omega, \omega\rangle / \mathrm{c}_{0}\right\}$. Otherwise, perform step 6.
6. Check whether $\phi \sim \psi$. If the frames are not in static equivalence then return tr. Otherwise, perform steps 1 to 6 by swapping the role of $P$ and $Q$.

### 4.2.3 Termination, soundness, and completeness

Deducibility and static equivalence are well known to be decidable for standard primitives.These two decidability results can easily be adapted in our setting. It is therefore easy to establish termination.

Proposition 4.2.1 (termination). Let $P$ and $Q$ be two bounded protocols. The algorithm $\mathcal{A}_{\mathcal{B}}$ applied on $P$ and $Q$ terminates.

Proof. Termination is ensured by the termination of the blackbox and the decidability of static equivalence.
A trace returned by our algorithm is indeed a witness of non-equivalence.
Proposition 4.2.2 (soundness). Let $P$ and $Q$ be two bounded protocols. If the algorithm $\mathcal{A}_{\mathcal{B}}$ applied on $P$ and $Q$ returns a witness $t r$ of non-equivalence, then we have that $P \not \approx Q$.

Proof. Step 4 clearly returns a witness of non equivalence. At step $5, \mathcal{A}_{\mathcal{B}}$ returns a trace that is executable in $P$ but which fails in $Q$ since some key becomes non atomic, which yields again a witness of non equivalence. For step 6, note that checking static equivalence for only one resulting frame $\psi$ is actually sufficient thanks to the determinacy hypothesis.

Establishing completeness is more involved. The main difficulty is to ensure that unification performed at step 2 of the algorithm is sufficient to produce all possible relevant equalities. In particular, to capture static equivalence, we have to ensure that this is sufficient to consider tests $R, R^{\prime}$ that reduce to some encrypted subterms. The fact that we consider only unification between encrypted subterms is a key element for proving that our algorithm indeed returns a well-typed witness when $P$ and $Q$ are non-equivalent (cf. Section 4.2.4).

Proposition 4.2.3 (completeness). Let $P$ and $Q$ be two bounded protocols such that $P \not \approx Q$. The algorithm $\mathcal{A}_{\mathcal{B}}$ applied on $P$ and $Q$ returns a minimal (in term of number of actions) witness tr of non-equivalence.

Proof. (Sketch) Since protocols are determinate, it is sufficient to check the alternative definition given in Definition 2.4.4 inclusion instead of static equivalence. Static inclusion, denoted $\phi \sqsubseteq_{s} \psi$, is when $\psi$ satisfies all the equalities of $\phi$, and $R \psi \downarrow$ is a message as soon as $R \phi \downarrow$ is a message. So if $P \not \approx Q$, there exists a witness trace tr such that $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ for some $\phi$ and

1. either $(\operatorname{tr}, \psi) \notin \operatorname{trace}(Q)$ for any $\psi$;
2. or for every $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$, we have that $\phi \not \rrbracket_{s} \psi$.
(or the contrary swapping the role of $P$ and $Q$.)
In the first case, using Lemma 4.2 .1 , the procedure $\mathcal{B}$ would output a valid trace $\operatorname{tr}^{\prime}$ such that $\operatorname{tr} \phi \downarrow=\operatorname{tr}^{\prime} \sigma$ for some $\sigma$. We can then play $\operatorname{tr}^{\prime}$ in $Q$ and show that if it were a valid trace in $Q$, $\operatorname{tr}$ would also be a valid trace in $Q$, contradiction. We deduce that $\mathcal{A}_{\mathcal{B}}$ would output $\operatorname{tr}^{\prime}$ (at step 4 or 5 ), a witness of non-equivalence.

In the second case, following the notation of the previous case, we have that $\left(\operatorname{tr}^{\prime}, \psi^{\prime}\right) \in \operatorname{trace}(Q)$ for some $\psi^{\prime}$ (the choice of the frame is not relevant since they are all in static equivalence due to determinacy of $Q$ ). The proof then involves a fine analysis of the relevant equalities that may yield to non static equivalence. We show that whenever there is a witness of non static inclusion for $t r$ (this witness can be an equality test or a test checking whether a given recipe yields a message or not), then there is indeed a trace $t r$ considered at step 2 for which we can exhibit a transformed test that witnesses non static inclusion for $\mathrm{tr}^{\prime}$.

The full proof is provided in Section A.1.2.

### 4.2.4 Type-preservation

The specificity of the algorithm we proposed in the previous section is that it further provides a pseudo-well-typed witness whenever the two processes are not in trace equivalence. This can not be achieved using any arbitrary blackbox $\mathcal{B}$. We have to require that the blackbox $\mathcal{B}$ is type-preserving.

Definition 4.2.4. A reachability blackbox $\mathcal{B}$ is type-preserving if: for any typing system $(\mathcal{T}, \delta)$, for any protocol $P$ type-compliant w.r.t. $(\mathcal{T}, \delta)$, for any well-typed first-order $\operatorname{trace}^{\operatorname{tr}} \mathrm{r}_{s}$ of $P$ given as input, it outputs well-typed substitutions $\sigma_{1}, \ldots, \sigma_{n}$ such that:

$$
E S t\left(\operatorname{tr}_{s} \sigma_{i}\right) \subseteq E S t\left(\operatorname{tr}_{s}\right) \sigma_{i} \text { for any } i \in\{1, \ldots, n\}
$$

Lemma 4.2.2. A type-preserving reachability blackbox exists.
Most of the existing algorithms (e.g. [56, 34, 66]) are actually not type-preserving (since they were not designed with such a goal in mind). However, in the case of the algorithm given in [34], it has already been shown how it can be turned into a type-preserving reachability blackbox [36].

Theorem 4.2.1. Let $P$ and $Q$ be two bounded protocols type-compliant w.r.t. $\left(\mathcal{T}_{1}, \delta_{1}\right)$ and $\left(\mathcal{T}_{2}, \delta_{2}\right)$ respectively, and such that $P \not \approx Q$. Assume the algorithm $\mathcal{A}_{\mathcal{B}}$ uses a type-preserving reachability blackbox $\mathcal{B}$ and a well-typed renaming $\rho$ at step 3. Then $\mathcal{A}_{\mathcal{B}}(P, Q)$ returns a trace tr such that

- either $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ for some $\phi$ and $(\operatorname{tr}, \phi)$ is pseudo-well-typed w.r.t. $\left(\mathcal{T}_{1}, \delta_{1}\right)$;
- or $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ for some $\psi$ and $(\operatorname{tr}, \psi)$ is pseudo-well-typed w.r.t. $\left(\mathcal{T}_{2}, \delta_{2}\right)$.

The proof of Theorem 4.2.1 follows from the fact that $\mathcal{A}_{\mathcal{B}}(P, Q)$ only manipulates well-typed traces. Indeed, it starts from traces provided by $\mathcal{B}$, which are well-typed since $\mathcal{B}$ is type-preserving. Then $\mathcal{A}_{\mathcal{B}}$ considers only unification between encrypted subterms (which are instances of the encrypted subterms of the protocols). Since $P$ are $Q$ are type-compliant, the resulting traces are well-typed. Actually, $\mathcal{A}_{\mathcal{B}}$ will output a well-typed trace when a failure occurs at step 4 or at step 6, and a pseudo-well-typed trace when failure occurs at step 5 . The complete proof is provided in Section A.2.

### 4.3 Conclusion

We have proposed a general typing result that reduces the search space for attacks. For simplicity, we proved this typing result for the case of symmetric encryption and concatenation but we believe that our result could be extended to the other standard cryptographic primitives such asymmetric encryption, signatures and hash functions.

Our main typing result relies on the design of a new procedure in the case of a bounded number of sessions, that preserves typing. Specifically, we show that it is sufficient to consider only unification between encrypted (sub)terms. We think that this result can be applied to existing decision procedures (in particular SPEC [65] and also APTE [22], with some more work) to speed up their corresponding tools. As future work, we plan to implement this optimisation and measure its benefit.

Our typing result finally lays the foundation for new decidability results for trace equivalence, discussed in Chapters 5 and 6.

## Part II

## Decidables classes

## Chapter 5

## Decidability of trace equivalence for simple protocols without nonces

In this chapter, we investigate a new class of protocols for which trace equivalence is decidable for an unbounded number of sessions. Decidability results for unbounded nonces are rare and complex, even in the reachability case. One of them has been established by Ramanujam and Suresh [60] for reachability, assuming a particular tagging scheme (which itself involves nonces). More recently, Fröschle [47] proposed a procedure to decide the leakiness property, a kind of reachability property, for a tagged protocols too. Chapter 4 introduced a notion typing system as well as a typing result aiming at greatly reducing the search space when trying to check trace equivalence. The finer the typing system is, the more our typing result restricts the attack search. But in general, our typing result does not yield directly a decidability result since even the simple property of reachability is undecidable for an unbounded number of sessions and arbitrary nonces, even if the messages are of bounded size (e.g. [4]). Indeed, our typing system ensures the existence of a well-typed attack (if any) but the number of well-typed traces may remain infinite. To obtain decidability, we further assume a finite number of terms of each type (i.e. in particular a finite number of nonces). Decidability of trace equivalence for an unbounded number of sessions then follows from our main typing result, for a class of simple protocols where each subprocess uses a distinct channel (intuitively, a session identifiers) and no nonce generation. These restrictions indeed allow us to bound the number of messages of any type, given a finite typing system, which leads to a bound on the length of a minimal witness of non-equivalence (if it exists) when combined with the typing result from Chapter 4. As a corollary, we also prove decidability of trace equivalence for simple tagged protocols without nonces.

### 5.1 Decidability result

We consider the formal model defined in Chapter 2 with a restricted signature. We consider the signature

$$
\Sigma=\left\{\text { senc, sdec, }\langle \rangle, \operatorname{proj}_{1}, \operatorname{proj}_{2}\right\} \uplus \Sigma_{0}
$$

where $\Sigma_{0}$ is a set of atomic data, representing pairing and symmetric encryption as defined in Example 2.1.1. We also do not use evaluation in our processes, i.e. no let, and instead rely only on input filtering to model decryption operations. Moreover, we will consider only encryption with atomic keys, meaning that the set $\mathcal{M}$ of messages will be defined by $\mathcal{M}=\mathcal{M}_{\text {atomic }}$.

Now, assuming finitely many terms of each type, and in particular finitely many nonces, we obtain a new decidability result for trace equivalence, for an unbounded number of sessions.

### 5.1.1 Main result

Our decidability result relies on the assumption that there are finitely many terms of each type (of the protocol), once the number of constants is bound for each type.

Formally, we say that a typing system $(\mathcal{T}, \delta)$ is finite if, for any set $\mathrm{A} \subseteq \mathcal{N} \cup \Sigma_{0}$ such that there is a finite number of names/constants of each type, then there are finitely many terms of each type, that is, for any $\tau \in \mathcal{T}$, the following set is finite and computable:

$$
\left\{t \in \mathcal{T}\left(\Sigma_{\mathrm{c}}, \mathrm{~A}\right) \mid \delta(t)=\tau\right\}
$$

Structure-preserving typing systems, as described in Definition 2.5.2 as well as the typing systems derived from tagged protocols (see Definition 2.5.6) are examples of finite typing systems.

Then, in that section, we restrict our attention to simple protocols without nonces, meaning protocols containing no instruction new $n$ for any name $n$. Even though this limitation appears unrealistic, it is actually mitigated by the soundness result from Chapter 3, and will be later improved in Chapter 6. Note that channels names are not concerned by this restriction and instructions of the form new $c^{\prime}$.out $\left(c, c^{\prime}\right)$ are still used in these protocols.

Our main theorem states that trace equivalence for simple protocols without nonces and type-compliant w.r.t. some finite typing systems is actually decidable.

Theorem 5.1.1. The problem of deciding whether two simple protocols without nonces $P$ and $Q$, type-compliant w.r.t. some finite typing systems $\left(\mathcal{T}_{1}, \delta_{1}\right)$ and $\left(\mathcal{T}_{2}, \delta_{2}\right)$ are trace equivalent (i.e. $P \approx Q$ ) is decidable.

Proof. (Sketch) Since simple protocols are determinate (see Lemma 2.4.1), we obtain, thanks to our typing result (Theorem 4.1.1), the existence of well-typed witness of non-equivalence when such a witness exists. We further show that we can bound the number of useful constants in the witness trace (Proposition 5.3.1). We then derive from the finiteness of the typing system that the witness trace uses finitely many distinct terms. Therefore any trace ultimately reproduces already existing transitions. Using the form of simple protocols, we can then show how to shorten the length of the witness trace.

We deduce then decidability of trace equivalence for simple tagged protocols without nonces.
Corollary 5.1.1. The problem of deciding whether two simple and tagged protocols without nonces $P$ and $Q$ are trace equivalent (i.e. $P \approx Q$ ) is decidable.

Proof. (Sketch) The first step of the proof consists in associating to a tagged protocol $P$, a typing system $\left(\mathcal{T}_{P}, \delta_{P}\right)$ such that $P$ is type-compliant w.r.t. $\left(\mathcal{T}_{P}, \delta_{P}\right)$. Intuitively, $\left(\mathcal{T}_{P}, \delta_{P}\right)$ is simply induced by $\sigma_{P}$, the substitution ensuring the tagged condition in Definition 2.5.4. For example, the type of a closed term $t$ is $t$ itself while the type of a variable $x$ in $P$ is simply $x \sigma_{P}$. This definition is then propagated to any term. With such typing systems, we can show that the size of a term (i.e. number of function symbols) is smaller than the size "indicated" by its type (i.e. the size of the type, viewed as a term). Thus the typing system $\left(\mathcal{T}_{P}, \delta_{P}\right)$ is finite. We then conclude by applying Theorem 5.1.1.

Example 5.1.1. Consider the protocol $\overline{P_{\mathrm{OR}}^{\prime}}$ obtained from the protocol $P_{\mathrm{OR}}^{\prime}$ defined in Example 2.5 .5 by removing the instructions corresponding to a name restriction. These protocols are still strongly tagged and are now simple without nonces. Thus, our algorithm can be used to check whether these two protocols are in trace equivalence or not. This equivalence actually models a notion of strong secrecy of the key received by $A$. Since we have bounded the number of nonces, this equivalence does not require that the key is renewed at each session but it requires the key to be indistinguishable from a (private) name, $n$ in our setting.

### 5.2 A sound procedure for simple protocols with nonces

Our result can be used as a proof technique to show that two simple protocols are in trace equivalence. In particular, we have that the transformation detailed in Chapter 3 can be applied to our class of protocols. Applying this to a simple, type-compliant protocol yields a process that belongs to our class to apply Theorem 5.1.1.

Proposition 5.2.1. Let $(\Sigma, \mathcal{R})$ be the theory given in Example 2.1.1 with $\mathcal{M}_{\Sigma}=\mathcal{M}_{\text {atomic. }}$. Let $P$ and $Q$ be two simple and type-compliant protocols built on $(\Sigma, \mathcal{R})$, and such that $\mathrm{Ch}(P)=\mathrm{Ch}(Q)$. Let N be the set of names that occur in $P$ or $Q$.

The problem of deciding whether $\bar{P}^{\mathrm{N}, c}$ and $\bar{Q}^{\mathrm{N}, c}$ are in trace equivalence is decidable (for any $c \in \mathrm{Ch}(P)$ ).

### 5.3 Proof of Theorem 5.1.1

In this section, we provide a proof of Theorem 5.1.1.
The first proposition we prove aims at ensuring it is always possible, for simple protocols without nonces which are type-compliant w.r.t. some finite typing systems, to find a witness of non-equivalence which only uses finitely many elements of any type, which is necessary to bound the number of useful constants in said witness.

Proposition 5.3.1. There exists a set of constants and names with finitely many elements of any type such that if $P$ and $Q$ are simple protocols without nonces and type-compliant w.r.t. some finite typing systems $\left(\mathcal{T}_{1}, \delta_{1}\right)$ and $\left(\mathcal{T}_{2}, \delta_{2}\right)$ and $P \not \overbrace{t} Q$ then there exists a pseudo-well-typed witness tr of non-equivalence which uses only those constants and names.

Proof. The proof here relies first on the fact that the blackbox algorithm we have described in Chapter 4 does not introduce constants or variables which were not initially in the protocol's specification. Then, as we need to cast any variable as a new constants in our algorithm to obtain a pseudo-well-typed witness of non-equivalence, we prove that we only need to preserve the difference between at most two constants of the same type. Then, by Lemma 2.4.1 and Theorem 4.1.1, we can conclude there exists a well-typed witness $\operatorname{tr}_{1}$ of non-equivalence.

In the following, we assume that $\operatorname{tr}_{1}$ has been discovered when applying the equivalence algorithm $\mathcal{A}_{\mathcal{B}}(P, Q)$ described in Section 4.2.1. The symmetric case is handled in the same fashion. Moreover, we can also assume the blackbox $\mathcal{B}$ used does not introduce new variables or constants as the procedure described [36], so that we can also assume that any constant in $\overline{\operatorname{tr}}_{1} \phi_{0} \downarrow\left(\right.$ where $\left(\overline{\operatorname{tr}}_{1}, \phi_{0}\right) \in \operatorname{trace}(P)$ ) is either an element of $\Sigma_{0}^{P} \cup \mathcal{N}^{P}$ (the constants and names in $P$ ) or a constant introduced at step 3 of our algorithm. Let $A=\left\{\alpha_{1}, \ldots, \alpha_{n}\right\}$ be the set of such constants. We also consider a set of special constant $\mathcal{C}=\bigcup_{\tau \in \mathcal{T}^{P}} \mathcal{C}_{\tau}$ where $\mathcal{C}_{\tau}=\left\{c_{1}^{\tau}, c_{2}^{\tau}, c_{3}^{\tau}\right\}$ and $\delta_{1}\left(c_{i}^{\tau}\right)=\tau$. Note that $\mathcal{T}_{0}\left(\Sigma_{\mathrm{c}}, \cup \Sigma_{0}^{P} \cup \mathcal{N}^{P} \cup \bigcup_{\tau} \mathcal{C}_{\tau}\right)$ is such that there are only finitely many terms of any given type.

Claim: there exists a (total) renaming $\rho$ from $A$ to $\bigcup_{\tau} \mathcal{C}_{\tau}$ such that $\operatorname{tr}_{1} \rho$ is a well-typed witness of $P \not \approx Q$ and for any term $t$ of $\operatorname{tr}_{1} \rho \phi_{0} \downarrow, t \in \mathcal{T}_{0}\left(\Sigma_{\mathrm{c}}, \cup \Sigma_{0}^{P} \cup \mathcal{N}^{P} \cup \bigcup_{\tau} \mathcal{C}_{\tau}\right)$; where $\phi_{0}$ is such that $\left(\operatorname{tr}_{1}, \phi_{0}\right) \in \operatorname{trace}(P)$.

Let $\rho_{0}$ be the special renaming such that for any $i$, if $\delta_{1}\left(\alpha_{i}\right)=\tau_{i}, \alpha_{i} \rho_{0}=c_{1}^{\tau_{i}}$.
$\overline{\operatorname{tr}}_{1}$ being a witness of $\bar{P} \not \approx \bar{Q}$, several cases can occur:

- There exists $\phi$ and $\psi$ such that $\left(\overline{\operatorname{tr}}_{1}, \phi\right) \in \operatorname{trace}(P)$ and $\left(\overline{\operatorname{tr}}_{1}, \psi\right) \in \operatorname{trace}(Q) ; \phi \nsim \psi$ and, for instance, there exist two recipes $R_{1}$ and $R_{2}$ such that $R_{1} \phi \downarrow=R_{2} \phi \downarrow$ but $R_{1} \psi \downarrow \neq R_{2} \psi \downarrow$ and all of them are messages. Let us examine $R_{1} \psi \downarrow$ and $R_{2} \psi \downarrow$. If the two terms do not share the same constructors, then $R_{1}\left(\psi \rho_{0}\right) \downarrow \neq R_{2}\left(\psi \rho_{0}\right) \downarrow$, but $R_{1}\left(\phi \rho_{0}\right) \downarrow=R_{2}\left(\phi \rho_{0}\right) \downarrow$ (as the collapsing of variables only add equalities to the frame). Now, if the two terms share the same constructors, there must exist a leaf position $p$ in them such that $\left.R_{1} \psi \downarrow\right|_{p} \neq\left. R_{2} \psi \downarrow\right|_{p}$. Let us call $t$ and $s$ these terms respectively. If $s$ or $t$ is not an $\alpha_{i}$ for some $i$, then $s \rho_{0} \neq t \rho_{0}$ as the constants in $\bigcup_{\tau} \mathcal{C}_{\tau}$ are fresh. As in the previous case, we get that $R_{1}\left(\psi \rho_{0}\right) \downarrow \neq R_{2}\left(\psi \rho_{0}\right) \downarrow$, but $R_{1}\left(\phi \rho_{0}\right) \downarrow=R_{2}\left(\phi \rho_{0}\right) \downarrow$. Else, assume $s=\alpha_{1}$ and $t=\alpha_{2}$, consider the renaming $\rho$ such that, if for any $i, \delta_{1}\left(\alpha_{i}\right)=\tau_{i}, \alpha_{1} \rho=c_{1}^{\tau_{1}}$, $\alpha_{2} \rho=c_{2}^{\tau_{2}}$ and $\alpha_{j} \rho=c_{3}^{\tau_{j}}$ for any $j>2$. Thus $s \rho \neq t \rho$ as the constants in $\bigcup_{\tau} \mathcal{C}_{\tau}$ are fresh, and finally we get that $R_{1}(\psi \rho) \downarrow \neq R_{2}(\psi \rho) \downarrow$, but $R_{1}(\phi \rho) \downarrow=R_{2}(\phi \rho) \downarrow$.
- Or there exists $\phi$ and $\psi$ such that $\left(\operatorname{tr}_{1}, \phi\right) \in \operatorname{trace}(P)$ and $\left(\operatorname{tr}_{1}, \psi\right) \in \operatorname{trace}(Q) ; \phi \nsim \psi$ and there exists a minimal (in term of size) recipe $R$ such that, for instance, $R \phi \downarrow$ is message while $R \psi \downarrow$ is not. If $R \psi \downarrow$ contains a element $\operatorname{dec}(\langle s, t\rangle)$ or $\operatorname{proj}_{i}(\operatorname{enc}(s, t))$, then $R\left(\psi \rho_{0}\right) \downarrow$ is not a message either, while $R\left(\phi \rho_{0}\right) \downarrow$ still is. Else, $R \psi \downarrow=\operatorname{dec}(\operatorname{enc}(u, v), w)$ for some terms $u, v$ and $w$ (by minimality) with $v \neq w$ : as keys are atomic, $v$ and $w$ are atoms. As in the case with equalities, we can define $\rho$ such that $v \rho \neq w \rho$, and thus $R(\psi \rho) \downarrow$ is not a message, while $R(\phi \rho) \downarrow$ is (as $\rho$ only introduces new equalities).
- Or, finally, there exists $\phi$ such that $\left(\operatorname{tr}_{1}, \phi\right) \in \operatorname{trace}(P)$ but for every $\psi,\left(\overline{\operatorname{tr}}_{1}, \psi\right) \notin$ trace $(Q)$ (the symmetric case is handled identically). If $\overline{\operatorname{tr}}_{1}$ end with an output, the renaming $\rho_{0}$ is adequate. So let us assume that the last action of $\overline{\operatorname{tr}}_{1}$ is $\operatorname{in}(c, R)$. Because protocols are simple, there exists at most one term $u_{P}$ in the execution of $\overline{\operatorname{tr}}_{1}$ in $P$, and at most one term $u_{Q}$ in the same execution in $Q$ such that there exists $\exists \theta\left(R \phi \downarrow=u_{P} \theta\right)$, but $\forall \theta^{\prime}\left(R \psi \downarrow \neq u_{Q} \theta^{\prime}\right)$. As $u_{Q}$ may contain several occurrences of variables, we need to be careful to define a renaming $\rho$. If there exists a position $p$ in $u_{Q}$ which is not a leaf such that $\left.u_{Q}\right|_{p} \neq\left. R \psi \downarrow\right|_{p}$, then $R\left(\psi \rho_{0}\right) \downarrow$ and $u_{Q} \rho_{0}$ are not unifiable (they disagree on already present constructors). Else if there exists a position $p$ in $u_{Q}$ which is a leaf but not a variable such that $\left.u_{Q}\right|_{p} \neq R \psi \psi_{p}$ : we define $\rho$ as in the first subcase when dealing with an inequality without variable. Finally, if $\operatorname{mgu}\left(R\left(\psi \rho_{0}\right) \downarrow, u_{Q}\right)=\perp$ we are done and can just take $\rho=\rho_{0}$; else, i.e. $\operatorname{mgu}\left(R \psi \downarrow, u_{Q}\right)=\perp$ and $\operatorname{mgu}\left(R\left(\psi \rho_{0}\right) \downarrow, u_{Q}\right) \neq \perp$, there exist two leaves with positions $p_{1}$ and $p_{2}$ in $R \psi \downarrow$ which corresponds to positions below variables in $u_{Q}$ such that $\left.R \psi \downarrow\right|_{p_{1}} \neq\left. R \psi \downarrow\right|_{p_{2}}$ but $\left.R\left(\psi \rho_{0}\right) \downarrow\right|_{p_{1}}=$ $R\left(\psi \rho_{0}\right) \psi_{p_{2}}$ : thus we can assume $R \psi \psi_{p_{1}}=\alpha_{1}$ and $R \psi \psi_{p_{2}}=\alpha_{2}$. We can now define $\rho$ such that, if for any $i, \delta_{1}\left(\alpha_{i}\right)=\tau_{i}, \alpha_{1} \rho=c_{1}^{\tau_{1}}, \alpha_{2} \rho=c_{2}^{\tau_{2}}$ and $\alpha_{j} \rho=c_{3}^{\tau_{j}}$ for any $j>2$. Then $\left.R(\psi \rho) \downarrow\right|_{p_{1}} \neq\left. R(\psi \rho) \downarrow\right|_{p_{2}}$ and $m g u\left(R(\psi \rho) \downarrow, u_{Q}\right)=\perp$, while $m g u\left(R(\phi \rho) \downarrow, u_{Q}\right) \neq \perp$ as $\rho$ only introduces new equalities.

In every case, $\operatorname{tr}_{1} \rho$ is valid trace of $\bar{P}$, and $\operatorname{tr}_{1} \rho$ is a trace of $P$ with frame $\phi_{0}$ which is well-typed ( $\rho$ is well-typed) and for any term $t$ of $\overline{\operatorname{tr}}_{1} \rho \phi_{0} \downarrow, t \in \mathcal{T}_{0}\left(\Sigma_{\mathrm{c}}, \cup \Sigma_{0}^{P} \cup \mathcal{N}^{P} \cup \bigcup_{\tau} \mathcal{C}_{\tau}\right)$.

We are now able to complete the proof of Theorem 5.1.1 by making sure any pseudo-well-typed witness of nonequivalence as discussed in Proposition 5.3.1 ultimately reproduces already existing transitions.

Theorem 5.1.1. The problem of deciding whether two simple protocols without nonces $P$ and $Q$, type-compliant w.r.t. some finite typing systems $\left(\mathcal{T}_{1}, \delta_{1}\right)$ and $\left(\mathcal{T}_{2}, \delta_{2}\right)$ are trace equivalent $(i . e . P \approx Q)$ is decidable.

Proof. By Proposition 5.3.1, if $P \not \boldsymbol{\not}_{t} Q$ there exists a well-typed witness of this non-equivalence built on a special set of terms. Let for instance $\left(\operatorname{tr}^{0}, \phi^{0}\right) \in \operatorname{trace}(P)$ be a minimal such witness and define $\operatorname{tr}=\operatorname{tr}^{0}{ }_{-1}$, where $\operatorname{tr}_{-1}^{0}$ denotes $\operatorname{tr}^{0}$ minus its last element, and $\phi$ the frame such that $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$. The minimality of $\operatorname{tr}^{0}$ implies there exists $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ and $\phi \sim_{s} \psi$.

$$
\begin{aligned}
P= & \text { !new } c_{1}^{\prime} \text {.out }\left(c_{1}, c_{1}^{\prime}\right) \cdot B_{1}|\ldots| \text { !new } c_{m}^{\prime} \text {.out }\left(c_{m}, c_{m}^{\prime}\right) \cdot B_{m} \\
Q= & \left|B_{m+1}\right| \ldots \mid B_{m+n} \\
& \text { new } c_{1}^{\prime} \text {.out }\left(c_{1}, c_{1}^{\prime}\right) \cdot B_{1}^{\prime}|\ldots| \text { !new } c_{m}^{\prime} \text {.out }\left(c_{m}, c_{m}^{\prime}\right) \cdot B_{m}^{\prime} \\
& \left|B_{m+1}^{\prime}\right| \ldots \mid B_{m+n^{\prime}}^{\prime}
\end{aligned}
$$

(We can safely assume the same number of restricted channels $(m)$ in $P$ and $Q$, as non-equivalence would trivially hold otherwise.) We define a function $\operatorname{proj}_{P}$ which takes a channel $c_{i}$ and returns $\left\{\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime}}\right\}_{c_{i}^{\prime}}$ the set of subtraces of $\operatorname{tr}$ corresponding of actions on channel $c_{i}^{\prime}$ and the action new $c_{i}^{\prime}$.out $\left(c_{i}, c_{i}^{\prime}\right)$ which originated it. It can be extended naturally to channels $c_{m+1}$ to $c_{m+n}$ (in that case, in absence of replication, each set is a singleton, which, for the sake of uniformity, we will denote by $\left\{\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime}}\right\}_{c_{i}^{\prime}}$ for $i \in\{m+1, \ldots, m+n\}$ too). We can similarly define proj${ }_{Q}$. We now claim:
Claim 1: $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q) \Rightarrow \operatorname{proj}_{P}=\operatorname{proj}_{Q}$, as subprocesses $B_{i}$ and $B_{i}^{\prime}$ use public fresh channels such that each $c_{i}^{\prime}$ is spawned from a unique channel $c_{i}$ which is visible in tr .

Moreover we define a relation $\mathcal{R}_{P}$ on elements of $\operatorname{img}\left(\operatorname{proj}_{P}\right)$. We say that $\left.\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime}} \preceq_{P} \operatorname{tr}\right|_{c_{i}, c_{i}^{\prime \prime}}$ if, and only if, $\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime}} \phi \downarrow$ is a prefix of $\left(\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime \prime}} \phi \downarrow\right)\left\{\left\{_{i}^{c_{i}^{\prime}} / c_{i}^{\prime \prime}\right\} . \mathcal{R}_{P}\right.$ is then defined as $\preceq_{P} \cap \preceq_{P}^{-1}$; and is an equivalence relation.

Symmetrically, we can define a relation $\mathcal{R}_{Q}$ with $\psi$ and make the following claim:
Claim 2: $\mathcal{R}_{P}=\mathcal{R}_{Q}=\mathcal{R}$, as $\operatorname{tr}^{0}$ is a minimal witness of $P \not \approx Q$. Indeed, if there are two elements $\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime}}$ and $\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime \prime}}$ such that $\left.\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime}} \mathcal{R}_{P} \operatorname{tr}\right|_{c_{i}, c_{i}^{\prime \prime}}$ but $\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime}}$ and $\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime \prime}}$ are not $\mathcal{R}_{Q}$-equivalent (or the other way around), then $\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime}} \psi \downarrow$ is not a prefix of $\left(\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime \prime}} \psi \downarrow\right)\left\{c_{i}^{\prime} / c_{i}^{\prime \prime}\right\}$ (or, once again, the other way around). Thus there exists an action $\mathrm{a}\left(c_{i}^{\prime}, R\right)(\mathrm{a} \in\{\mathrm{in}$, out $\})$ of $\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime}}$ and an action a $\left(c_{i}^{\prime \prime}, R^{\prime}\right)$ of $\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime \prime}}$ (these actions must be two inputs or two outputs as $\left.\left.\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime}} \mathcal{R}_{P} \operatorname{tr}\right|_{c_{i}, c_{i}^{\prime \prime}}\right)$ such that $R \psi \downarrow \neq R^{\prime} \psi \downarrow$ while $R \phi \downarrow=R^{\prime} \phi \downarrow$ (as $\left.\left.\operatorname{tr}\right|_{c_{i}, c_{i}^{\prime}} \mathcal{R}_{P} \operatorname{tr}\right|_{c_{i}, c_{i}^{\prime \prime}}$ ), which would contradict the minimality of $\mathrm{tr}^{0}$.

Intuitively, two subtraces are in equivalence w.r.t. the relation $\mathcal{R}$ if they are identical, modulo the name of the fresh channel they use. The general idea to then bound the length of tr is to observe that if tr contains two equivalent subtraces, then one of them, the one occurring "later" can be safely removed as it adds no new branch or new terms to the execution. That way, we will prove that because $\operatorname{tr}^{0}$ is a minimal witness, $\operatorname{tr}$ can only contain one representative of each class, otherwise we could obtain a shorter witness by eliminating this extra element. To do so, we define which actions should be kept during this elimination and how to generate the new trace.

Given an action $\alpha$ we map it to $\beta(\alpha)$ its occurrence index in $\operatorname{tr}$. Consequently we can define $\min \left(\alpha, \alpha^{\prime}\right)$ as the action with the lowest occurrence index; and lift it to sequences of actions:

$$
\min \left(\alpha_{1} \ldots \alpha_{n}, \alpha_{1}^{\prime} \ldots \alpha_{n}^{\prime}\right)=\min \left(\alpha_{1}, \alpha_{1}^{\prime}\right) \ldots . \min \left(\alpha_{n}, \alpha_{n}^{\prime}\right)
$$

Similarly, we can define $\max \left(\alpha, \alpha^{\prime}\right)$ as the action with the highest occurrence index in tr and lift it to sequence of actions.

$$
\max \left(\alpha_{1} \ldots \alpha_{n}, \alpha_{1}^{\prime} \ldots \alpha_{n}^{\prime}\right)=\max \left(\alpha_{1}, \alpha_{1}^{\prime}\right) \ldots . \max \left(\alpha_{n}, \alpha_{n}^{\prime}\right)
$$

We define an operation merge $\left(\operatorname{tr},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime}},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime \prime}}\right)$ where $\left.\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime}} \mathcal{R} \operatorname{tr}\right|_{c_{j}, c_{j}^{\prime \prime}},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime}}=\alpha_{1} \ldots \alpha_{n}$ and $\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime \prime}}=$ $\alpha_{1}^{\prime} \ldots \alpha_{n}^{\prime}$. Note that if two subtraces are equivalent w.r.t. $\mathcal{R}$ they must have the same length as they must each be a prefix of the other. For each $i \in\{1, \ldots, n\}$, we want to delete from tr the later action $\max \left(\alpha_{i}, \alpha_{i}^{\prime}\right)$, while renaming the channel used by the earlier action $\min \left(\alpha_{i}, \alpha_{i}^{\prime}\right)$ to $c_{j}^{\prime}$ (we assume that $\min \left(\alpha_{1}, \alpha_{1}^{\prime}\right)=\alpha_{1}=$ new $c_{j}^{\prime}$.out $\left(c_{j}, c_{j}^{\prime}\right)$, without loss of generality) and rename in tr all the occurrences of deleted output variables. We denote by $\mathrm{w}_{i}^{\max }$ the variable used by $\max \left(\alpha_{i}, \alpha_{i}^{\prime}\right)$ if it is an output, i.e. if $\max \left(\alpha_{i}, \alpha_{i}^{\prime}\right)=\operatorname{out}\left(c, \mathrm{w}^{\max }\right)$ for some $c$ and w ; and by $\mathrm{w}_{i}^{\min }$ the variable used by $\min \left(\alpha_{i}, \alpha_{i}^{\prime}\right)$ if it is an output, i.e. if $\min \left(\alpha_{i}, \alpha_{i}^{\prime}\right)=\operatorname{out}\left(c, \mathrm{w}^{\min }\right)$ for some $c$ and w . Because $\alpha_{1} \ldots \alpha_{n} \mathcal{R} \alpha_{1}^{\prime} \ldots \alpha_{n}^{\prime}, \mathrm{w}_{i}^{\max } \phi \downarrow=\mathrm{w}_{i}^{\min } \phi \downarrow$ and $\mathrm{w}_{i}^{\max } \psi \downarrow=\mathrm{w}_{i}^{\min } \psi \downarrow$ for any $i \in\{1, \ldots, n\}$. We denote by $\sigma$ the substitution that maps $\mathrm{w}_{i}^{\max }$ to $\mathrm{w}_{i}^{\min }$ for any $i \in\{1, \ldots, n\}$. Let then $\operatorname{tr}^{-}$be $\operatorname{tr}$ minus any action in $\max \left(\alpha_{1} \ldots \alpha_{n}, \alpha_{1}^{\prime} \ldots \alpha_{n}^{\prime}\right)$ : we define merge $\left(\operatorname{tr},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime}},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime \prime}}\right)=\operatorname{tr}^{-} \sigma\left\{{ }^{c_{j}^{\prime}} / c_{j}^{\prime \prime}\right\}$.

In particular, there exist $\phi^{\prime}$ and $\psi^{\prime}$ such that (merge $\left.\left(\operatorname{tr},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime}},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime \prime}}\right), \phi^{\prime}\right) \in \operatorname{trace}(P),\left(\operatorname{merge}\left(\operatorname{tr},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime}},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime \prime}}\right), \psi^{\prime}\right) \in$ $\operatorname{trace}(Q)$. merge $\left(\operatorname{tr},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime}},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime \prime}}\right)$ is indeed a valid trace in both $P$ and $Q$ : the actions of $\min \left(\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime}},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime \prime}}\right)$ occur on the same channel $c_{j}^{\prime}$, as $\min \left(\alpha_{1}, \alpha_{1}^{\prime}\right)=\alpha_{1}=$ new $c_{j}^{\prime}$.out $\left(c_{j}, c_{j}^{\prime}\right)$ and because $\mathrm{w}_{i}^{\max }$ is renamed to $\mathrm{w}_{i}^{\min }$ for any $i \in\{1, \ldots, n\}$, for any recipe $R$ in $\operatorname{tr}$, $R \phi \downarrow=(R \sigma) \phi \downarrow$ (and $R \psi \downarrow=(R \sigma) \psi \downarrow$ ) and for any transition $\left(\mathcal{P}_{k}, \phi_{k}\right) \xrightarrow{\operatorname{in}(c, R)}\left(\mathcal{P}_{k+1}, \phi_{k+1}\right)$ in $\operatorname{tr}, \operatorname{vars}(R \sigma) \subseteq \operatorname{dom}\left(\phi_{k}\right)$ as we kept the first occurrence of any output with $\min \left(\alpha_{i}, \alpha_{i}^{\prime}\right)$. Moreover we get that $\phi^{\prime} \approx \psi^{\prime}$. Indeed, merge $\left(\operatorname{tr},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime}},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime \prime}}\right) \phi^{\prime} \downarrow$ is a subtrace of $\operatorname{tr}\left\{c_{j}^{\prime} / c_{j}^{\prime \prime}\right\} \phi \downarrow$, and merge $\left(\operatorname{tr},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime}},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime \prime}}\right) \psi^{\prime} \downarrow$ is a subtrace of $\operatorname{tr}\left\{c_{j}^{\prime} / c_{j}^{\prime \prime}\right\} \psi \downarrow$.

Let $\left[\operatorname{tr}_{1}\right], \ldots,\left[\operatorname{tr}_{M}\right]$ be the equivalence classes of $\mathcal{R}$, then, by minimality of $\operatorname{tr}^{0}$, each class has at exactly one element. If some class $\left[\operatorname{tr}_{i}\right]$ were to have two elements $\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime}}$ and $\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime \prime}}$, merge $\left(\operatorname{tr},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime}},\left.\operatorname{tr}\right|_{c_{j}, c_{j}^{\prime}}\right) \cdot\left(\alpha \sigma\left\{c_{j}^{\prime} / c_{c_{j}^{\prime \prime}}\right\}\right)$ would provide a shorter witness of $P \not \approx Q$, where $\alpha$ is the last action of $\operatorname{tr}^{0}$ (which was excluded in tr).

From Proposition 5.3.1, we know there exists a set of atoms such that there exists only finitely element of the same type and such that any pseudo-well-typed trace only uses those. As the type systems we consider are finite, there exists only finitely many terms of each type. And finally, as the trace is pseudo-well-typed, each type in $\operatorname{tr}^{0} \phi^{0} \downarrow$ appears in $P$. Hence there are only finitely types and finitely many terms that can occur in any pseudo-well-typed trace of $P$ : let $T$ be that number. Thus we claim that $M \leq(n+m) \times \sum_{i=0}^{B} T^{i}$ where $B$ is the maximal length (in terms of number
of actions) of a parallel branch in $P$, i.e. $\max _{k}\left|\operatorname{tr}_{k}\right|$. Indeed a class is defined by its sequence of actions (bounded by the maximum number of actions in any branch of $P$ ) and the first-order terms it contains (which is bounded by the total number of existing eligible terms). As there are $n+m$ branches in $P$, of length at most $B$, there are at most $(n+m) T^{i}$ different first-order sequences of length $i \in[0, B]$ in $P$. Then, as $|\operatorname{tr}| \leq M \times B$ (tr contains at most one representative for each equivalence class, each being of length at most $B$ ), we finally get $|\operatorname{tr}| \leq(n+m) \times B \times \sum_{i=0}^{B} T^{i}$. Hence, an upper bound on the length of a well-typed witness of $P \not \chi_{t} Q$ is $N=(n+m) B \sum_{i=0}^{B} T^{i}+1$, and the number of such traces in trace $(P)$ is bounded by $(2 T)^{N}$ as each element of a trace is either an input or an output of a term, which provides a straightforward algorithm to decide trace equivalence.

### 5.4 Proof of Corollary 5.1.1

For every tagged protocol, we can define a induced typing system as shown in Definition 2.5 .6 which is finite, assuming a bounded number of nonces, to prove Corollary 5.1.1. We recall that any tagged protocol is actually type-compliant w.r.t. its induced typing system, as per Proposition 2.5.1.

Corollary 5.1.1. The problem of deciding whether two simple and tagged protocols without nonces $P$ and $Q$ are trace equivalent (i.e. $P \approx Q$ ) is decidable.

Proof. Since $P$ (resp. $Q$ ) is tagged, thanks to Proposition 2.5.1, we know that $P$ (resp. $Q$ ) is type-compliant w.r.t. $\left(\mathcal{T}_{P}, \delta_{P}\right)$ (resp. $\left(\mathcal{T}_{Q}, \delta_{Q}\right)$ ), the typing system associated to $P$ (resp. $Q$ ) as defined in Definition 2.5.6. With such typing systems, we have that the size of a term (i.e. number of function symbols) is smaller that the size "indicated" by its type (i.e. the size of the type, viewed as a term). Thus, it is then easy to see that the set:

$$
\left\{t \in \mathcal{T}\left(\Sigma_{\mathrm{c}}, \mathrm{~A}\right) \mid \delta(t)=\tau\right\}
$$

is finite for any $\tau \in \mathcal{T}_{P}$ (and similarly for $Q$ ) as soon as A is a set of names and constants that contains only a finite number of names/constants of each type. We conclude by applying Theorem 5.1.1.

### 5.5 Conclusion

From a general typing result that reduces the search space for attacks described in Chapter 4, we derive decidability for an unbounded number of sessions and simple protocols, assuming a finite number of nonces. This result can naturally be applied to simple tagged protocols without nonces as well. Even though limiting the number of nonces seems quite impractical, Chapter 3 offers a sound approach to lift this decidability result to a sound terminating procedure for checking trace equivalence with arbitrary nonces. Because our proof method to achieve decidability relies on bounding the number of terms occurring in a minimal witness of non-equivalence, it suggests further results could be obtained from existing decidability for equivalence in process algebra without terms, such as the processes described in [29].

## Chapter 6

## Decidability of trace equivalence for acyclic simple protocols with nonces

We propose in this chapter the first decidability result for trace equivalence, for an unbounded number of sessions and with nonces. Since even simple reachability properties are undecidable in this context, we make some assumptions.

Simple processes. This notion has been introduced in [33] and is defined in Chapter 2. Intuitively, we assume that each process communicates on a distinct channel. In practice, each machine has its own IP address and each session is characterised by some session identifier. We also assume that each process consists of a sequence of inputs and outputs (with some tests). This models very well standard security protocols (with no else branches).

Type compliant protocols. Intuitively, we assume that ciphertexts cannot be confused. A similar notion has been formally introduced in [15] and developed in Chapters 2 and 4 and was shown to ensure termination of ProVerif (without nonces). This condition is part of the good design practices and is easy to enforce by adding some identifier (a tag) in each ciphertext. Of course the same tags are re-used in all sessions.

Acyclic dependency graph. Considering constructions used in undecidability results, one can notice that the encodings rely on some form of cyclicity. Typically, the last message of the protocol is re-injected at the first step of the protocol, forming an infinite loop. We therefore introduce the notion of dependency graph, with two notions of dependencies:

- sequential dependency: some action can only be taken after some other actions;
- data dependency: some message can only be built once some information is learnt from another message.

This graph can be computed (automatically) from the protocol's specification. To detect data dependencies, we actually consider a particular typed instantiation of the protocol. Therefore, the definition of a dependency graph relies itself on the typing system. Moreover, finer typing systems are more likely to yield acyclic dependency graphs.

The objective of this chapter is to show that the equivalence between simple and type-compliant protocols with an acyclic dependency graph is decidable, for protocols using symmetric encryption, concatenation, and nonces. Our class encompasses most symmetric key protocols we considered, including Needham-Schroeder with symmetric key, Otway-Rees, Denning-Sacco, or Wide-Mouthed-Frog. For some of these protocols, we had to consider an explicitly tagged version.

Proof technique. We show decidability in two main steps. First, thanks to the type-compliance assumption, we show that we can apply the typing result from Chapter 4, yielding a bound on the size of the messages: if there is a witness of non-equivalence then there is a well-typed witness, and this induces a strict format for the messages occurring in such a witness. Note that the number of distinct messages remains unbounded due to nonces.

The second step of the proof relies on the dependency graph. We show that any well-typed execution trace complies with the execution order induced by the dependency graph, which allows to split well-typed traces into small independent traces, which in turn yields decidability.

Scope. The scope of our result depends on how often protocols induce an acyclic dependency graph. For the sake of clarity, we first provide a generic definition of a dependency graph (Definition 6.2.2). However, some interesting protocols such as the Needham-Schroeder symmetric key protocol are cyclic with this definition. In a second step, we provide a criterion that safely allows to remove edges in the dependency graph, yielding acyclicity for most of the protocols we considered. This more flexible notion of dependency graph is called refined dependency graph (Definition 6.3.4). Contemporaneously to our work, Sybille Fröschle [47] has proposed a new decidability result for the "leakiness" property and the class of "well-founded protocols". We provide in Section 6.4.3 a detailed comparison with our result. In brief, our result are incomparable since [47] considers a larger class of primitives but a less accurate security property and more restriction on the protocols (e.g. ciphertext forwarding is again prohibited and as in [54] a typed model is considered). We believe that our approach provides a good level of flexibility. In case some protocols were found to be cyclic with our current definition of a dependency graph, it should be possible to develop other criteria that soundly remove edges.

### 6.1 Annotated model for security protocols

In addition to the model we already introduced in Chapter 2 and precised in Chapter 4, we assume annotations in our protocols. These annotations are meant to make it easier to pinpoint a particular action in the protocol specification and are completely invisible to the attacker.

More precisely, we assume an infinite set $\mathcal{L}$ used to name input and output actions of processes. Protocols are now modelled through processes built by the following grammar:

$$
\begin{array}{cc}
P, Q & := \\
& 0 \\
& \alpha: \operatorname{in}(c, u) \cdot P \\
& \alpha: \operatorname{out}(c, u) \cdot P \\
& (P \mid Q) \\
& !P \\
& \text { new } n . P \\
& \text { new } c^{\prime} . \text { out }\left(c, c^{\prime}\right) . P
\end{array}
$$

where $u \in \mathcal{T}\left(\Sigma_{\mathrm{c}}, \Sigma_{0} \cup \mathcal{N} \cup \mathcal{X}\right), n \in \mathcal{N}, c, c^{\prime} \in \mathcal{C} h$, and $\alpha \in \mathcal{L}$. The only difference with the process algebra defined in Section 2.1 is the presence of a label $\alpha$ in $\alpha: \operatorname{in}(c, u) . P$ and $\alpha:$ out $(c, u) . P$, to serve as an easy way to later refer to these actions.

Example 6.1.1. The Denning Sacco protocol described in Example 2.2.1 can be rewritten with labels as follows. $k_{a s}$, $k_{b s}, k_{a b}$ are names, whereas a and b are constants from $\Sigma_{0}$. The protocol is modelled by the parallel composition of three processes $P_{A}, P_{B}$, and $P_{S}$, corresponding to the roles of $A, B$, and $S$.

$$
\begin{aligned}
P_{\mathrm{DS}}= & \text { !new } c_{1} \text {.out }\left(c_{A}, c_{1}\right) \cdot P_{A} \mid \text { !new } c_{2} \text {.out }\left(c_{B}, c_{2}\right) \cdot P_{B} \\
& \mid \text { !new } c_{3} \text {.out }\left(c_{S}, c_{3}\right) \cdot P_{S}
\end{aligned}
$$

The processes $P_{A}, P_{B}$, and $P_{S}$ are given below.

$$
\begin{aligned}
P_{A}= & \alpha_{1}: \operatorname{out}\left(c_{1},\langle\mathrm{a}, \mathrm{~b}\rangle\right) . \\
& \alpha_{2}: \operatorname{in}\left(c_{1}, \operatorname{enc}\left(\left\langle\mathrm{~b}, x_{A B}, x_{B}\right\rangle, k_{a s}\right)\right) . \\
& \alpha_{3}: \operatorname{out}\left(c_{1}, x_{B}\right) \\
P_{B}= & \beta_{1}: \operatorname{in}\left(c_{2}, \operatorname{enc}\left(\left\langle y_{A B}, \mathrm{a}\right\rangle, k_{b s}\right)\right) \\
P_{S}= & \gamma_{1}: \operatorname{in}\left(c_{3},\langle\mathrm{a}, \mathrm{~b}\rangle\right) \cdot \operatorname{new} k_{a b} . \\
& \gamma_{2}: \operatorname{out}\left(c_{3}, \operatorname{enc}\left(\left\langle\mathrm{~b}, k_{a b}, \operatorname{enc}\left(\left\langle k_{a b}, \mathrm{a}\right\rangle, k_{b s}\right)\right\rangle, k_{a s}\right)\right)
\end{aligned}
$$

The semantics are left virtually unchanged by the annotations, which lets us use the same definitions as in Chapter 2. Figure 6.1 has the same transitions rules as Figure 2.1, leading to the same semantics as in Section 2.3. Note in particular that labels are absent from the transitions in Figure 6.1, which leaves them unobservable for the attacker and leads to the same set of traces as the un-annotated version of the protocol.

$$
\begin{aligned}
& (\alpha: \operatorname{in}(c, u) . P \cup \mathcal{P} ; \phi) \xrightarrow{\text { in }(c, R)}(P \sigma \cup \mathcal{P} ; \phi) \text { where } R \text { is a recipe such that } R \phi \downarrow \\
& \text { is a message and } R \phi \downarrow=u \sigma \text { for some } \sigma \text { with } \operatorname{dom}(\sigma)=\operatorname{vars}(u) \\
& (\alpha: \operatorname{out}(c, u) . P \cup \mathcal{P} ; \phi) \xrightarrow{\text { out }\left(c, w_{i+1}\right)}\left(P \cup \mathcal{P} ; \phi \cup\left\{\mathrm{w}_{i+1} \triangleright u\right\}\right) \\
& \text { where } u \text { is a message and } i \text { is the number of elements in } \phi \\
& \text { (new } \left.c^{\prime} . \text { out }\left(c, c^{\prime}\right) . P \cup \mathcal{P} ; \phi\right) \xrightarrow{\text { out }\left(c, c h_{i}\right)}\left(P\left\{{ }^{c h_{i}} / c^{\prime}\right\} \cup \mathcal{P} ; \phi\right) \\
& \text { where } c h_{i} \text { is the "next" fresh channel name available in } \mathcal{C} h^{\text {fresh }} \\
& \text { (new } n . P \cup \mathcal{P} ; \phi) \xrightarrow{\tau}\left(P\left\{n^{\prime} / n\right\} \cup \mathcal{P} ; \phi\right) \quad \text { where } n^{\prime} \text { is a fresh name in } \mathcal{N} \\
& (!P \cup \mathcal{P} ; \phi) \xrightarrow{\tau}(P \cup!P \cup \mathcal{P} ; \phi)
\end{aligned}
$$

Figure 6.1: Annotated semantics of the processes
The definition of simple processes has to be slightly adapted too, to account for the new labels.
Definition 6.1.1. A simple protocol $P$ is a protocol of the form

$$
\begin{gathered}
\text { !new } c_{1}^{\prime} \text {.out }\left(c_{1}, c_{1}^{\prime}\right) \cdot B_{1}|\ldots| \text { !new } c_{m}^{\prime} \text {.out }\left(c_{m}, c_{m}^{\prime}\right) \cdot B_{m} \\
\left|B_{m+1}\right| \ldots \mid B_{m+n}
\end{gathered}
$$

where each $B_{i}$ with $1 \leq i \leq m$ (resp. $m<i \leq m+n$ ) is a ground process on channel $c_{i}^{\prime}$ (resp. $c_{i}$ ) built using the following grammar:

$$
B:=0\left|\alpha: \operatorname{in}\left(c_{i}^{\prime}, u\right) \cdot B\right| \alpha: \operatorname{out}\left(c_{i}^{\prime}, u\right) . B \mid \text { new } n . B
$$

where $u \in \mathcal{T}_{0}\left(\Sigma_{\mathrm{c}}, \Sigma_{0} \cup \mathcal{N} \cup \mathcal{X}\right)$. Moreover, we assume that $c_{1}, \ldots, c_{n}, c_{n+1}, \ldots, c_{n+m}$ are pairwise distinct, as well as the labels for each action.

Given a simple protocol $P$, and $\alpha, \beta \in \mathcal{L}(P)$, we say that $\beta$ directly follows $\alpha$ in $P$ if both actions are in sequence in the description of $P$, with $\beta$ after $\alpha$, and no other visible action in between. When some other visible actions occur between $\alpha$ and $\beta$, we simply say that $\beta$ follows $\alpha$.

### 6.2 A first decidability result

Trace equivalence is undecidable in general for an unbounded number of sessions, inheriting undecidability from the standard secrecy case (see e.g. [44]). We present here our two main assumptions for obtaining decidability: typecompliance and acyclic dependency graph. For the clarity of the presentation, we present in this section a rather coarse definition of dependency graph. In the next section, we provide a sound criterion to remove some of its edges.

### 6.2.1 Dependency graph

We consider a protocol $P$ which is type-compliant w.r.t. a structure-preserving typing system $\left(\mathcal{T}_{P}, \delta_{P}\right)$. To define our dependency graph, we first define public and honest types. Terms of public type are always deducible for an adversary, whereas terms of honest type will be guaranteed to be secret (except those built using public constants only).

A type $\tau_{p}$ is public if $\delta_{P}(n) \notin S t\left(\tau_{p}\right)$ for any name $n$ occurring in $P$. Intuitively, in a well-typed execution, a term having a public type is a term built using public constant only, and is thus deducible from the beginning of any execution.

An atomic type $\tau_{h}$ is honest if $(i) \tau_{h}$ does not appear in plaintext position in $u \delta_{P}$ for any term $u$ occurring in $P$; (ii) $\tau_{h} \neq \delta_{P}(a)$ for any constant/variable $a$ occurring in $P$. Intuitively, this ensures that, in a well-typed execution, terms of type $\tau_{h}$ will never occur in plaintext position, and no public constant of this type will be used in key position.

Example 6.2.1. Going back to Example 6.1.1, we have that $\tau_{\mathrm{a}}, \tau_{\mathrm{b}}, \tau_{\mathrm{m}}$ are public types while $\tau_{\text {kas }}$ and $\tau_{k b s}$ are honest types. In contrast, $\tau_{k a b}$ is neither a public nor an honest type. Indeed, $\tau_{k a b}=\delta_{P}\left(y_{A B}\right)$ and the variable $y_{A B}$ occurs in $P$.

We define inductively a function $\rho_{\mathrm{i}}$ that inspects a type $\tau$ and returns its set of deducible subterms (where $\tau$ is viewed as a term) together with the set of keys needed to access each subterm. For this, we introduce a new syntactic symbol \#.

Definition 6.2.1. Given a type $\tau$, a position $p$ and a set $S$ of types, the function $\rho_{\mathrm{io}}$ is inductively defined as follows:

- $\rho_{\text {io }}\left(\tau_{0}, p, S\right)=\left\{\left(\tau_{0}, p\right) \# S\right\}$ for any atomic type $\tau_{0}$;
- $\rho_{\mathrm{io}}\left(\left\langle\tau_{1}, \tau_{2}\right\rangle, p, S\right)=\rho_{\mathrm{io}}\left(\tau_{1}, p .1, S\right) \cup \rho_{\mathrm{io}}\left(\tau_{2}, p .2, S\right)$;
- $\rho_{\mathrm{io}}\left(\operatorname{enc}\left(\tau_{1}, \tau_{2}\right), p, S\right)=$

$$
\left\{\begin{array}{l}
\left\{\left(\operatorname{enc}\left(\tau_{1}, \tau_{2}\right), p\right) \# S\right\} \text { if } \tau_{2} \text { is an honest type; } \\
\left\{\left(\operatorname{enc}\left(\tau_{1}, \tau_{2}\right), p\right) \# S\right\} \cup \rho_{\mathrm{io}}\left(\tau_{1}, p .1, S \cup\left\{\tau_{2}\right\}\right) \text { otherwise. }
\end{array}\right.
$$

Given a type $\tau$, the function $\rho_{\mathrm{io}}(\tau, \epsilon, \emptyset)$ computes a set of elements of the form $\left(\tau_{i}, p_{i}\right) \# S_{i}$. Intuitively, it means that the term of type $\tau_{i}$ at position $p_{i}$ in $\tau$ is accessible from the term $\tau$ after some decryptions using keys occurring in the set $S_{i}$.

We also define two functions $\rho_{\text {out }}$ and $\rho_{\text {in }}$ that help us to define the flows that may happen during a protocol execution.

$$
\begin{aligned}
& \rho_{\mathrm{out}}\left(\tau^{\prime}\right)=\left\{(\tau, p) \mid(\tau, p) \# S \in \rho_{\mathrm{io}}\left(\tau^{\prime}, \epsilon, \emptyset\right)\right\} ; \text { and } \\
& \rho_{\mathrm{in}}\left(\tau^{\prime}\right)=\left\{\tau, \tau_{1}, \ldots, \tau_{k} \mid(\tau, p) \#\left\{\tau_{1}, \ldots, \tau_{k}\right\} \in \rho_{\mathrm{io}}\left(\tau^{\prime}, \epsilon, \emptyset\right)\right\} .
\end{aligned}
$$

Intuitively, $\rho_{\text {out }}\left(\tau^{\prime}\right)$ returns the types of the terms that may be deducible by the attacker once a term of type $\tau^{\prime}$ is outputted, whereas $\rho_{\text {in }}\left(\tau^{\prime}\right)$ returns all the types that may be used by the attacker to fill an input of type $\tau^{\prime}$. In case of an output, we also return the position at which the type occurred. This information will be added in our dependency graph, and used in Section 6.3 to present our refined dependency graph.

Example 6.2.2. Continuing our running example, we have that:

$$
\begin{aligned}
& \rho_{\text {out }}\left(\left\langle\tau_{\mathrm{a}}, \tau_{\mathrm{b}}\right\rangle\right)=\left\{\left(\tau_{\mathrm{a}}, 1\right),\left(\tau_{\mathrm{b}}, 2\right)\right\} \text { and } \rho_{\text {in }}\left(\left\langle\tau_{\mathrm{a}}, \tau_{\mathrm{b}}\right\rangle\right)=\left\{\tau_{\mathrm{a}}, \tau_{\mathrm{b}}\right\} ; \\
& \rho_{\text {out }}\left(\operatorname{enc}\left(\left\langle y_{A B} \delta_{P}, \tau_{\mathrm{a}}\right\rangle, \tau_{k b s}\right)\right)=\left\{\left(\operatorname{enc}\left(\left\langle\tau_{k a b}, \tau_{\mathrm{a}}\right\rangle, \tau_{k b s}\right), \epsilon\right)\right\} ; \\
& \rho_{\text {in }}\left(\operatorname{enc}\left(\left\langle y_{A B} \delta_{P}, \tau_{\mathrm{a}}\right\rangle, \tau_{k b s}\right)\right)=\left\{\operatorname{enc}\left(\left\langle\tau_{k a b}, \tau_{\mathrm{a}}\right\rangle, \tau_{k b s}\right)\right\} .
\end{aligned}
$$

since $\tau_{k b s}$ is an honest type.

We are now ready to define the dependency graph. It captures two main sources of dependencies: sequential dependencies, when an action may only occur after another one, and data dependencies, when the production of a term depends on other sent terms.

Definition 6.2.2. The dependency graph associated to a type-compliant, simple protocol $P$ (w.r.t. a structure-preserving typing system $\left.\left(\mathcal{T}_{P}, \delta_{P}\right)\right)$ is a graph having $\mathcal{L}(P)$ as vertices and that are connected as follows:

1. for every action with label $\alpha$ in $P$ that directly follows an action with label $\beta$ in $P$, there is an edge $\alpha \rightarrow \beta$;
2. for every " $\alpha: \operatorname{in}(c, u)$ " and " $\beta$ : out $(d, v)$ " in $P$, there is an edge $\alpha \rightarrow^{p} \beta$ if there exists $\tau \in \rho_{\text {in }}\left(u \delta_{P}\right)$ such that

$$
(\tau, p) \in \rho_{\text {out }}\left(v \delta_{P}\right)
$$

and $\tau$ is not a public type.
3. for every " $\alpha$ : out $(c, u)$ " and " $\beta$ : out $(d, v)$ " in $P$, there is an edge $\alpha \rightarrow^{p} \beta$ if $(\tau, q) \#\left(S \cup\left\{\tau_{k}\right\}\right) \in \rho_{\mathrm{io}}\left(u \delta_{P}, \epsilon, \emptyset\right)$ for some $\tau, q, S$, and $\tau_{k}$ such that

$$
\left(\tau_{k}, p\right) \in \rho_{\text {out }}\left(v \delta_{P}\right)
$$

and $\tau_{k}$ is not a public type.

Intuitively, if there exists an edge from $\alpha$ to $\beta$, it implies that the action $\alpha$ may depend on action $\beta$. More precisely, item 1 captures sequential dependencies, whereas items 2 and 3 are about data dependencies. Item 2 captures dependencies that occur due to the fact that the attacker need to produce a term to comply with the given input. For this, all the needed pieces may come from different outputs (but at a plaintext position). Now, item 3 is needed because, when such a piece occurs at a plaintext position (for instance under an encryption with $k$ ), it may be important for the attacker to learn the key $k$, and this generates new dependencies.

Example 6.2.3. The dependency graph for the protocol $P_{\text {DS }}^{1}$ defined in Example 2.4.3 w.r.t. the typing system $\left(\mathcal{T}_{\mathrm{DS}}, \delta_{\mathrm{DS}}\right)$ given in Example 2.5.2 is depicted in Figure 6.2. The vertical arrows correspond to sequential dependencies (item 1) whereas all the other arrows are actually due to item 2 . In this example, item 3 does not produce any arrow.

Intuitively, these arrows mean that the input $\alpha_{2}$ (resp. $\beta_{1}$ ) may depend on the output $\gamma_{2}$ (resp. $\alpha_{3}$ ). In other words the outputted term may be (partially) used to fill the input. The relevant parts of the output are indicated by the position $p$ on top of the arrows.

Note that for $P_{\mathrm{DS}}^{2}$ (also defined in Example 2.4.3), we can introduce an additional atomic type $\tau_{k}$ for name $k$ (or reuse the atomic type $\tau_{k a b}$. In both cases, the dependency graph of $P_{\mathrm{DS}}^{2}$ will be exactly the same as the one obtained for $P_{\mathrm{DS}}^{1}$.

Example 6.2.4. Let $P$ be the protocol

$$
P=\alpha: \operatorname{in}\left(c_{1}, k_{1}\right)\left|\beta: \operatorname{out}\left(c_{2}, \operatorname{enc}\left(k_{1}, k_{2}\right)\right)\right| \gamma: \operatorname{out}\left(c_{3}, k_{2}\right)
$$

Consider the typing system $(\mathcal{T}, \delta)$ where $\mathcal{T}=\left\{\tau_{1}, \tau_{2}\right\} ; \delta\left(k_{1}\right)=\tau_{1}$ and $\delta\left(k_{2}\right)=\tau_{2}$. Its dependency graph is shown in Figure 6.3. The edge from $\beta$ to $\gamma$ is an edge introduced by the third item in Definition 6.2.2. Indeed, $\rho_{\mathrm{io}}\left(\operatorname{enc}\left(\tau_{1}, \tau_{2}\right), \epsilon, \emptyset\right)=\left\{\left(\operatorname{enc}\left(\tau_{1}, \tau_{2}\right), \epsilon\right) \# \emptyset,\left(\tau_{1}, 1\right) \#\left\{\tau_{2}\right\}\right\}$ and $\rho_{\text {out }}\left(\tau_{2}\right)=\left\{\left(\tau_{2}, \epsilon\right)\right\}$.

Figure 6.2: Dependency graph for $P_{\mathrm{DS}}^{1}$ w.r.t. $\left(\mathcal{T}_{\mathrm{DS}}, \delta_{\mathrm{DS}}\right)$

Figure 6.3: Dependency graph for $P$ w.r.t. $(\mathcal{T}, \delta)$

### 6.2.2 Our result

Trace equivalence is decidable for simple, type-compliant, acyclic protocols.
Theorem 6.2.1. Let $P$ and $Q$ be two simple protocols type-compliant w.r.t. some structure-preserving typing systems $\left(\mathcal{T}_{P}, \delta_{P}\right)$ and $\left(\mathcal{T}_{Q}, \delta_{Q}\right)$, and with acyclic dependency graphs. The problem of deciding whether $P$ and $Q$ are in trace equivalence (i.e. $P \approx Q$ ) is decidable.

Theorem 6.2 .1 will be proved in Section 6.5 in a more general setting.
Example 6.2.5. The protocols $P_{\mathrm{DS}}^{1}$ and $P_{\mathrm{DS}}^{2}$ given in Example 2.4 .3 are simple, type-compliant w.r.t. $\left(\mathcal{T}_{\mathrm{DS}}, \delta_{\mathrm{DS}}\right)$ and their respective dependency graph is acyclic. Thus these protocols fall into our decidable class.

### 6.3 An improved version of our decidability result

In the previous section we have presented a first decidability result for trace equivalence of simple, type-compliant, acyclic protocols. The Denning-Sacco protocol satisfies these hypotheses. However, some reasonable protocols do not fall in our class. In the next paragraph, we explain why the Needham-Schroeder protocol induces a cyclic dependency graph. However, in that case, the cycle is created by a false dependency. Therefore, in the subsequent paragraphs, we devise a criterion to remove some edges of the dependency graph.

### 6.3.1 Motivating example

We consider a corrected version of the well-known Needham Schroeder key establishment protocol [58]. It can be described informally as follows:

1. $A \rightarrow S: A, B, N_{a}$
2. $S \rightarrow A:\left\{N_{a}, B, K_{a b},\left\{K_{a b}, A\right\}_{K_{b s}}\right\}_{K_{a s}}$
3. $A \rightarrow B:\left\{K_{a b}, A\right\}_{K_{b s}}$
4. $B \rightarrow A:\left\{r e q, N_{b}\right\}_{K_{a b}}$
5. $A \rightarrow B:\left\{\operatorname{rep}, N_{b}\right\}_{K_{a b}}$

We propose a modelling of this protocol in our formalism. Below, $k_{a s}, k_{b s}, k_{a b}, n_{a}, n_{b}$, and $k$ are names, whereas $a, b$, req, rep, $m_{1}$ and $m_{2}$ are constants from $\Sigma_{0}$.

$$
\begin{aligned}
P_{\mathrm{NS}}= & \text { !new } c_{1} \text {.out }\left(c_{A}, c_{1}\right) \cdot P_{A} \mid \text { !new } c_{2} \text {.out }\left(c_{B}, c_{2}\right) \cdot P_{B} \\
& \mid \text { !new } c_{3} \text {.out }\left(c_{S}, c_{3}\right) \cdot P_{S}
\end{aligned}
$$

where the processes $P_{A}, P_{B}$, and $P_{S}$ are given below.

$$
\begin{aligned}
P_{A}= & \operatorname{new} n_{a} . \\
& \alpha_{1}: \operatorname{out}\left(c_{1},\left\langle\mathrm{a}, \mathrm{~b}, n_{a}\right\rangle\right) . \\
& \alpha_{2}: \operatorname{in}\left(c_{1}, \operatorname{enc}\left(\left\langle n_{a}, \mathrm{~b}, x_{A B}, x_{B}\right\rangle, k_{a s}\right)\right) . \\
& \alpha_{3}: \operatorname{out}\left(c_{1}, x_{B}\right) . \\
& \alpha_{4}: \operatorname{in}\left(c_{1}, \operatorname{enc}\left(\left\langle\operatorname{req}, x_{N B}\right\rangle, x_{A B}\right)\right) . \\
& \alpha_{5}: \operatorname{out}\left(c_{1}, \operatorname{enc}\left(\left\langle\operatorname{rep}, x_{N B}\right\rangle, x_{A B}\right)\right) \\
P_{B}= & \beta_{1}: \operatorname{in}\left(c_{2}, \operatorname{enc}\left(\left\langle y_{A B}, \mathrm{a}\right\rangle, k_{b s}\right)\right) . \text { new } n_{b} . \\
& \beta_{2}: \operatorname{out}\left(c_{2}, \operatorname{enc}\left(\left\langle\operatorname{req}, n_{b}\right\rangle, y_{A B}\right)\right) . \\
& \beta_{3}: \operatorname{in}\left(c_{2}, \operatorname{enc}\left(\left\langle\operatorname{rep}, n_{b}\right\rangle, y_{A B}\right)\right) \\
P_{S}= & \gamma_{1}: \operatorname{in}\left(c_{3},\left\langle\mathrm{a}, \mathrm{~b}, z_{N A}\right\rangle\right) \cdot \text { new } k_{a b} . \\
& \gamma_{2}: \operatorname{out}\left(c_{3}, \operatorname{enc}\left(\left\langle z_{N A}, \mathrm{~b}, k_{a b}, \operatorname{enc}\left(\left\langle k_{a b}, \mathrm{a}\right\rangle, k_{b s}\right)\right\rangle, k_{a s}\right)\right)
\end{aligned}
$$

As in Example 2.4.3, we model the security of the exchanged key by requiring that $P_{\mathrm{NS}}^{1} \approx P_{\mathrm{NS}}^{2}$ where $P_{\mathrm{NS}}^{1}$ and $P_{\mathrm{NS}}^{2}$ are defined as follows:

- $P_{\mathrm{NS}}^{1}$ is as the protocol $P_{\mathrm{NS}}$ but we add the instruction " $\beta_{4}$ : out $\left(c_{2}, \operatorname{enc}\left(\mathrm{~m}_{1}, y_{A B}\right)\right)$ " at the end of $P_{B}$;
- $P_{\mathrm{NS}}^{2}$ is as the protocol $P_{\mathrm{NS}}$ but we add the instruction "new $k . \beta_{4}$ : out $\left(c_{2}, \operatorname{enc}\left(\mathrm{~m}_{2}, k\right)\right)$ " at the end of $P_{B}$.

As for the Denning Sacco protocol (see Example 2.5.3), type-compliance is satisfied. We only have to introduce some new atomic types: $\tau_{n a}, \tau_{n b}, \tau_{\text {req }}, \tau_{\text {rep }}$ and we type each constant (resp. name and variable) as expected. We denote $\left(\mathcal{T}_{\mathrm{NS}}, \delta_{\mathrm{NS}}\right)$ the resulting structure-preserving typing system.

The resulting dependency graph is depicted in Figure 6.4 (and the dashed arrow is part of the dependency graph). There is no arrow due to item 3 (dependencies between outputs). As in the Denning Sacco protocol, $\tau_{k a s}$ and $\tau_{k b s}$ are honest types whereas $\tau_{\mathrm{a}}, \tau_{\mathrm{b}}, \tau_{\mathrm{m}}, \tau_{\text {req }}$, and $\tau_{\text {rep }}$ are public types. Due to the fact that $\tau_{k a b}$ can not be considered as an honest type, many arrows (those that are labelled with 1.2) are added to the dependency graph. This reflects executions that will build ciphertexts with such a key.

The dependency graph is cyclic. Intuitively, this is due to the fact that the subterm at position 1.2 (the nonce $N_{b}$ ) outputted in $\alpha_{5}$ may be used in input at $\alpha_{4}$. However, if the attacker is able to access this subterm at position 1.2 in $\alpha_{5}$, it necessarily means that he already knew this subterm already. Thus, intuitively, this dependency is not necessary. We formalise this notion in the next section. This will lead to a notion of refined dependency graph which is a dependency graph in which some arrows have been removed.

### 6.3.2 Appropriate marking

We first devise a general criterion to remove some of the edges of the dependency graph. We proceed by marking some of the positions of the graph.

Definition 6.3.1. A marked position of a protocol $P$ is a pair $(\alpha, p)$ where $\alpha$ : out $(c, u)$ is an output action occurring in $P$, and $p$ is a position of the term $u$. A marking of a protocol $P$ is a set of marked positions of $P$.

Figure 6.4: Dependency graph for $P_{\mathrm{NS}}^{i}$ w.r.t. $\left(\mathcal{T}_{\mathrm{NS}}, \delta_{\mathrm{NS}}\right)$

This notion of marking is very general. We consider that a marking strategy is appropriate for our dependency graph if it indicates subterms that, if deducible, must be deducible earlier using a smaller set of keys.

We define a function $\rho_{\mathrm{i}}$ on terms very similar to the function $\rho_{\mathrm{io}}$ defined on types in Section 6.2.
Definition 6.3.2. Given a term $t$, a position $p$ and a multiset of terms $S$, the function $\rho_{\mathrm{io}}$ is inductively defined for terms as follows:

- $\rho_{\mathrm{io}}\left(t_{0}, p, S\right)=\left\{\left(t_{0}, p\right) \# S\right\}$ for any atomic term $t_{0}$ (name, constant or variable);
- $\rho_{\mathrm{io}}\left(\left\langle t_{1}, t_{2}\right\rangle, p, S\right)=\rho_{\mathrm{io}}\left(t_{1}, p .1, S\right) \cup \rho_{\mathrm{io}}\left(t_{2}, p .2, S\right)$;
- $\rho_{\mathrm{io}}\left(\operatorname{enc}\left(t_{1}, t_{2}\right), p, S\right)=$ $\left\{\begin{array}{l}\left\{\left(\operatorname{enc}\left(t_{1}, t_{2}\right), p\right) \# S\right\} \text { if } \delta_{0}\left(t_{2}\right) \text { is an honest type; } \\ \left\{\left(\operatorname{enc}\left(t_{1}, t_{2}\right), p\right) \# S\right\} \cup \rho_{\mathrm{io}}\left(t_{1}, p .1, S \cup\left\{t_{2}\right\}\right) \text { otherwise. }\end{array}\right.$

Intuitively, $\left(u_{0}, p\right) \# S \in \rho_{\mathrm{io}}(u, \epsilon, \emptyset)$ if the multiset $S$ of keys suffices to access the subterm $u_{0}=\left.u\right|_{p}$.
We show that it is always appropriate to mark a position if the corresponding subterm appears earlier in the protocol, protected by a smaller set of keys.

Definition 6.3.3. Let $(\alpha, p)$ be a marked position in $P .(\alpha, p)$ is an appropriate marked position for $P$ if there exists an input action $\beta: \operatorname{in}(d, v)$ (or an output action $\beta:$ out $(d, v)$ ) in $P$ such that:

1. $\alpha$ : out $(c, u)$ follows $\beta$ in $P$;
2. $\left(u_{0}, p\right) \# S \in \rho_{\text {io }}(u, \epsilon, \emptyset)$ for some $u_{0}$, and some $S$; and
3. $\left(u_{0}, q\right) \# S^{\prime} \in \rho_{\mathrm{io}}(v, \epsilon, \emptyset)$ for some $q$, and some $S^{\prime} \subseteq_{m u l} S$.

A marking $\mathcal{M}$ of $P$ is appropriate if all the pairs in $\mathcal{M}$ are appropriate marked positions.

Example 6.3.1. We pursue our example started in Section 6.3.1. We may set $\left(\alpha_{5}, 1.2\right)$ to be a marked position of $P_{\text {NS }}^{1}$ (resp. $P_{\mathrm{NS}}^{2}$ ). Intuitively, it is an appropriate marked position since the message $x_{N B} \sigma$ sent by the process $P_{A}$ cannot be learnt at the step $\alpha_{5}$ : either $x_{N B} \sigma$ remains secret or it was learnt earlier using fewer keys. Definition 6.3.3 allows us to state that $\left(\alpha_{5}, 1.2\right)$ is an appropriate marked position for $P_{\mathrm{NS}}^{1}$ (resp. $P_{\mathrm{NS}}^{2}$ ). Indeed, we have that:

1. $\alpha_{5}: \operatorname{out}\left(c_{1}, \operatorname{enc}\left(\left\langle\operatorname{rep}, x_{N B}\right\rangle, x_{A B}\right)\right)$ follows $\alpha_{4}$ in $P_{N S}^{1}$;
2. $\left(x_{N B}, 1.2\right) \#\left\{x_{A B}\right\} \in \rho_{\mathrm{io}}\left(\operatorname{enc}\left(\left\langle\operatorname{rep}, x_{N B}\right\rangle, x_{A B}\right)\right)$; and
3. $\left(x_{N B}, 1.2\right) \#\left\{x_{A B}\right\} \in \rho_{\text {io }}\left(\operatorname{enc}\left(\left\langle\right.\right.\right.$ req,$\left.\left.\left.x_{N B}\right\rangle, x_{A B}\right)\right)$.

Definition 6.3.3 provides a simple criterion for choosing which position to mark in a protocol.

### 6.3.3 Refined dependency graph

We refine our dependency graph by simply removing any arrow that points towards an appropriate marked position.
Definition 6.3.4. Let $P$ be a type-compliant protocol $P$ (w.r.t. a structure-preserving typing system $\left(\mathcal{T}_{P}, \delta_{P}\right)$ ) and $\mathcal{M}$ be a marking of $P$. The refined dependency graph associated to $P$ and $\mathcal{M}$ is obtained from the dependency graph of $P$ by simply removing any arrow of the form $\alpha \rightarrow^{p} \beta$ for which

$$
(\beta, q) \in \mathcal{M} \text { and } q \text { is a prefix of } p
$$

Example 6.3.2. The refined dependency graph associated to $P_{N S}^{1}$ (resp. $P_{N S}^{2}$ ) and $\mathcal{M}=\left\{\left(\alpha_{5}, 1.2\right)\right\}$ is the graph depicted in Figure 6.4, when removing the dashed arrow. This dashed arrow is removed thanks to the (appropriate) marking.

Then trace equivalence is decidable for simple, type-compliant protocols, as soon as their corresponding refined dependency graph is acyclic.

Theorem 6.3.1. The problem of deciding whether two simple protocols $P$ and $Q$, type-compliant w.r.t. some structurepreserving typing systems $\left(\mathcal{T}_{P}, \delta_{P}\right)$ and $\left(\mathcal{T}_{Q}, \delta_{Q}\right)$, and with acyclic refined dependency graphs obtained relying on appropriate markings $\mathcal{M}_{P}$ and $\mathcal{M}_{Q}$ are trace equivalence (i.e. $P \approx Q$ ) is decidable.

The proof of this theorem will be the object of Section 6.5. Theorem 6.2.1 is actually a direct consequence of Theorem 6.3.1. The proof can be summarised in three steps: we first use our type-compliance assumption to focus on well-typed traces such that every message is computed as soon as possible. Then we show that every dependency is such a trace appears on the refined dependency graph of the protocols, allowing us to bound the width and depth of such a witness. Finally, we manage to bound the length of a minimal witness of non-equivalence.

### 6.4 Results

We review several protocols of the literature and identify whether they fall in our decidable class. We first discuss which corruption scenario is considered.

Figure 6.5: Dependency graph for $P_{\mathrm{DS}}^{+}$w.r.t. $\left(\mathcal{T}_{\mathrm{DS}}^{+}, \delta_{\mathrm{DS}}^{+}\right)$

### 6.4.1 Scenario with corruption

The scenario we considered so far for the Denning-Sacco protocol (as well as the Needham-Schroeder protocol) is quite simple. We only consider sessions between two honest agents a and b. Such a scenario is known to be too simplistic and some attacks may be missed, such as the well-known man-in-the-middle attack on the NeedhamSchroeder public key protocol [53].

We therefore consider a scenario where honest agents are also willing to engage communications with a dishonest agent c. Let us develop this corruption scenario on the Denning-Sacco protocol. Formally, we consider $P_{\mathrm{DS}}^{i+}$ obtained from $P_{\mathrm{DS}}^{i}$ by adding $P_{\mathrm{DS}}^{\prime}$ as well as $P_{\mathrm{DS}}^{\prime \prime}$ in parallel. The purpose of $P_{\mathrm{DS}}^{\prime}$ is to consider that the agent a may be involved in some other sessions with a corrupted agent c, and the server $S$ is ready to answer requests coming from them. Similarly $P_{\mathrm{DS}}^{\prime \prime}$ models the fact that the agent b may be involved in some sessions where the role of $A$ is played by the corrupted agent c . Thus, we consider

$$
P_{\mathrm{DS}}^{\prime}=\text { ! new } c_{1} \text {.out }\left(c_{A}^{\prime}, c_{1}\right) \cdot P_{A}^{\prime} \mid \text { ! new } c_{3} . \text { out }\left(c_{S}^{\prime}, c_{3}\right) \cdot P_{S}^{\prime}
$$

where $P_{A}^{\prime}$ and $P_{S}^{\prime}$ are as follows:

$$
\begin{aligned}
P_{A}^{\prime}= & \alpha_{1}^{\prime}: \operatorname{out}\left(c_{1},\langle\mathrm{a}, \mathrm{c}\rangle\right) \\
& \alpha_{2}^{\prime}: \operatorname{in}\left(c_{1}, \operatorname{enc}\left(\left\langle\mathrm{~b}, x_{A B}^{\prime}, x_{B}^{\prime}\right\rangle, k_{a s}\right)\right) . \\
& \alpha_{3}^{\prime}: \operatorname{out}\left(c_{1}, x_{B}^{\prime}\right) \\
P_{S}^{\prime}= & \gamma_{1}^{\prime}: \operatorname{in}\left(c_{3},\langle\mathrm{a}, \mathrm{c}\rangle\right) . \operatorname{new} k_{a b}^{\prime} . \\
& \gamma_{2}^{\prime}: \operatorname{out}\left(c_{3}, \operatorname{enc}\left(\left\langle\mathrm{c}, k_{a b}^{\prime}, \operatorname{enc}\left(\left\langle k_{a b}^{\prime}, \mathrm{a}\right\rangle, k_{c s}\right)\right\rangle, k_{a s}\right)\right)
\end{aligned}
$$

We consider also:

$$
P_{\mathrm{DS}}^{\prime \prime}=\text { ! new } c_{2} \text {.out }\left(c_{B}^{\prime \prime}, c_{2}\right) \cdot P_{B}^{\prime \prime} \mid!\text { new } c_{3} . \text { out }\left(c_{S}^{\prime \prime}, c_{3}\right) \cdot P_{S}^{\prime \prime}
$$

where $P_{B}^{\prime \prime}$ and $P_{S}^{\prime \prime}$ are as follows:

$$
\begin{aligned}
P_{B}^{\prime \prime}= & \beta_{1}^{\prime \prime}: \operatorname{in}\left(c_{2}, \operatorname{enc}\left(\left\langle y_{A B}^{\prime \prime}, \mathbf{c}\right\rangle, k_{b s}\right)\right) \\
P_{S}^{\prime \prime}= & \gamma_{1}^{\prime \prime}: \operatorname{in}\left(c_{3},\langle\mathrm{c}, \mathrm{~b}\rangle\right) \cdot \operatorname{new} k_{a b}^{\prime \prime} . \\
& \gamma_{2}^{\prime \prime}: \operatorname{out}\left(c_{3}, \operatorname{enc}\left(\left\langle\mathbf{b}, k_{a b}^{\prime \prime}, \operatorname{enc}\left(\left\langle k_{a b}^{\prime \prime}, \mathbf{c}\right\rangle, k_{b s}\right)\right\rangle, k_{c s}\right)\right)
\end{aligned}
$$

The resulting protocols $P_{\mathrm{DS}}^{1+}$ and $P_{\mathrm{DS}}^{2+}$ are simple protocols. They are also type-compliant w.r.t. $\left(\mathcal{T}_{\mathrm{DS}}^{+}, \delta_{\mathrm{DS}}^{+}\right)$where $\mathcal{T}_{\mathrm{DS}}^{+}$is an enriched version of $\mathcal{T}_{\mathrm{DS}}$ with new atomic types: $\tau_{\mathrm{c}}, \tau_{k c s}, \tau_{k a b^{\prime}}$, and $\tau_{k a b^{\prime \prime}}$. In particular, we have typecompliance for a notion of type that gives different types to $k_{a b}, k_{a b}^{\prime}$, and $k_{a b}^{\prime \prime}$. The type $\tau_{c}$ is public.

The resulting dependency graph remains acyclic and is depicted in Figure 6.5. Note that there is an arrow from $\beta_{1}^{\prime \prime}$ to $\gamma_{2}^{\prime \prime}$ for the following reason. We have that

$$
\left(\operatorname{enc}\left(\left\langle\tau_{k a b^{\prime \prime}}, \tau_{\mathrm{c}}\right\rangle, \tau_{k b s}\right), 1.2 .2\right) \in \rho_{\text {out }}\left(u_{2}^{\prime \prime} \delta_{\mathrm{DS}}^{+}\right)
$$

where $u_{2}^{\prime \prime}$ is the term occurring in the action labelled $\gamma_{2}^{\prime \prime}$. Intuitively, this is because the output labelled $\gamma_{2}^{\prime \prime}$ is an encryption with a compromised key $k_{c s}$, and thus the attacker could analyse this term and learn a term of type enc $\left(\left\langle\tau_{k a b^{\prime \prime}}, \tau_{\mathrm{c}}\right\rangle, \tau_{k b s}\right)$. A term of such a type could be used to fill the input $\beta_{1}^{\prime \prime}$. This possible dependency is represented by an arrow from $\beta_{1}^{\prime \prime}$ to $\gamma_{2}^{\prime \prime}$. The label indicates the position at which such a term is available in the output.

The resulting dependency graph is composed of three components that are completely disconnected. This reflects the fact that the protocol ensures that there is no interaction between a session involving honest participants, and sessions that may involve some dishonest participants. Also there is no confusion between messages used at the different stages of the protocol.

For a complete corruption scenario, we then need to consider the cases where the role $A$ is played by the agent b and the role $B$ is played by the agent a. The resulting dependency graph is obtained by symmetry from the one displayed in Figure 6.5. It remains acyclic and is composed of six disjoint components.

In the remaining of the section, we study several symmetric key protocols of the literature and discuss whether they fall in our decidable class. For all of them, we consider the complete corruption scenario as described above on the Denning-Sacco protocol.

### 6.4.2 Review of symmetric key protocols

Most of the protocols we considered from [30] actually fall in our decidable class. We sometimes need them to include some explicit tags. For some of them, we need to consider a refined version of our typing graph, and we consider the one obtained using Definition 6.3 .3 to mark position appropriately. Our findings are summarised in Figure 6.6. We discuss below each protocol individually.

|  | Dependency graph |  | In our |
| :--- | :---: | :---: | :---: |
| Normal | Refined | class |  |
| Denning-Sacco | $\checkmark$ | $\checkmark$ | yes |
| Needham-Schroeder |  | $\checkmark$ | yes |
| Otway-Rees |  | $\checkmark$ | yes |
| Yahalom (Paulson) |  | $\checkmark$ | yes |
| Wide-Mouthed-Frog | $\checkmark$ | $\checkmark$ | yes |
| Yahalom |  |  | no |
| Kao-Chow (modified) |  | $\checkmark$ | yes |

Figure 6.6: A $\checkmark$ means that the corresponding dependency graph is acyclic.

Denning-Sacco This protocol forms our running example and its dependency graph is acyclic, without any tagging (see Example 6.2.5).

Needham-Schroeder As discussed in Section 6.3.1, its dependency graph is not acyclic but its refined dependency graph is, even when considering the complete corruption scenario. We do not need to add explicit tags. However, contrary to what happens in the Denning-Sacco protocol, the resulting dependency graph is more complex. It is composed of six components connected with several arrows. This is due to the fact that to get type-compliance we have to give the same type to all the names that play the role of the key $K_{a b}$ (resp. $N_{b}$ ) with no distinction between those involved in an honest or a dishonest session.

This can be done as follows: agents a and b are both willing to start sessions with a malicious agent c . Below, $k_{a s}$, $k_{b s}, k_{c s}, k_{a b}, k_{a b}^{\prime}, k_{a b}^{\prime \prime}, n_{a}, n_{a}^{\prime}, n_{b}, n_{b}^{\prime \prime}$, and $k$ are names, whereas $\mathrm{a}, \mathrm{b}, \mathrm{c}$, req, rep, $\mathrm{m}_{1}$ and $\mathrm{m}_{2}$ are constants from $\Sigma_{0}$. As in Example 2.4.3, we model the security of the exchanged key by requiring that $P_{\mathrm{NS}}^{1+} \approx P_{\mathrm{NS}}^{2+}$ where $P_{\mathrm{NS}}^{1+}$ and $P_{\mathrm{NS}}^{2+}$ are defined as follows:

- $P_{\mathrm{NS}}^{1+}$ is as the protocol $P_{\mathrm{NS}}^{+}$(see below) but we add the instruction " $\beta_{4}$ : out $\left(c_{2}, \operatorname{enc}\left(\mathrm{~m}_{1}, y_{A B}\right)\right.$ )" at the end of $P_{B}$;
- $P_{\mathrm{NS}}^{2+}$ is as the protocol $P_{\mathrm{NS}}^{+}$but we add the instruction "new $k . \beta_{4}$ : out $\left(c_{2}, \operatorname{enc}\left(\mathrm{~m}_{2}, k\right)\right)$ " at the end of $P_{B}$.

$$
\begin{aligned}
P_{\mathrm{NS}}^{+}= & !\text {new } c_{1} \text {.out }\left(c_{A}, c_{1}\right) \cdot P_{A} \mid \text { ! new } c_{2} \text {.out }\left(c_{B}, c_{2}\right) \cdot P_{B} \\
& \mid \text { new } c_{3} \text {.out }\left(c_{S}, c_{3}\right) \cdot P_{S} \\
& \mid \text { !new } c_{1} \text {.out }\left(c_{A}^{\prime}, c_{1}\right) \cdot P_{A}^{\prime} \mid \text { !new } c_{3} \text {.out }\left(c_{S}^{\prime}, c_{3}\right) \cdot P_{S}^{\prime} \\
& \mid \text { new } c_{2} \text {.out }\left(c_{B}^{\prime \prime}, c_{2}\right) \cdot P_{B}^{\prime \prime} \mid \text { !new } c_{3} \text {.out }\left(c_{S}^{\prime \prime}, c_{3}\right) \cdot P_{S}^{\prime \prime}
\end{aligned}
$$

where processes $P_{A}, P_{A}^{\prime}, P_{B}, P_{B}^{\prime \prime}, P_{S}, P_{S}^{\prime}, P_{S}^{\prime \prime}$ are as follows.

$$
\begin{aligned}
& P_{A}=\text { new } n_{a} \text {. } \\
& \alpha_{1}: \operatorname{out}\left(c_{1},\left\langle\mathrm{a}, \mathrm{~b}, n_{a}\right\rangle\right) \text {. } \\
& \alpha_{2}: \operatorname{in}\left(c_{1}, \operatorname{enc}\left(\left\langle n_{a}, \mathrm{~b}, x_{A B}, x_{B}\right\rangle, k_{a s}\right)\right) \text {. } \\
& \alpha_{3}: \text { out }\left(c_{1}, x_{B}\right) \text {. } \\
& \alpha_{4}: \operatorname{in}\left(c_{1}, \text { enc }\left(\left\langle\text { req, } x_{N B}\right\rangle, x_{A B}\right)\right) \text {. } \\
& \alpha_{5}: \operatorname{out}\left(c_{1}, \operatorname{enc}\left(\left\langle\operatorname{rep}, x_{N B}\right\rangle, x_{A B}\right)\right) \\
& P_{A}^{\prime}=\text { new } n_{a}^{\prime} \text {. } \\
& \alpha_{1}^{\prime}: \operatorname{out}\left(c_{1},\left\langle\mathrm{a}, \mathrm{c}, n_{a}^{\prime}\right\rangle\right) . \\
& \alpha_{2}^{\prime}: \operatorname{in}\left(c_{1}, \operatorname{enc}\left(\left\langle n_{a}^{\prime}, \mathrm{c}, x_{A B}^{\prime}, x_{B}^{\prime}\right\rangle, k_{a s}\right)\right) \text {. } \\
& \alpha_{3}^{\prime} \text { : out }\left(c_{1}, x_{B}^{\prime}\right) \text {. } \\
& \alpha_{4}^{\prime}: \operatorname{in}\left(c_{1}, \operatorname{enc}\left(\left\langle\text { req }, x_{N B}^{\prime}\right\rangle, x_{A B}^{\prime}\right)\right) \text {. } \\
& \alpha_{5}^{\prime}: \operatorname{out}\left(c_{1}, \operatorname{enc}\left(\left\langle\operatorname{rep}, x_{N B}^{\prime}\right\rangle, x_{A B}^{\prime}\right)\right) \\
& P_{B}=\beta_{1}: \operatorname{in}\left(c_{2}, \operatorname{enc}\left(\left\langle y_{A B}, \mathrm{a}\right\rangle, k_{b s}\right)\right) \text {.new } n_{b} \text {. } \\
& \beta_{2}: \operatorname{out}\left(c_{2}, \operatorname{enc}\left(\left\langle\text { req, } n_{b}\right\rangle, y_{A B}\right)\right) \text {. } \\
& \beta_{3}: \operatorname{in}\left(c_{2}, \operatorname{enc}\left(\left\langle\operatorname{rep}, n_{b}\right\rangle, y_{A B}\right)\right) \\
& P_{B}^{\prime \prime}=\beta_{1}^{\prime \prime}: \operatorname{in}\left(c_{2}, \operatorname{enc}\left(\left\langle y_{A B}^{\prime \prime}, \mathrm{c}\right\rangle, k_{b s}\right)\right) \text {.new } n_{b}^{\prime \prime} \text {. } \\
& \beta_{2}^{\prime \prime}: \operatorname{out}\left(c_{2}, \operatorname{enc}\left(\left\langle\mathrm{req}, n_{b}^{\prime \prime}\right\rangle, y_{A B}^{\prime \prime}\right)\right) \text {. } \\
& \beta_{3}^{\prime \prime}: \operatorname{in}\left(c_{2}, \operatorname{enc}\left(\left\langle\text { rep }, n_{b}^{\prime \prime}\right\rangle, y_{A B}^{\prime \prime}\right)\right) \\
& P_{S}=\gamma_{1}: \operatorname{in}\left(c_{3},\left\langle\mathrm{a}, \mathrm{~b}, z_{N A}\right\rangle\right) \text {.new } k_{a b} \text {. } \\
& \gamma_{2}: \operatorname{out}\left(c_{3}, \operatorname{enc}\left(\left\langle z_{N A}, \mathrm{~b}, k_{a b}, \operatorname{enc}\left(\left\langle k_{a b}, \mathrm{a}\right\rangle, k_{b s}\right)\right\rangle, k_{a s}\right)\right) \\
& P_{S}^{\prime}=\gamma_{1}^{\prime}: \operatorname{in}\left(c_{3},\left\langle\mathrm{a}, \mathrm{c}, z_{N A}^{\prime}\right\rangle\right) \text {.new } k_{a b}^{\prime} \text {. } \\
& \gamma_{2}^{\prime}: \operatorname{out}\left(c_{3}, \operatorname{enc}\left(\left\langle z_{N A}^{\prime}, \mathrm{c}, k_{a b}^{\prime}, \operatorname{enc}\left(\left\langle k_{a b}^{\prime}, \mathrm{a}\right\rangle, k_{c s}\right)\right\rangle, k_{a s}\right)\right) \\
& P_{S}^{\prime \prime}=\gamma_{1}^{\prime \prime}: \operatorname{in}\left(c_{3},\left\langle\mathrm{c}, \mathrm{~b}, z_{N A}^{\prime \prime}\right\rangle\right) \text {.new } k_{a b}^{\prime \prime} \text {. } \\
& \gamma_{2}^{\prime \prime}: \operatorname{out}\left(c_{3}, \operatorname{enc}\left(\left\langle z_{N A}^{\prime \prime}, \mathrm{b}, k_{a b}^{\prime \prime}, \operatorname{enc}\left(\left\langle k_{a b}^{\prime \prime}, \mathrm{c}\right\rangle, k_{b s}\right)\right\rangle, k_{c s}\right)\right)
\end{aligned}
$$

To ensure the protocol is type-compliant, we need to consider a typing system $\left(\mathcal{T}_{N S}^{+}, \delta_{\text {NS }}^{+}\right)$such that $x_{N B}, x_{N B}^{\prime}, n_{b}$ and $n_{b}^{\prime \prime}$ share the same type, $\tau_{n b} ; x_{A B}, x_{A B}^{\prime}, y_{A B}, y_{A B}^{\prime \prime}, k_{a b}, k_{a b}^{\prime}, k_{a b}^{\prime \prime}, k$ have all type $\tau_{k a b}$; and both $n_{a}$ and $z_{N A}$ (resp. $n_{a}^{\prime}$ and $\left.z_{N A}^{\prime}\right)$ have type $\tau_{n a}$. Which implies that $\delta_{N S}^{+}\left(x_{B}\right)=\operatorname{enc}\left(\left\langle\tau_{k a b}, \tau_{\mathrm{a}}\right\rangle, \tau_{k b s}\right), \delta_{\mathrm{NS}}^{+}\left(x_{B}^{\prime}\right)=\operatorname{enc}\left(\left\langle\tau_{k a b}, \tau_{\mathrm{a}}\right\rangle, \tau_{k c s}\right)$ and both $\mathrm{m}_{1}$ and $\mathrm{m}_{2}$ must have type $\tau_{\mathrm{m}}$. Moreover, $\tau_{k a s}$ and $\tau_{k b s}$ are honest types whereas $\tau_{\mathrm{a}}, \tau_{\mathrm{b}}, \tau_{\mathrm{c}}, \tau_{\mathrm{m}}, \tau_{\text {req }}$, and $\tau_{\text {rep }}$ are public types.

The dependency graph for $P_{\text {NS }}^{i+}$ (for any $i \in\{1,2\}$ ) w.r.t. this scenario is then given in Figure 6.7, split into three graphs displaying edges of type 1,2 and 3 respectively. Applying Definition 6.3.3 enables us to consider $\left(\alpha_{5}, 1.2\right)$ and $\left(\alpha_{5}^{\prime}, 1.2\right)$ as appropriate marked position in $P_{\mathrm{NS}}^{1+}$ and $P_{\mathrm{NS}}^{2+}$, which allows us to discard type 2 arrows from $\alpha_{4}, \beta_{3}, \alpha_{4}^{\prime}$ and $\beta_{3}^{\prime \prime}$ towards $\alpha_{5}$ and $\alpha_{5}^{\prime}$ with label 1.2.

Edges towards $\alpha_{3}^{\prime}$ (resp. $\gamma_{2}^{\prime \prime}$ ) are all with label 1.1 (resp. 1.2.2.1) and exist because both labels correspond to outputs of keys known to the agent c (encrypted by $k_{c s}$ ). As all keys generated by the server share the same type $\tau_{k a b}$, any use of such a key create an edge towards those two nodes. Similarly, as nonces created by b and outputted at labels $\beta_{2}$ and $\beta_{2}^{\prime \prime}$ share the same type $\tau_{n b}$ and are encrypted by keys of (non-honest) type $\tau_{k a b}$, inputs using such nonces all point towards these nodes. Finally, arrows with label $\epsilon$ correspond to regular executions of the protocol, albeit with some collision between messages because of the previously detailed equal types.

Otway-Rees The tagged version of the Otway-Rees protocol can be informally described as follows.

$$
\begin{aligned}
& A \rightarrow B: M, A, B,\left\{1, N_{a}, M, A, B\right\}_{K_{a s}} \\
& B \rightarrow S: M, A, B,\left\{1, N_{a}, M, A, B\right\}_{K_{a s}},\left\{2, N_{b}, M, A, B\right\}_{K_{b s}} \\
& S \rightarrow B: M,\left\{3, N_{a}, K_{a b}\right\}_{K_{a s}},\left\{4, N_{b}, K_{a b}\right\}_{K_{b s}} \\
& B \rightarrow A: M,\left\{3, N_{a}, K_{a b}\right\}_{K_{a s}}
\end{aligned}
$$

Note that, considering a scenario with no corruption, its untagged version can be shown to be simple and typecompliant by typing $k_{a b}$ with the same type as $\langle m, \mathrm{a}, \mathrm{b}\rangle$. However, its dependency graph would be cyclic (a cycle will appear between the two actions of the role $S$ ). We therefore consider the tagged version of the Otway-Rees protocol. Its dependency graph is still cyclic but becomes acyclic when marking several positions. In particular, we have to mark

1. all the positions (in roles $B$ and $S$ ) where $M$ appears in plaintext position;
2. the positions (in roles $A$ and $B$ ) at which the variables modelling ciphertext forwarding occur; and
3. the positions in roles $S$ (only those that involve the dishonest agent c) that correspond to $N_{a}$ (in case c plays the role $A$ ) and $N_{b}$ (in case c plays the role $B$ ).

The fact that this marking strategy is appropriate is a direct consequence of Definition 6.3.3.
Similarly, the Wide-Mouthed-Frog and the Yahalom (Paulson version) protocols need to be explicitly tagged. Their refined dependency graphs are acyclic. Actually the normal dependency graph of the Wide-Mouthed-Frog protocol is already acyclic.

Yahalom Consider now the original Yahalom protocol. Its tagged version can be informally described as follows.

$$
\begin{aligned}
& \text { 1. } A \rightarrow B: A, N_{a} \\
& \text { 2. } B \rightarrow S: B,\left\{1, A, N_{a}, N_{b}\right\}_{K_{b s}} \\
& \text { 3. } S \rightarrow A:\left\{2, B, K_{a b}, N_{a}, N_{b}\right\}_{K_{a s} s},\left\{3, A, K_{a b}\right\}_{K_{b s}} \\
& \text { 4. } A \rightarrow B:\left\{3, A, K_{a b}\right\}_{K_{b s}},\left\{4, N_{b}\right\}_{K_{a b}}
\end{aligned}
$$

When considering only honest sessions, the corresponding dependency graph is acyclic. However, cycles appear if sessions with dishonest agents are considered. Intuitively, this is due to the fact that the nonce $N_{b}$ sent at the final step is encrypted under the key $K_{a b}$ which secrecy cannot be statically guaranteed. Therefore, the nonce $N_{b}$ could potentially be learnt at step 4 and be reused earlier (at Step 2 for example). Note that such a protocol would be declared leaky in [47].

Figure 6.7: Dependency graph for $P_{\text {NS }}^{i+}$ w.r.t. $\left(\mathcal{T}_{\mathrm{NS}}^{+}, \delta_{\mathrm{NS}}^{+}\right)$

Kao-Chow Again, it is necessary to tag this protocol to obtain type-compliance w.r.t. a relatively fine-grained typing system, and to avoid some cycles in the dependency graph.

1. $A \rightarrow S: A, B, N_{a}$
2. $S \rightarrow B:\left\{1, A, B, N_{a}, K_{a b}\right\}_{K_{a s}},\left\{2, A, B, N_{a}, K_{a b}\right\}_{K_{b s}}$
3. $B \rightarrow A:\left\{1, A, B, N_{a}, K_{a b}\right\}_{K_{a s}},\left\{3, N_{a}\right\}_{K_{a b}}, N_{b}$
4. $A \rightarrow B:\left\{4, N_{b}\right\}_{K_{a b}}$

Even with explicit tags, the resulting dependency graph contains a cycle due to the fact that, at the third step, $B$ sends the nonce $N_{a}$ under $K_{a b}$, which security cannot be statically asserted. However, $N_{a}$ is intuitively public. We therefore slightly modify this protocol, assuming that $S$ also sends $N_{a}$ in clear at the second step, which suffices to obtained an acyclic (refined) dependency graph using Definition 6.3.3. This is a typical example where another marking strategy could be applied to (soundly) obtain an acyclic graph.

### 6.4.3 Detailed comparison with [47]

Sibylle Fröschle has recently obtained [47] a decidability result for an unbounded number of sessions, for the property of "leakiness". Our decidability result differs from Fröschle's result on several general points, in particular in terms of primitives and properties that can be handled. Strictly speaking the two results are incomparable since we study trace equivalence while [47] analyses "leakiness", a specially designed property that implies secrecy. In this section, we highlight the main similarities and differences of the two approaches.

Primitives. Fröschle's result applies to all standard cryptographic primitives (concatenation, symmetric and asymmetric encryption, hash, and signatures) while we only consider concatenation and symmetric encryption. This is due to the fact that our decidability result builds upon [24] (to limit ourselves to well-typed traces), which scope is limited to concatenation and symmetric encryption.

Properties. We consider more general security properties since we can decide any equivalence-based property (provided the processes fall into our class), while [47] only applies to the particular leakiness property. Leakiness enforces that a data (a nonce or a key) is either immediately deducible or secret. Note that leakiness is strictly stronger than secrecy. It disallows protocols with temporary secrets but it also discards some very reasonable protocols such as the Needham-Schroeder symmetric key protocol, due to parallel sessions between honest and dishonest agents. Indeed, assume $A$ initiates (honestly) a session with $C$. Then the key $K_{a c}$ generated by the server is not immediately deducible to the attacker since it is protected by $K_{a s}$ but will be deducible as soon as $A$ forwards it to $C$ under the key $K_{c s}$. The protocol will be declared leaky although no one cares about the secrecy of $K_{a c}$.

Dependency graph. One important common point between [47] and our result is the notion of dependency graph that should be acyclic. The graph defined in [47] reflects sequential dependencies similarly to our dependency graph. Regarding data dependencies, there is an edge between two actions as soon as their corresponding terms can be instantiated such that they share a common ciphertext as subterm. As a consequence, acyclicity can only be satisfied in a typed model. Therefore, [47] assumes that agents can recognise the type of a data, e.g. do not confuse a nonce with a ciphertext or a pair of nonces. Fröschle's result cannot consider protocols with ciphertext forwarding. In some cases where ciphertexts are just appended to the rest of the message, [47] devises a simple transformation. However, this transformation does not apply to protocols including more involved ciphertext forwarding such as the Denning-Sacco and the Needham-Schroeder protocols.

The graph considered in [47] is somewhat simpler (i.e. contains less arrows). In particular, this graph does not consider key dependencies (item 3 of Definition 6.2.2). This is due to the leakiness property: there is no temporary secret thus a key is either secret or public.

### 6.5 Proof of our decidability results

We prove our decidability results (Theorems 6.2.1 and 6.3.1) in three main steps. In both cases, we bound the length of a witness of non-equivalence, and then conclude by invoking a decidability result for a bounded number of sessions (e.g. [24]).

Given two simple protocols $P$ and $Q$, a witness of non-inclusion for $P \nsubseteq Q$ is a trace $\operatorname{tr}$ for which there exists $\phi$ such that $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ and:

- either there does not exist $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$,
- or such a $\psi$ exists and $\phi \nsim \psi$.

A witness of non-equivalence is a trace tr that is a witness for $P \nsubseteq Q$ or $Q \nsubseteq P$.
Note that for a simple protocol, once the sequence $t r$ is fixed, all the frames reachable through tr are actually in static equivalence, which ensures the unicity of $\psi$, if it exists, up-to static equivalence.

The three main steps of our proof can be summarised as follows:

1. We first rely on our type-compliance assumption. We show that we can restrict our attention to witnesses that are well-typed and we further show that each message occurring in such a trace can be computed as soon as possible (asap) (see Lemmas 6.5.1 and 6.5.2). Intuitively, recipes should refer to messages that occur as early as possible.
2. Then, we show that all the dependencies occurring in such a well-typed and asap trace comply with the dependency graph. Hence, we bound the width (Lemma 6.5.7) as well as the depth (Corollary 6.5.1) of such a witness exploiting the acyclicity of our dependency graph.
3. Lastly, we explain how to bound the length of a minimal witness (Lemma 6.5.9).

### 6.5.1 Reducing equivalence

We first show that we may focus on pseudo-well-typed witnesses of attacks. Formally, we cast Theorem 4.1.1 in our framework.

Theorem 6.5.1 (Theorem 4.1.1 revisited). Let $P$ and $Q$ be two simple protocols type-compliant w.r.t. some structurepreserving typing systems $\left(\mathcal{T}_{P}, \delta_{P}\right)$ and $\left(\mathcal{T}_{Q}, \delta_{Q}\right)$. We have that $P \not \approx Q$ if, and only if, there exists a witness of non-equivalence tr such that:

- either $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ for some $\phi$ and $(\operatorname{tr}, \phi)$ is pseudo-well-typed w.r.t. $\left(\mathcal{T}_{P}, \delta_{P}\right)$.
- or $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ for some $\psi$ and $(\operatorname{tr}, \psi)$ is pseudo-well-typed w.r.t. $\left(\mathcal{T}_{Q}, \delta_{Q}\right)$.

Moreover, there is no $\mathrm{c} \in \Sigma_{0}$ having an honest type occurring in key position in tr.
Proof. Compared to Theorem 4.1.1, we consider structure-preserving typing system, instead of typing systems, and we moreover need to make sure that there exists no constant with an honest type occurring in key position in a pseudo-well-typed witness of non-equivalence. Lemma 2.5.1 ensures that ( $\mathcal{T}_{P}, \delta_{P}$ ) and ( $\mathcal{T}_{Q}, \delta_{Q}$ ) are typing systems. Then Theorem 4.1.1 ensures that if there exists a witness of non-equivalence $\operatorname{tr}$ of $P \not \approx Q$, the first two items of Definition 4.1.1 hold. We still need to show that for any $\mathrm{c} \in \Sigma_{0}$ such that $\delta(\mathrm{c})$ is honest, c does not appear in key position in $\operatorname{tr} \phi \downarrow$. From Lemma 4.1.1, $\operatorname{tr} \phi \downarrow=\operatorname{tr}_{s} \sigma$ for some first-order trace $\operatorname{tr}_{s}$ and substitution $\sigma$ well-typed (by Definition 4.1.1). The proof of Theorem 4.2.1 ensures $E S t(\operatorname{tr} \phi \downarrow) \subseteq E S t\left(\operatorname{tr}_{s}\right) \sigma$ where $E S t$ denotes the set of encrypted subterms of its argument (defined for terms and naturally extended to traces). Let enc $(u, v) \in E S t(\operatorname{tr} \phi \downarrow)$. There exists enc $\left(u^{\prime}, v^{\prime}\right) \in E S t\left(\operatorname{tr}_{s}\right)$ such that enc $(u, v)=\operatorname{enc}\left(u^{\prime}, v^{\prime}\right) \sigma=\operatorname{enc}\left(u^{\prime} \sigma, v^{\prime} \sigma\right)$. Because keys are atomic
in our model, $v$ and $v^{\prime}$ are atoms. Suppose ad absurdum $v \in \Sigma_{0}$ and $\delta_{P}(v)$ is honest. Because $\sigma$ is well-typed, $\delta_{P}\left(v^{\prime}\right)=\delta_{P}(v)$. If $v^{\prime}$ were a variable or a constant in $\Sigma_{0}, \delta_{P}\left(v^{\prime}\right)$ cannot be honest, it would be in contradiction with item (ii) of the definition of honest type. Then $v^{\prime}$ has to be a name, causing $v=v^{\prime} \sigma=v^{\prime}$ to be a name too; contradiction once again. Thus no term in a key position in $\operatorname{tr} \phi \downarrow$ can be an element of $\Sigma_{0}$ and of an honest type. Hence $(\operatorname{tr}, \phi)$ is indeed pseudo-well-typed.

To bound the length of a witness, it is important to avoid some unnecessary detours, and this is the purpose of computing messages as soon as possible.

Definition 6.5.1. Given a trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ and a message $m$ such that $\phi \vdash m$. We say that $R$ is an asap recipe of $m$ if:

- $R \phi \downarrow=m$,
- $R=C\left[R_{1}, \ldots, R_{n}\right]$ where $C$ contains only constructors, for any $i, R_{i}$ contains only destructors and $R_{i} \phi \downarrow$ is not a pair,
- $R$ is the minimal recipe satisfying those conditions, w.r.t. to the following order: for any $\mathrm{w}, \mathrm{w}^{\prime} \in \operatorname{dom}(\phi)$, $\mathrm{w}<\mathrm{w}^{\prime}$ if w occurs before $\mathrm{w}^{\prime}$ in $\phi$, and for any recipe $R, R^{\prime}, R<R^{\prime}$ if $\operatorname{vars}^{\#}(R)<_{\text {mul }} \operatorname{vars}^{\#}\left(R^{\prime}\right)$; where $<_{m u l}$ is the multiset extension of $<$ and vars $^{\#}(R)$ denotes the multiset of variables in $R$.
We say that a trace $(\operatorname{tr}, \phi)$ of a protocol $P$ is an asap trace if for any input recipe $R$ occurring in tr, we have that $R$ is an asap recipe of $R \phi \downarrow$ w.r.t. $(\operatorname{tr}, \phi)$.

Example 6.5.1. The trace $(\operatorname{tr}, \phi)$ given in Example 2.3 .1 is not an asap trace. Indeed, $\operatorname{in}\left(c h_{3}, w_{1}\right)$ occurs in tr and $w_{1} \phi \downarrow=\langle a, b\rangle$. Thus $w_{1}$ is a recipe of $\langle a, b\rangle$. However, it is not an asap recipe since $\langle a, b\rangle$ is deducible from the empty frame (remember that a and b are public constants from $\Sigma_{0}$ ). For the same reason, ( $\operatorname{tr}^{\prime}, \phi_{1}^{\prime}$ ) and $\left(\operatorname{tr}^{\prime}, \phi_{2}^{\prime}\right)$ are not asap traces.

In the following lemma, we prove it is always possible to find an asap recipe which reduces to a deducible term in any given frame.

Lemma 6.5.1. Given a trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ and a message $t$ such that $\phi \vdash t$, there exists an asap recipe $R$ of $t$.
Proof. As $\phi \vdash t$, there exists a recipe $R$ such that $R \phi \downarrow=t$. Let us consider the rewriting rules

$$
\begin{aligned}
& \operatorname{dec}(\operatorname{enc}(x, y), z) \Rightarrow x \\
& \operatorname{proj}_{i}\left(\left\langle x_{1}, x_{2}\right\rangle\right) \Rightarrow x_{i}
\end{aligned}
$$

and for any recipe $R$, let $R \Downarrow$ be the normal form for the $\Rightarrow$ rewriting. As $t$ is a message, from Lemma A.1.2, we get that $R \Downarrow \phi \downarrow=t . R \Downarrow$ is of the form $C\left[R_{1}, \ldots, R_{n}\right]$ where $C$ contains only constructors and for any $i, R_{i}$ only destructors (without being asap at this point) as keys are atomic in our model. At this point, we proved that given a frame $\phi$ and $t$ such that $\phi \vdash t$, there exists a recipe $R$ of $t$ such that $R=C\left[R_{1}, \ldots, R_{n}\right]$ where $C$ contains only constructors; for any $i, R_{i}$ contains only destructors.

Furthermore, to ensure $R_{i} \phi \downarrow$ is not a pair, for any recipe $M=C\left[R_{1}, \ldots, R_{n}\right]$ such that $C$ is constructor-only, $R_{i}$ destructor-only, consider the following induction on $\sum_{i=1}^{n}\left|R_{i} \phi \downarrow\right|$; where $|t|$ denotes the size of the term $t$ :

- if $R_{i} \phi \downarrow$ is an atom or encryption for any $i$ : we have the final result.
- if $R_{i} \phi \downarrow=\langle s, t\rangle$ for some $i$ : applying the already proven result on $\operatorname{proj}_{1}\left(R_{i}\right)$ (resp. $\operatorname{proj}_{2}\left(R_{i}\right)$ ) gives a recipe $R_{i}^{\prime}=C_{i}^{\prime}\left[R_{1}^{\prime}, \ldots, R_{p}^{\prime}\right]$ (resp. $R_{i}^{\prime \prime}=C_{i}^{\prime \prime}\left[R_{1}^{\prime \prime}, \ldots, R_{q}^{\prime \prime}\right]$ ) such that $C_{i}^{\prime}$ (resp. $C_{i}^{\prime \prime}$ ) is constructor-only and each $R_{j}^{\prime}$ (resp. $R_{j}^{\prime \prime}$ ) contains only destructors. $M^{\prime}=C\left[R_{1}, \ldots,\left\langle R_{i}^{\prime}, R_{i}^{\prime \prime}\right\rangle, \ldots, R_{n}\right]$ is made of constructor on top of destructors and $\sum_{j \neq i}\left|R_{j} \phi \downarrow\right|+\left|R_{i}^{\prime} \phi \downarrow\right|+\left|R_{i}^{\prime \prime} \phi \downarrow\right|<\sum_{i=1}^{n}\left|R_{i} \phi \downarrow\right|$.

An asap recipe is hence obtained by considering a minimal element among the recipes satisfying those properties.

Trace equivalence can be equivalently redefined by considering only asap recipes in Definition 2.4.2. We expose here a definition for well-typed asap trace equivalence and prove in Lemma 6.5.2, its equivalence with traditional trace equivalence for the protocols we consider. The intuition behind asap traces is to consider only input messages that are built as soon as they can be deducible. In particular, with asap recipes, the attacker cannot take detours to deduce a particular message. Yet it does not hinder the power of the attacker as static equivalence still ensures that recipes leading to the same term in one frame must do the same in the other frame.

Definition 6.5.2 (well-typed asap trace equivalence). Two protocols $P$ and $Q$ type-compliant w.r.t. their respective structure-preserving typing systems $\left(\mathcal{T}_{P}, \delta_{P}\right)$ and $\left(\mathcal{T}_{Q}, \delta_{Q}\right)$ are in well-typed asap trace equivalence, denoted $P \approx^{\prime} Q$ if, and only if:

- for every asap trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ which is pseudo-well-typed w.r.t. $\left(P, \delta_{P}\right)$ there exists a trace $(\operatorname{tr}, \psi) \in$ trace $(Q)$ such that $\phi \sim \psi$,
- for every asap trace $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ which is pseudo-well-typed w.r.t. $\left(Q, \delta_{Q}\right)$ there exists a trace $(\operatorname{tr}, \phi) \in$ trace $(P)$ such that $\psi \sim \phi$.

We now prove that this variant of trace equivalence matches, for our class of protocols, to the original definition of trace equivalence. To do so, we use Theorem 6.5.1 to focus only on pseudo-well-typed trace and then show that considering only asap trace does not affect the ability for the attacker to distinguish between two protocols.

Lemma 6.5.2. Let $P$ and $Q$ be two protocols type-compliant w.r.t. their respective structure-preserving typing systems $\left(\mathcal{T}_{P}, \delta_{P}\right)$ and $\left(\mathcal{T}_{Q}, \delta_{Q}\right)$. Then $P \approx Q$ if, and only if, $P \approx^{\prime} Q$.

Proof. The direct implication is direct. Let us then assume that $P \not \approx Q$ and prove that $P \not \chi^{\prime} Q$. Theorem 6.5.1 enables us to only consider a pseudo-well-typed witness of non-equivalence. The proof is then carried by induction on the length of the minimal witness of non-equivalence. Note that making a trace asap does not change its first-order values.

We are then able to show that, when looking for an attack, i.e. a witness of non-equivalence, we can further restrict our attention to consider pseudo-well-typed witnesses that are also asap.

### 6.5.2 Exploiting the dependency graph

Given an asap and pseudo-well-typed execution trace $(\operatorname{tr}, \phi)$ of a simple protocol $P$, we can see it as a dag $D$ (directed acyclic graph) whose vertices are actions of tr, and edges represent sequential dependencies and data dependencies. Note that such a dag can be computed simply from tr since sequential dependencies may be inferred from the channel names occurring in tr, and data dependencies are inferred from input recipes that occur in tr.

Our ultimate goal is to bound the length of tr, and thus the number of vertices in $D$. We first show that we are able to bound its depth and its width.

The first lemma links the actions of any trace of the protocol with the actions of the protocol themselves.
Lemma 6.5.3. Given a simple protocol $P,(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$, and an action $a$ appearing in $\operatorname{tr}$, there exists a unique action in $P$ which corresponds to the execution of $a$ in $\operatorname{tr}$.

Proof. Direct consequence of our semantics and the use of fresh channel names which identify actions in the trace.
We can now define an execution graph and ensure that, for simple protocols, any trace corresponds to a unique execution graph.

Figure 6.8: Execution graph $D$ of $\operatorname{tr}$ w.r.t. $P_{\mathrm{DS}}$

Definition 6.5.3. Let $P$ be a protocol, $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$. An execution graph of tr w.r.t. $P$ is a directed acyclic graph $D$ whose vertices are the actions of tr and whose edges are defined as follows:

- there is an edge from in $(c, R)$ to an action out $(d, \mathrm{w})$ if $\mathrm{w} \in \operatorname{vars}(R)$;
- there is an edge from an action $a_{2}$ to an other action $a_{1}$ if the action corresponding to $a_{2}$ in $P$ directly follows the action corresponding to $a_{1}$ in $P$.

Note that such an action is uniquely defined thanks to Lemma 6.5.3.

Example 6.5.2. Consider the trace

$$
\operatorname{tr}=\operatorname{out}\left(c_{A}, \operatorname{ch}_{1}\right) . \operatorname{out}\left(c_{S}, c h_{3}\right) \cdot \operatorname{out}\left(c h_{1}, \mathrm{w}_{1}\right) \cdot \operatorname{in}\left(c h_{3}, \mathrm{w}_{1}\right) \cdot \operatorname{out}\left(c h_{3}, \mathrm{w}_{2}\right)
$$

and

$$
\phi=\left\{\mathrm{w}_{1} \triangleright\langle\mathrm{a}, \mathrm{~b}\rangle, \mathrm{w}_{2} \triangleright \operatorname{enc}\left(\left\langle\mathrm{~b}, k_{a b}, \mathrm{enc}\left(\left\langle k_{a b}, \mathrm{a}\right\rangle, k_{b s}\right)\right\rangle, k_{a s}\right),\right\}
$$

We have that $(\operatorname{tr}, \phi) \in \operatorname{trace}\left(P_{\mathrm{DS}}\right)$ (see Example 6.1.1). For the sake of clarity, let us define $a_{i}$ to be the $i$-th action of $\operatorname{tr}$. Then $\operatorname{tr}=a_{1} \cdot a_{2} \cdot a_{3} \cdot a_{4} \cdot a_{5}$. Let $D$ be the directed acyclic graph defined in Figure 6.8: $D$ is an execution graph $D$ of tr w.r.t. $P_{\mathrm{DS}}$. Similarly to what we did with dependency graphs, we drew in in red edges of the first kind, corresponding to data dependencies and drew in blue edges of the second kind, corresponding the sequential dependencies.
Lemma 6.5.4. If $P$ is a simple protocol and $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$, then there exists a unique execution graph of tr w.r.t. $P$. Moreover, if $Q$ is a simple protocol and there exists $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$, then the execution graph of $\operatorname{tr}$ w.r.t. $Q$ is equal to the execution graph of $\operatorname{tr}$ w.r.t. $P$.

Proof. We prove that we can build the execution graph by looking solely at tr in the case of simple protocols: data dependencies are explicit through the recipes, while sequential dependencies can be deduced from the channel $c^{\prime}$ of an action, new $c^{\prime}$.out $\left(c, c^{\prime}\right)$ the action that created it, and the position of this action in the sequence of all actions on channel $c^{\prime}$. Hence, we have that $\operatorname{tr}$ completely and uniquely defines an execution graph for $\operatorname{tr}$ w.r.t. $P$. Moreover, as the dependencies depend on tr alone, the graph does not vary depending on whether $\operatorname{tr}$ is a trace of $P$ or $Q$.

## Bounding the depth of $D$

Intuitively, any sequential and data dependency occurring in a well-typed and asap trace is already present in the dependency graph. This is obvious regarding sequential dependencies since all these dependencies have been added in the dependency graph. However, regarding data dependencies, this result strongly relies on the fact that we consider well-typed and asap traces.

In this first lemma we justify the appellations of honest and public by their consequences in terms of deducibility for terms of such a type.

Lemma 6.5.5. Let $P$ be a protocol type-compliant w.r.t. a structure-preserving typing system $(\mathcal{T}, \delta)$.

- If $\tau$ is an honest type, $n$ a name such that $\delta(n)=\tau$, then for any well-typed trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$, we have that $\phi \nvdash n$.
- If $\tau$ is a public type, $t$ a term such that $\delta(t)=\tau$, then for any well-typed $(\operatorname{tr}, \phi) \in \operatorname{trace}(P), \phi \vdash t$ implies $\phi_{0} \vdash t$; where $\phi_{0}$ denotes the empty frame.

Proof. We consider the two items separately:

- As $\tau$ is honest, $\tau$ does not appear in plaintext position in $u \delta_{P}$ for any $u$ in $P$. Suppose ad absurdum there exists $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ pseudo-well-typed such that $\phi \vdash n$. There exists a recipe $R$ with only destructors (see Lemma 6.5.1; as $n$ is atomic, the context $C$ is empty) such that $R \phi \downarrow=n$. Let w be the leaf of $R$ at the leftmost position (i.e. at the longest position $p=11 \ldots 1$ such that $\left.R\right|_{p}$ is defined): $n$ appears in plaintext position of $\mathrm{w} \phi$. Because $\phi$ is well-typed, $\delta_{P}(\mathrm{w} \phi)=u \delta_{P}$ for some output $u$ in $P$. But then, as $n$ is a subterm of w $\phi$ in plaintext position, $\delta_{P}(n)$ is a subterm of $u \delta_{P}$ in plaintext position: thus $\tau$ appears in plaintext position in some $u \delta_{P}$ with $u$ in $P$. Contradiction with $\tau$ being an honest type. Hence $\phi \nvdash n$.
- Suppose $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ is a well-typed trace such that $\phi \vdash t$. Let $a$ be a leaf of $t: a$ is an atom and can be an element of $\Sigma_{0}$ (constant) or $\mathcal{N}$ (name). Let us consider the latter: because names are initially unknown to the attacker, $\phi_{0} \nvdash a$ and $\delta_{P}(a)=\delta_{P}(n)$ for some name $n$ in $P$. The name $a$ being a subterm of $t, \delta_{P}(n)$ is a subterm of $\delta_{P}(t)=\tau$ and thus $\tau$ would not be public. Hence every leaf of $t$ is a constant in $\Sigma_{0}$ and so $\phi_{0} \vdash t$.

As we did after Definition 6.2.1, from Definition 6.3.2, we extend the definition of $\rho_{\text {in }}$ and $\rho_{\text {out }}$ to terms.

$$
\begin{aligned}
& \rho_{\text {out }}\left(t^{\prime}\right)=\left\{(t, p) \mid(t, p) \# S \in \rho_{\mathrm{io}}\left(t^{\prime}, \epsilon, \emptyset\right)\right\} ; \text { and } \\
& \rho_{\text {in }}\left(t^{\prime}\right)=\left\{t, t_{1}, \ldots, t_{k} \mid(t, p) \#\left\{t_{1}, \ldots, t_{k}\right\} \in \rho_{\mathrm{io}}\left(t^{\prime}, \epsilon, \emptyset\right)\right\} .
\end{aligned}
$$

Intuitively, $\rho_{\text {out }}\left(t^{\prime}\right)$ returns the terms that may be deducible by the attacker once $t^{\prime}$ is outputted, whereas $\rho_{\text {in }}\left(t^{\prime}\right)$ returns all the terms that may be used by the attacker to fill an input with term $t^{\prime}$. Next, Lemma 6.5.6 ensures these definitions are consistent with Definition 6.2 .1 when considering the type $\delta(t)$ of any term $t$.

Lemma 6.5.6. Let $P$ be a protocol type-compliant w.r.t. a structure-preserving typing system $(\mathcal{T}, \delta)$. For any $u, t \in$ $\mathcal{T}_{0}\left(\Sigma_{\mathrm{c}}, \Sigma_{0} \cup \mathcal{N}\right)$ such that no $\mathrm{c} \in \Sigma_{0}$ occurs in key position in $t$ and for any position $p$ :

- $(u, p) \# S \in \rho_{\mathrm{io}}(t, \epsilon, \emptyset) \Rightarrow(\delta(u), p) \# \delta(S) \in \rho_{\mathrm{io}}(\delta(t), \epsilon, \emptyset)$; where $\delta(S)=\{\delta(s) \mid s \in S\}$
- $(u, p) \in \rho_{\text {out }}(t) \Rightarrow(\delta(u), p) \in \rho_{\text {out }}(\delta(t))$
- $u \in \rho_{\text {in }}(t) \Rightarrow \delta(u) \in \rho_{\text {in }}(\delta(t))$

Proof. The typing function of a structure-preserving typing system $(\mathcal{T}, \delta)$ behaves like a substitution and therefore the two definitions of $\rho_{\mathrm{io}}$, defined through inductions on terms are compatible. $t$ (resp. $u$ ) and $\delta(t)$ (resp. $\delta(u)$ ) share a similar structure (any position defined in $t$ is defined in $\delta(t)$ ) and any key used to open an encryption in $t$, and thus deducible, cannot be a constant by hypothesis nor be honest (as per Lemma 6.5.5) and thus the corresponding encryption in $\delta(t)$ is also opened.

The next proposition is one of our key results. It requires to control data dependencies and in particular data dependencies that may occur due to keys: it may be necessary to decrypt to obtain a new key that in turn will be used to learn another key and so on. We show that our dependency graph actually captures all dependencies. When refining the dependency graph with appropriate marking, the main idea is that edges that are removed correspond to dependencies that can not happen in any asap trace.

Proposition 6.5.1. Let $P$ be a simple protocol type-compliant w.r.t. some structure-preserving typing systems $\left(\mathcal{T}_{P}, \delta_{P}\right)$. Let $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ be an asap and pseudo-well-typed trace w.r.t. $\left(\mathcal{T}_{P}, \delta_{P}\right)$.

For any pair of actions in $(d, R) /$ out $(c, \mathrm{w})$ occurring in $\operatorname{tr}$ with $\mathrm{w} \in \operatorname{vars}(R)$, we have that $\alpha \rightarrow_{G}^{+} \beta$ where:

- $\alpha, \beta \in \mathcal{L}(P)$ are the labels associated to the actions in $(d, R)$ and out $(c, \mathrm{w})$ respectively;
- $\rightarrow_{G}^{+}$is the transitive closure of the relation $\rightarrow$ in the dependency graph $G$ associated to $P$.

Proof. Let $a / b$ be such a pair of actions in tr: $b$ corresponds to an output action out $(c, \mathrm{w})$ and $a$ to an input action in $(d, R)$ in $\operatorname{tr}$ with $\mathrm{w} \in \operatorname{vars}(R)$.

As tr is asap, $R=C\left[R_{1}, \ldots, R_{n}\right]$ for some $C$ which contains only pairs and encryption and such that for every $i \in\{1, \ldots, n\}, R_{i}$ is made of projections and decryption only; and moreover $R_{i} \phi \downarrow$ is either an atom or an encrypted subterm. As such, for every $\mathrm{w} \in \operatorname{dom}(\phi)$, either w appears at the leftmost position of $R_{i}$ for some $i$; or w is used as a decryption key (i.e. w always appears as the second argument of some decryption).

Let us consider the first case for w: because $R_{i} \phi \downarrow$ is a subterm of $\mathrm{w} \phi$ and w occurs as a plaintext operand in $R_{i}$, $R_{i} \phi \downarrow \in \rho_{\text {out }}(\mathrm{w} \phi)$; and similarly $R_{i} \phi \downarrow$ is a subterm of $R \phi \downarrow$ (as $C$ is constructor-only), leading to $R_{i} \phi \downarrow \in \rho_{\text {in }}(R \phi \downarrow)$ (see Lemma 6.5.5: $\phi$ does not contain any constant of $\Sigma_{0}$ in key position, deducible keys have then to be nonces, which cannot be honestly typed if deducible). As such there exist two positions $p, q$ such that $\left.\mathrm{w} \phi\right|_{p}=\left.R \phi \downarrow\right|_{q}=t$ for some $i$ and some term $t$ which is either an encrypted term, a name or a constant. .

Let $u$ (resp. $v$ ) be the term occurring at label $\beta$ (resp. $\alpha$ ) in $P$. There exist two ground substitutions $\sigma_{u}, \sigma_{v}$ such that $\left.u \sigma_{u}\right|_{p}=t=\left.v \sigma_{v}\right|_{q}$. Because ( $\left.\operatorname{tr}, \phi\right)$ is well-typed, $\delta_{P}(R \phi \downarrow)=\delta_{P}(v)$ as they share the same type, and similarly, $\delta_{P}(\mathrm{w} \phi)=\delta_{P}(u)$. Because a structure-preserving typing system is a substitution (whose domain is extended to elements of $\Sigma_{0} \cup \mathcal{N}$ ) and thus compatible with subterms (i.e. $\delta_{P}\left(\left.u\right|_{p}\right)=\left.\delta_{P}(u)\right|_{p}$ for any term $u$ and position $p$ which is defined for $u$ ), we get that $\delta_{P}\left(\left.R \phi \downarrow\right|_{q}\right)=\left.\delta_{P}(v)\right|_{q}$ and $\delta\left(\left.\mathrm{w} \phi\right|_{p}\right)=\left.\delta_{P}(u)\right|_{p}$. Thus $\left.\delta_{P}(u)\right|_{p}=\left.\delta_{P}(v)\right|_{q}$, which can be rewritten as $\left.u \delta_{P}\right|_{p}=\left.v \delta_{P}\right|_{q}$ (using the traditional substitution notation). From Lemma 6.5.6, $\left.u \delta_{P}\right|_{p} \in \rho_{\text {out }}\left(u \delta_{P}\right)$ and $\left.v \delta_{P}\right|_{q} \in \rho_{\text {in }}\left(v \delta_{P}\right)$. It follows then, by Definitions 6.2 .2 and 6.3 .4 , that an edge could exist from $\alpha$ to $\beta$. If it is the case, we are done. If $\left.u \delta_{P}\right|_{p}$ is public type, Lemma 6.5 .5 ensures $\left.\phi_{0} \vdash u \sigma_{u}\right|_{p}$, which contradicts the fact that $R$ is an asap recipe (as one of its subterms is not asap). Otherwise there exists a appropriate marked position ( $\beta, p^{\prime}$ ) such that $p^{\prime}$ is a prefix of $p$. As such, because there exists $i \in\{1, \ldots, n\}$ such that $R_{i} \phi \downarrow=\left.u \sigma_{u}\right|_{p}$, there exists a subterm $R_{i}^{\prime}$ of $R_{i}$ such that $R_{i}^{\prime} \phi \downarrow=\left.u \sigma_{u}\right|_{p^{\prime}}$ (as $p^{\prime}$ is a prefix of $p$ and $R_{i}$ is made of destructors only). According to Definition 6.3.3, there exists an action $\gamma: \operatorname{in}\left(d, u^{\prime}\right)$ (or $\left.\gamma: \operatorname{out}\left(d, u^{\prime}\right)\right)$ such that $\beta$ follows $\gamma,\left(\left.u\right|_{p^{\prime}}, p^{\prime}\right) \# S \in \rho_{\text {io }}(u, \epsilon, \emptyset)$ for some multiset $S$; and $\left(\left.u\right|_{p^{\prime}}, q\right) \# S^{\prime} \in \rho_{\mathrm{io}}\left(u^{\prime}, \epsilon, \emptyset\right)$ for some $q$, and some $S^{\prime} \subseteq_{m u l} S$. Note that because marked positions are defined on the specification of the protocol $P,\left.u\right|_{p^{\prime}}$ is well-defined and $\left.u\right|_{p^{\prime}} \sigma_{u}=\left.u \sigma_{u}\right|_{p^{\prime}}$. In particular, $\left.\phi \vdash u \sigma_{u}\right|_{p^{\prime}}$ using a destructor-only recipe $R_{i}^{\prime}$ with w in its leftmost position implies that for every $k \in S$, there exists a subterm $R^{k}$ of $R_{i}^{\prime}$ such that $R^{k} \phi \downarrow=k$. As $\gamma$ occurs before $\beta$ in $P$, let $R^{\prime \prime}$ be the recipe used with this action $\gamma: \operatorname{in}\left(d, u^{\prime}\right)$ (or $\gamma:$ out $\left(d, u^{\prime}\right)$ ) in tr. As tr is asap, $R^{\prime \prime}$ is asap and $R^{\prime \prime} \phi \downarrow=u^{\prime} \sigma_{u}$. As $\left(\left.u\right|_{p^{\prime}}, q\right) \# S^{\prime} \in \rho_{\text {io }}\left(u^{\prime}, \epsilon, \emptyset\right)$, there exists a destructor-only context $R_{1}^{\prime \prime}\left[\_\right]$with a hole in its leftmost leaf position such that $R_{1}^{\prime \prime}\left[R^{\prime \prime}\right] \phi \downarrow=\left.u^{\prime}\right|_{q} \sigma_{u}=\left.u\right|_{p^{\prime}} \sigma_{u}$ and $\operatorname{vars}^{\#}\left(R_{1}^{\prime \prime}\right)=\bigcup_{k \in S^{\prime}} \operatorname{vars}^{\#}\left(R^{k}\right) \subseteq \bigcup_{k \in S} \operatorname{vars}^{\#}\left(R^{k}\right)$ as $S^{\prime} \subseteq_{m u l} S$ and by using the $R^{k}$ as decryption keys when needed. Note that in this context $\operatorname{vars}(R)$ denotes the multiset of variables occurring in $R$. As $R^{\prime \prime}$ is asap and $R^{\prime \prime} \phi \downarrow$ is a message, $R_{1}^{\prime \prime}\left[R^{\prime \prime}\right] \Downarrow$ is a recipe made of a context of constructors on top of destructor-only recipes too (see the definition of $\Downarrow$ in the proof of Lemma 6.5.1). Lemma A.1.2 ensures $R_{1}^{\prime \prime}\left[R^{\prime \prime}\right] \Downarrow \phi \downarrow=\left.u\right|_{p^{\prime}} \sigma_{u}$. Because $\gamma$ occurred before $\beta$, vars ${ }^{\#}\left(R^{\prime \prime}\right)<_{\text {mul }}\{\mathrm{w}\}$, which leads to vars $\#\left(R_{1}^{\prime \prime}\left[R^{\prime \prime}\right] \Downarrow\right)<\operatorname{vars}^{\#}\left(R_{i}^{\prime}\right)$ and implies that $R_{i}^{\prime}$ is not minimal. $R_{i}^{\prime}$ not being minimal implies $R_{i}$ is not either. Then $R$ would not be asap; and hence $\alpha \rightarrow \beta$.

Now consider the second case for w . Let $\mathrm{w}_{0}$ be the variable at the leftmost position in $R_{i}$ (i.e. $\left.R_{i}\right|_{p_{0}}=\mathrm{w}_{0}$ where $p_{0}$ is the longest position $1^{k}$ such that $\left.R_{i}\right|_{p_{0}}$ is defined). Note that $\mathrm{w}_{0} \neq \mathrm{w}$ as otherwise we would be in the first case. For position $p$, we define $\mathrm{w}_{p}$ to be the leaf of $R_{i}$ at position $p .1 \ldots 1, \alpha_{P}$ the label at which the output of $\mathrm{w}_{p}$ took place, $u_{p}$ the output term at label $\alpha_{p}$ in (the specification) $P$ and $\sigma_{p}$ the substitution such that $\mathrm{w}_{p} \phi=u_{p} \sigma_{p}$. As $\left.R_{i}\right|_{p} \phi \downarrow$ is a subterm of $\mathrm{w}_{p} \phi$, there exists a position $\tilde{p}$ such that $\left.R_{i}\right|_{p} \phi \downarrow=\left.u_{p} \sigma_{p}\right|_{\tilde{p}}$. We then define a number of sets of positions as
follows: for any $j \in \mathbb{N}^{*}$

$$
\begin{aligned}
& K_{j}=\left\{p \text { s.t. }\left.R_{i}\right|_{p}\right. \text { is defined and } \\
& \left.\quad \exists m_{1}, \ldots m_{j} \in \mathbb{N}, p=1^{m_{1}} .2 \ldots 1^{m_{j}} .2\right\}
\end{aligned}
$$

Note that because $R_{i}$ is finite, there exits $j_{0} \in \mathbb{N}$ such that $\forall j>j_{0}, K_{j}=\emptyset$. In particular, for any $p \in K_{1},\left.R_{i}\right|_{p} \phi \downarrow$ corresponds to a subterm of $\mathrm{w}_{p} \phi$ and an atom (as keys are atomic) used to decrypt the first layers of encryption of $\mathrm{w}_{0} \phi$. It implies that $R_{i} \phi \downarrow$ appears as a plaintext (or subterm of plaintext) of encryptions by $\left.R_{i}\right|_{p} \phi \downarrow$ for any $p \in K_{1}$. Similarly, for any $p \in K_{j+1},\left.R_{i}\right|_{p} \phi \downarrow$ is a subterm of $\mathrm{w}_{p} \phi \downarrow$ and an atomic key used to decrypt some $\left.R_{i}\right|_{q} \phi \downarrow$ where $q \in K_{j}$.

More formally, for any $j$ and any $p \in K_{j+1}$, there exists $q \in K_{j}$ and a multiset of terms $S$ such that

$$
\left(\left.R_{i}\right|_{q} \phi \downarrow, \tilde{q}\right) \#\left(S \cup\left\{\left.R_{i}\right|_{p} \phi \downarrow\right\}\right) \in \rho_{\mathrm{io}}\left(\mathrm{w}_{q} \phi, \epsilon, \emptyset\right) .
$$

For short, $\rho_{\mathrm{io}}(t, \epsilon, \emptyset)$ will be written as $\rho_{\mathrm{io}}(t)$. This can be rewritten using $u_{p}$ and $u_{q}$ as:

$$
\left(\left.u_{q} \sigma_{q}\right|_{\tilde{q}}, \tilde{q}\right) \#\left(S \cup\left\{\left.u_{p} \sigma_{p}\right|_{\tilde{p}}\right\}\right) \in \rho_{\mathrm{io}}\left(u_{q} \sigma_{q}\right)
$$

Moreover, if $s \# S \in \rho_{\mathrm{io}}(t)$ then $\delta_{P}(s) \# \delta_{P}(S) \in \rho_{\mathrm{io}}\left(\delta_{P}(t)\right)$ thanks to Lemma 6.5.6, it translates to

$$
\left(\delta_{P}\left(u_{q} \sigma_{q} \mid \tilde{q}\right), \tilde{q}\right) \#\left(\delta_{P}(S) \cup\left\{\delta_{P}\left(u_{q} \sigma_{p} \mid \tilde{p}\right)\right\}\right) \in \rho_{\mathrm{io}}\left(\delta_{P}\left(u_{q} \sigma_{q}\right)\right)
$$

and as $\delta_{P}\left(\left.u\right|_{p}\right)=\left.\delta_{P}(u)\right|_{p}$ for any term $u$ and position $p$ :

$$
\left(\left.\delta_{P}\left(u_{q} \sigma_{q}\right)\right|_{\tilde{q}}, \tilde{q}\right) \#\left(\delta_{P}(S) \cup\left\{\left.\delta_{P}\left(u_{q} \sigma_{p}\right)\right|_{\tilde{p}}\right\}\right) \in \rho_{\mathrm{io}}\left(\delta_{P}\left(u_{q} \sigma_{q}\right)\right)
$$

where $\delta_{P}(S)$ is just $\left\{\delta_{P}(s) \mid s \in S\right\}$. Because ( $\operatorname{tr}, \phi$ ) is well-typed, $\sigma_{p}$ and $\sigma_{q}$ are well-typed substitutions and we get

$$
\left(\left.\delta_{P}\left(u_{q}\right)\right|_{\tilde{q}}, \tilde{q}\right) \#\left(\delta_{P}(S) \cup\left\{\left.\delta_{P}\left(u_{q}\right)\right|_{\tilde{p}}\right\}\right) \in \rho_{\mathrm{io}}\left(\delta_{P}\left(u_{q}\right)\right)
$$

which we rewrite to use the substitution-style notation for $\delta_{P}$, to be:

$$
\left(\left.u_{q} \delta_{P}\right|_{\tilde{q}}, \tilde{q}\right) \#\left(\delta_{P}(S) \cup\left\{\left.u_{q} \delta_{P}\right|_{\tilde{p}}\right\}\right) \in \rho_{\mathrm{io}}\left(u_{q} \delta_{P}\right)
$$

It corresponds to an edge $\alpha_{q} \rightarrow^{\tilde{p}} \alpha_{p}$ in the (unrefined) dependency graph of $P$ as $\left.u_{q} \delta_{P}\right|_{\tilde{q}} \in \rho_{\text {out }}\left(u_{q} \delta_{P}\right)$ and $\left.u_{q} \delta_{P}\right|_{\tilde{p}} \in \rho_{\text {out }}\left(u_{q} \delta_{P}\right)$ (see Lemma 6.5.5: $\phi$ does not contain any constant of $\Sigma_{0}$ in key position, deducible keys have then to be nonces, which cannot be honestly typed if deducible). If $\alpha_{q} \rightarrow^{\tilde{p}} \alpha_{p}$ is absent from the refined dependency graph, $\left.u_{q} \delta_{P}\right|_{\tilde{q}}$ could be public type, Lemma 6.5.5 ensures then $\left.\phi_{0} \vdash u_{q} \sigma_{q}\right|_{\tilde{q}}$, which contradicts the fact that $R_{i}$ is an asap recipe (as one of its subterms is not asap).

Otherwise, there exists a marked subterm $\left(\alpha_{p}, p^{\prime}\right)$ such that $p^{\prime}$ is a prefix of $\tilde{p} .\left.u_{q} \sigma_{q}\right|_{\tilde{q}}$ was deduced with the recipe $\left.R_{i}\right|_{q}$ and so, because $R_{i}$ contains only destructors, there exists a prefix $q^{\prime \prime}$ of $q$ such that $\left.R_{i}\right|_{q^{\prime \prime}} \phi \downarrow=\left.u_{q} \sigma_{q}\right|_{q^{\prime}}$. As such, similarly to the previous case and using Definition 6.3.3 for appropriate marked positions, $\left.u_{q} \sigma_{q}\right|_{q^{\prime}}$ is not deduced with an asap recipe, and neither is $\left.u_{q} \sigma_{q}\right|_{q}$, which contradicts the asap hypothesis on $(\operatorname{tr}, \phi)$, and let us conclude that $\alpha_{q} \rightarrow^{\tilde{p}} \alpha_{p}$. Consequently, for any $p \in \bigcup_{j \geq 1} K_{j}, \alpha_{0} \rightarrow^{+} \alpha_{p}$. In particular, by considering the position $p$ such that $\alpha_{p}=\beta$ and the previous case, be get that $\alpha \rightarrow \alpha_{0}$ and $\alpha_{0} \rightarrow^{+} \beta$, which leads to $\alpha \rightarrow^{+} \beta$.

To conclude, we finally need to address the case where $(\operatorname{tr}, \phi)$ is only pseudo well-typed, without being welltyped. In that case, there exists a public constant $d \in \Sigma_{0}$, a substitution $\gamma=\{d \mapsto\langle\omega, \omega\rangle\}$ and a well-typed trace $\left(\operatorname{tr}^{\prime}, \phi^{\prime}\right) \in \operatorname{trace}(P)$ such that $\operatorname{tr}=\operatorname{tr}^{\prime} \gamma$. Because $\left(\operatorname{tr}^{\prime}, \phi^{\prime}\right)$ is well-typed, the result proved so far can be applied, and because $P$ is a simple protocol, the sequential dependencies of $\operatorname{tr}^{\prime}$ and $t r$ are identical. As $t r$ and $\operatorname{tr}^{\prime}$ are asap traces, and both $d$ and $\omega$ are in the initial knowledge of the attacker, the execution graph of tr and $\mathrm{tr}^{\prime}$ are identical, hence ensuring that the execution graph of $(\operatorname{tr}, \phi)$ is respectful.

Note that, in the class of simple process, once the trace $\operatorname{tr}$ is fixed, the label $\alpha \in \mathcal{L}(P)$ of an action occurring in tr is uniquely defined.

As Proposition 6.5.1 ensures paths from the execution graph of a trace can be mapped to paths of the dependency graph of a protocol, Corollary 6.5 .1 enables us to then derive a bound on the depth of such an execution graph, thus providing us the first step to bound the length of the trace itself.

Corollary 6.5.1. Let $P$ be a simple protocol type-compliant w.r.t. some structure-preserving typing systems $\left(\mathcal{T}_{P}, \delta_{P}\right)$ and with an acyclic (possibly refined) dependency graph $G$. Let $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ be an asap and pseudo-well-typed trace w.r.t. $\left(\mathcal{T}_{P}, \delta_{P}\right)$, and $D$ its corresponding execution graph. We have that:

$$
\operatorname{depth}(D) \leq \operatorname{depth}(G)+1
$$

Proof. Let $a$ and $b$ be actions of $\operatorname{tr}, a \rightarrow b$ be an edge of $D$. Let $\alpha$ (resp. $\beta$ ) be the label of action $a$ (resp. $b$ ). As $P$ is simple, any action out $\left(c, c^{\prime}\right)$ for two channels $c$ and $c^{\prime}$ appears without outgoing edge in $D$. As such the depth of $D$ is the length of a maximal path in $D$ between actions which are not outputs of fresh channels plus one. Suppose now $a$ and $b$ corresponds to actions which are not outputs of fresh channels.

Now, we need to prove that $\alpha \rightarrow^{+} \beta$. By Definition 6.5.3, this arrow can either correspond to a sequential dependency or a data dependency (for an input). In the first case, by Definition 6.2.2, the same arrow exists in the refined dependency graph if $b$ is not an action out $\left(c, c^{\prime}\right)$ for some channels $c$ and $c^{\prime}$; and in the latter, Proposition 6.5.1 ensures also $\alpha \rightarrow^{+} \beta$. As the relation $\rightarrow^{+}$if finite with depth depth $(G)$, we finally get (taking into account the additional edge for the output of a fresh channel):

$$
\operatorname{depth}(D) \leq \operatorname{depth}(G)+1
$$

## Bounding the width of $D$

The width of $D$ is the maximal number of outgoing edges of any vertex of $D$. Actually, any recipe involved in an asap and pseudo-well-typed trace is of the form $C\left[R_{1}, \ldots, R_{n}\right]$ where $C$ contains only constructors and each $R_{i}$ contains only destructors. Since messages stored in the frame are well-typed, we can not stack more than $\|$ out $_{P} \|$ (maximal size of an outputted term in a well-typed trace) destructors in such a recipe. Note that some key chains may be needed to deduce a message, but the length of such a chain is bounded by depth $(G)$. Hence, we have that each $R_{i}$ involves no more than $\left(1+\| \text { out }_{P} \|\right)^{\operatorname{depth}(G)+1}$ recipe variables, and we have also that $n \leq \|$ in $_{P} \|$ where $\|$ in $_{P} \|$ denotes the maximal size of any input term in a well-typed trace. Thus, we have that:

$$
\text { width }(D) \leq 1+\left(1+\| \text { out }_{P} \|\right)^{\operatorname{depth}(G)+1} \times\left\|\operatorname{in}_{P}\right\|
$$

To prove that, Corollary 6.5 .2 first aims at bounding the size of any destructor-only asap recipe used in a well-typed witness of equivalence. It relies on the fact that chains of keys that may appear in such a recipe are necessarily bounded thanks to Proposition 6.5.1.

Corollary 6.5.2. Let $P$ be a simple protocol type-compliant w.r.t. a structure-preserving typing system $\left(\mathcal{T}_{P}, \delta_{P}\right)$ with refined dependency graph $G,(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ a pseudo-well-typed trace of $P$. Then if $R$ is an asap recipe with $M$ leaves of $R \phi \downarrow$ and contains only destructors, then $M \leq\left(1+\| \text { out }_{P} \|\right)^{\operatorname{depth}(G)+1}$.

Proof. Uses proof of Proposition 6.5.1. Using the same notations, $M=\left|\bigcup_{j \in \mathbb{N}} K_{i}\right|$. Note that there exists $j_{0}$ such that $\forall j>j_{0}, K_{j}=\emptyset$, and as such this union is indeed finite. Moreover, for any $j \in\left\{1, \ldots, j_{0}\right\}$ and $p \in K_{j}$, there exists $q \in K_{j-1}$ such that $\alpha_{q} \rightarrow \tilde{p} \quad \alpha_{q}$. As such, the labels of the elements of $\bigcup_{j \in \mathbb{N}} K_{j}$ form a subtree of $G$
of root $\alpha_{0}$, and of depth lesser or equal than depth $(G)$. The degree of this subtree is bounded by the number of constructors (and thus the number of encryption layers) in any term of a pseudo-well-typed frame, which is it self bounded by $\|$ out $_{P} \|$. Hence its degree is at most $\|$ out $_{P} \|$, leading to a subtree of size at most $\sum_{k=0}^{\operatorname{depth}(G)} \|$ out $_{P} \|^{k}$ and thus $M \leq\left(1+\| \text { out }_{P} \|\right)^{\operatorname{depth}(G)+1}$.

Having bounded the size of recipes used in our witness of non-equivalence, we can translate it into a bound on the width of the execution graph of this witness, as the maximal size of recipes corresponds to the maximal arity of such a graph; thus providing us with the second step towards the final bound on the length of a minimal witness of non-equivalence.

Lemma 6.5.7. Let $P$ and $Q$ be two simple protocol type-compliant w.r.t. their respective structure-preserving typing systems $\left(\mathcal{T}_{P}, \delta_{P}\right)$ and $\left(\mathcal{T}_{Q}, \delta_{Q}\right)$; and $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ a witness of $P \not \chi^{\prime} Q$ (i.e. the witness is a trace of $P$ without necessarily being a trace of $Q$ ) with execution graph $D$. Then

$$
\operatorname{width}(D) \leq 1+\left(1+\| \text { out }_{P} \|\right)^{\operatorname{depth}(G)+1} \times\left\|\operatorname{in}_{P}\right\|
$$

Proof. The bound comes from Corollary 6.5.2: any term can have at most one sequential predecessor and any asap input recipe of tr is of the form $C\left[R_{1}, \ldots, R_{n}\right]$ where $C$ contains only constructors and for any $i, R_{i}$ has $M_{i}$ leaves and contains only destructors and as such $M_{i} \leq \|$ out $_{P} \|^{\operatorname{depth}(G)}$. Because ( $\left.\operatorname{tr}, \phi\right)$ is pseudo-well-typed, each input from the protocol has at most $\left\|\mathrm{in}_{P}\right\|$ leaves. Hence any action of $D$ can have at most 1 predecessor (for the sequential dependency) and $\|$ out $_{P}\left\|^{\operatorname{depth}(G)} \times\right\|$ in $_{P} \|$ other predecessors for the data dependencies, leading to the desired result.

### 6.5.3 Bounding the length of a minimal witness

To conclude, we need to bound the length of a minimal witness of non-equivalence. We have already seen that we can consider a witness that is asap and pseudo-well-typed, and we have bound the depth and the width of its associated dag. Still, the length of such a trace may be arbitrary long. We now show that we can bound the number of roots (vertices with no ingoing edge) in a minimal witness of non-equivalence.

To do so, we introduce the notion of pruning of a graph w.r.t. some vertices. It intuitively corresponds, for an execution graph, to the retrieving of the causal dependencies required to fire some action.

Definition 6.5.4 (pruning). Given an execution graph $D=(V, E)$ and a set $R$ of roots of $D$, we define the pruning $D_{R}=\left(V_{R}, E_{R}\right)$ of $D$ w.r.t. $R$ as follows:

- $V_{R}=\left\{v \in V \mid \exists r \in R, r \rightarrow^{*} v\right\}$
- $E_{R}=\left\{(u, v) \in E \mid u, v \in V_{R}\right\}$
where $\rightarrow^{*}$ denotes the transitive closure of the relation induced by $E$.
Lemma 6.5 .8 (properties of pruning). Let $P$ be a simple protocol, $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ and $D$ the execution graph of tr w.r.t. $P$. Let $R=\left\{v_{1}, \ldots, v_{p}\right\}$ be a set of nodes of $D$ and $D_{R}$ the pruning of $D$ w.r.t. $R$. Then there exits $\left(\operatorname{tr}_{R}, \phi_{R}\right) \in \operatorname{trace}(P)$ such that:
- $D_{R}$ is the execution graph of $\operatorname{tr}_{R}$ w.r.t. $P$,
- $\operatorname{tr}_{R}$ is a subtrace of $\operatorname{tr}$ and $\phi_{R}$ is a subframe of $\phi$,

Proof. Intuitively, the execution graph captures all the dependencies to execute any vertex/action in the corresponding trace. The closure of $D_{R}$ ensures that any action occurring in $\operatorname{tr}_{R}$ has the needed predecessors.

Lemma 6.5.9. Let $P$ and $Q$ be two simple protocols type-compliant w.r.t. some structure-preserving typing systems $\left(\mathcal{T}_{P}, \delta_{P}\right)$ and $\left(\mathcal{T}_{Q}, \delta_{Q}\right)$, and such that $P \nsubseteq Q$. Let $(\operatorname{tr}, \phi)$ be a witness of non-inclusion which is asap, pseudo-welltyped and with minimal length, and $D$ be its corresponding execution graph. We have that:

$$
\operatorname{nbroot}(D) \leq 2 \times\left(1+\| \text { out }_{P} \|\right)^{\operatorname{depth}(G)+1}
$$

Proof. There are two main reasons of non inclusion.

- Either $Q$ is not able to mimic the last action of the trace tr. In that case, we prune $D$ by selecting only the last action of tr and its (successive) sons.
- Or the resulting frames are not in static equivalence. Consider an equality test $R_{1}=R_{2}$ that witnesses non static equivalence. We show that $R_{1}$ and $R_{2}$ can be chosen to be destructor-only, and we bound the number of recipe variables involved in $R_{1}$ and $R_{2}$ by $\left(1+\| \text { out }_{P} \|\right)^{\text {depth }(G)+1}$. Thus, in this case, we prune $D$ by selecting the actions producing these variables and their successive sons.

More formally, $(\operatorname{tr}, \phi)$ can be of two forms:

- If there exists $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ and $\phi \nsim \psi$. From Lemma A.1.13, any meaningful test to distinguish between two frames is always made of two destructor-only recipes $R$ and $R^{\prime}$ such that, for instance, $R \phi \downarrow=R^{\prime} \phi \downarrow$ while $R \psi \downarrow \neq R^{\prime} \psi \downarrow$. Thus only twice as many variables as the number of leaves in such a recipe are needed in the frames to distinguish between them. Such recipes have at most $\left(1+\left\|\operatorname{out}_{P}\right\|\right)^{\text {depth }(G)+1}$ leaves as per Corollary 6.5.2. Thus by selecting those $2 \times\left(1+\| \text { out }_{P} \|\right)^{\text {depth }(G)+1}$ variables (as there are two recipes) in $\phi$ and pruning $D$ w.r.t. these, we obtain $\left(\operatorname{tr}_{0}, \phi_{0}\right)$ which is both a trace of $P$ and $Q$ (by Lemma 6.5.8) and such that $\phi_{0}\left(\right.$ resp $\left.\psi_{0}\right)$ is a subframe of $\phi$ (resp. $\psi$ ) such that $\operatorname{dom}(R) \cup \operatorname{dom}\left(R^{\prime}\right) \subseteq \operatorname{dom}\left(\phi_{0}\right)$ (resp. $\left.\operatorname{dom}(R) \cup \operatorname{dom}\left(R^{\prime}\right) \subseteq \operatorname{dom}\left(\psi_{0}\right)\right)$. Thus $R \phi \downarrow=R \phi_{0} \downarrow, R^{\prime} \phi \downarrow=R^{\prime} \phi_{0} \downarrow, R \psi \downarrow=R \psi_{0} \downarrow$ and $R^{\prime} \psi \downarrow=R^{\prime} \psi_{0} \downarrow$, leading to $R \phi_{0} \downarrow=R^{\prime} \phi_{0} \downarrow$ and $R \psi_{0} \downarrow \neq R^{\prime} \psi_{0} \downarrow$, and witnessing $\phi_{0} \nsim \psi_{0}$.
- Or $(\operatorname{tr}, \psi) \notin \operatorname{trace}(Q)$ for any $\psi$. There exists an action a of tr which cannot be executed in $Q$. Let us prune tr w.r.t. this single action. We obtain $\left(\operatorname{tr}_{0}, \phi_{0}\right)$ which is a trace of $P$ (by Lemma 6.5.8) and such that for any $\psi_{0}$, $\left(\operatorname{tr}, \psi_{0}\right) \notin \operatorname{trace}(Q)$ as Lemma 6.5 .8 ensures the execution steps of $\operatorname{tr}_{0}$ through are unchanged compared to the corresponding actions in tr. Consequently, in this case, we need only to consider only one root.

Putting the two bounds together, we need at most $2 \times\left(1+\| \text { out }_{P} \|\right)^{\operatorname{depth}(G)+1}$ roots in $D$ to get a witness of $P \nsubseteq Q$.
In conclusion, we have bound the (minimal) length of a witness of non equivalence. This, in turn, bounds the number of sessions. We then conclude using e.g. Chapter 5 since trace equivalence is decidable for a bounded number of sessions. Since trace equivalence is NP for a bounded number of sessions [12], we deduce decidability in triple exponential time, in the size of the protocols.

Theorem 6.3.1. The problem of deciding whether two simple protocols $P$ and $Q$, type-compliant w.r.t. some structurepreserving typing systems $\left(\mathcal{T}_{P}, \delta_{P}\right)$ and $\left(\mathcal{T}_{Q}, \delta_{Q}\right)$, and with acyclic refined dependency graphs obtained relying on appropriate markings $\mathcal{M}_{P}$ and $\mathcal{M}_{Q}$ are trace equivalence (i.e. $P \approx Q$ ) is decidable.

Proof. Suppose $P \not \not \approx Q$. By Lemma 6.5.2, $P \not \not \not \boldsymbol{z}^{\prime} Q$. Two cases occur, depending on whether the witness of nonequivalence is a trace of $P$ or $Q$ (see Definition 6.5.2). In the first case, as the witness is asap and pseudo-well-typed, we can apply Corollary 6.5.1, Lemma 6.5.7 and Lemma 6.5 .9 to respectively obtain a bound on the depth, the width and the number of roots for the execution graph corresponding to this witness. Let $G_{P}$ (resp. $G_{Q}$ ) be the (refined) dependency graph of $P\left(\operatorname{resp} . G_{Q}\right)$. Thus, we get a bound on the length $A$ of such a minimal witness:

$$
2\left(1+\| \text { out }_{P} \|\right)^{\operatorname{depth}\left(G_{P}\right)+1}\left(1+\left\|\operatorname{in}_{P}\right\|\left(1+\| \text { out }_{P} \|\right)^{\operatorname{depth}\left(G_{P}\right)+1}\right)^{\operatorname{depth}\left(G_{P}\right)+1}
$$

The second case is handled symmetrically, leading to a bound $B$ on the size of a witness in trace $(Q)$ :

$$
2\left(1+\| \text { out }_{Q} \|\right)^{\operatorname{depth}\left(G_{Q}\right)+1}\left(1+\| \text { in }_{Q} \|\left(1+\| \text { out }_{Q} \|\right)^{\operatorname{depth}\left(G_{Q}\right)+1}\right)^{\operatorname{depth}\left(G_{Q}\right)+1}
$$

Hence a witness of $P \not \approx Q$ has length at $\operatorname{most} \max (A, B)$. We conclude by invoking a decidability result for a bounded number of sessions such as Theorem 5.1.1.

### 6.6 Conclusion

We have obtained the first decidability result for trace equivalence, for an unbounded number of sessions and unrestricted nonces.

Generating a structure-preserving typing system (actually the more fine-grained one) for which type-compliance is satisfied, and checking acyclicity of the resulting dependency graph is not difficult but rather cumbersome. We plan to devise a script to perform these steps automatically. We also plan to study how to relax some of our assumptions. First, we think that the "simple protocols" assumption could be relaxed to consider action-determinate protocols. Second, we plan to investigate other criteria to soundly remove edges in the dependency graph, in order to get rid of meaningless cycles. Lastly, our result applies only to protocols with concatenation and symmetric encryption. We inherit this restriction from Chapter 4 . We believe that once the typing result of Chapter 4 is extended to all standard primitives then our decidability result will extend as well.

The current complexity of our result is too high to use existing tools that decide trace equivalence for a bounded number of sessions (they typically handle up to 2-3 sessions). However, since our result bounds quite precisely the form of a minimal attack, it seems possible to improve its complexity and to use model-checkers instead.

Our decidability result intuitively encompasses decidability of secrecy, expressed as a trace property, since secrecy can be encoded using trace equivalence. We believe that our proof technique could be applied to decide authentication properties as well, for which we are not aware of any decidability result. The main difficulty induced by authentication properties is that authentication implicitly introduces disequalities (there might be an attack because agent $B$ received a message different from the one sent by agent $A$ ). However, deciding trace equivalence also requires a careful treatment of disequalities. As future work, we plan to formally apply our technique to obtain decidability of a fragment of trace properties that encompasses secrecy and authentication.

## Chapter 7

## Decidability of trace equivalence for ping-pong protocols

In this chapter, we study the decidability of a class of protocols for which trace equivalence is decidable. As secrecy is already undecidable in general, we therefore focus on a class of protocols for which secrecy is decidable [31]. This class, called ping-pong protocols, typically assumes that each protocol rule manipulates at most one variable and that the protocol is formed of a set of independent in/out rules. Intuitively, this corresponds to the assumption that, at each step of the protocol, upon receiving a message there is at most one part of it that is unknown to the agent (typically a key, a nonce, or an encrypted packet).

Surprisingly, while this class is decidable for reachability, even a fragment of it (with only symmetric encryption) turns out to be undecidable for equivalence properties. We consequently further assume our protocols to be deterministic (that is, given an input, there is at most one possible output). We show that equivalence is decidable for an unbounded number of sessions and for protocols with randomised symmetric and asymmetric encryption, and signatures. Since we need to assume our constructors to be randomised and since we assume "at most one variable", we can only handle a very limited notion of (randomised) concatenation that appends atomic values.

Interestingly, we show that checking for equivalence of protocols actually amounts into checking equality of languages of deterministic pushdown automata. The decidability of equality of languages of deterministic pushdown automata is a difficult problem, shown to be decidable [62]. We actually characterise equivalence of protocols in terms of equivalence of deterministic generalised real-time pushdown automata, that is deterministic pushdown automata with no epsilon-transition but such that the automata may unstack several symbols at a time. More precisely, we show how to associate to a process $P$ an automata $\mathcal{A}_{P}$ such that two processes are equivalent if, and only if, their corresponding automata yield the same language and, reciprocally, we show how to associate to an automata $\mathcal{A}$ a process $P_{\mathcal{A}}$ such that two automata yield the same language if, and only if, their corresponding processes are equivalent, that is:

$$
P \approx Q \Leftrightarrow L\left(\mathcal{A}_{P}\right)=L\left(\mathcal{A}_{Q}\right) \quad \text { and } \quad L(\mathcal{A})=L(\mathcal{B}) \Leftrightarrow P_{\mathcal{A}} \approx P_{\mathcal{B}}
$$

Therefore, checking for equivalence of protocols is as difficult as checking equivalence of deterministic generalised real-time pushdown automata.

To transform equivalence of processes into equivalence of pushdown automata, we first show how to get rid of an active attacker. More precisely, we show that

$$
P \approx Q \Leftrightarrow P^{\prime} \approx_{\mathrm{fwd}} Q^{\prime}
$$

where $\approx_{f w d}$ intuitively represents equivalence of processes when the attacker may only forward messages. This equivalence is obtained by partially encoding the attacker in $P^{\prime}$ and $Q^{\prime}$, still preserving equivalence.

The decision procedure for checking equivalence of deterministic pushdown automata has been recently implemented by G. Sénizergues [50]. We have therefore implemented our transformation from processes to pushdown automata, yielding the first tool that decides equivalence of (some class of) protocols for an unbounded number of sessions. As an application, we have analysed several protocols of the literature, including a simplified version of the basic access control protocol (BAC) of the biometric passport [52].

We characterise the notion of ping-pong protocols in Section 7.1 and state our main results. Sections 7.2 and 7.3 are devoted to decidability. More precisely, we show in Section 7.2 how to get rid of an active attacker by encoding it directly in the process. Next, we show in Section 7.3 how to encode equivalence between processes (in presence of a forwarder attacker) into equivalence of pushdown automata, characterising further which cases may result in non equivalence. Finally, we study in Section 7.4 the converse translation and show that equivalence of pushdown automata can be reduced to equivalence of protocols. We present our implementation and its application to protocols in Section 7.5. Concluding remarks can be found in Section 7.6.

### 7.1 Ping-pong protocols

We aim at providing a decidability result for the problem of trace equivalence between protocols in presence of replication. However, it is well-known that replication leads to undecidability even for the simple case of reachability properties. Thus, we consider a class of protocols, called $\mathcal{C}_{\mathrm{pp}}$, for which (in a slightly different setting), reachability has already been proved decidable [31].

### 7.1.1 Term algebra

In order to express the results of the chapter, we introduce a variation of our term algebra, compared to one detailed in Chapter 2. In particular, we consider a signature which can be seen as an instance of our original one, with sorts attached to terms. Moreover, we do not consider pairing, and focus on randomised encryption with atomic keys. Other definitions, such as the process algebra and semantics, stay as described in Chapter 2.

As usual, messages are represented by terms. More specifically, we consider a sorted signature with six sorts rand, key, msg, SymKey, PrivKey and PubKey that represent respectively random numbers, keys, messages, symmetric keys, private keys and public keys. We assume that msg subsumes the five other sorts, key subsumes SymKey, PrivKey and PubKey. We consider six function symbols senc and sdec, raenc and radec, sign and check that represent symmetric, asymmetric encryption and decryption as well as signatures. Since we are interested in the analysis of indistinguishability properties, we consider a randomised encryption scheme:

| senc: | $\mathrm{msg} \times$ SymKey $\times$ rand $\rightarrow \mathrm{msg}$ | $\mathrm{sdec}:$ | $\mathrm{msg} \times$ SymKey $\rightarrow \mathrm{msg}$ |
| ---: | :--- | ---: | :--- |
| raenc: | $\mathrm{msg} \times$ PubKey $\times$ rand | $\rightarrow \mathrm{msg}$ | radec: |
| sign: | $\mathrm{msg} \times$ PrivKey $\times$ rand $\times$ PrivKey $\rightarrow \mathrm{msg}$ |  |  |
| $\rightarrow \mathrm{msg}$ | check: | $\mathrm{msg} \times$ PubKey $\rightarrow \mathrm{msg}$ |  |

We discuss in Section 7.5 how we can handle a limited notion of (randomised) concatenation.
We further assume an infinite set $\Sigma_{0}$ of constant symbols of sort key or msg, an infinite set $\mathcal{C} h$ of constant symbols of sort channel, two infinite sets of variables $\mathcal{X}, \mathcal{W}$, and an infinite set of names $\mathcal{N}=\mathcal{N}_{\text {pub }} \uplus \mathcal{N}_{\text {priv }}$ of names of sort rand: $\mathcal{N}_{\text {pub }}$ represents the random numbers drawn by the attacker while $\mathcal{N}_{\text {priv }}$ represents the random numbers drawn by the protocol's participants.

As usual, terms are defined as names, variables, and function symbols applied to other terms. We denote by $\mathcal{T}(\mathcal{F}, \mathcal{N}, \mathcal{X})$ the set of terms built on function symbols in $\mathcal{F}$, names in $\mathcal{N}$, and variables in $\mathcal{X}$. We simply write $\mathcal{T}(\mathcal{F}, \mathcal{N})$ when $\mathcal{X}=\emptyset$. We consider three particular signatures:

$$
\begin{gathered}
\Sigma_{\text {pub }}=\{\text { senc, sdec, raenc, radec, sign, check, start }\} \\
\Sigma^{+}=\Sigma_{\text {pub }} \cup \Sigma_{0} \quad \Sigma=\{\text { senc, raenc, sign, start }\} \cup \Sigma_{0}
\end{gathered}
$$

where start $\notin \Sigma_{0}$ is a constant symbol of sort msg. The signature $\Sigma_{\text {pub }}$ represents the functions/data available to the attacker, including a constant start used to start sessions of the protocols. The signature $\Sigma^{+}$is the most general signature, while $\Sigma$ models actual messages (with no failed computation). We assume a bijection between elements of sort PrivKey and PubKey. If $k$ is a constant of sort PrivKey, $\mathrm{k}^{-1}$ will denotes its image by this function, called inverse. The inverse of the inverse function is also denoted by ${ }^{-1}$, so that $\left(k^{-1}\right)^{-1}=k$. To keep homogeneous notations, we extend this function to symmetric keys: if $k$ is of sort SymKey, then $k^{-1}=k$. The relation between encryption and decryption is represented through the following rewriting rules, yielding a convergent rewrite system:

$$
\begin{gathered}
\operatorname{sdec}\left(\operatorname{senc}\left(x, \mathrm{k}_{1}, z\right), \mathrm{k}_{1}\right) \rightarrow x \\
\operatorname{radec}\left(\operatorname{raenc}\left(x, \mathrm{k}_{2}, z\right), \mathrm{k}_{2}^{-1}\right) \rightarrow x \quad \operatorname{check}\left(\operatorname{sign}\left(x, \mathrm{k}_{3}, z\right), \mathrm{k}_{3}^{-1}\right) \rightarrow x
\end{gathered}
$$

with $k_{1}$ of sort SymKey, $k_{2}$ of sort PubKey, and $k_{3}$ of sort PrivKey. For instance, the first rule models the fact that the decryption of a ciphertext will return the associated plaintext when the right key is used to perform decryption. The two last rules are used to model asymmetric encryption and signatures. We denote by $t \downarrow$ the normal form of a term $t \in \mathcal{T}\left(\Sigma^{+}, \mathcal{N}, \mathcal{X}\right)$.

Example 7.1.1. We consider a simplified version of the protocol presented in [41]. The purpose of this protocol informally described below is to establish a key $\mathrm{k}_{A B}$ between two participants $A$ and $B$ using public key encryption and signature.

$$
\begin{array}{ll}
\text { 1. } & A \rightarrow B: \quad \text { raenc }\left(\operatorname{sign}\left(\mathrm{k}_{A B}, \mathrm{sk}_{A}, r_{A}^{1}\right), \mathrm{pk}_{B}, r_{A}^{2}\right) \\
\text { 2. } & B \rightarrow A: \text { ack }
\end{array}
$$

The agent $A$ sends a symmetric key $\mathrm{k}_{A B}$ signed with A's private key $\mathrm{sk}_{A}$ (using a fresh random number $r_{A}^{1}$ ), and the resulting ciphertext is encrypted with B 's public key $\mathrm{pk}_{B}$ (using a fresh random number $r_{A}^{2}$ ). The agent $B$ answers to this request by decrypting this message, and verifying the signature. If all checks succeed, $B$ informs the agent $A$ by sending an acknowledgement, i.e. the constant ack. The agents $A$ and $B$ can now use the symmetric key $\mathrm{k}_{A B}$ to communicate.

The role of agent $A$ is modelled by a process $P_{A}$ while the role of agent $B$ is modelled by $P_{B}$. We have that:

$$
\begin{align*}
& P_{A} \stackrel{\text { def }}{=}!\operatorname{in}\left(c_{A}, \text { start }\right) . \text { new } r_{A}^{1} \cdot \operatorname{new} r_{A}^{2} \cdot \operatorname{out}\left(c_{A}, \operatorname{raenc}\left(\operatorname{sign}\left(\mathrm{k}_{A B}, \mathrm{sk}_{A}, r_{A}^{1}\right), \mathrm{pk}_{B}, r_{A}^{2}\right)\right)  \tag{1}\\
&!!\operatorname{in}\left(c_{A}^{\prime}, \text { start }\right) \cdot \text { new } r_{A}^{1} \cdot \operatorname{new} r_{A}^{2} \cdot \operatorname{out}\left(c_{A}^{\prime}, \operatorname{raenc}\left(\operatorname{sign}\left(\mathrm{k}_{A C}, \mathrm{sk}_{A}, r_{A}^{1}\right), \mathrm{pk}_{C}, r_{A}^{2}\right)\right)  \tag{2}\\
& P_{B} \stackrel{\text { def }}{=}!\operatorname{in}\left(c_{B}, \operatorname{raenc}\left(\operatorname{sign}\left(x, \operatorname{sk}_{A}, z_{1}\right), \operatorname{pk}_{B}, z_{2}\right)\right) \cdot \operatorname{out}\left(c_{B}, \operatorname{ack}\right) \tag{3}
\end{align*}
$$

The constants $c_{A}, c_{A}^{\prime}$ and $c_{B}$ are constants of sort channel, ack is a constant of sort msg, whereas the constants $\mathrm{k}_{A B}, \mathrm{k}_{A C}, \mathrm{sk}_{A}, \mathrm{sk}_{B}, \mathrm{sk}_{C}, \mathrm{pk}_{A}, \mathrm{pk}_{B}, \mathrm{pk}_{C}$ which are in $\Sigma_{0}$ are such that:

- $\mathrm{k}_{A B}, \mathrm{k}_{A C}$ are of sort SymKey,
- $\mathrm{sk}_{A}, \mathrm{sk}_{B}, \mathrm{sk}_{C}$ are of sort PrivKey, and
- $\mathrm{pk}_{A}, \mathrm{pk}_{B}, \mathrm{pk}_{C}$ of sort PubKey.

Moreover, we have that $\mathrm{sk}_{X}^{-1}=\mathrm{pk}_{X}$ for $X \in\{A, B, C\}$ whereas $\mathrm{k}_{A B}^{-1}=\mathrm{k}_{A B}$ and $\mathrm{k}_{A C}^{-1}=\mathrm{k}_{A C}$. Finally, $r_{A}^{1}, r_{A}^{2}$ are names of sort rand, and $x$ (resp. $z_{1}, z_{2}$ ) is a variable of sort msg (resp. rand).

Intuitively, $P_{A}$ sends $\mathrm{k}_{A B}$ signed with $\mathrm{sk}_{A}$ and encrypted with $\mathrm{pk}_{B}$ to the agent $B$ (branch 1 ). More generally, the agent $A$ can start different sessions with different agents. Thus, the process $P_{A}$ models the agent $A$ initiating a session with $B$ (branch 1) as well as with $C$ (branch 2). The process $P_{B}$ models the agent $B$ answering a request from $A$. We could also consider the scenario where the agent $B$ is also willing to talk to $C$ or where the initiator, here played by $A$, is also played by other agents such as $B$. We consider here only a simpler case to keep the example reasonably short.

To model the whole protocol, we sent the public key $\mathrm{pk}_{A}, \mathrm{pk}_{B}, \mathrm{pk}_{C}$ in clear, as well as the private key $\mathrm{sk}_{C}$, to model the fact that the attacker may learn the private keys of some corrupted agents. This is modelled through the following process $P_{\text {key }}$ :

$$
\begin{aligned}
P_{\text {key }} \stackrel{\text { def }}{=} & !\operatorname{in}\left(c_{1}, \text { start }\right) . \text { out }\left(c_{1}, \mathrm{pk}_{A}\right) \mid!\operatorname{in}\left(c_{2}, \operatorname{start}\right) . \text { out }\left(c_{1}, \mathrm{pk}_{B}\right) \mid \\
& !\text { in }\left(c_{3}, \text { start }\right) . \operatorname{out}\left(c_{3}, \mathrm{pk}_{C}\right) \mid!\text { in }\left(c_{4}, \operatorname{start}\right) . \text { out }\left(c_{4}, \mathrm{sk}_{C}\right)
\end{aligned}
$$

Then, the whole protocol is given by $P$, where $P_{A}, P_{B}$, and $P_{\text {key }}$ evolve in parallel:

$$
P \stackrel{\text { def }}{=} P_{A}\left|P_{B}\right| P_{\text {key }}
$$

This protocol is actually insecure as demonstrated by the following attack:

$$
\begin{array}{lll}
\text { 1. } & A \rightarrow C: & \text { raenc }\left(\operatorname{sign}\left(\mathrm{k}_{A C}, \mathrm{sk}_{A}, r_{A}^{1}\right), \mathrm{pk}_{C}, r_{A}^{2}\right) \\
2 . & C(A) \rightarrow B: & \text { raenc }\left(\operatorname{sign}\left(\mathrm{k}_{A C}, \mathrm{sk}_{A}, r_{A}^{1}\right), \mathrm{pk}_{B}, r_{C}^{1}\right) \\
3 . & B \rightarrow A: & \text { ack }
\end{array}
$$

$A$ initiates a session with a malicious user $C$ sending him a key $\mathrm{k}_{A C}$. This malicious user then legally learns $\mathrm{k}_{A C}$ but also its signature $\operatorname{sign}\left(\mathrm{k}_{A C}, \mathrm{sk}_{A}, r_{A}^{1}\right)$ under the signing key of $A$. He may then resend this key to $B$ in the name of $A$. The agent $B$ accepts the key $\mathrm{k}_{A C}$ as being a secret key between $A$ and $B$.

This attack can be formalised in our model as follows:

1. The public keys of all the participants are disclosed as well as the secret key $\mathrm{sk}_{C}$ of the corrupted agent $C$.

Formally, let $K_{0} \stackrel{\text { def }}{=}(P ; \emptyset)$, we have that:

$$
K_{0} \xlongequal{\text { in }\left(c_{1}, \text { start }\right) . \text { out }\left(c_{1}, \mathbf{w}_{1}\right) \cdot \operatorname{in}\left(c_{2}, \text { start }\right) . \text { out }\left(c_{2}, \mathbf{w}_{2}\right) \cdot \operatorname{in}\left(c_{3}, \text { start }\right) . \text { out }\left(c_{3}, \mathrm{w}_{3}\right)} \xrightarrow{\xlongequal{\operatorname{in}\left(c_{4}, \operatorname{start}\right) \cdot \text { out }\left(c_{4}, \mathrm{w}_{4}\right)}}\left(P ; \sigma_{0}\right)
$$

where $\sigma_{0}=\left\{\mathrm{w}_{1} \triangleright \mathrm{pk}_{A}, \mathrm{w}_{2} \triangleright \mathrm{pk}_{B}, \mathrm{w}_{3} \triangleright \mathrm{pk}_{C}, \mathrm{w}_{4} \triangleright \mathrm{sk}_{C}\right\}$.
2. The agent $A$ initiates a session with $C$ and sends the corresponding encrypted message. More formally, we have that:

$$
\left(P ; \sigma_{0}\right) \xlongequal{\text { in }\left(c_{A}^{\prime}, \text { start }\right) . \text { out }\left(c_{A}^{\prime}, w_{5}\right)}(P ; \sigma)
$$

where $\sigma=\sigma_{0} \cup\left\{\mathrm{w}_{5} \triangleright \operatorname{raenc}\left(\operatorname{sign}\left(\mathrm{k}_{A C}, \mathrm{sk}_{A}, r_{A}^{1}\right), \mathrm{pk}_{C}, r_{A}^{2}\right)\right\}$ and $r_{A}^{1}, r_{A}^{2}$ are (fresh) names in $\mathcal{N}_{\text {priv. }}$.
Hence, we have that $(\operatorname{tr}, \sigma) \in \operatorname{trace}\left(K_{0}\right)$ where:

$$
\begin{aligned}
\operatorname{tr}= & \operatorname{in}\left(c_{1}, \operatorname{start}\right) . \text { out }\left(c_{1}, \mathrm{w}_{1}\right) \cdot \operatorname{in}\left(c_{2}, \operatorname{start}\right) \cdot \text { out }\left(c_{2}, \mathrm{w}_{2}\right) \cdot \operatorname{in}\left(c_{3}, \operatorname{start}\right) \cdot \text { out }\left(c_{3}, \mathrm{w}_{3}\right) . \\
& \operatorname{in}\left(c_{4}, \operatorname{start}\right) \cdot \operatorname{out}\left(c_{4}, \mathrm{w}_{4}\right) \cdot \operatorname{in}\left(c_{A}^{\prime}, \operatorname{start}\right) \cdot \operatorname{out}\left(c_{A}^{\prime}, \mathrm{w}_{5}\right) .
\end{aligned}
$$

In this execution trace, first the keys $\mathrm{pk}_{A}, \mathrm{pk}_{B}, \mathrm{pk}_{C}$ and $\mathrm{sk}_{C}$ are sent after having called the corresponding process. Then, branch (2) of $P$ is triggered. Going further, our naive protocol is secure if the key received by $B$ remains private. To model this, we modify the process $P_{B}$ as follows:

$$
\begin{array}{lll}
P_{B}^{l} & \stackrel{\text { def }}{=} & !\operatorname{in}\left(c_{B}, \operatorname{raenc}\left(\operatorname{sign}\left(x, \mathrm{sk}_{A}, z_{1}\right), \mathrm{pk}_{B}, z_{2}\right)\right) \cdot \operatorname{out}\left(c_{B}, x\right) \\
P_{B}^{r} & \stackrel{\text { def }}{=} & !\operatorname{in}\left(c_{B}, \operatorname{raenc}\left(\operatorname{sign}\left(x, \mathrm{sk}_{A}, z_{1}\right), \mathrm{pk}_{B}, z_{2}\right)\right) \cdot \operatorname{out}\left(c_{B}, \mathrm{k}\right)
\end{array}
$$

Then, to model secrecy of the key received by $B$, we consider the following equivalence: $P_{A}\left|P_{B}^{l}\right| P_{\text {key }} \approx P_{A}\left|P_{B}^{r}\right|$ $P_{\text {key }}$. An attacker should not distinguish between two instances of the protocol, one where $B$ used the key established through the protocol and one where a magic key k is used instead.

However, our protocol is insecure. An attacker may easily learn $\mathrm{k}_{A C}$, and sends to $B$ a message of the expected form (as if it was issued by $A$ ) and that will contain this corrupted key instead of $\mathrm{k}_{A B}$. Formally, we have that:

$$
P_{A}\left|P_{B}^{l}\right| P_{\text {key }} \not \approx P_{A}\left|P_{B}^{r}\right| P_{\text {key }}
$$

This is reflected by the trace $\operatorname{tr}^{\prime}$ described below:

$$
\operatorname{tr}^{\prime} \stackrel{\text { def }}{=} \operatorname{tr} . \operatorname{in}\left(c_{B}, \operatorname{raenc}\left(\operatorname{radec}\left(\mathrm{w}_{5}, \mathrm{sk}_{C}\right), \mathrm{w}_{2}, r_{C}\right)\right) . \operatorname{out}\left(c_{B}, \mathrm{w}_{6}\right)
$$

where $r_{C}$ is a name in $\mathcal{N}_{\text {pub }}$.
We have that $\left(\operatorname{tr}^{\prime}, \sigma_{1}\right) \in \operatorname{trace}\left(K_{0}\right)$ with $K_{0}=\left(P_{A}\left|P_{B}^{l}\right| P_{\text {key }} ; \sigma_{1}\right)$ where $\sigma_{1}$ is defined below. Because of the existence of only one branch using each channel, there is only one possible execution of $P_{A}\left|P_{B}^{r}\right| P_{\text {key }}$ (up to a bijective renaming of the private names of sort rand) matching the labels in $\mathrm{tr}^{\prime}$, and the corresponding execution will allow us to reach the frame $\sigma_{2}$ as described below:

1. $\sigma_{1} \stackrel{\text { def }}{=} \sigma_{0} \cup\left\{\mathrm{w}_{5} \triangleright \operatorname{raenc}\left(\operatorname{sign}\left(\mathrm{k}_{A C}, \mathrm{sk}_{A}, r_{A}^{1}\right), \mathrm{pk}_{C}, r_{A}^{2}\right), \mathrm{w}_{6} \triangleright \mathrm{k}_{A C}\right\}$,
2. $\sigma_{2} \stackrel{\text { def }}{=} \sigma_{0} \cup\left\{\mathrm{w}_{5} \triangleright \operatorname{raenc}\left(\operatorname{sign}\left(\mathrm{k}_{A C}, \mathrm{sk}_{A}, r_{A}^{1}\right), \mathrm{pk}_{C}, r_{A}^{2}\right), \mathrm{w}_{6} \triangleright \mathrm{k}\right\}$.
where k is a (private) constant in $\Sigma_{0}$. We have that $\sigma_{1} \nsim \sigma_{2}$. Indeed, consider the recipes $R_{1}=\operatorname{check}\left(\operatorname{radec}\left(\mathrm{w}_{5}, \mathrm{w}_{4}\right), \mathrm{w}_{1}\right)$ and $R_{2}=\mathrm{w}_{6}$. We have that $R_{1} \sigma_{1} \downarrow=R_{2} \sigma_{1} \downarrow=\mathrm{k}_{A C}$, whereas $R_{1} \sigma_{2} \downarrow=\mathrm{k}_{A C}$ and $R_{2} \sigma_{2} \downarrow=\mathrm{k}$ thus $R_{1} \sigma_{2} \downarrow \neq R_{2} \sigma_{2} \downarrow$. Hence $\sigma_{1} \nsim \sigma_{2}$ and $P_{A}\left|P_{B}^{l}\right| P_{\text {key }} \not \approx P_{A}\left|P_{B}^{r}\right| P_{\text {key }}$.

### 7.1.2 Class $\mathcal{C}_{\mathrm{pp}}$

We basically consider ping-pong protocols (an output is computed using only the message previously received in input), and we assume a kind of determinism. Moreover, we restrict the terms that are manipulated throughout the protocols: only one unknown message (modelled by the use of a variable of sort msg ) can be received at each step.

We fix a variable $x \in \mathcal{X}$ of sort msg. An input term (resp. output term) is a term defined by the grammars given below:

$$
u:=x|\mathrm{~s}| \mathrm{f}(u, \mathrm{k}, z) \quad v:=x|\mathrm{~s}| \mathrm{f}(v, \mathrm{k}, r)
$$

where $\mathrm{s}, \mathrm{k} \in \Sigma_{0} \cup\{$ start $\}, z \in \mathcal{X}, \mathrm{f} \in\{$ senc, raenc, $\operatorname{sign}\}$ and $r \in \mathcal{N}$. Intuitively, no destructor should be used explicitly. Moreover, we assume that each variable (resp. name) occurs at most once in $u$ (resp. $v$ ).

Definition 7.1.1. $\mathcal{C}_{\mathrm{pp}}$ is the class of protocol of the form:

$$
P=\left.\left.\right|_{i=1} ^{n}\right|_{j=1} ^{p_{i}}!\operatorname{in}\left(c_{i}, u_{i}^{j}\right) \text {.new } r_{1} \ldots \ldots \text { new } r_{k_{j}^{i}} . \text { out }\left(c_{i}, v_{i}^{j}\right)
$$

such that:

1. for all $i \in\{1, \ldots, n\}$, and $j \in\left\{1, \ldots, p_{i}\right\}, k_{i}^{j} \in \mathbb{N}, u_{i}^{j}$ is an input term, and $v_{i}^{j}$ is an output term where names occurring in $v_{i}^{j}$ are included in $\left\{r_{1}, \ldots, r_{k_{i}^{j}}\right\}$;
2. for all $i \in\{1, \ldots, n\}$, and $j_{1}, j_{2} \in\left\{1, \ldots, p_{i}\right\}$, if $j_{1} \neq j_{2}$ then for any renaming of variables, $u_{i}^{j_{1}}$ and $u_{i}^{j_{2}}$ are not unifiable ${ }^{1}$.

Each subprocess in $\left(c_{i}, u_{i}^{j}\right)$.new $r_{1} \ldots$. new $r_{k_{j}^{i}}$. out $\left(c_{i}, v_{i}^{j}\right)$ is called a branch of $P$.

[^0]Item $l$ holds for any process representing a protocol: the variables of the output should be bound by the input. Item 2 enforces a deterministic behaviour: a particular input action can only be accepted by one branch of the protocol. This is a natural restriction since most of the protocols are indeed deterministic: an agent should usually know exactly what to do once he has received a message. Actually, the main limitations of the class $\mathcal{C}_{\mathrm{pp}}$ is that we consider a restricted signature (e.g. no pair, no hash function), and names can only be used to produce randomised ciphertexts.

Example 7.1.2. The protocols described in Example 7.1.1 are in $\mathcal{C}_{\mathrm{pp}}$. For instance, we can check that:

- $\operatorname{raenc}\left(\operatorname{sign}\left(x, \mathrm{sk}_{A}, z_{1}\right), \mathrm{pk}_{B}, z_{2}\right)$ is an input term, and
- $\operatorname{raenc}\left(\operatorname{sign}\left(\mathrm{k}_{A B}, \mathrm{sk}_{A}, r_{A}^{1}\right), \mathrm{pk}_{B}, r_{A}^{2}\right)$ is an output term.

Moreover, the determinism condition (item 2) is clearly satisfied: each branch of the protocol $P_{A}\left|P_{B}^{l}\right| P_{\text {key }}$ (resp. $P_{A}\left|P_{B}^{r}\right| P_{\text {key }}$ ) uses a different channel.

When studying trace equivalence (or even trace inclusion) we can even safely force a process to perform an input action followed directly by its associated output action.

We consider a set of "big-step" traces, defined as follows.

$$
\operatorname{trace}^{\mathrm{i} * *}(K)=\left\{\begin{array}{l|l}
(\operatorname{tr}, \sigma) & \begin{array}{c}
K \underset{\text { with } \operatorname{tr} \text { sequence of input-output blocks. }}{\mathrm{tr}}(\mathcal{P} ; \sigma) \text { for some configuration }(\mathcal{P} ; \sigma)
\end{array}
\end{array}\right\}
$$

The notion of trace inclusion (resp. trace equivalence) w.r.t. big-step traces is defined accordingly.
Definition 7.1.2. Let $P$ and $Q$ be two protocols. We have that $P \sqsubseteq^{\mathrm{i} 0 *} Q$ if for every $(\operatorname{tr}, \sigma) \in \operatorname{trace}^{\mathrm{i} * *}(P)$, there exists $\left(\operatorname{tr}^{\prime}, \sigma^{\prime}\right) \in \operatorname{trace}{ }^{\mathrm{io} *}(Q)$ such that $\operatorname{tr}=\operatorname{tr}^{\prime}$ and $\sigma \sim \sigma^{\prime}$. They are trace equivalent, written $P \approx^{\text {io* }} Q$, if $P \sqsubseteq^{\text {io* }} Q$ and $Q \sqsubseteq \sqsubseteq^{\text {io* }} P$.

Due to the form of protocols in $\mathcal{C}_{\mathrm{pp}}$, any trace made up of inputs and outputs actions can be first completed with all the available output actions, and then be mapped to a trace that is made up of input-output blocks only. Thus, we have that the two notions of trace equivalence coincide.

Proposition 7.1.1. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}$. We have that $P \sqsubseteq^{\text {io* }} Q$ if, and only if, $P \sqsubseteq Q$.
This proposition easily follows from that fact that for any process of $\mathcal{C}_{\mathrm{pp}}$, any input is immediately followed by an output.

### 7.1.3 Main results

Our first main contribution is a decision procedure for trace equivalence of processes in $\mathcal{C}_{\mathrm{pp}}$.
Theorem 7.1.1. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}$. The problem whether $P$ and $Q$ are trace equivalent, i.e. $P \approx Q$, is decidable.

Deciding trace equivalence is done in two main steps.

1. First, we show how to reduce trace equivalence between protocols in $\mathcal{C}_{\mathrm{pp}}$, to the problem of deciding trace equivalence (still between protocols in $\mathcal{C}_{\mathrm{pp}}$ ) when the attacker acts as a forwarder, that is, when the attacker may only forward messages obtained through the protocol. This step is detailed in Section 7.2.
2. Then, we encode the problem of deciding trace equivalence for forwarding attackers into the problem of language equivalence for real-time generalised pushdown deterministic automata (GPDA), that is, deterministic pushdown automata with no epsilon-transition but such that the automata may unstack several symbols at a time. This step is detailed in Section 7.3

We also provide an implementation of our translation from protocols to pushdown automata, yielding a tool for automatically checking equivalence of security protocols, for an unbounded number of sessions. This contribution is described in Section 7.5.

Actually, we characterise equivalence of protocols in terms of equivalence of GPDA. Indeed, Step (2) above shows how to associate to a process $P$ an automata $\mathcal{A}_{P}$ such that two processes are equivalent if, and only if, their corresponding automata yield the same language. Conversely, we also show how to associate to an automata $\mathcal{A}$ a process $P_{\mathcal{A}}$ such that two automata yield the same language if, and only if, their corresponding processes are equivalent. This reverse encoding, from pushdown automata to protocols is explained in Section 7.4.

Our second contribution is an undecidability result. The class $\mathcal{C}_{\mathrm{pp}}$ is somewhat limited but extending $\mathcal{C}_{\mathrm{pp}}$ to non deterministic processes immediately yields undecidability of trace equivalence. More precisely, we have that trace inclusion of processes in $\mathcal{C}_{\mathrm{pp}}$ is undecidable.

Theorem 7.1.2. The following problem is undecidable.
Input $P$ and $Q$ two protocols in $\mathcal{C}_{\mathrm{pp}}$.
Output Whether $P$ is trace included in $Q$, i.e. $P \sqsubseteq Q$.
A direct encoding of the Post Correspondence Problem (PCP) into an inclusion of two protocols of this class is given in Appendix B.1. Alternatively, this undecidability result is also a consequence of the reduction result established in Section 7.4 and the undecidability result established in [46]. Nonetheless, we present in Appendix B. 1 the direct encoding of PCP into protocol equivalence since some ideas might be reused to show undecidability of trace equivalence for some other classes whereas the alternative proof required a first encoding to transform a protocol into a pushdown automaton.

Undecidability of trace inclusion actually implies undecidability of trace equivalence as soon as processes are non deterministic. Indeed consider the choice operator + whose (standard) semantics is given by the following rules:

$$
(\{P+Q\} \cup \mathcal{P} ; \sigma) \xrightarrow{\tau}(P \cup \mathcal{P} ; \sigma) \quad(\{P+Q\} \cup \mathcal{P} ; \sigma) \xrightarrow{\tau}(Q \cup \mathcal{P} ; \sigma)
$$

Corollary 7.1.1. Let $P, Q_{1}$, and $Q_{2}$ be three protocols in $\mathcal{C}_{\mathrm{pp}}$. The problem whether $P$ is equivalent to $Q_{1}+Q_{2}$, i.e. $P \approx Q_{1}+Q_{2}$, is undecidable.

Indeed, consider $P$ and $Q_{1}$, for which trace inclusion encodes PCP, and let $Q_{2}=P$. Trivially, $P \sqsubseteq Q_{1}+Q_{2}$. Thus $P \approx Q_{1}+Q_{2}$ if, and only if, $Q_{1}+Q_{2} \sqsubseteq P$, i.e. if, and only if, $Q_{1} \sqsubseteq P$, hence the undecidability result.

### 7.2 Getting rid of the full attacker

We show in this section how to reduce trace equivalence between protocols in $\mathcal{C}_{\mathrm{pp}}$ to the problem of deciding trace equivalence (still between protocols in $\mathcal{C}_{\mathrm{pp}}$ ) when the attacker acts as a forwarder, that is, when the attacker may only forward messages obtained through the protocols. This new semantics induced a new notion of trace equivalence, denoted $\approx_{f w d}$, which is formally defined in Section 7.2.1.

To counterbalance the effects of this simple forwarder semantics, the key idea consists in modifying the protocols under study by adding new rules that encrypt and decrypt messages on demand for the forwarder. Formally, we define a transformation $\mathcal{T}_{\text {fwd }}$ (see Section 7.2.2) that associates to a pair of protocols in $\mathcal{C}_{\mathrm{pp}}$ a finite set of pairs of protocols (still in $\mathcal{C}_{\mathrm{pp}}$ ), and we show the following result:

Proposition 7.2.1. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}$. We have that:

$$
P \approx Q \text { if, and only if, } P^{\prime} \approx_{\text {fwd }} Q^{\prime} \text { for some }\left(P^{\prime}, Q^{\prime}\right) \in \mathcal{T}_{\text {fwd }}(P, Q)
$$

$$
\begin{aligned}
& (\operatorname{in}(c, u) . P \cup \mathcal{P} ; \sigma) \xrightarrow{\text { in }(c, R)_{\text {fwd }}}(P \theta \cup \mathcal{P} ; \sigma) \\
& \text { where } R \in\{\text { start }\} \cup \mathcal{W} \text { and } R \sigma \downarrow=u \theta \text { for some } \theta \\
& \text { (out }(c, u) . P \cup \mathcal{P} ; \sigma) \xrightarrow{\text { out }\left(c, \mathrm{w}_{i+1}\right)}{ }_{\text {fwd }}\left(P \cup \mathcal{P} ; \sigma \cup\left\{\mathrm{w}_{i+1} \triangleright u\right\}\right) \\
& \text { where } i \text { is the number of elements in } \sigma \\
& (!P \cup \mathcal{P} ; \sigma) \xrightarrow{\tau}_{\mathrm{fwd}}(P \cup!P \cup \mathcal{P} ; \sigma) \\
& \text { (new } n . P \cup \mathcal{P} ; \sigma) \xrightarrow{\tau} \text { fwd }\left(P\left\{n^{\prime} / n\right\} \cup \mathcal{P} ; \sigma\right) \quad \text { where } n^{\prime} \text { is a fresh name in } \mathcal{N}_{\text {priv }}
\end{aligned}
$$

Figure 7.1: Semantics for a forwarder attacker.

### 7.2.1 Forwarder semantics

We first define the actions of a forwarder by modifying our semantics. Roughly, we restrict the recipes $R, R_{1}$, and $R_{2}$ that are used in the In rule and in static equivalence (Definition 2.4.1) to be either the public constant start or a variable in $\mathcal{W}$. Intuitively, this corresponds to the fact that the forwarder attacker should no longer build a message on his own. This leads us to consider a new relation $\rightarrow_{\text {fwd }}$ between configurations which is the relation induced by the rules described in Figure 7.1.

The relations $\xrightarrow{\mathrm{tr}}_{\mathrm{fwd}}$ and $\stackrel{\mathrm{tr}}{\Longrightarrow}_{\text {fwd }}$ between configurations where tr is a sequence of actions (resp. observable actions) are defined as expected. For every configuration $K$, we define its set of traces w.r.t. the forwarder semantics as follows:

$$
\operatorname{trace}_{\mathrm{fwd}}(K)=\left\{(\operatorname{tr}, \sigma) \left\lvert\, \begin{array}{l|l}
\underset{\text { with }}{\mathrm{tr}} & \mathrm{P} \text { sequence of input-output blocks. }
\end{array}\right.\right\}
$$

We need also to adapt our notion of static equivalence.
Definition 7.2.1. Two frames $\sigma_{1}$ and $\sigma_{2}$ are statically equivalent w.r.t. the forwarder semantics, denoted $\sigma_{1} \sim_{\text {fwd }} \sigma_{2}$, when we have that $\operatorname{dom}\left(\sigma_{1}\right)=\operatorname{dom}\left(\sigma_{2}\right)$, and for all recipes $R_{1}$ and $R_{2}$ in $\{$ start $\} \cup \mathcal{W}$, we have that $R_{1} \sigma_{1}=R_{2} \sigma_{1}$ if, and only if, $R_{1} \sigma_{2}=R_{2} \sigma_{2}$.

This induces a new notion of trace equivalence which is formally defined as follows:
Definition 7.2.2. Let $P$ and $Q$ be two protocols. We have that $P \sqsubseteq_{\text {fwd }} Q$ if for every $(\operatorname{tr}, \sigma) \in \operatorname{trace} \mathrm{f}_{\mathrm{fwd}}(P)$, there exists $\left(\operatorname{tr}^{\prime}, \sigma^{\prime}\right) \in \operatorname{trace}_{\mathrm{fwd}}(Q)$ such that $\operatorname{tr}=\operatorname{tr}^{\prime}$ and $\sigma \sim_{\mathrm{fwd}} \sigma^{\prime}$. They are trace equivalent w.r.t. the forwarder semantics, written $P \approx_{\mathrm{fwd}} Q$, if $P \sqsubseteq_{\mathrm{fwd}} Q$ and $Q \sqsubseteq_{\mathrm{fwd}} P$.

Example 7.2.1. The trace exhibited in Example 7.1.1 is still a valid one according to the forwarder semantics, but the frames $\sigma_{1}$ and $\sigma_{2}$ are now in equivalence w.r.t. $\sim_{\text {fwd }}$. Actually, we have that $P_{A}\left|P_{B}^{l}\right| P_{\text {key }} \approx_{\text {fwd }} P_{A}\left|P_{B}^{r}\right| P_{\text {key }}$. Indeed, the fact that a forwarder simply acts as a relay prevents him to mount the aforementioned attack.

### 7.2.2 Towards a forwarder attacker

As illustrated in Example 7.2.1, the forwarder semantics is very restrictive: a forwarder cannot rely on his deduction capabilities to mount an attack. We show however that we can still restrict ourselves to trace equivalence w.r.t. a forwarder.

Intuitively, we transform any two processes $P, Q$ into processes $\bar{P}, \bar{Q}$ such that $P \approx Q$ if and only if $\bar{P} \approx_{\text {fwd }} \bar{Q}$. Roughly this transformation consists in two steps.

1. First, we guess among the keys of the protocols $P$ and the keys of the protocols $Q$ those that are deducible by the attacker, as well as a bijection $\alpha$ between these two sets. We can show that such a bijection necessarily exists when $P \approx Q$.
2. Then, to compensate the fact that the attacker is a simple forwarder, we give him access to encryption/decryption oracles for any deducible key k , adding branches in the processes.

To maintain the equivalence, we do a similar transformation in both $P$ and $Q$ relying on the bijection $\alpha$. We ensure that the set of deducible keys has been correctly guessed by adding of some extra processes. Then the main step of the proof consists of showing that the forwarder has now the same power as a full attacker, even though he cannot reuse the same randomness in two distinct encryptions, as a real attacker could.

Example 7.2.2. To better illustrate this section, we consider a variant of the processes introduced in Section 7.1., where agent $A$ is now willing to talk only to $B$.

$$
P \stackrel{\text { def }}{=} P_{A}^{\prime}\left|P_{B}^{l}\right| P_{\text {key }} \quad Q \stackrel{\text { def }}{=} P_{A}^{\prime}\left|P_{B}^{r}\right| P_{\text {key }}
$$

where $P_{B}^{l}, P_{B}^{r}$ are defined in Example 7.1.1 and $P_{\text {key }}$ is defined in Example 7.1.1, whereas $P_{A}^{\prime}$ is defined as follows (only the first branch of $P_{A}$ )

$$
P_{A}^{\prime} \stackrel{\text { def }}{=}!\text { in }\left(c_{A}, \text { start }\right) \text {.new } r_{A}^{1} \text {.new } r_{A}^{2} \text {. out }\left(c_{A}, \text { raenc }\left(\operatorname{sign}\left(\mathrm{k}_{A B}, \mathrm{sk}_{A}, r_{A}^{1}\right), \mathrm{pk}_{B}, r_{A}^{2}\right)\right)
$$

This scenario excludes the aforementioned attack and we have that $P \approx Q$. This has been formally checked using our prototype (see Section 7.5).

## Guessing deducible keys

The purpose of this section is to restrict our attention to protocols that explicitly disclose their deducible keys $\mathcal{K}_{P}$ and $\mathcal{K}_{Q}$. Since we do not want to rely on a particular procedure for computing these two sets, the idea is to guess a possibly superset of each set, namely $K$ and $K^{\prime}$, and then ensure that these sets $K$ and $K^{\prime}$ contain at least the deducible keys.

Definition 7.2.3. Let $P$ be a protocol in $\mathcal{C}_{\mathrm{pp}}$. A term $t$ is deducible in $P$ if there exists a trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ and a recipe $R\left(\right.$ i.e. a term in $\mathcal{T}\left(\Sigma_{\text {pub }}, \mathcal{N}_{\text {pub }}, \mathcal{W}\right)$ ) such that $R \phi \downarrow=t$.

Example 7.2.3. Continuing Example 7.2.2, we have that $P$ and $Q$ are in $\mathcal{C}_{\mathrm{pp}}$. It is easy to notice that $\mathrm{k}_{A B}$ is deducible in $P$ whereas k is deducible in $Q$ since these keys are revealed at the end of $B$ 's execution. For both $P$ and $Q$, the trace $\operatorname{tr}=\operatorname{in}\left(c_{A}\right.$, start $)$.out $\left(c_{A}, \mathrm{w}_{1}\right) . \operatorname{in}\left(c_{B}, \mathrm{w}_{1}\right)$.out $\left(c_{B}, w_{2}\right)$ and the recipe $R=\mathrm{w}_{2}$ is a witness of this fact.

Two equivalent processes have the same set of deducible keys, up to some bijective renaming.
Lemma 7.2.1. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}, \mathcal{K}_{P}$ (resp. $\mathcal{K}_{Q}$ ) be the set of deducible constants of sort key that occur in $P$ (resp. $Q$ ), if $P \approx Q$ then there exists a unique bijection $\alpha$ from $\mathcal{K}_{P}$ to $\mathcal{K}_{Q}$ such that for every trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ there exists a trace $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ such that for any recipe $R$ and any $\mathrm{k} \in \mathcal{K}_{P}$ :

- $R \phi \downarrow$ is of sort s if, and only if, $R \psi \downarrow$ is of sort s;
where $s \in\{$ SymKey, PubKey, PrivKey $\}$.
- $R \phi \downarrow=\mathrm{k}$ if, and only if, $R \psi \downarrow=\alpha(\mathrm{k})$;
- $R \phi \downarrow=\mathrm{k}^{-1}$ if, and only if, $R \psi \downarrow=(\alpha(\mathrm{k}))^{-1}$;
and conversely, for every $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ there exists a trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ satisfying the same properties.
Proof. (sketch) The relation $\alpha$ is defined as follows:
for every $\mathrm{k} \in \mathcal{K}_{P}$ of sort s , and every trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ and recipe $R$ such that $R \phi \downarrow=\mathrm{k}$, we define $\alpha(\mathbf{k})=R \psi \downarrow$ where $\psi$ is the only frame such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$.

The existence of such a frame comes from the fact that $P \approx Q$, whereas its unicity is a consequence of the determinism of protocols in $\mathcal{C}_{\mathrm{pp}}$.

Then, we show that this relation $\alpha$ is uniquely defined and satisfied all the requirements exploiting the strong relationship between $P$ and $Q$ through the relation $P \approx Q$.

Example 7.2.4. Continuing Example 7.2.2, we have $\mathcal{K}_{P}=\left\{\mathrm{pk}_{A}, \mathrm{pk}_{B}, \mathrm{pk}_{C}, \mathrm{sk}_{C}, \mathrm{k}_{A B}\right\}$ whereas $\mathcal{K}_{Q}=\left\{\mathrm{pk}_{A}, \mathrm{pk}_{B}, \mathrm{pk}_{C}\right.$, $\mathrm{sk}_{C}$, k$\}$. The unique bijection $\alpha$ mentioned in the previous lemma is defined as follows: $\alpha\left(\mathrm{k}_{A B}\right)=\mathrm{k}$, and $\alpha\left(\mathrm{k}^{\prime}\right)=\mathrm{k}^{\prime}$ otherwise.

Definition 7.2.4. Let $P$ be a protocol in $\mathcal{C}_{\mathrm{pp}}, K$ be a set of constants of sort key that occur in $P$. If for every $\mathrm{k} \in K$ there exist a channel name $c_{\mathrm{k}}$ and a branch $\operatorname{lin}\left(c_{\mathrm{k}}, \operatorname{start}\right)$.out $\left(c_{\mathrm{k}}, \mathrm{k}\right)$ in $P$, then $P$ is said to disclose $K$.

Example 7.2.5. Continuing our running example, $P$ and $Q$ clearly disclose $K=\left\{\mathrm{pk}_{A}, \mathrm{pk}_{B}, \mathrm{pk}_{C}, \mathrm{sk}_{C}\right\}$.
Lemma 7.2.2. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}, S$ (resp. $S^{\prime}$ ) the set of keys of $P$ (resp. $Q$ ). Then $P \approx Q$ if, and only if, there exist two sets $K \subseteq S$ and $K^{\prime} \subseteq S^{\prime}$ and a bijection $\alpha: K \rightarrow K^{\prime}$ such that $\bar{P} \approx \bar{Q}$ where:

$$
\begin{array}{l|l}
\bar{P}=P & !\operatorname{in}\left(c^{0}, \operatorname{start}\right) . \text { out }\left(c^{0}, 0\right) \mid!\operatorname{in}\left(c^{1}, \operatorname{start}\right) . \text { out }\left(c^{1}, 1\right) \\
& \left|\left.\right|_{\mathrm{k} \in K}!\operatorname{in}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}, \operatorname{start}\right) \cdot \operatorname{out}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}, \mathrm{k}\right)\right|_{\mathrm{k} \in S \backslash K}^{\mid}!\operatorname{in}(c, \mathrm{k}) . \text { out }(c, 0) \\
\bar{Q}=Q & !\operatorname{in}\left(c^{0}, \operatorname{start}\right) . \text { out }\left(c^{0}, 0\right) \mid \operatorname{in}\left(c^{1}, \operatorname{start}\right) . \text { out }\left(c^{1}, 1\right) \\
& \left|\underset{\mathrm{k} \in K}{ }!\operatorname{in}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}, \operatorname{start}\right) \cdot \operatorname{out}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}, \alpha(\mathrm{k})\right)\right|_{\mathrm{k} \in S^{\prime} \backslash K^{\prime}}^{\mid}!\operatorname{in}(c, \mathrm{k}) . \text { out }(c, 1)
\end{array}
$$

and 0,1 are new constants, $c^{0}, c^{1}$, the $c_{\mathrm{k}, \alpha(\mathrm{k})}$ and $c$ are fresh channels.
Moreover, assuming the existence of such sets and bijection such that $\bar{P} \approx \bar{Q}$, the two protocols are disclosing their deducible keys.

We call $\mathcal{T}_{\text {key }}(P, Q)$ the set of such pairs $(\bar{P}, \bar{Q})$ of modified protocols.
Proof. Let $\mathcal{K}_{P}$ (resp. $\mathcal{K}_{Q}$ ) be the set of deducible constants of sort key that occur in $P$ (resp. $Q$ ). We prove the two directions separately.
$(\Rightarrow)$ If $P \approx Q$, by Lemma 7.2.1, for $K=\mathcal{K}_{P}$ and $K^{\prime}=\mathcal{K}_{Q}$, we get the existence of such a bijection $\alpha$. Because keys in $S \backslash \mathcal{K}_{P}$ and $S^{\prime} \backslash \mathcal{K}_{Q}$ are not deducible, the branches on channel $c$ can never be triggered. Moreover, as $P \approx Q$, any trace of $P$ (resp. $Q$ ) inputting or outputting on a channel $c_{\mathrm{k}, \alpha(\mathrm{k})}$ for k in $\mathcal{K}_{P}$ can be matched in $Q$ (resp. $P)$. Indeed, for every couple ( $\mathrm{k}, \mathrm{k}^{-1}$ ) of deducible keys and for any recipe reducing to k (resp. $\mathrm{k}^{-1}$ ) in $P$, the same recipe reduces to $\alpha(\mathrm{k})\left(\right.$ resp. $\alpha(\mathrm{k})^{-1}$ ) in $Q$, thanks to the properties of $\alpha$ described in Lemma 7.2.1.
$(\Leftarrow)$ For the converse implication, we first remark that necessarily we have that $\mathcal{K}_{P} \subseteq K$ and $\mathcal{K}_{Q} \subseteq K^{\prime}$. Indeed, suppose there exists, for instance, $\mathrm{k} \in \mathcal{K}_{P} \backslash K$. Since k is deducible, there exists a trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ and a recipe $R$ such that $R \phi \downarrow=\mathrm{k}$. Since ( $\operatorname{tr}, \phi$ ) is also a trace of $\bar{P}$, we consider the trace:

$$
\operatorname{tr}^{\prime}=\operatorname{tr} \cdot \operatorname{in}(c, R) \cdot \mathrm{out}\left(c, \mathrm{w}_{|\phi|+1}\right) \cdot \operatorname{in}\left(c^{0}, \operatorname{start}\right) \cdot \mathrm{out}\left(c^{0}, \mathrm{w}_{|\phi|+2}\right) \cdot \operatorname{in}\left(c^{1}, \operatorname{start}\right) \cdot \mathrm{out}\left(c^{1}, \mathrm{w}_{|\phi|+3}\right)
$$

along with its frame $\phi^{\prime}=\phi \cup\left\{\mathrm{w}_{|\phi|+1} \triangleright 0, \mathrm{w}_{|\phi|+2} \triangleright 0, \mathrm{w}_{|\phi|+3} \triangleright 1\right\}$. If $\bar{P} \approx \bar{Q}$, then there exists $\left(\operatorname{tr}^{\prime}, \psi^{\prime}\right) \in \operatorname{trace}(\bar{Q})$ such that $\phi$ and $\psi$ are statically equivalent. But any output on $c$ in $Q$ leads to the constant 1, breaking static equivalence. We conclude in a similar way in case $\mathrm{k} \in \mathcal{K}_{Q} \backslash K^{\prime}$.

Finally we need to prove that $\bar{P} \approx \bar{Q}$ implies $P \approx Q$. For every trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P),(\operatorname{tr}, \phi) \in \operatorname{trace}(\bar{P})$, and as $\bar{P} \approx \bar{Q}$, there exists a trace $(\operatorname{tr}, \psi) \in \operatorname{trace}(\bar{Q})$ such that $\phi$ is statically equivalent to $\psi$. Because $c^{0}, c^{1}, c$ and the $c_{\mathrm{k}, \alpha(\mathrm{k})}$ are new channels, tr does not use transitions on those, thus $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$. The same goes for any trace of $Q$, hence showing the trace equivalence of $P$ and $Q$.

Example 7.2.6. Continuing our example, let $K=\mathcal{K}_{P}$ and $K^{\prime}=\mathcal{K}_{Q}$, and $\alpha$ the bijection defined in Example 7.2.4. Checking equivalence of $P \approx Q$ amounts into checking whether $\bar{P} \approx \bar{Q}$ where $\bar{P}$ and $\bar{Q}$ are defined as follows.

$$
\begin{array}{l|l}
\bar{P}=P & !\operatorname{in}\left(c^{0}, \operatorname{start}\right) \cdot \text { out }\left(c^{0}, 0\right) \mid \operatorname{in}\left(c^{1}, \operatorname{start}\right) \cdot \operatorname{out}\left(c^{1}, 1\right) \\
& !\operatorname{in}\left(c_{\mathrm{k}_{A B}, \mathrm{k}}, \operatorname{start}\right) \cdot \operatorname{out}\left(c_{\mathrm{k}_{A B}, \mathrm{k}}, \mathrm{k}_{A B}\right) \\
& !\operatorname{in}\left(c, \operatorname{sk_{A}}\right) \cdot \text { out }(c, 0) \mid \operatorname{lin}\left(c, \operatorname{sk}_{B}\right) \cdot \text { out }(c, 0) \\
\bar{Q}=Q & !\operatorname{in}\left(c^{0}, \operatorname{start}\right) \cdot \text { out }\left(c^{0}, 0\right) \mid \operatorname{in}\left(c^{1}, \operatorname{start}\right) \cdot \text { out }\left(c^{1}, 1\right) \\
& !\operatorname{in}\left(c_{\mathrm{k}_{A B}, \mathrm{k}}, \operatorname{start}\right) \cdot \text { out }\left(c_{\mathrm{k}_{A B}, \mathrm{k}}, \mathrm{k}\right) \\
& !\operatorname{in}\left(c, \operatorname{sk}_{A}\right) \cdot \text { out }(c, 1) \mid!\operatorname{in}\left(c, \operatorname{sk}_{B}\right) \cdot \text { out }(c, 1)
\end{array}
$$

If $\bar{P} \approx \bar{Q}$, then $\mathrm{sk}_{A}$ and $\mathrm{sk}_{B}$ cannot be deducible thus $\bar{P}$ and $\bar{Q}$ disclose their set of deducible keys.

## Adding oracles

To compensate the fact that the attacker is a simple forwarder, we give him access to encryption/decryption oracles for any deducible key k , adding branches in the processes. We rely on the bijection $\alpha$ computed in the previous section to do this in a compatible way on both sides of the equivalence.

Lemma 7.2.3. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\text {pp }}$ respectively disclosing two sets of keys $K$ and $K^{\prime}$ as in Lemma 7.2.2. Then $P \approx Q$ if, and only if, $\bar{P} \approx_{\text {fwd }} \bar{Q}$ where:

$$
\begin{aligned}
& \bar{Q}=Q \quad|\quad| \quad \mid \quad \operatorname{lin}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {senc }}, x\right) \text {.new } n \text {.out }\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {senc }}, \operatorname{senc}(x, \alpha(\mathrm{k}), n)\right) \\
& \mid \underset{\mathrm{k} \in K^{\text {symKey }}}{ }!\operatorname{in}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {sdec }}, \operatorname{senc}(x, \alpha(\mathrm{k}), y)\right) \cdot \operatorname{out}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {sdec }}, x\right) \\
& \mid \underset{\mathrm{k} \in K^{\text {PubKey }}}{\mid} \operatorname{in}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {raenc }}, x\right) \text {.new } n \text {.out }\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {raenc }}, \operatorname{raenc}(x, \alpha(\mathrm{k}), n)\right) \\
& \mid \underset{\mathrm{k} \in K^{\text {Privkey }}}{ } \operatorname{lin}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {radec }}, \operatorname{raenc}(x, \alpha(\mathrm{k}), y)\right) \operatorname{out}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {radec }}, x\right) \\
& \mid \underset{\mathrm{k} \in K^{\text {PrivKey }}}{ } \operatorname{in}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {sign }}, x\right) \text {.new } n \text {.out }\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {sign }}, \operatorname{sign}(x, \alpha(\mathrm{k}), n)\right) \\
& \mid \underset{\mathrm{k} \in K^{\text {PubKey }}}{ } \operatorname{lin}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {check }}, \operatorname{check}(x, \alpha(\mathrm{k}), y)\right) \text {.out }\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {check }}, x\right)
\end{aligned}
$$

where $K^{\text {s }}$ denotes the keys of sort s of $K$. We call $\mathcal{T}_{\text {oracle }}$ the transformation taking a pair of protocols $(P, Q)$ satisfying the aforementioned condition and returning the pair $(\bar{P}, \bar{Q})$ presently defined.

Proof. (sketch) First, thanks to Lemma 7.2.2, we know that $P, \bar{P}, Q$ and $\bar{Q}$ disclose all their deducible keys.
$(\Rightarrow)$ Given a witness of non-equivalence for $\bar{P} \approx_{\text {fwd }} \bar{Q}$, it is quite easy to build a witness of non-equivalence for $P \not \approx Q$ replacing the use of the oracle by the corresponding attacker construction. This yields a witness of non-equivalence for $P \approx Q$.
$(\Leftarrow)$ This direction is actually more involved. The idea is to replace the use of an attacker construction, e.g. an encryption with a deducible key, by the corresponding oracle. However, the attacker has the ability to use the same random seed more than once whereas this is impossible when using the oracles to perform those computations. Thus, we first show that this additional ability does not give any power to the attacker. Then, we do the replacement as expected in order to conclude.

The full proof is provided in Appendix B.2.

Example 7.2.7. Continuing our example, this last transformation will add 10 branches ( 2 per deducible key). For instance, regarding the key $\mathrm{k}_{A B}$, the two following branches will be be added:

For process $P$ :

$$
\begin{aligned}
& \operatorname{in}\left(c_{\mathrm{k}_{A B}, \mathrm{k}}^{\text {senc }}, x\right) . \text { new } n . \operatorname{out}\left(c_{\mathrm{k}_{A B}, \mathrm{k}}, \operatorname{senc}\left(x, \mathrm{k}_{A B}, n\right)\right) \\
\quad & \operatorname{in}\left(c_{\mathrm{k}_{A B}, \mathrm{k}}^{\text {sdec }}, \operatorname{senc}\left(x, \mathrm{k}_{A B}, y\right)\right) \cdot \operatorname{out}\left(c_{\mathrm{k}_{A B}, \mathrm{k}}^{\text {sdec }}, x\right)
\end{aligned}
$$

For process $Q$ :

$$
\begin{aligned}
& !\operatorname{in}\left(c_{\mathrm{k}_{A B}, \mathrm{k}}^{\text {senc }}, x\right) \cdot \text { new } n \cdot \operatorname{out}\left(c_{\mathrm{k}_{A B}, \mathrm{k}}, \operatorname{senc}(x, \mathrm{k}, n)\right) \\
\mid & !\operatorname{in}\left(c_{\mathrm{k}_{A B}, \mathrm{k}}^{\text {sdec }}, \operatorname{senc}(x, \mathrm{k}, y)\right) \cdot \operatorname{out}\left(c_{\mathrm{k}_{A B}, \mathrm{k}}^{\text {sec }}, x\right)
\end{aligned}
$$

Regarding the keys $\mathrm{pk}_{A}, \mathrm{pk}_{B}, \mathrm{pk}_{C}$ and $\mathrm{sk}_{C}$, since $\alpha\left(\mathrm{k}^{\prime}\right)=\mathrm{k}^{\prime}$ for each of these keys, we add the following branches on both sides:

```
\(\mid \quad \operatorname{lin}\left(c_{\mathrm{pk}_{A}, p k_{A}}^{\text {raenc }}, x\right)\).new \(n\).out \(\left(c_{\mathrm{pk}_{A}, \mathrm{pk}_{A}}^{\text {raenc }}, \operatorname{raenc}\left(x, \mathrm{pk}_{A}, n\right)\right)\)
    \(\mid \quad \operatorname{in}\left(c_{\mathrm{pk}_{B}, p k_{B}}^{\text {ranc }}, x\right)\).new \(\operatorname{n.out}\left(c_{\mathrm{pk}_{B}, \mathrm{pk}_{B}}^{\text {raenc }}, \operatorname{raenc}\left(x, \mathrm{pk}_{B}, n\right)\right)\)
    \(\mid \quad \operatorname{in}\left(c_{\mathrm{pk}_{C}, p k_{C}}^{\text {raenc }}, x\right)\).new \(n\).out \(\left(c_{\mathrm{pk}_{C}, \mathrm{pk}_{C}}^{\text {raenc }}, \operatorname{raenc}\left(x, \mathrm{pk}_{C}, n\right)\right)\)
    \(\mid \quad \operatorname{lin}\left(c_{\mathrm{sk}_{C}, \mathrm{sk}_{C}}^{\mathrm{radec}}, \operatorname{raenc}\left(x, \mathrm{pk}_{C}, y\right)\right) \cdot \operatorname{out}\left(c_{\mathrm{sk}_{C}, \mathrm{sk}_{C}}^{\mathrm{radec}}, x\right)\)
    \(\mid \quad \operatorname{lin}\left(c_{\mathrm{sk}_{C}, \text { sk }_{C}}^{\mathrm{sign}}, x\right)\).new \(n\). out \(\left(c_{\mathrm{sk}_{C}, \mathrm{sk}_{C}}^{\mathrm{sign}}, \operatorname{sign}\left(x, \mathrm{sk}_{C}, n\right)\right)\)
    \(\mid \quad \operatorname{lin}\left(c_{\mathrm{pk}_{A}, \mathrm{pk}_{A}}^{\text {check }}, \operatorname{sign}\left(x, \mathrm{sk}_{A}, y\right)\right) \cdot \operatorname{out}\left(c_{\mathrm{pk}_{A}, \mathrm{pk}_{A}}^{\text {check }}, x\right)\)
    \(\mid \quad \operatorname{in}\left(c_{\mathrm{pk}_{B}, \mathrm{pk}_{B}}^{\text {check }}, \operatorname{sign}\left(x, \mathrm{sk}_{B}, y\right)\right) \cdot \operatorname{out}\left(c_{\mathrm{pk}_{B}, \mathrm{pk}_{B}}^{\text {check }}, x\right)\)
    \(\mid \quad \operatorname{lin}\left(c_{\mathrm{pk}_{C}, \mathrm{pk}_{C}}^{\text {check }}, \operatorname{sign}\left(x, \mathrm{sk}_{C}, y\right)\right) \cdot \operatorname{out}\left(c_{\mathrm{pk}_{C}, \mathrm{pk}_{C}}^{\text {check }}, x\right)\)
```

## Transformation $\mathcal{T}_{\text {fwd }}$

Thanks to Lemmas 7.2.2 and 7.2.3, we are now able to formally define our transformation that gets rid of a fully active attacker. For every pair of protocols $(P, Q)$ in $\mathcal{C}_{\mathrm{pp}}$, we consider

$$
\mathcal{T}_{\text {fwd }}(P, Q)=\left\{\mathcal{T}_{\text {oracle }}\left(P^{\prime}, Q^{\prime}\right) \mid\left(P^{\prime}, Q^{\prime}\right) \in \mathcal{T}_{\text {key }}(P, Q)\right\}
$$

Combination of the two previous results yields to the desired result.
Proposition 7.2.1. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}$. We have that:

$$
P \approx Q \text { if, and only if, } P^{\prime} \approx_{\text {fwd }} Q^{\prime} \text { for some }\left(P^{\prime}, Q^{\prime}\right) \in \mathcal{T}_{\text {fwd }}(P, Q)
$$

### 7.3 Encoding protocols into real-time GPDAs

We first introduce the notion of real-time generalised pushdown automaton (GPDA) (see Section 7.3.1) before explaining in details (see Sections 7.3.2 and 7.3.3) our encoding from protocols to real-time generalised pushdown automata.

More precisely, for any process $P \in \mathcal{C}_{\mathrm{pp}}$, we show that it is possible to define a polynomial-sized real-time generalised pushdown automaton $\mathcal{A}_{P}$ such that trace equivalence w.r.t. the forwarder semantics coincides with language equivalence of the two corresponding automata.

Theorem 7.3.1. Let $P$ and $Q$ in $\mathcal{C}_{\mathrm{pp}}$, we have that:

$$
P \approx_{\mathrm{fwd}} Q \Longleftrightarrow \mathcal{L}\left(\mathcal{A}_{P}\right)=\mathcal{L}\left(\mathcal{A}_{Q}\right)
$$

The proof of this theorem consists of three main steps.

1. First, we provide a new characterisation of trace equivalence w.r.t. the forwarder semantics. Intuitively, we show that it is not necessary to consider all possible tests (when checking static equivalence). Indeed, our Lemma 7.3.1 states that it is sufficient to check for constant tests (that is, tests of the form $x=c$ where $c$ is a constant) and some specific class of tests that we call guarded and pulled-up.
2. Then we associate to processes $P, Q \in \mathcal{C}_{\mathrm{pp}}$ real-time GPDAs that check whether they satisfy the same constant tests (Lemma 7.3.2).
3. And we associate to processes $P, Q \in \mathcal{C}_{\mathrm{pp}}$ real-time GPDAs that check whether they satisfy the same guarded tests (Lemma 7.3.3).

All along this section, we illustrate the definitions with the protocol displayed in Figure 7.2. This example should be read step by step, when reading the examples of this section.

### 7.3.1 Generalised pushdown automata

Language equivalence of deterministic pushdown automata (DPA) is known to be decidable [63]. We actually encode equivalence of protocols into a fragment of DPA: real-time GPDA with final-state acceptance. GPDA differ from deterministic pushdown automata (DPA) as they can unstack several symbols at a time. Real-time automata are automata that do not include epsilon-transitions. Formally, the class of real-time GPDA is defined as follows.

Definition 7.3.1. A real-time $G P D A$ is a 7-tuple $\mathcal{A}=\left(Q, \Pi, \Gamma, q_{0}, \omega, Q_{f}, \delta\right)$ where $Q$ is a finite set of states, $q_{0} \in Q$ is an initial state, $Q_{f} \subseteq Q$ is a set of accepting states, $\Pi$ is a finite input-alphabet, $\Gamma$ is a finite stack-alphabet, $\omega$ is the initial stack symbol, and $\delta:\left(Q \times \Pi \times \Gamma_{0}\right) \rightarrow Q \times \Gamma_{0}$ is a partial transition function such that:

- $\Gamma_{0}$ is a finite subset of $\Gamma^{*}$; and
- for any $(q, a, x) \in \operatorname{dom}(\delta)$ and $y$ suffix strict of $x$, we have that $(q, a, y) \notin \operatorname{dom}(\delta)$.

Let $q, q^{\prime} \in Q, u, u^{\prime}, \gamma \in \Gamma^{*}, m \in \Pi^{*}, a \in \Pi$; we note $(q u \gamma, a m) \rightsquigarrow_{\mathcal{A}}\left(q^{\prime} u u^{\prime}, m\right)$ if $\left(q^{\prime}, u^{\prime}\right)=\delta(q, a, \gamma)$. The relation $\rightsquigarrow_{\mathcal{A}}^{*}$ is the reflexive and transitive closure of $\rightsquigarrow_{\mathcal{A}}$. For every $q u, q^{\prime} u^{\prime}$ in $Q \Gamma^{*}$ and $m \in \Pi^{*}$, we note $q u \xrightarrow{m} q^{\prime} q^{\prime} u^{\prime}$ if, and only if, $(q u, m) \rightsquigarrow_{\mathcal{A}}^{*}\left(q^{\prime} u^{\prime}, \epsilon\right)$. For sake of clarity, a transition from $q$ to $q^{\prime}$ reading $a$, popping $\gamma$ from the stack and pushing $u^{\prime}$ will be denoted by $q \xrightarrow{a ; \gamma / u^{\prime}} q^{\prime}$.

Let $\mathcal{A}$ be a GPDA. The language recognised by $\mathcal{A}$ is defined by:

$$
\mathcal{L}(\mathcal{A})=\left\{m \in \Pi^{*} \mid q_{0} \omega \text { start } \xrightarrow{m} \mathcal{A} q_{f} u \text { for some } q_{f} \in Q_{f} \text { and } u \in \Gamma^{*}\right\} .
$$

Note that the language is defined starting with the word $\omega$ start in the stack.
A real-time GPDA can easily be converted into a DPA by adding new states and $\epsilon$-transitions. Thus, the problem of language equivalence for two real-time GPDA $\mathcal{A}_{1}$ and $\mathcal{A}_{2}$, i.e. deciding whether $\mathcal{L}\left(\mathcal{A}_{1}\right)=\mathcal{L}\left(\mathcal{A}_{2}\right)$ is decidable [63]. Whether deciding equivalence of real-time GPDA could be easier than deciding equivalence of DPA is an open question.

We illustrate the different steps of our translation of protocols to automata using a (mock) ping-pong protocol $P_{\text {toy }}$. We define io $(c, R, \mathrm{w}) \stackrel{\text { def }}{=} \operatorname{in}(c, R)$.out $(c, \mathrm{w})$.

```
\(P_{\text {toy }}=\)
    |! in \(\left(c_{1}\right.\), start \()\).new \(r_{1}\).out \(\left(c_{1}, \operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{1}\right)\right)\)
    \(\mid!\operatorname{in}\left(c_{2}, \operatorname{senc}\left(x, \mathrm{k}_{2}, z_{1}\right)\right)\).new \(r_{1}\).out \(\left(c_{2}, \operatorname{senc}\left(x, \mathrm{k}_{1}, r_{1}\right)\right)\)
    \(\mid!\operatorname{in}\left(c_{3}, x\right)\).new \(r_{1}\).out \(\left(c_{3}, \operatorname{senc}\left(x, \mathrm{k}_{2}, r_{1}\right)\right)\)
    \(\mid!\operatorname{in}\left(c_{4}, \operatorname{senc}\left(\operatorname{senc}\left(x, \mathrm{k}_{1}, z_{1}\right), \mathrm{k}_{2}, z_{2}\right)\right)\).new \(r_{1}, r_{2}\).out \(\left(c_{4}, \operatorname{senc}\left(\operatorname{senc}\left(x, \mathrm{k}_{2}, r_{1}\right), \mathrm{k}_{1}, r_{2}\right)\right)\)
    \(\mid!\operatorname{in}\left(c_{5}, \operatorname{senc}\left(\operatorname{senc}\left(x, \mathrm{k}_{2}, z_{1}\right), \mathrm{k}_{1}, z_{2}\right)\right)\).out \(\left(c_{5}, x\right)\)
```

For illustrative purpose, we consider different execution traces of this protocol. For instance, we have that $\left(\operatorname{tr}_{1}, \sigma_{1}\right) \in$ $\operatorname{trace}_{\text {fwd }}\left(P_{\text {toy }}\right)$ where:

- $\operatorname{tr}_{1}=\mathrm{io}\left(c_{1}, \operatorname{start}, \mathrm{w}_{1}\right) \cdot \mathrm{io}\left(c_{2}, \mathrm{w}_{1}, \mathrm{w}_{2}\right) \cdot \mathrm{io}\left(c_{3}, \mathrm{w}_{2}, \mathrm{w}_{3}\right) \cdot \mathrm{io}\left(c_{4}, \mathrm{w}_{3}, \mathrm{w}_{4}\right) \cdot \mathrm{io}\left(c_{5}, \mathrm{w}_{4}, \mathrm{w}_{5}\right)$, and
- $\sigma_{1}=\left\{\mathrm{w}_{1} \triangleright \operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{1}\right), \mathrm{w}_{2} \triangleright \operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{1}, r_{2}\right), \mathrm{w}_{3} \triangleright \operatorname{senc}\left(\operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{1}, r_{2}\right), \mathrm{k}_{2}, r_{3}\right)\right.$,

$$
\left.\mathrm{w}_{4} \triangleright \operatorname{senc}\left(\operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{4}\right), \mathrm{k}_{1}, r_{5}\right), \mathrm{w}_{5} \triangleright \mathrm{a}\right\} .
$$

This execution may be continued as follows:

- $\operatorname{tr}_{2}=\mathrm{io}\left(c_{3}, \mathrm{w}_{1}, \mathrm{w}_{6}\right) \cdot \mathrm{io}\left(c_{2}, \mathrm{w}_{6}, \mathrm{w}_{7}\right) \cdot \mathrm{io}\left(c_{5}, \mathrm{w}_{7}, \mathrm{w}_{8}\right)$, and
- $\sigma_{2}=\left\{\mathrm{w}_{6} \triangleright \operatorname{senc}\left(\operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{1}\right), \mathrm{k}_{2}, r_{6}\right), \mathrm{w}_{7} \triangleright \operatorname{senc}\left(\operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{1}\right), \mathrm{k}_{1}, r_{7}\right)\right.$,

$$
\left.\mathrm{w}_{8} \triangleright \mathrm{a}\right\} .
$$

Let $\sigma_{1 / 2}=\sigma_{1} \cup \sigma_{2}$. We have that $\left(\operatorname{tr}_{1} \cdot \operatorname{tr}_{2}, \sigma_{1 / 2}\right)$ is a trace of $P_{\text {toy }}$ w.r.t. the forwarder semantics. We have that the test $\mathrm{w}_{5}=\mathrm{w}_{8}$ is valid in $\sigma_{1 / 2}$. Indeed $\mathrm{w}_{5} \sigma_{1 / 2} \downarrow=\mathrm{w}_{8} \sigma_{1 / 2} \downarrow=\mathrm{a}$.

We have also that $\left(\operatorname{tr}_{1}^{\prime}, \sigma_{1}^{\prime}\right) \in \operatorname{trace}_{\text {fwd }}\left(P_{\text {toy }}\right)$ with:

- $\operatorname{tr}_{1}^{\prime}=\mathrm{io}\left(c_{1}, \operatorname{start}, \mathrm{w}_{1}\right) \cdot \mathrm{io}\left(c_{2}, \mathrm{w}_{1}, \mathrm{w}_{2}\right) \cdot \mathrm{io}\left(c_{3}, \mathrm{w}_{2}, \mathrm{w}_{3}\right) \cdot \mathrm{io}\left(c_{4}, \mathrm{w}_{3}, \mathrm{w}_{4}\right) \cdot \mathrm{io}\left(c_{3}, \mathrm{w}_{4}, \mathrm{w}_{5}\right)$, and
- $\sigma_{1}^{\prime}=\left\{\mathrm{w}_{1} \triangleright \operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{1}\right), \mathrm{w}_{2} \triangleright \operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{1}, r_{2}\right)\right.$,

$$
\begin{array}{r}
\mathrm{w}_{3} \triangleright \operatorname{senc}\left(\operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{1}, r_{2}\right), \mathrm{k}_{2}, r_{3}\right), \mathrm{w}_{4} \triangleright \operatorname{senc}\left(\operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{4}\right), \mathrm{k}_{1}, r_{5}\right), \\
\left.\mathrm{w}_{5} \triangleright \operatorname{senc}\left(\operatorname{senc}\left(\operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{4}\right), \mathrm{k}_{1}, r_{5}\right), \mathrm{k}_{2}, r_{6}\right)\right\} .
\end{array}
$$

This execution may be continued as follows:

- $\operatorname{tr}_{2}^{\prime}=\mathrm{io}\left(c_{4}, \mathrm{w}_{5}, \mathrm{w}_{6}\right) \cdot \mathrm{io}\left(c_{5}, \mathrm{w}_{6}, \mathrm{w}_{7}\right) \cdot \mathrm{io}\left(c_{4}, \mathrm{w}_{5}, \mathrm{w}_{8}\right) \cdot \mathrm{io}\left(c_{5}, \mathrm{w}_{8} \cdot \mathrm{w}_{9}\right)$,
- $\sigma_{2}^{\prime}=\left\{\mathrm{w}_{6} \triangleright \operatorname{senc}\left(\operatorname{senc}\left(\operatorname{senc}\left(a, \mathrm{k}_{2}, r_{4}\right), \mathrm{k}_{2}, r_{7}\right), \mathrm{k}_{1}, r_{8}\right), \mathrm{w}_{7} \triangleright \operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{4}\right)\right.$,
$\left.\mathrm{w}_{8} \triangleright \operatorname{senc}\left(\operatorname{senc}\left(\operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{4}\right), \mathrm{k}_{2}, r_{7}^{\prime}\right), \mathrm{k}_{1}, r_{8}^{\prime}\right), \mathrm{w}_{9} \triangleright \operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{4}\right)\right\}$.
Let $\sigma_{1 / 2}^{\prime}=\sigma_{1}^{\prime} \cup \sigma_{2}^{\prime}$. We have that $\left(\operatorname{tr}_{1}^{\prime} \cdot \operatorname{tr}_{2}^{\prime}, \sigma_{1 / 2}^{\prime}\right)$ is a trace of $P_{\text {toy }}$ w.r.t. the forwarder semantics. We have that the test $\mathrm{w}_{7}=\mathrm{w}_{9}$ is valid in $\sigma_{1 / 2}^{\prime}$.

Figure 7.2: Running example.

### 7.3.2 Characterisation of trace equivalence

To construct the automaton associated to a process $P \in \mathcal{C}_{\mathrm{pp}}$, we need to construct an automaton that recognises any execution of $P$ and the corresponding valid tests.

We first propose a new characterisation of trace equivalence allowing us to restrict our attention to executions of $P$ and valid tests that have a special form.

Given a trace $(\operatorname{tr}, \sigma)$ and an element w of a frame $\sigma$, we can extract from tr the sequence of actions that conducted to the production of this element $w$.

Definition 7.3.2. Let $P$ be a protocol in $\mathcal{C}_{\mathrm{pp}}$, $\operatorname{tr}$ be a trace of $P$ w.r.t. the forwarder semantics, i.e. such that $(\operatorname{tr}, \sigma) \in$ $\operatorname{trace}_{\mathrm{fwd}}(P)$ for some $\sigma$, and w be a variable that occurs in tr. The sequence associated to w in tr , denoted seq $\mathrm{g}_{\mathrm{tr}}(\mathrm{w})$, is the subsequence of tr of the following form:

$$
\operatorname{seq}_{\mathrm{tr}}(\mathrm{w})=\operatorname{io}\left(c_{i_{0}}, \text { start }, \mathrm{w}_{j_{0}}\right) \cdot \operatorname{io}\left(c_{i_{1}}, \mathrm{w}_{j_{0}}, \mathrm{w}_{j_{1}}\right) \ldots \operatorname{io}\left(c_{i_{p}}, \mathrm{w}_{j_{p-1}}, \mathrm{w}\right) .
$$

Example 7.3.1. Consider the protocol defined in Figure 7.2. Then,

- $\operatorname{seq}_{\mathrm{tr}_{1} \cdot \mathrm{tr}_{2}}\left(\mathrm{w}_{5}\right)=\operatorname{tr}_{1}$;
- $\operatorname{seq}_{\mathrm{tr}_{1} \cdot \mathrm{tr}_{2}}\left(\mathrm{w}_{8}\right)=\mathrm{io}\left(c_{1}\right.$, start, $\left.\mathrm{w}_{1}\right) \cdot \operatorname{tr}_{2}$;
- $\operatorname{seq}_{\mathrm{tr}_{1}^{\prime} \cdot \mathrm{tr}_{2}^{\prime}}\left(\mathrm{w}_{7}\right)=\operatorname{tr}_{1}^{\prime} \cdot \mathrm{io}\left(c_{4}, \mathrm{w}_{5} \cdot \mathrm{w}_{6}\right) \cdot \mathrm{io}\left(c_{5}, \mathrm{w}_{6}, \mathrm{w}_{7}\right)$;
- $\operatorname{seq}_{\mathrm{tr}_{1}^{\prime} \cdot \operatorname{tr}_{2}^{\prime}}\left(\mathrm{w}_{9}\right)=\operatorname{tr}_{1}^{\prime} \cdot \mathrm{io}\left(c_{4}, \mathrm{w}_{5}, \mathrm{w}_{8}\right) \cdot \mathrm{io}\left(c_{5}, \mathrm{w}_{8}, \mathrm{w}_{9}\right)$.

We consider some particular class of tests, called pulled-up tests.
Definition 7.3.3. Let $P$ be a protocol in $\mathcal{C}_{\mathrm{pp}},(\operatorname{tr}, \sigma) \in \operatorname{trace}_{\mathrm{fwd}}(P)$, and $\mathrm{w}, \mathrm{w}^{\prime} \in \operatorname{dom}(\sigma)$ such that:

1. the test $\mathrm{w}=\mathrm{w}^{\prime}$ is $\sigma$-valid, i.e. $\mathrm{w} \sigma=\mathrm{w}^{\prime} \sigma$; and
2. the test $\mathrm{w}=\mathrm{w}^{\prime}$ is $\sigma$-guarded, i.e. the head symbol of $\mathrm{w} \sigma$ (or equivalently $\mathrm{w}^{\prime} \sigma$ ) is in \{senc, raenc, sign\}.

Let io $\left(c_{i_{0}}\right.$, start, $\left.\mathrm{w}_{j_{0}}\right) \ldots$ io $\left(c_{i_{p}}, \mathrm{w}_{j_{p-1}}, \mathrm{w}_{j_{p}}\right)$ be the maximal common prefix of $\operatorname{seq}_{\mathrm{tr}}(\mathrm{w})$ and $\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)$. The test $\mathrm{w}=\mathrm{w}^{\prime}$ is said to be pulled-up in $(\operatorname{tr}, \sigma)$ if $p=0$, or $p \geq 1$ and $\mathrm{w} \sigma$ does not occur as a subterm in $\mathrm{w}_{j_{0}} \sigma, \ldots, \mathrm{w}_{j_{p-1}} \sigma$.

Intuitively, to perform a test $w=w^{\prime}$, the attacker (who acts as a forwarder) relies on the protocol rules to produce successive outputs, and ultimately the ones stored in $w$ and $w^{\prime}$. The attacker may produce $w$ and $w^{\prime}$ independently (the common prefix of $\operatorname{seq}_{t r}(\mathrm{w})$ and $\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)$ is empty), and in such a case the test is pulled-up by definition. This is not, of course, always possible. In particular, a test $w=w^{\prime}$ satisfying conditions (1) and (2) of the previous definition is necessarily a "forked" test, i.e. a test for which the common prefix of $\operatorname{seq}_{\mathrm{tr}}(\mathrm{w})$ and $\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)$ is not reduced to the empty sequence, and thus $p \geq 1$. Indeed, $\mathrm{w} \sigma$ is a term of the form $\mathrm{f}(u, \mathrm{k}, r)$ with some random $r$. Since nonces are uniquely generated, the variables $\mathrm{w}_{i}$ that generates it, i.e. the smallest $i$ such that $r$ occurs in $\mathrm{w}_{i} \sigma$, occurs both in $\operatorname{seq}_{\mathrm{tr}}(\mathrm{w})$ and $\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)$. For this kind of "forked" test, we can restrict the attacker to consider tests that are pulledup, i.e. we consider tests for which the size of the common prefix between $\operatorname{seq}_{t r}(w)$ and $\operatorname{seq}_{t r}\left(w^{\prime}\right)$ is reduced to the minimum. This can be done by duplicating some execution steps since all the branches are under a replication.

Example 7.3.2. Continuing our running example, we have that $w_{5}=w_{8}$ is a test that is $\sigma_{1 / 2}$-valid but it is not $\sigma_{1 / 2}$-guarded since $\mathrm{w}_{5} \sigma_{1 / 2}=\mathrm{w}_{8} \sigma_{1 / 2}=\mathrm{a}$.

The test $\mathrm{w}_{7}=\mathrm{w}_{9}$ is a test that is $\sigma_{1 / 2}^{\prime}$-valid and $\sigma_{1 / 2}^{\prime}$-guarded. Indeed, we have that $\mathrm{w}_{7} \sigma_{1 / 2}^{\prime}=\mathrm{w}_{9} \sigma_{1 / 2}^{\prime}=$ $\operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{4}\right)$. The maximal common prefix of $\operatorname{seq}_{\mathrm{tr}_{1}^{\prime} \cdot \operatorname{tr}_{2}^{\prime}}\left(\mathrm{w}_{7}\right)$ and $\mathrm{seq}_{\mathrm{tr}}^{1}$. $\operatorname{tr}_{2}^{\prime}\left(\mathrm{w}_{9}\right)$ is actually

$$
\operatorname{tr}_{1}^{\prime}=\operatorname{io}\left(c_{1}, \operatorname{start}, \mathrm{w}_{1}\right) \cdot \operatorname{io}\left(c_{2}, \mathrm{w}_{1}, \mathrm{w}_{2}\right) \cdot \mathrm{io}\left(c_{3}, \mathrm{w}_{2}, \mathrm{w}_{3}\right) \cdot \operatorname{io}\left(c_{4}, \mathrm{w}_{3}, \mathrm{w}_{4}\right) \cdot \mathrm{io}\left(c_{3}, \mathrm{w}_{4}, \mathrm{w}_{5}\right) .
$$

Actually, $\mathrm{w}_{7} \sigma_{1 / 2}^{\prime}$ occurs as a subterm in $\mathrm{w}_{4} \sigma_{1 / 2}^{\prime}$, thus the test $\mathrm{w}_{7}=\mathrm{w}_{9}$ is not pulled-up in $\left(\operatorname{tr}_{1}^{\prime} \cdot \operatorname{tr}_{2}^{\prime}, \sigma_{1 / 2}^{\prime}\right)$.

We are now able to state our characterisation lemma. Intuitively, we show that for tests that are valid and guarded, it is sufficient to consider pulled-up tests. We first illustrate through an example how a test that is valid and guarded can be converted into a pulled-up one.
Example 7.3.3. Continuing Example 7.3.1, we consider the test $w_{7}=w_{9}$ which is not pulled-up in $\left(\operatorname{tr}_{1}^{\prime} \cdot \operatorname{tr}_{2}^{\prime}, \sigma_{1 / 2}^{\prime}\right)$. Consider the execution

$$
\operatorname{tr}^{\prime}=\operatorname{tr}_{1}^{\prime} \cdot \operatorname{io}\left(c_{4}, \mathrm{w}_{5}, \mathrm{w}_{6}\right) \cdot \operatorname{io}\left(c_{5}, \mathrm{w}_{6}, \mathrm{w}_{7}\right) \cdot \operatorname{io}\left(c_{3}, \mathrm{w}_{4}, \mathrm{w}_{8}\right) \cdot \operatorname{io}\left(c_{4}, \mathrm{w}_{8}, \mathrm{w}_{9}\right) \cdot \operatorname{io}\left(c_{5}, \mathrm{w}_{9}, \mathrm{w}_{10}\right)
$$

This execution is almost similar to $\operatorname{tr}_{1}^{\prime}$. $\operatorname{tr}_{2}^{\prime}$. The main difference is that the computation performed at the end of $\operatorname{tr}_{1}^{\prime}$ using channel $c_{3}$ with input $\mathrm{w}_{4}$ is duplicated. Both io $\left(c_{3}, \mathrm{w}_{4}, \mathrm{w}_{5}\right)$ and io $\left(c_{3}, \mathrm{w}_{4}, \mathrm{w}_{8}\right)$ occur in $\mathrm{tr}^{\prime}$. The resulting frame is:

$$
\begin{aligned}
& \sigma_{1}^{\prime} \cup \quad\left\{\mathrm{w}_{6} \triangleright \operatorname{senc}\left(\operatorname{senc}\left(\operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{4}\right), \mathrm{k}_{2}, r_{7}\right), \mathrm{k}_{1}, r_{8}\right), \mathrm{w}_{7} \triangleright \operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{4}\right),\right. \\
& \mathrm{w}_{8} \triangleright \operatorname{senc}\left(\operatorname{senc}\left(\operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{4}\right), \mathrm{k}_{1}, r_{5}\right), \mathrm{k}_{2}, r_{6}^{\prime}\right), \\
&\left.\mathrm{w}_{9} \triangleright \operatorname{senc}\left(\operatorname{senc}\left(\operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{4}\right), \mathrm{k}_{2}, r_{7}^{\prime}\right), \mathrm{k}_{1}, r_{8}^{\prime}\right), \mathrm{w}_{10} \triangleright \operatorname{senc}\left(\mathrm{a}, \mathrm{k}_{2}, r_{4}\right)\right\} .
\end{aligned}
$$

The terms stored in $w_{5}$ and $w_{8}$ differ by their random seeds:

$$
\operatorname{senc}\left(\operatorname{senc}\left(\operatorname{senc}\left(a, k_{2}, r_{4}\right), \mathrm{k}_{1}, r_{5}\right), \mathrm{k}_{2}, r_{6}\right) \text { and } \operatorname{senc}\left(\operatorname{senc}\left(\operatorname{senc}\left(a, \mathrm{k}_{2}, r_{4}\right), \mathrm{k}_{1}, r_{5}\right), \mathrm{k}_{2}, r_{6}^{\prime}\right)
$$

This frame is almost the same as $\sigma_{1 / 2}^{\prime}$ with an additional element $\left(w_{8}\right)$. The term stored in $\mathrm{w}_{8}$ is the same as the one stored in $\mathrm{w}_{5}$ up to the choice of some random seeds ( $r_{6}$ is replaced by the fresh random $r_{6}^{\prime}$ ). Moreover, the presence of this additional element leads us to reindex the following elements of the frame, and to replace some occurrences of $r_{6}$ with $r_{6}^{\prime}$. It is important to note that the introduced randoms $r_{6}^{\prime}$ and $r_{8}^{\prime}$ could potentially break equality tests. They however do not appear anymore in the last outputted term stored in $\mathrm{w}_{10}$ that is checked for equality.

This example shows that when considering the trace $\left(\operatorname{tr}_{1}^{\prime} \cdot \operatorname{tr}_{2}^{\prime}, \sigma_{1 / 2}^{\prime}\right)$, we may have to consider the test $\mathrm{w}_{7}=\mathrm{w}_{9}$ which is not pulled-up. However, this test is essentially the same than the pulled-up test $\mathrm{w}_{7}=\mathrm{w}_{10}$ issued from the trace given above.

The transformation explained in the previous example can be generalised to any protocol.
Lemma 7.3.1. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}$, then $P \approx_{\mathrm{fwd}} Q$ if, and only if, the following four conditions are satisfied:

- $\operatorname{Const}_{P}$ : For all $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace} \mathrm{f}_{\mathrm{fwd}}(P)$, there exists a frame $\sigma_{Q}$ such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in \operatorname{trace}_{\mathrm{fwd}}(Q)$ and for every $\mathrm{w}, \mathrm{w}^{\prime} \in \operatorname{dom}\left(\sigma_{P}\right)$ and for every constant $\mathrm{c} \in \Sigma_{0} \cup\{$ start $\}, \mathrm{w} \sigma_{P}=\mathrm{w}^{\prime} \sigma_{Q}=\mathrm{c}$ if, and only if, there exists a constant $\mathrm{c}^{\prime} \in \Sigma_{0} \cup\{$ start $\}$ such that $\mathrm{w} \sigma_{Q}=\mathrm{w}^{\prime} \sigma_{Q}=\mathrm{c}^{\prime}$.
- $\operatorname{Const}_{Q}$ : Similarly swapping the roles of $P$ and $Q$.
- $\operatorname{GuARDED}_{P}$ : For all $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace}_{\mathrm{fwd}}(P)$, there exists a frame $\sigma_{Q}$ such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in \operatorname{trace} \mathrm{e}_{\mathrm{fwd}}(Q)$ and every test that is $\sigma_{P}$-valid, $\sigma_{P}$-guarded, and pulled-up in $\left(\operatorname{tr}, \sigma_{P}\right)$ is also $\sigma_{Q}$-valid, $\sigma_{Q}$-guarded, and pulled-up in $\left(\operatorname{tr}, \sigma_{Q}\right)$.
- Guarded ${ }_{Q}$ : Similarly swapping the roles of $P$ and $Q$.

## Proof. (sketch)

$(\Rightarrow)$ For this direction, when considering $\operatorname{Const}_{P}$, the only difficulty is to show that the test $\mathrm{w} \sigma_{Q}=\mathrm{w}^{\prime} \sigma_{Q}$ leads to a constant $\mathrm{c}^{\prime}$. Actually, such a test can not lead to a guarded test since otherwise a replay of the entire sequence (this replay is possible since we consider a class of protocol that allows this) will lead to a different guarded term in $Q$ and not in $P$ (due to the presence of fresh randoms in guarded terms).

When considering $\operatorname{GUARDED}_{P}$, the difficulty is to show that the test $\mathrm{w}=\mathrm{w}^{\prime}$ is necessarily pulled-up in ( $\left.\operatorname{tr}, \sigma_{Q}\right)$. Let pref $=\mathrm{io}\left(c_{i_{0}}\right.$, start, $\left.\mathrm{w}_{j_{0}}\right) \ldots \mathrm{io}\left(c_{i_{p}}, \mathrm{w}_{j_{p-1}}, \mathrm{w}_{j_{p}}\right)$ be the maximal common prefix of seq $\mathrm{tr}(\mathrm{w})$ and seq $\mathrm{q}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)$. Since
$\mathrm{w}=\mathrm{w}^{\prime}$ is pulled-up in $\left(\operatorname{tr}, \sigma_{P}\right)$, we know that the first occurrence of $\mathrm{w} \sigma_{P}$ in pref $\sigma_{P}$ (if any) is at the very end of the sequence. We can easily show that $\mathrm{w}=\mathrm{w}^{\prime}$ is $\sigma_{Q}$-valid and $\sigma_{Q}$-guarded, and thus $\mathrm{w} \sigma_{Q}$ occurs also as a subterm in $\operatorname{pref} \sigma_{Q}$. The only problem is if $\mathrm{w} \sigma_{Q}$ occurs in $\operatorname{pref} \sigma_{Q}$ but not at the very end of this sequence. The idea is that in such a case, we can modify the trace $\left(\operatorname{tr}, \sigma_{Q}\right)$ and the test $\mathrm{w}=\mathrm{w}^{\prime}$ to build $\left(\operatorname{tr}^{*}, \sigma_{Q}^{*}\right)$ and a new test $\mathrm{w}_{*}=\mathrm{w}_{*}^{\prime}$ which will be pulled-up in $\left(\operatorname{tr}^{*}, \sigma_{Q}^{*}\right)$. The idea is to split the two sequences $\operatorname{seq}_{\mathrm{tr}}(\mathrm{w})$ and $\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)$ earlier without compromising the fact that the test will be valid in the resulting frame. This corresponds to the construction illustrated in Example 7.3.3. This trace $\mathrm{tr}^{*}$ is actually a witness of non-equivalence. Actually, the test $\mathrm{w}_{*}=\mathrm{w}_{*}^{\prime}$ is a fortiori not valid on the $P$ side, and this contradicts our hypothesis $P \approx_{\mathrm{fwd}} Q$.
$(\Leftarrow)$ Actually, for this direction, assume that we have a witness of the fact that $P \not \approx Q$, i.e. a trace $\left(\operatorname{tr}, \sigma_{P}\right) \in$ $\operatorname{trace}_{\mathrm{fwd}}(P)$, a trace $\left(\operatorname{tr}, \sigma_{Q}\right) \in \operatorname{trace}_{\mathrm{fwd}}(Q)$, and a test $\mathrm{w}=\mathrm{w}^{\prime}$ that is $\sigma_{P}$-valid but not $\sigma_{Q}$-valid. In case the resulting term is a constant, we easily conclude that $\operatorname{Const}_{P}$ fails. Otherwise, it means that $\mathrm{w}=\mathrm{w}^{\prime}$ is $\sigma_{P}$-guarded. In order to show that $\operatorname{GUARDED}_{P}$ fails, we have to ensure that the test $\mathrm{w}=\mathrm{w}^{\prime}$ is pulled-up w.r.t. ( $\operatorname{tr}, \sigma_{P}$ ). Since, this is not necessarily the case, we have to build another trace $\left(\operatorname{tr}^{*}, \sigma_{P}^{*}\right)$ that will lead us to a pulled-up test. Roughly, the transformation consists in splitting the two sequences $\operatorname{seq}_{t r}(w)$ and $\operatorname{seq}_{t r}\left(w^{\prime}\right)$ earlier without compromising the fact that the test will be valid in the resulting frame. Actually, such a transformation can not transform a test that was not valid in a valid one, thus this test is still not valid for $Q$ and it is still a witness of non-equivalence, but a pulled-up one allowing us to conclude.

The detailed proof can be found in Appendix B.3.1.

### 7.3.3 From trace equivalence to language equivalence

Our goal is to associate an automaton $\mathcal{A}_{P}$ to a protocol $P$ such that $\mathcal{A}_{P}$ recognises the words (a sequence of channels) that correspond to a possible execution of the protocol. The stack of the automaton $\mathcal{A}_{P}$ is used to store a (partial) representation of the last outputted term. This first requires to convert a term into a word.

Given an input term or an output term $u$ (see Section 7.1.2), we define inductively $\bar{u}$ in the following way:

$$
\begin{cases}\bar{u}=\bar{v} . \mathrm{k} & \text { if } u=\mathrm{f}(v, \mathrm{k}, r) \text { and } \mathrm{f} \in\{\text { senc, raenc, sign }\} \\ \overline{\mathrm{c}}=\omega \mathrm{c} & \text { for any constant } \mathrm{c} \in \Sigma_{0} \cup\{\text { start }\} \\ \bar{x}=\epsilon & \text { for any variable } x\end{cases}
$$

where $\epsilon$ denotes the empty word. Note that, using this representation, random seeds are not part of the encoding. We denote by $\|u\|$ the height of the term $u$ which is equal to the number of occurrence of senc, raenc, and sign in $u$.

We now consider an arbitrary ping-pong protocol $P$ (using the same notation as the one introduced in Section 7.1):

$$
\begin{equation*}
\left.\left.P \stackrel{\text { def }}{=}\right|_{i=1} ^{n}\right|_{j=1} ^{p_{i}} \operatorname{lin}\left(c_{i}, u_{i}^{j}\right) \text {.new } r_{1} \ldots . \text { new } r_{k_{i}^{j}} . \text { out }\left(c_{i}, v_{i}^{j}\right) \tag{*}
\end{equation*}
$$

In the remaining of the section, we denote by $\Sigma_{0}^{P}$ the finite set of constants of $\Sigma_{0} \cup\{$ start $\}$ that actually occur in the protocol $P$.

## Encoding of the conditions $\operatorname{Const}_{P}$ and $\operatorname{CoNst}_{Q}$

We first build an automaton that recognises tests of the form $w=w^{\prime}$ such that the corresponding term is actually a constant. We define $\mathcal{A}_{\text {Const }}^{P}$ as follows:

$$
\mathcal{A}_{\mathrm{CONST}}^{P}=\left(\left\{q_{0}, q_{\mathrm{f}}\right\} \cup\left\{q_{\mathrm{c}} \mid \mathrm{c} \in \Sigma_{0}^{P}\right\},\left\{c_{1}, \ldots, c_{n}\right\} \cup\left\{c_{\mathrm{test}}, c_{\mathrm{end}}\right\}, \Sigma_{0}^{P}, q_{0}, \omega,\left\{q_{0}, q_{\mathrm{f}}\right\}, \delta\right)
$$

where the transition function $\delta$ is defined as follows:

Figure 7.3: Automaton $\mathcal{A}_{\text {Const }}^{P}$

1. for every $q \in\left\{q_{0}\right\} \cup\left\{q_{\mathrm{c}} \mid c \in \Sigma_{0}^{P}\right\}$, for every $i \in\{1, \ldots, n\}$, for every $j \in\left\{1, \ldots, p_{i}\right\}$, there is a transition $q \xrightarrow{c_{i} ; \bar{u}_{j}^{i} / \overline{v_{j}^{i}}} q$;
2. for every constant c , there is a transition $q_{0} \xrightarrow{c_{\text {test }} ; \omega \mathrm{c} / \omega \text { start }} q_{\mathrm{c}}$;
3. for every constant c , there is a transition $q_{\mathrm{c}} \xrightarrow{c_{\text {end }} ; \omega \mathrm{c} / \omega} q_{\mathrm{f}}$.

The automaton is depicted in Figure 7.3. Intuitively, the basic building blocks (e.g. $q_{0}$ with the transitions from $q_{0}$ to itself) mimic an execution of $P$ where each input is fed with the last outputted term. Then, to recognise the tests of the form $w=w^{\prime}$ that are true in such an execution, it is sufficient to memorise the constant $c$ that is associated to w (adding a new state $q_{\mathrm{c}}$ ), and to see whether it is possible to reach a state where the stack contains cagain. More formally, we have the following result.
Lemma 7.3.2. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}$, the two real-time GPDA $\mathcal{A}_{\mathrm{CONST}}^{P}$ and $A_{\mathrm{CONST}}^{Q}$ are such that:

$$
P \text { and } Q \text { satisfy conditions } \operatorname{CoNST}_{P} \text { and } \operatorname{CoNST}_{Q} \text { iff } \mathcal{L}\left(\mathcal{A}_{\mathrm{CONST}}^{P}\right)=\mathcal{L}\left(\mathcal{A}_{\mathrm{CONST}}^{Q}\right) .
$$

The proof can be found in Appendix B.3.2.
Example 7.3.4. Going back to our running example, i.e. the protocol $P$ described in Figure 7.2, the automaton $\mathcal{A}_{\text {Const }}^{P}$ is depicted below:

The word that represents the trace $\left(\operatorname{tr}_{1} \cdot \operatorname{tr}_{2}, \sigma_{1 / 2}\right)$ and the test $\mathrm{w}_{5}=\mathrm{w}_{8}$ as given in Figure 7.2 is: $c_{1} c_{2} c_{3} c_{4} c_{5} c_{\text {test }} c_{1} c_{3} c_{2} c_{5} c_{\text {end }}$. The fact that this test is a valid one that leads to a constant a means that the word will be accepted by the automaton given above. The corresponding run goes through the state $q_{\mathrm{a}}$ and halts in state $q_{\mathrm{f}}$.
$\mathcal{A}_{\text {CONST }}^{P}$ has a number of states polynomial in the number of constants in $P$, and for each state a number of transitions linear in the number of branches in $P$. Thus, $\mathcal{A}_{\text {CONST }}^{P}$ is of size polynomial with respect to the size of $P$.

## Encoding of the conditions GUARDED ${ }_{P}$ and GUARDED ${ }_{Q}$

Capturing tests that lead to non-constant symbols (i.e. terms of the form $f(u, k, r)$ with $f \in\{$ senc, raenc, sign\}) is more tricky for several reasons. First, it is not possible anymore to memorise the resulting term in a state of the automaton. Second, names of sort rand play a role in such a test, while they are forgotten in our encoding. We rely on

our characterisation introduced in Section 7.3.2 and we construct a more complex automaton that uses some special track symbols to encode when randomised ciphertexts may be reused.

More precisely, we consider:

- $\Pi=\left\{c_{1}, \ldots, c_{n}, c_{\text {test }}, c_{\text {end }}\right\} \cup\left\{c_{\text {fork }}^{i} \mid 1 \leq i \leq n\right\}$, and
- $\Gamma=\Sigma_{0}^{P} \cup\{\operatorname{test}\} \cup\left\{\left(\right.\right.$ fork $\left._{i}^{j}, k\right) \mid 1 \leq i \leq n, 1 \leq j \leq p_{i}$, and $\left.1 \leq k \leq\left\|u_{i}^{j}\right\|\right\}$.

Note that $n$ and $p_{i}$ are induced by the definition of protocol $P$ (see equation (*)). The input alphabet contains the channel names $c_{1}, \ldots, c_{n}$, plus some additional symbols, denoted $c_{\text {fork }}^{1}, \ldots, c_{\text {fork }}^{n}$, that will be used once and whose purpose will be to mark the end of the common prefix between $\operatorname{seq}_{\mathrm{tr}}(\mathrm{w})$ and $\mathrm{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)$.

The stack-alphabet is more involved. We still have one symbol per constant in $\Sigma_{0}^{P}$, and a special symbol test that will be put on top of the stack when the stack contains the target term (i.e. w $\sigma$ ). In such an automaton, the idea is to consider pulled-up tests only. The tile (fork ${ }_{i}^{j}, k$ ) is placed on the stack when the automaton has finished to build the term corresponding to the left hand side of a pulled-up test.

The transition function $\delta$ is defined as follows:

1. for $q \in\left\{q_{0}, q_{1}, q_{2}\right\}$, for every $i \in\{1, \ldots, n\}$ and $j \in\left\{1, \ldots, p_{i}\right\}$, there is a transition $q \xrightarrow{c_{i} ; \overline{u_{i}^{j}} \overline{v_{i}^{j}}} q$;
2. for every $i \in\{1, \ldots, n\}$ and $j \in\left\{1, \ldots, p_{i}\right\}$ such that $\left\|v_{i}^{j}\right\| \geq 1$, there is a transition

$$
q_{0} \xrightarrow{c_{\text {cork }}^{i} ; \overline{u_{i}^{j}} / \omega \overline{v_{i}^{j}}\left(\text { fork } k_{i}^{j},\left\|v_{i}^{j}\right\|\right)} q_{1}
$$

3. for every $i \in\{1, \ldots, n\}$ and $j \in\left\{1, \ldots, p_{i}\right\}$, for every $i^{\prime} \in\{1, \ldots, n\}$ and $j^{\prime} \in\left\{1, \ldots, p_{i^{\prime}}\right\}$, for every $m$ such that $1<m \leq\left\|v_{i^{\prime}}^{j^{\prime}}\right\|$, and for every subterm $u_{0}$ of $u_{i}^{j}$ of height $k \in\{1, \ldots, m-1\}$ such that $\overline{u_{i}^{j}}=\overline{u_{0}} \cdot s^{\prime}$ there is a transition

$$
q_{1} \xrightarrow{c_{i} ; \overline{u_{0}} \cdot\left(\text { fork } i_{i^{\prime}}^{j^{\prime}}, m\right) \cdot s^{\prime} /\left(\text { fork } k_{i}^{\prime}, m-k\right) \overline{v_{i}^{j}}} q_{1} .
$$

4. for every $i \in\{1, \ldots, n\}$ and $j \in\left\{1, \ldots, p_{i}\right\}$, for every $m$ such that $1 \leq m \leq\left\|v_{i}^{j}\right\|$, there is a transition $q_{1} \xrightarrow{c_{\text {test }}\left(\text { fork } k_{i}^{j}, m\right) / \text { test } s_{i, m}^{j}} q_{2}$ where $s_{i, m}^{j}$ is the suffix of length $\left\|v_{i}^{j}\right\|-m$ of $\overline{v_{i}^{j}}$.
5. there is a transition $q_{2} \xrightarrow{c_{\text {end } ; ~ t e s t ~} / \epsilon} q_{\mathrm{f}}$.

Figure 7.4: Automaton $\mathcal{A}_{\text {GUARDED }}^{P}$

The loop in $q_{0}$ (item 1) represents the regular execution of the protocol by the attacker: through unstacking and stacking, she builds a term on the stack along a particular trace. The transitions $q_{0} \xrightarrow{c_{\text {fork }}^{i} ; z / z^{\prime}} q_{1}$ (item 2) enable her to mark a fork when building a test in her frame with a particular stack symbol fork ${ }_{i}^{j}$, enriched with some information. Intuitively, the part of the execution that is performed until here should correspond to the maximal prefix shared between the sequences $\operatorname{seq}_{\mathrm{tr}}(\mathrm{w})$ and $\mathrm{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)$. By looping in $q_{1}$, the attacker can continue building the first term of an equality, following the usual execution of the protocol, if it were for the presence of the stack symbol (fork ${ }_{i}^{j}$, $k$ ) which can only go down on the stack for at most $k-1$ times. When the symbol (fork ${ }_{i}^{j}, k$ ) appears on top of the stack, the attacker may decide that she has built the first part of a pulled-up test. Then test will be put on the top of the stack and a part of the stack (following the instructions memorised in the symbol (fork ${ }_{i}^{j}, k$ )) will be regenerated. The idea is that the stack has to contain the same term as the one stored just after forking. Then the attacker tries to build the second member of the test. If this second term manages to end up exactly as the previous one (the position in the stack is marked using the tile test), an equality is reached and the word is recognised by the automata, witnessing the equality induced by the pulled-up test.

What remains now is to prove that $P$ and $Q$ satisfy conditions GuARDED $_{P}$ and GuARDED $_{Q}$ if, and only if, $\mathcal{L}\left(\mathcal{A}_{\text {Guarded }}^{P}\right)=\mathcal{L}\left(\mathcal{A}_{\text {GUarded }}^{Q}\right)$. This is formally stated in the following lemma.

Lemma 7.3.3. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}$, the two real-time GPDA $\mathcal{A}_{\text {GUARDED }}^{P}$ and $A_{\text {GUARDED }}^{Q}$ are such that:

$$
P \text { and } Q \text { satisfy conditions GUARDED } P_{P} \text { and } \operatorname{GUARDED}_{Q} \text { iff } \mathcal{L}\left(\mathcal{A}_{\text {Guarded }}^{P}\right)=\mathcal{L}\left(\mathcal{A}_{\text {GUarded } \left.^{Q}\right) . ~}^{\text {. }}\right.
$$

The proof can be found in Appendix B.3.2.
Example 7.3.5. Going back to our running example, i.e. the protocol $P$ described in Figure 7.2, the automaton $\mathcal{A}_{\text {Guarded }}^{P}$ is depicted below.

The set of transitions R is the one defined in Example 7.3.4. The situation where the stack symbol (fork ${ }_{i}^{j}, k$ ) goes down occurs for instance when considering the word $c_{1} c_{2} c_{3} c_{\text {fork }}^{4} c_{3} c_{4} c_{5} c_{\text {test }} c_{3} c_{4} c_{5}$. The evolution of the stack during the run of the automaton is depicted below. On the second line, we can see that this symbol goes down and $k$ goes from 2 to 1 .

$$
\xrightarrow{c_{\text {test }}}\left|\begin{array}{c}
\mathrm{k}_{1} \\
\text { test } \\
\mathrm{k}_{2} \\
\omega \\
\mathrm{a} \\
\omega
\end{array}\right| \xrightarrow{c_{3}}\left|\begin{array}{c}
\mathrm{k}_{2} \\
\mathrm{k}_{1} \\
\text { test } \\
\mathrm{k}_{2} \\
\omega \\
\mathrm{a} \\
\omega
\end{array}\right| \xrightarrow{c_{4}}\left|\begin{array}{c}
\mathrm{k}_{1} \\
\mathrm{k}_{2} \\
\text { test } \\
\mathrm{k}_{2} \\
\omega \\
\mathrm{a} \\
\omega
\end{array}\right| \xrightarrow{c_{5}}\left|\begin{array}{c} 
\\
\text { test } \\
\mathrm{k}_{2} \\
\omega \\
\mathrm{a} \\
\omega
\end{array}\right| \xrightarrow{c_{\text {end }}}\left|\begin{array}{l}
\mathrm{k}_{2} \\
\omega \\
\mathrm{a} \\
\omega
\end{array}\right|
$$

The trace $(\operatorname{tr}, \sigma) \in \operatorname{trace}_{\mathrm{fwd}}(P)$ and the pulled-up test $\mathrm{w}=\mathrm{w}^{\prime}$ that correspond to this execution is the ones introduced in Example 7.3.3, i.e. $\operatorname{tr}^{\prime}$ together with the test $w_{7}=w_{10}$.

We can notice that up to the special stack-symbols, namely test and (fork ${ }_{i}^{j}, k$ ), the contents of the stack after reading $c_{\text {fork }}^{i}$ (here $i=4$ ) and $c_{\text {test }}$ are the same. The stack actually represents the term obtained after executing the common prefix shared between $\operatorname{seq}_{t r^{\prime}}\left(w_{7}\right)$ and $\operatorname{seq}_{t r^{\prime}}\left(\mathrm{w}_{10}\right)$, i.e. $\operatorname{senc}\left(\operatorname{senc}\left(a, \mathrm{k}_{2}, r_{4}\right), \mathrm{k}_{1}, r_{5}\right)$ stored in $\mathrm{w}_{4}$. We have also that the contents of the stack before reading $c_{\text {test }}$ and after reading $c_{\text {end }}$ are also the same (up to some special stack symbols). They actually represent the terms stored respectively in $w_{7}$ and $w_{10}$.

Note that $\mathcal{A}_{\text {GUARDED }}^{P}$ has a fixed number of states, and a polynomial number of transitions : transitions are added for each branch and suffix of any input term. Thus, $\mathcal{A}_{\text {GUARDED }}^{P}$ is of size polynomial with respect to the size of $P$.

### 7.4 From language equivalence to trace equivalence

We have seen how to encode trace equivalence between processes in $\mathcal{C}_{\mathrm{pp}}$ into language equivalence between real-time GPDA. The two problems are actually equivalent. Indeed, in this section, we show that we can conversely encode any
real-time GPDA $\mathcal{A}$ into a process $P_{\mathcal{A}}$ in $\mathcal{C}_{\mathrm{pp}}$ such that $\mathcal{L}(\mathcal{A}) \subseteq \mathcal{L}(\mathcal{B})$ implies $P_{\mathcal{A}} \sqsubseteq P_{\mathcal{B}}$.
Consider an automaton $\mathcal{A}=\left(Q, \Pi, \Gamma, q_{0}, \omega, Q_{f}, \delta\right)$. The process $P_{\mathcal{A}}$ associated to $\mathcal{A}$ is built using symmetric encryption only. For the purpose of the encoding, we consider the following constants of sort SymKey:

- for each $q \in Q$, we denote $q$ its counterpart in $\Sigma_{0}$;
- for each $\alpha \in \Gamma$, we denote $\mathrm{k}_{\alpha}$ its counterpart in $\Sigma_{0}$;
- a constant $\mathrm{k}_{\text {well }}$.

Let also $c_{0}, c_{a}, c_{f}$ with $a \in \Pi$ be constant symbols of sort channel in $\mathcal{C} h$. Words in $\Gamma^{*}$, i.e. stacks, will be represented through nested encryptions with keys representing their counterparts in $\Gamma$. For the sake of brevity, given a word $u=\alpha_{1} \ldots \alpha_{p}$ of $\Gamma^{*}$, we denote by $\overline{x . u}$ :

- either the term $\operatorname{senc}\left(\ldots \operatorname{senc}\left(x, \mathrm{k}_{\alpha_{1}}, z_{1}\right) \ldots, \mathrm{k}_{\alpha_{p}}, z_{p}\right)$ where $z_{1}$ through $z_{p}$ are variables used for nonces when $\overline{x . u}$ is used in as an input pattern;
- or the term $\operatorname{senc}\left(\ldots \operatorname{senc}\left(x, \mathrm{k}_{\alpha_{1}}, r_{1}\right) \ldots, \mathrm{k}_{\alpha_{p}}, r_{p}\right)$ where $r_{1}$ through $r_{p}$ are fresh randoms when $\overline{x . u}$ is used as an output pattern.

Below, we use new $\tilde{r}$ as shortcut for new $r_{1} \ldots$ new $r_{p}$ such that the sequence will bind every nonce occurring in the following output.

The stack of the automaton $\mathcal{A}$ is encoded as a pile of encryptions (where each key encodes a letter of the stack). Then, upon receiving such a pile of encryptions encrypted by $q$ on channel $c_{a}$, the process $P_{\mathcal{A}}$ will mimic the transition of $\mathcal{A}$ that is triggered when the automaton is at state $q$ upon reading $a$ with the stack corresponding to that pile of encryptions.

More formally, the process $P_{\mathcal{A}}$ is defined as follows:

$$
\begin{align*}
& \left.P_{\mathcal{A}} \stackrel{\text { def }}{=} \quad \operatorname{in}\left(c_{0}, \text { start }\right) \text {.new } \tilde{r} \text {.out }\left(c_{0}, \operatorname{enc}\left(\operatorname{enc}\left(\text { start }, \mathrm{k}_{\omega}, r_{1}\right), \mathrm{k}_{\text {start }}, r_{2}\right), q_{0}, r_{3}\right)\right)  \tag{0}\\
& \text { | ! in }\left(c_{a}, \operatorname{enc}(\overline{x . u}, q, z)\right) \text {.new } \tilde{r} \text {.out }\left(c_{a}, \operatorname{enc}\left(\overline{x . v}, q^{\prime}, r\right)\right)  \tag{1}\\
& \text { | ! in }\left(c_{a} \text {, enc }\left(\overline{x . u^{\prime}}, q, z\right)\right) \text { new } r \text {.out }\left(c_{a}, \text { enc }\left(\text { start }, \mathrm{k}_{\text {well }}, r\right)\right)  \tag{1a}\\
& \text { | ! in }\left(c_{a}, \text { enc }\left(\text { start }, \mathrm{k}_{\text {well }}, z\right)\right) \text {.new } r \text {.out }\left(c_{a} \text {, enc }\left(\text { start }, \mathrm{k}_{\text {well }}, r\right)\right)  \tag{1b}\\
& \text { | ! in }\left(c_{f}, \operatorname{enc}\left(x, q_{f}, z\right)\right) \text {.new } r \text {.out }\left(c_{f}, \operatorname{enc}\left(\operatorname{start}, q_{f}, r\right)\right) \tag{2}
\end{align*}
$$

where $a$ quantifies over $\Pi, q$ over $Q, u$ over words in $\Gamma^{*}$ such that $(q, a, u) \in \operatorname{dom}(\delta), q_{f}$ over $Q_{f}$, and $\left(q^{\prime}, v\right)=$ $\delta(q, a, u)$. Lastly, $u^{\prime}$ ranges over $U_{q, a}^{\prime} \stackrel{\text { def }}{=} \alpha \cdot S S_{q, a} \backslash S_{q, a}$ where $S_{q, a}$ (resp. $S S_{q, a}$ ) is the set that contains suffixes (resp. strict suffixes) of some $u$ with $(q, a, u) \in \operatorname{dom}(\delta)$. This set $U_{q, a}^{\prime}$ corresponds intuitively to the set of shortest words which are not suffixes of any word in $\{u \mid(q, a, u) \in \operatorname{dom}(\delta)\}$, and, thus the shortest words to unstack to be sure that no transition from $q$ reading $a$ is possible in the automaton.

Example 7.4.1. Consider a real-time GPDA such that $\Gamma=\{\alpha, \beta, \gamma, \omega\}, q \in Q$, and $a \in \Pi$. Assume that $\{u \mid(q, a, u) \in$ $\operatorname{dom}(\delta)\}=\{\beta \alpha, \beta \alpha \alpha\}$. We have $S S_{q, a}=\{\epsilon, \alpha, \alpha \alpha\}$, and $S_{q, a}=S S_{q, a} \cup\{\beta \alpha, \beta \alpha \alpha\}$. Thus, we have that:

$$
U_{q, a}^{\prime}=\{\omega, \beta, \gamma, \omega \alpha, \gamma \alpha, \omega \alpha \alpha, \alpha \alpha \alpha, \gamma \alpha \alpha\} .
$$

In the encoding above, the branches (0) and (1) mimic the behaviour of the automaton $\mathcal{A}$. Branch (2) is triggered in case a final state $q_{f}$ is reached. In case we are considering a behaviour that is not authorised by the automaton, we obtain a message encrypted with $k_{\text {well }}$ through branches $(1 a)$. Then branches $(1 b)$ allow to pursue the execution of the protocol outputting messages that look fresh.

Lemma 7.4.1. The protocol $P_{\mathcal{A}}$ described above is in $\mathcal{C}_{\mathrm{pp}}$ and of size polynomial w.r.t. $\mathcal{A}$.
Proof. First, note that because $\operatorname{dom}(\delta)$ is finite, as the automaton is finitely described, the sets $\{u \mid(q, a, u) \in \operatorname{dom}(\delta)\}$ and $U_{q, a}^{\prime}$ are also finite for any $a \in \Pi$ and $q \in Q$. Moreover, the automaton being deterministic, given $q \in Q$ and $a \in \Pi$, for every word $s \in \Gamma^{*}$ :

- either there exists a unique suffix $u$ of $s$ such that $(q, a, u) \in \operatorname{dom}(\delta)$;
- or there exists a unique suffix $u^{\prime}$ of $s$ such that $u^{\prime} \in U_{q, a}^{\prime}$,
and this disjunction is exclusive. This allows us to ensure that condition (2) of Definition 7.1.1 is satisfied, and thus $P_{\mathcal{A}}$ belongs to $\mathcal{C}_{\mathrm{pp}}$.

Regarding the size of the protocol, the only non-trivial point is to check that the number of branches $(1 a)$ is polynomially bounded. Let $q \in Q$, and $a \in \Pi$, and assume that the maximal length of a word $u$ in a transition $q \xrightarrow{a ; u / v} q^{\prime}$ of the automaton is $\ell_{q, a}$, we have that the number of branches $(1 a)$ for state $q$ and letter $a$ is bounded by $\ell_{q, a} \times \# \Gamma \times \#\{u \mid(q, a, u) \in \operatorname{dom}(\delta)\}$ where $\# S$ is the cardinality of set $S$. This allows us to conclude.

This polynomial encoding preserves inclusion.
Proposition 7.4.1. Let $\mathcal{A}$ and $\mathcal{B}$ be two real-time GPDA. We have that:

$$
\mathcal{L}(\mathcal{A}) \subseteq \mathcal{L}(\mathcal{B}) \Longleftrightarrow P_{\mathcal{A}} \sqsubseteq P_{\mathcal{B}} .
$$

Proof. Let $\mathcal{A}=\left(Q, \Pi, \Gamma, q_{0}, \omega, Q_{f}, \delta\right)$ and $\mathcal{B}=\left(Q^{\prime}, \Pi, \Gamma^{\prime}, q_{0}^{\prime}, \omega, Q_{f}^{\prime}, \delta^{\prime}\right)$. We show the two implications separately. $(\Leftarrow)$ Assume that there exists a word $t \in \mathcal{L}(\mathcal{A}) \backslash \mathcal{L}(\mathcal{B})$. We will build a trace $(\operatorname{tr}, \phi) \in \operatorname{trace}\left(P_{\mathcal{A}}\right)$ such that there exists no trace $(\operatorname{tr}, \psi) \in \operatorname{trace}\left(P_{\mathcal{B}}\right)$ allowing us to conclude that $P_{A} \nsubseteq P_{\mathcal{B}}$. To build $(\operatorname{tr}, \phi)$, we will mimic the behaviour of $\mathcal{A}$ when reading $t$. The first branch to use is ( 0 ), enabling the attacker to activate other branches of the process $P_{\mathcal{A}}$. As $t \in \mathcal{L}(\mathcal{A})$ and $\mathcal{A}$ is deterministic, there exists a unique sequence of transitions leading to an accepting state $q_{f} \in Q_{f}$. For every such transition the attacker will activate the corresponding branch (1) in $P_{\mathcal{A}}$. If $t=a_{1} \ldots a_{n}$, we define ( $\mathrm{tr}, \phi$ ) as follows:

$$
\operatorname{tr}=\mathrm{io}\left(c_{0}, \operatorname{start}, \mathrm{w}_{1}\right) \cdot \mathrm{io}\left(c_{a_{1}}, \mathrm{w}_{1}, \mathrm{w}_{2}\right) \ldots \mathrm{io}\left(c_{a_{n}}, \mathrm{w}_{n}, \mathrm{w}_{n+1}\right) \cdot \mathrm{io}\left(c_{f}, \mathrm{w}_{n+1}, \mathrm{w}_{n+2}\right)
$$

and $\phi$ is defined as expected given our semantics. Because of the definition of the branch (1), the inputs on the channels $c_{a_{i}}$ are possible, the stack of the automaton upon reading $a_{i}$ and its current state being faithfully represented by the term $\mathrm{w}_{i} \phi$. Thus, $(\operatorname{tr}, \phi)$ is indeed a trace of $P_{\mathcal{A}}$. When reaching $q_{f}$, the attacker can use the branch $(2)$ and output the message senc(start, $\left.q_{f}, r\right)$. As $t \notin \mathcal{L}(\mathcal{B})$, the corresponding sequence of transitions in $\mathcal{B}$ does not lead to any accepting state:

- either at some point of the execution of the automaton a transition from state $q$ reading $a$ is not possible with the current stack $s$. This means that there does not exist a suffix $u$ of $s$ such that $(q, a, u) \in \operatorname{dom}\left(\delta^{\prime}\right)$, and thus, by definition of $U_{q, a}^{\prime}$, there exists a suffix $u^{\prime}$ of $s$ such that $u^{\prime} \in U_{q, a}^{\prime}$, enabling a transition (1a) on channel $c_{a}$ for the attacker, and every subsequent transition is done using branches $(1 b)$,
- or the state reached in $\mathcal{B}$ after reading $t$ is not an accepting state, i.e. not in $Q_{f}^{\prime}$ : the sequence in $\left(c_{f}, \mathrm{w}_{n+1}\right)$.out $\left(c_{f}, \mathrm{w}_{n+2}\right)$ cannot occur in $P_{\mathcal{B}}$.

Consequently, there exists no trace $(\operatorname{tr}, \psi) \in \operatorname{trace}\left(P_{\mathcal{B}}\right)$ (for any $\psi$ ), thus $P_{\mathcal{A}} \nsubseteq P_{\mathcal{B}}$.
$(\Rightarrow)$ First note that, for every frame $\phi(\operatorname{resp} \psi)$ such that $(\operatorname{tr}, \phi) \in \operatorname{trace}\left(P_{\mathcal{A}}\right)\left(\operatorname{resp} .(\operatorname{tr}, \psi) \in \operatorname{trace}\left(P_{\mathcal{B}}\right)\right)$, we have that $\phi$ (resp. $\psi$ ) is of the form

$$
\left\{\mathrm{w}_{1} \triangleright \operatorname{senc}\left(m_{1}, k_{1}, r_{1}\right), \ldots, \mathrm{w}_{n} \triangleright \operatorname{senc}\left(m_{n}, k_{n}, r_{n}\right)\right\}
$$

where the $k_{i}$ are non deducible and the $r_{i}$ are "fresh" in the sense that they are all distinct and non deducible. This means that no equality (but the trivial ones) holds in such a frame. Now consider the shortest trace $(\operatorname{tr}, \phi) \in \operatorname{trace}\left(P_{\mathcal{A}}\right)$, in terms of number of transitions, such that there exists no equivalent frame $(\operatorname{tr}, \psi) \in \operatorname{trace}\left(P_{\mathcal{B}}\right)$. Since keys are nondeducible, we may assume w.l.o.g that $(\operatorname{tr}, \phi) \in \operatorname{trace}_{\mathrm{fwd}}\left(P_{\mathcal{A}}\right)$. Because of the branches $(1),(1 a)$ and $(1 b)$ and in particular of the definition of $U_{q, a}^{\prime}$, for any $q \in Q$, for any $a \in \Pi$, a transition of channel $c_{a}$ is always possible, and we have seen that the resulting frames are necessarily in static equivalence. Thus, the only shortest trace where $P_{\mathcal{B}}$ will not be able to follow is when tr ends with an input/output on channel $c_{f}$. Let $w \in \operatorname{dom}(\phi)$ be the corresponding variable in the frame $\phi$. Consider the subsequence $\operatorname{seq}_{\mathrm{tr}}(\mathrm{w})$ of tr and more precisely the sequence of channels that occurs in this subsequence. Such a sequence is of the form: $c_{0} \cdot c_{a_{1}} \ldots c_{a_{n}} \cdot c_{f}$.

Let $v=a_{1} \ldots a_{n}$. We have that $v$ is a word of $\Pi^{*}$, and, in particular,

- $v \in \mathcal{L}(\mathcal{A})$ : indeed, branches (1) in $P_{\mathcal{A}}$ faithfully represent transitions $(q, a, u) \in \operatorname{dom}(\delta)$ and a branch (2) can only be fired if $q_{f} \in Q_{f}$.
- $v \notin \mathcal{L}(\mathcal{B})$ : indeed branch (2) could not be fired, either $\mathcal{B}$ cannot read $v$ or, after reading $v, \mathcal{B}$ is not in any state of $Q_{f}^{\prime}$.

Hence $v \in \mathcal{L}(\mathcal{A}) \backslash \mathcal{L}(\mathcal{B})$, proving that $\mathcal{L}(\mathcal{A}) \nsubseteq \mathcal{L}(\mathcal{B})$.
Therefore, checking for equivalence of protocols is as difficult as checking equivalence of real-time generalised pushdown deterministic automata.

### 7.5 Implementation

In this section, we detail our tool Cpp 2 dpa to convert protocols in $\mathcal{C}_{\mathrm{pp}}$ into GDPA, available online at

```
http://www.lsv.ens-cachan.fr/~chretien/cpp2dpa.php.
```

This tool takes two protocols in $\mathcal{C}_{\mathrm{pp}}$ as input, turn them into GDPA and, through the tool 1A1BlC [51], outputs whether the two protocols were in equivalence, yielding a witness of non-equivalence in the negative case in the form of a sequence of channels leading to an attack. The tool focuses on the encoding as described in Section 7.3. In particular, we assume the prior steps of Section 7.2 were successfully applied to the pair of protocols; namely the bijection $\alpha$ as in Lemma 7.2.2 was successfully guessed and the oracles of Section 7.2.2 correctly added.

The tool Cpp2dpa is written in Python 3. From pairs of protocols in $\mathcal{C}_{\mathrm{pp}}$, it generates three pairs of normalised deterministic pushdown automaton, instead of directly two pairs of GPDA (as described in Section 7.3). This was necessary so as to interface with 1 AlBlC, and involves no loss of generality, as the former are more expressive than our GDPA. The normalisation process still has the inconvenient, in order to preserve the determinacy of the result, to output automata that may duplicate actions. More specifically, when necessary, the channels appearing in the potential witness of non-equivalence may be doubled. This technical detail does not impair the ability for the combined tool to prove equivalence or find witnesses, nevertheless.

### 7.5.1 Encoding pairs

Most protocols use pairs. While our formalism does not directly support pairs, we may encode a restricted kind of pairing, when there are only constants (such as identities) on the right. Formally, this amounts into encoding a pair $\langle t, a\rangle$, where $t$ is a term and $a$ some constant, by an encryption senc $(t, a, r)$ for some random seed $r$. Provided constants used in concatenation are disjoint from constants used as keys, this encoding does not introduce any confusion. Note that since encryption is randomised, this pairing operator also differs as it is randomised.

### 7.5.2 Biometric passport

We are interested here in proving the unlinkability of the electronic passport protocol. A detailed specification of it can be found in [5]. Here, we only consider the passport's role and forget about the reader. The first case we consider is the flawed version corresponding to the French implementation of the passport, in which an attack arises from the ability for the attacker to observe whether a MAC check succeeds or not. As our framework does not directly enables us to deal with pairs of messages with their MAC, we model it by a signature: the attacker is able to obtain the plaintext of it (which amounts to retrieving the first component of the real pair) but cannot forge it (the attacker is not a priori able to forge a valid MAC). The resulting process is defined as follows.

$$
\begin{align*}
& P_{A} \stackrel{\text { def }}{=}!\operatorname{in}\left(c_{1}, \operatorname{start}\right) . \operatorname{new} \tilde{r}^{\prime} . \\
& \quad \operatorname{out}\left(c_{1}, \operatorname{sign}\left(\operatorname{senc}\left(\operatorname{senc}\left(\operatorname{senc}\left(n_{r}, \mathrm{k}_{r}, r_{1}^{\prime}\right), n_{p}, r_{2}^{\prime}\right), \mathrm{k}_{E}, r_{3}^{\prime}\right), \operatorname{mac}_{\mathrm{k}_{m}}, r_{4}^{\prime}\right)\right)  \tag{1}\\
& \mid!\operatorname{in}\left(c_{2}, \operatorname{sign}\left(\operatorname{senc}\left(x, \mathrm{k}_{E}, z_{1}\right), \operatorname{mac}_{\mathrm{k}_{m}}, z_{2}\right)\right) \cdot \operatorname{new} r_{5} \cdot \operatorname{out}\left(c_{2}, \operatorname{sign}\left(x, \operatorname{mac}_{\mathrm{ok}}, r_{5}\right)\right)  \tag{2a}\\
& \mid!\operatorname{inn}\left(c_{2}^{\prime}, \operatorname{sign}\left(\operatorname{senc}\left(x, n_{p}, z_{1}\right), \operatorname{mac} \operatorname{mak}_{2}, z_{2}\right)\right) \cdot \operatorname{new} \tilde{r}^{\prime \prime} . \\
& \quad \operatorname{out}\left(c_{2}^{\prime}, \operatorname{sign}\left(\operatorname{senc}\left(\operatorname{senc}\left(x, n_{p}, r_{1}^{\prime \prime}\right), \mathrm{k}_{p}, r_{2}^{\prime \prime}\right), \operatorname{mac}_{\mathrm{k}_{m}}, r_{3}^{\prime \prime}\right)\right) \tag{2b}
\end{align*}
$$

where new $\tilde{r}$ is a shortcut of new $r_{1}$. new $r_{2}$.new $r_{3}$.new $r_{4}$ (and similarly for new $\tilde{r}^{\prime}$ and new $\tilde{r}^{\prime \prime}$ ). The protocol is modelled through three rules. Branch (1) corresponds to a message from the current session, emitted by the reader. While the original protocol can check the authenticity of the MAC and the value of the nonce sent to the passport, our formalism requires us to separate this into two steps: branches $(2 a)$ and $(2 b)$. Branch $(2 a)$ checks the validity of the MAC: if it is, it send a message signed with mac ${ }_{\mathrm{ok}}$. On the other hand, branch $(2 b)$ checks the value of the nonce (i.e. $n_{p}$ ) and finally emits the last message of the protocol. To retrieve the attack, we introduce the message sent by the reader from a previous session with a new branch denoted (0):

$$
\begin{align*}
& !\operatorname{in}\left(c_{0}, \operatorname{start}\right) \cdot \operatorname{new} \tilde{r} . \\
& \quad \quad \text { out }\left(c_{0}, \operatorname{sign}\left(\operatorname{senc}\left(\operatorname{senc}\left(\operatorname{senc}\left(n_{r}^{0}, \mathrm{k}_{r}^{0}, r_{1}\right), n_{p}^{0}, r_{2}\right), \mathrm{k}_{E}, r_{3}\right), \operatorname{mac}_{\mathrm{k}_{m}}, r_{4}\right)\right) \tag{0}
\end{align*}
$$

Another protocol $P_{B}$ is obtained by replacing mac $_{k_{m}}$ by mac $_{\mathrm{k}_{m}^{\prime}}$ in branches (1), (2a) and (2b). Our tool Cpp2dpa can automatically check that $P_{A} \not \not \approx P_{B}$.

Another version $P_{A}^{\prime}$ is obtained by replacing branches $(2 a)$ and $(2 b)$ by the branch

$$
\begin{align*}
& !\operatorname{in}\left(c_{2}, \operatorname{sign}\left(\operatorname{senc}\left(\operatorname{senc}\left(x, n_{p}, z_{1}\right), \mathrm{k}_{E}, z_{2}\right), \operatorname{mac}_{\mathrm{k}_{m}}, z_{3}\right)\right) \text {.new } \tilde{r}^{\prime \prime} . \\
& \quad \operatorname{out}\left(c_{2}, \operatorname{sign}\left(\operatorname{senc}\left(\operatorname{senc}\left(x, n_{p}, r_{1}^{\prime \prime}\right), \mathrm{k}_{E}, r_{2}^{\prime \prime}\right), \operatorname{mac}_{\mathrm{k}_{m}}, r_{3}^{\prime \prime}\right)\right) \tag{2}
\end{align*}
$$

The protocol $P_{B}^{\prime}$ is similarly defined, with mac $_{\mathrm{k}_{m}^{\prime}}$ instead of mac $_{\mathrm{k}_{m}}$ in this branch (2). This version models the safe implementation of the protocol, where the success or failure of the MAC check is invisible to the attacker. Our tool Cpp2dpa can automatically prove that $P_{A}^{\prime} \approx P_{B}^{\prime}$.

### 7.5.3 Experiments

We have tested our tool Cpp2dpa on the running example as defined in Example 7.1.1 and Example 7.2.2; as well as on an encoding of the electronic passport protocol, described in Section 7.5.2 in two versions, unsafe and safe (see [5] for more details).

|  | Automata (in ms) | Grammars (in s) | Equivalence (in s) |
| :--- | :---: | :---: | :---: |
| Example 7.1.1 | 7.1 | 9.2 | 3462 (attack) |
| Example 7.2.2 | 7.0 | 3.1 | 9788 (proof) |
| Unsafe passport | 7.1 | 23.2 | 4.89 (attack) |
| Safe passport | 8.1 | 15.0 | 76.1 (proof) |

Figure 7.5: Complexity bounds for equivalence of ping-pong protocols.

The experiments were conducted on a $\operatorname{Intel}(\mathrm{R}) \mathrm{Xeon}(\mathrm{R}) \mathrm{CPU}$ X5650 @ 2.67 GHz with 47 Go of RAM, using one core only. The first column corresponds to the cumulative time required to produce the different automata; the second one the time needed to convert the automata into grammars to be processed by 1AlBlC and the third one to the status of the equivalence (proof or witness of non-equivalence) and the cumulative time spent to prove the equivalence (when it is the case) or the execution time to find a witness of non-equivalence, when possible. There is non-equivalence as soon as one of our three pairs of automata are not in equivalence. Since we execute 1A1BlC in parallel for each of these three pairs, the execution time corresponds to the first pair that is found to be not in equivalence. Converting the automata to grammars required an optimisation of the built-in functionality in 1A1BlC in order to reach reasonable execution times. Other protocols were considered, namely variants of the Wide Mouthed Frog, Denning-Sacco and Private Authentication protocols. Unfortunately, for these ones, albeit the generation of automata was quick, it was impossible to prove (non-)equivalence in reasonable time with lAlBlC.

### 7.6 Conclusion

We have shown a first decidability result for equivalence of (deterministic) ping-pong protocols for an unbounded number of sessions by reducing it to the equality of languages of deterministic, generalised, real-time pushdown automata (GPDA). We further show that deciding equivalence of ping-pong protocols is actually at least as hard as deciding equality of languages of GPDA. Complexity-wise, the situation is slightly less clear. While the reduction from GPDA to ping-pong protocols is polynomial, the reduction from ping-pong protocols to GPDA requires an exponential blow-up. Indeed, to get rid of the attacker, we guess a correspondence between the keys of $P$ and $Q$, and exponentially many such correspondences should be checked. In addition, the complexity of equivalence of various classes of pushdown automata are not very well-known. It follows that the exact complexity of checking equivalence of protocols is unknown. The only upper bound is that equivalence is at most primitive recursive. This bound comes from the algorithm proposed by C. Stirling for equivalence of DPA [64]. The lower bound comes from the fact that real-time deterministic pushdown automata are at least NL-hard [16]. Whether equivalence of DPA (or even real-time GPDA) is e.g. at least NP-hard is unknown. The complexity hierarchy known so far for equivalence of ping-pong protocols is displayed in Figure 7.5.

Note that the complexity of GPDA and ping-pong protocols is actually quite close since the reduction from pingpong protocols to GPDA is "just" exponential. Moreover, assume now that we consider only procedures that return a witness of non equivalence (if any). Then the complexity classes of GPDA and ping-pong protocols should actually coincide. Indeed, assume that there is a procedure for checking equivalence of GPDA that ends in time $f(n)$ where $n$ is the size of the inputs, and that returns a witness when two automata are not in equivalence. This witness must be of size at most $f(n)$. Then given two ping-pong protocols $P$ and $Q$, we would construct $\bar{P}$ and $\bar{Q}$ as defined in Lemma 7.2.2 step by step.

Instead of guessing the sets $K$ and $K^{\prime}$, we would start from the empty sets $K=K^{\prime}=\emptyset$. If $\bar{P} \not \approx \bar{Q}$, that is if
$\mathcal{A}_{\bar{P}} \not \approx \mathcal{A}_{\bar{Q}}$, we consider a witness of non equivalence. Either it is a witness of $P \not \approx Q$ (and we are done), or there must exist a key k that is deducible in $P$ and a corresponding key $\mathrm{k}^{\prime}$ deducible with the same actions in $Q$. We start over with $K=\{\mathrm{k}\}$ and $K^{\prime}=\left\{\mathrm{k}^{\prime}\right\}$.

This algorithm has at most $n$ steps and each step involve a call to the GPDA procedure $\left(\mathcal{A}_{\bar{P}} \approx \mathcal{A}_{\bar{Q}}\right)$ and involves replaying a witness of size $f(n)$. This yields a procedure of complexity $O(f(n))$.

Our class of security protocols handles only randomised primitives, namely symmetric/asymmetric encryptions and signatures. Our decidability result could be extended to handle deterministic primitives instead of the randomised one (the reverse encoding - from real-time GPDAs to processes with deterministic encryption - may not hold anymore). Due to the use of pushdown automata, extending our decidability result to protocols with pairing is not straightforward. A direction is to use pushdown automata for which stacks are terms.

Our tool Cpp2dpa in combination with IAlBlC yields the first implementation of a decidability procedure for equivalence of protocols, for an unbounded number of sessions. However, the number of protocols covered so far is limited. A first reason yields in the limitations of the class of ping-pong protocols. However, another reason is the (too long) time needed to check for equivalence. Our transformation from protocols to automata using Cpp2dpa remains reasonably fast. Most of the execution time comes from lAlBlC. Since this tool is still in its early stage of development, we may hope for significant improvement of 1 AlBlC ' performance in the next years.

## Chapter 8

## Conclusion and perspectives

This thesis reports my contributions to the automated verification of trace equivalence for cryptographic protocols. In particular, we focused our efforts on the issue of deciding trace equivalence for an unbounded number of sessions. Doing so, we propose two ways of easing equivalence checking in general and several classes of cryptographic protocols for which trace equivalence can be decided. We recall here our main contributions to this topic and open further perspectives.

## Easing trace equivalence with nonce deletion

Chapter 3 is devoted to the definition of a transformation on simple protocols using a broad variety of cryptographic primitives which allows us to soundly check for trace equivalence without nonces. By making sure any equivalence between such transformed protocols leads to an equivalence between the original protocols with nonces, we turn decidability results for trace equivalence for an unbounded number of sessions but without nonces, such as the one described in Chapter 5, into a sound terminating procedure to prove protocols with nonces. Even though the hypothesis on simple protocols is still practical, it may be possible to extend it further to encompass more semantic definitions of determinism, such as action-determinism [8]. Similarly, our definition of adequate theories focuses on theories with destructors and constructors but can potentially be extended to more arbitrary theories, to the cost of a slight generalisation of our transformation. More specifically, our transformation introduces one extra copy of each deleted nonce to account for the simple structure of the rewriting rules which describe adequate theories such as encryption. When dealing with more complex theories, adding more copies of the said nonce could allow us to extend our soundness result. The most promising extension to this work yet lies into its application to bounds of different natures. In the same way we bound the number of nonces to use when soundly checking trace equivalence, quantities like the number of agents interacting in a protocol may also be soundly bounded with our approach [38].

## Easing trace equivalence with typing

Chapter 4 offers a new typing result for trace equivalence of determinate protocols with symmetric encryption. Akin to a previous result for reachability properties [6], it can be seen as an extension to trace equivalence with more general typing systems, although for a smaller set of primitives. This typing result offers an important reduction in the size of the search space to consider when checking for trace equivalence and provides the corner stone to the decidability results of both Chapter 5 and Chapter 6. As this result is proven by designing a new decision procedure to check equivalence for a bounded number of sessions which limits the amount of unification between terms by only considering terms of the exact same type, a further application would be to apply this optimisation to existing tools such as Apte [20] or Spec [65] to improve their performances. Another natural improvement is to extend the rewriting rules we considered to include other standard primitives like asymmetric encryption, signatures or hashes. To do so,
we need to redefine the procedure we designed for a bounded number of sessions. In particular, while symmetric encryption offers inversibility (as the encryption and decryption keys are identical) which greatly limits the amount of unification to do in our algorithm, other primitives such as asymmetric encryption or signatures lack it, forcing us to adapt this step of the algorithm. This extension would also most likely provide an extension to the decidability results in Chapters 5 and 6.

## A new decidable class: simple type-compliant protocols without nonces

Chapter 5 presents one of the first class of protocols for which trace equivalence is decidable for an unbounded number of sessions. This class is made of simple, type-compliant protocols without nonces using symmetric encryption. Simple tagged protocols without nonces form an interesting subclass of these. Although forbidding arbitrary nonces seems unpractical, the result from Chapter 3 offers a practical and sound extension of this result to checking trace equivalence for an unbounded number of sessions with nonces. As mentioned earlier, this result relies deeply on the typing result from Chapter 4 and any extension of the original signature would likely carry over to the decidability result. Another axis of research is more closely related to our proof method: by bounding the nonces and bounding the size of terms thanks to typing, we were able to bound the total number of messages which can be generated in a minimal witness of non-equivalence. This limitation seems to bring our process algebra closer to process algebra without terms, such as CCS, for which some (unbounded) equivalences such as bisimulation are decidable [48] and could constitute an interesting new approach to decidability if a tight bound on the number of terms can be computed.

## A new decidable class: simple type-compliant acyclic protocols with nonces

Chapter 6 describes the first decidability result for trace equivalence for an unbounded number of sessions with nonces. It does so by defining a practical class of simple type-compliant acyclic protocols, which can be thought as simple acyclic tagged protocols. It introduces the notion of dependency graph to statically evaluate the high-level information flow of a type-compliant protocol based on its specification to define acyclic protocols. This notion was independently described in [47] to decide leakiness for tagged protocols. Relying on the typing result from Chapter 4, it supports only symmetric encryption but still deals with a large number of protocols from the literature, and is likely to be extended at the same time as the typing result. The notion of dependency graph is also prone to improvements: as it fundamentally describes an over-approximation in the causal dependencies between actions in the specification of a protocol, and introduces more edges than needed as a result, it can be refined, and pruned, by considering additional sources of information, such as already proved security properties to refine the abstraction. This would for instance be profitable when dealing with protocols using temporary secrets, which are currently considered cyclic. As secrecy properties can be expressed as equivalence properties, this result also provides a new decidable class of tagged protocols for these properties. Finally, Chapter 6 exposes an upper bound on the length of any minimal witness of non-equivalence (if existing) and thus could be useful to turn existing tools for bounded trace equivalence into tools able to check for full unbounded trace equivalence.

## A new decidable class: ping-pong protocols without nonces

Chapter 7 also details one of the first class of protocols for which trace equivalence is decidable for an unbounded number of sessions. It focuses on ping-pong protocols without nonces and without pairing to provide a two-way reduction between cryptographic protocols and generalised deterministic pushdown automata, linking trace equivalence to the language equivalence of deterministic pushdown automata, proven to be decidable [63]. The reduction from automata to protocols moreover offers a very general undecidability result for trace inclusion and equivalence, underlying the inherent difficulty of finding interesting decidable classes. Looking at the complexity of the reductions between these models, it offers some insight on the complexity of trace equivalence for ping-pong protocols. The results from Chapter 7 also lead to a tool, Cpp2dpa, interfacing with the tool IAlBlC [51] for language equivalence checking, to automatically check for trace equivalence between such protocols. Improvements can be made to offer
more efficient verification. A more theoretical approach to extend the class of protocols we consider would be to move from traditional pushdown automata to automata with stacks of stacks or terms, for which deciding equivalence would likely be more difficult.

Existing decidability results for equivalence for an unbounded number of sessions, including those presented in this thesis, all rely on some determinism hypothesis, e.g. determinate or simple protocols, to be proven. These hypotheses also constrain the process algebra which is considered, for instance frequently barring else branches. Unfortunately, properties like untraceability rely on non-determinism in the protocol modelling to hold, as they are inherently related to the ability for protocols to conceal their actions. To be able to prove this property, as well as a number of other interesting properties for privacy, one would need to design new classes, and new proof methods, for the equivalence of non-deterministic protocols.

Despite the new decidability results offered by this thesis, their direct application to fully deployed cryptographic protocols still suffers from the high complexity cost of all the procedures designed so far. Even when accounting for the increase in raw computing performance of computers, scalability is a deep issue for protocol verification. Composition results [36] offer a possible approach, and, in general, considering modelling and proof frameworks with built-in composability seems like a fruitful direction.

In the process of designing and proving new classes of protocols for which equivalence is decidable, one crucial point lies in the choice of the restrictions to use. They should be practical enough to include as many realistic protocols and still provide a theoretical edge to prove decidability. Tagging schemes, and the generalisation we proposed with type-compliant protocols, along with typing results offer a great example of such a combination and lead to powerful results for both reachability and equivalence properties. To obtain more comprehensive decidability results, and possibly results effectively compatible with tool support, a promising approach would be to deepen our understanding of the structure of protocols and translate it into structures which enable powerful methods to be applied on them. Dependency graphs as described in Chapter 6 and [47] are probably a first step in that direction.

## Appendix A

## Well-typed executions

Section A. 1 will focus on the proof of completeness of the said procedure, as stated in Proposition 4.2.3 later in the appendix. Section A. 2 will provide the complete proofs of Proposition 4.1.1 and Theorem 4.1.1.

## A. 1 Proof of Proposition 4.2.3

The proof of Proposition 4.2.3 requires a number of technicalities so as to reduce a concrete witness of non-equivalence between two protocols into a valid output of the algorithm described in Section 4.2. In particular, recipes used by the attacker to discriminate between two frames need to be modified to be proper tests in the symbolic frames introduced by the said algorithm. Section A.1.1 will deal with this aspect; while Section A.1.2 will define a more operational notion of static equivalence and formally link symbolic traces from the algorithm to concrete executions of the protocols, which will be needed to finally prove Proposition 4.2.3.

## A.1.1 Simplifying recipes

In this section, we present how equalities between arbitrary recipes can be transformed into a set of equalities between recipes sharing interesting properties, defined in the next definitions. In the following, $\phi$ and $\psi$ represent two (concrete) frames, while $\phi_{S}$ and $\psi_{S}$ are two symbolic frames such that $\phi=\phi_{S} \lambda_{P}$ and $\psi=\psi_{S} \lambda_{Q}$, where $\lambda_{P}=(\theta \phi) \downarrow$ and $\lambda_{Q}=(\theta \psi) \downarrow$ and $\theta$ is a substitution such that $\left(\operatorname{vars}\left(\phi_{S}\right) \cup \operatorname{vars}\left(\psi_{S}\right)\right) \subseteq \operatorname{dom}(\theta)$ and $\operatorname{img}(\theta) \subseteq \mathcal{T}_{0}\left(\Sigma, \Sigma_{0} \cup \mathcal{W}\right)$. These relations are justified later by Lemmas A.1.14 and A.1.16 in Section A.1.2.

The notions of precompact and compact recipes restrict the tests that can be made by the attacker when trying to distinguish between two frames. Lemma A.1.13 in Section A.1.2 will prove later this is not, in our setting, an actual restriction.

Definition A.1.1 (precompact recipe). Given a frame $\phi$, a recipe $R$ is said to be $\phi$-precompact if:

- $R \phi \downarrow$ is a message
- $R$ contains only destructors
- $R \phi \downarrow$ is neither a pair nor an encryption by a key deducible in $\phi$

We now introduce the notion of symbolic second-order trace, which is helpful to reason on the objects generated in the decision algorithm of Section 4.2.

Definition A.1.2. $\left(\operatorname{tr}_{S}, \phi_{S}\right)$ is a symbolic second-order trace of a protocol $P$ if there exists a bijective renaming $\rho$ from $\operatorname{vars}\left(\operatorname{tr}_{S} \phi_{S} \downarrow\right)$ such that $\left(\operatorname{tr}_{S} \rho, \phi_{S} \rho\right) \in \operatorname{trace}(P)$. In that case, $\phi_{S}$ is called a symbolic frame.

Definition A.1.3 (compact recipe). Given a symbolic frame $\phi_{S}, R$ is said to be $\phi_{S}$-compact if $R$ is $\phi_{S}$-precompact and $R \phi_{S} \downarrow$ is not a variable.

A recipe $R$ is said to be destructor-only if $R \in \mathcal{T}\left(\Sigma_{\mathrm{d}}, \Sigma_{0} \cup \mathcal{W} \cup \mathcal{X}\right)$, i.e. contains no constructor.
We introduce a new predicate on recipe, msg, with the natural semantics: $\phi \models \operatorname{msg}(R)$ if $R \phi \downarrow$ is a message (with or without variables, i.e. an element of $\mathcal{T}_{0}\left(\Sigma_{c}, \Sigma_{0} \cup \mathcal{N} \cup \mathcal{X}\right)$ ). Given a term, we introduce a rightmost-first order on its positions, which corresponds to the anti-lexicographic order on positions in a term, denoted by $<$. $<$ denotes the order on positions such that $p \ll q$ iff $q$ is a strict prefix of $p$. Note that: $p \ll q \Rightarrow p<q$. We will sometimes refer to a term as the rightmost term verifying a property, i.e. the term verifying this property whose position is the lowest by the $<$ order.

Definition A.1.4 (transformation of concrete recipes for $\phi$ ). Given $\phi$, a destructor-only recipe $R, \phi_{S}$ and $\theta$ as introduced earlier, we define this transformation $\mathcal{T}$ as follows:

- if there exists $R^{\prime} \in \operatorname{st}(R)$ such that $R=C\left[R^{\prime}\right]$ and $R^{\prime}$ is the rightmost recipe verifying one the following two conditions:

1. if $R^{\prime}=\operatorname{dec}\left(R_{1}, R_{2}\right)$ and there exists a variable $x$ such that $R_{1} \phi_{S} \downarrow=\operatorname{enc}(t, x)$ and $R_{2} \neq x$ for some term $t$, then $\mathcal{T}(R, \mathcal{R})=\left(C\left[\operatorname{dec}\left(R_{1}, x\right)\right], \mathcal{R} \cup\left\{\operatorname{msg}\left(\operatorname{dec}\left(R_{1}, x\right)\right)\right\}\right)$
2. else, and if there exists a variable $y$ such that $R^{\prime} \phi_{S} \downarrow=y$ and $R^{\prime} \neq y$, then $\mathcal{T}(R, \mathcal{R})=\left(C[y \theta] \Downarrow, \mathcal{R} \cup\left\{R^{\prime}=\right.\right.$ $y\})$

- if no such recipe exists, $\mathcal{T}(R, \mathcal{R})=(R, \mathcal{R})$;
where $\Downarrow$ is the normal form associated to the rewriting rules $\pi_{i}\left(\left\langle x_{1}, x_{2}\right\rangle\right) \rightarrow x_{i}$ and $\operatorname{dec}(\operatorname{enc}(x, y), z) \rightarrow x$.
We denote the iterated application of $\mathcal{T}$ to $(R, \emptyset)$ by $\mathcal{T}^{*}(R)$ or $\mathcal{T}^{m}(R)$ (when iterated $m$ times).
The iterated transformation $\mathcal{T}^{*}$ aims at transforming a $\phi$-precompact recipe (which is still a quite general class of recipes) into a $\phi_{S}$-compact recipe, i.e. a recipe which can reduce properly in a symbolic frame and will satisfy somewhat similar equalities. The next lemmas will gradually prove the properties we need for $\mathcal{T}^{*}$, ultimately ending with Lemmas A.1.10, A.1.11 and A.1.12.

Lemma A.1.1 (consistency of $\mathcal{R}$ ). Let $R$ be a destructor-only recipe, $\mathcal{T}^{*}(R)=\left(R^{*}, \mathcal{R}\right)$ : if $R \phi \downarrow$ is a message, $\phi_{S} \models \mathcal{R}$.

Proof. A test $\operatorname{msg}(\operatorname{dec}(R, x))$ or $R=x$ is added to $\mathcal{R}$ in Definition A.1.4 only if $R \phi_{S} \downarrow=\operatorname{enc}(t, x)$ where $t$ is a term (in the first case) or if $R \phi_{S} \downarrow=x$ (in the second case). As $\phi_{S}$ only contains symbolic messages in its image; $t$ has to be a symbolic message.

This lemma witnesses the fact that the equalities we insert in $\mathcal{R}$, which correspond to equalities holding in the concrete frame, actually hold in its symbolic version. Lemmas A.1.2 and A.1.3 witness rather general properties of destructor-only recipes and of the $\Downarrow$ reduction.

Lemma A.1.2. If $R$ is a recipe such that $R \phi \downarrow$ is a message, then $R \downarrow \phi \downarrow=R \phi \downarrow$
Proof. If $R \phi \downarrow$ is a message, every reduction step of the form $\operatorname{dec}(\operatorname{enc}(x, y), z) \Rightarrow x$ in an innermost derivation in $R \Downarrow$ happens with $y \phi=z \phi$ and is then actually a reduction step of the form $\operatorname{dec}(\operatorname{enc}(x, y), y) \rightarrow x$ in $R \phi$.

Lemma A.1.3. If $R$ is a destructor-only recipe and $\phi$ a frame such that $R \phi \downarrow$ is a message, then for every subterm $R^{\prime}$ of $R, R^{\prime} \phi \downarrow$ is a message.

Proof. Suppose there exists a highest (in terms of position, i.e. closest to the root) subterm $R^{\prime}$ of $R$ such that $R^{\prime} \phi \downarrow$ is not a message and $R=C\left[R^{\prime}\right]$ (and $C$ is linear). Let us proceed by induction on $C$ to show that $C\left[R^{\prime}\right] \phi \downarrow$ is not a message either. Note that, because $R$ is destructor-only, we only consider $C$ to be destructor-only.

- $C=\__{\_}$: then $R=R^{\prime}$ and $R \phi \downarrow$ is not a message.
- $C=\operatorname{proj}_{i}\left(C^{\prime}\right)$ and $C^{\prime}\left[R^{\prime}\right] \phi \downarrow$ is not a message: then $\operatorname{proj}_{i}\left(C^{\prime}\left[R^{\prime}\right]\right) \phi \downarrow$ will not be a message either.
- $C=\operatorname{dec}\left(R^{\prime \prime}, C^{\prime}\right), C^{\prime}\left[R^{\prime}\right] \phi \downarrow$ and $C^{\prime}\left[R^{\prime}\right] \phi \downarrow$ is not a message. For $C\left[R^{\prime}\right] \phi \downarrow$ to be a message, it would require $R^{\prime \prime} \phi \downarrow=\operatorname{enc}\left(s, C^{\prime}\left[R^{\prime}\right] \phi \downarrow\right)$ for some message $s$. As $\phi$ only contains messages in its image and enc $\left(s, C^{\prime}\left[R^{\prime}\right] \phi \downarrow\right)$ is not one ( $C^{\prime}\left[R^{\prime}\right] \phi \downarrow$ is not a message) the enc function symbol would need to appear in $C$, which is destructoronly: contradiction. Hence $C\left[R^{\prime}\right] \phi \downarrow$ is not a message.
- $C=\operatorname{dec}\left(C^{\prime}, R^{\prime \prime}\right), C^{\prime}\left[R^{\prime}\right] \phi \downarrow$ is not a message: $C\left[R^{\prime}\right] \phi \downarrow$ being a message would imply $C^{\prime}\left[R^{\prime}\right] \phi \downarrow=\operatorname{enc}\left(s, R^{\prime \prime} \phi \downarrow\right)$ for some term $s$. As before, because $\phi$ contains only messages in its image and $C^{\prime}\left[R^{\prime}\right] \phi \downarrow$ is not, the enc symbol need to occur in $C^{\prime}\left[R^{\prime}\right]$ which is destructor-only, as a subterm of $R$.

Thus every subterm $R^{\prime}$ of $R$ is such that $R^{\prime} \phi \downarrow$ is a message.
Lemma A.1.4 (preservation of normal forms). If $R$ is a destructor-only recipe, $(R \theta) \phi \downarrow$ is a message, $(\bar{R}, \mathcal{R})=\mathcal{T}(R)$, then $(R \theta) \phi \downarrow=(\bar{R} \theta) \phi \downarrow$.

Proof. Using the notations introduced in Definition A.1.4, $R=C\left[R^{\prime}\right], R^{\prime}$ is the rightmost subterm of $R$ verifying one of the two conditions of $\mathcal{T}$.

1. if $R^{\prime}=\operatorname{dec}\left(R_{1}, R_{2}\right), R_{1} \phi_{S} \downarrow=\operatorname{enc}(t, x)$ and $R_{2} \neq x: \bar{R}=C\left[\operatorname{dec}\left(R_{1}, x\right)\right]$. We have that $\bar{R} \theta=C\left[\operatorname{dec}\left(R_{1} \theta, x \theta\right)\right] \theta$. And thus $(\bar{R} \theta) \phi \downarrow=\left(C\left[\operatorname{dec}\left(R_{1} \theta, x \theta\right)\right] \theta\right) \phi \downarrow=(C[t \theta] \theta) \phi \downarrow$. As $R_{1} \phi_{S} \downarrow=\operatorname{enc}(t, x)$ and $(R \theta) \phi \downarrow$ is a message, $\left(R^{\prime} \theta\right) \phi \downarrow$ is a message too (Lemma A.1.3) and $\left(R^{\prime} \theta\right) \phi \downarrow=\left(R_{1} \theta \phi\right) \downarrow=t \theta \phi$. Hence $(C[t \theta] \theta) \phi \downarrow=\left(C\left[R^{\prime}\right] \theta\right) \phi \downarrow=$ $(R \theta) \phi \downarrow$, giving the result.
2. else, and if $R^{\prime} \phi_{S} \downarrow=y$ and $R^{\prime} \neq y: \bar{R}=C[y \theta] \Downarrow$. We have $y \theta \phi \downarrow=\left(R^{\prime} \theta\right) \phi \downarrow$. Indeed, as $R^{\prime} \phi_{S} \downarrow=$ $y, R^{\prime} \phi_{S} \downarrow \theta \phi \downarrow=y \theta \phi \downarrow$. Then $\left(R^{\prime} \theta\right) \phi \downarrow=y \theta \phi \downarrow$, as $\phi=\phi_{S} \lambda_{P}$ (works with $\psi=\psi_{S} \lambda_{Q}$ too, thanks to Lemma A.1.16). To conclude, we show that $(R \theta) \phi \downarrow=\left(C\left[\left(R^{\prime} \theta\right) \phi \downarrow\right] \theta\right) \phi \downarrow$, and as $(R \theta) \phi \downarrow$ is a message and by Lemma sA.1.2, this is equal to $(C[y \theta \phi \downarrow] \theta) \phi \downarrow=(C[y \theta] \theta) \phi \downarrow=(C[y \theta] \Downarrow \theta) \phi \downarrow=(\bar{R} \theta) \phi \downarrow$.

This lemma proves that the transformation $\mathcal{T}$, from the point of view of the concrete frame, does not alter the normal form of tests (up to a particular substitution $\theta$ ). Previous lemmas are stated with $\phi$ and $\phi_{S}$, but can be symmetrically applied with $\psi$ and $\psi_{S}$. When the context is not obvious, we will denote by $\mathcal{T}_{\phi}$ the transformation introduced at Definition A.1.4 when applied with $\phi_{S}$, and $\mathcal{T}_{\psi}$ when applied with $\psi_{S}$.

Lemma A.1.5 (termination of $\left.\mathcal{T}^{*}\right) . \mathcal{T}$ is deterministic and $\mathcal{T}^{*}(R)$ is well-defined.
Proof. Introduce an ordering on variables based on how soon they appear in the trace $\left(\operatorname{tr}_{S}, \phi_{S}\right)$ and consider the induced multi-set order $<_{\text {var }}$. The second item in Definition A.1.4 strictly reduces this measure. Now consider the number of destructor of a (destructor-only) recipe $R$, plus the number of variables in $\operatorname{dom}(\phi)$ (without counting the variables in $\operatorname{dom}(\theta)$ ). Let $<_{\text {size }}$ be the order induced by this measure. The first item in Definition A.1.4 strictly reduces this measure. Finally, let $<$ be the lexicographical order built on $\left(<_{\text {var }},<_{\text {size }}\right)$. The transformation $\mathcal{T}$ decreases its induced measure.

Lemmas A.1.6, A.1.7 and Corollary A.1.1 provide the general invariants for the transformation $\mathcal{T}$ : mostly that it operates locally, does not introduce new constructors and preserves the fact for a subterm of being a message.

Lemma A.1.6. If $R$ is $\phi$-precompact, then for every $n \in \mathbb{N}, \mathcal{T}_{\phi}^{n}(R)$ is destructor-only.
Proof. Suppose there exists $n_{0} \in \mathbb{N}$ such that $R_{n_{0}}=\mathcal{T}^{n_{0}}(R)$ contains a constructor $c$ at position $p$. Let us further assume $p$ is the highest position where a constructor occurs.

- if $p=\epsilon$ : as $\left(R_{n_{0}} \theta\right) \phi \downarrow=R \phi \downarrow$ by Lemma A.1.4, $R$ cannot be $\phi$-precompact,
- if $p>\epsilon$ and $c=\left\langle_{-}, \quad\right\rangle: c$ occurs below a destructor $d$ (as $p$ is the highest position a constructor can appear).
- If $d=\operatorname{proj}_{i}$ for $i \in\{1,2\}$ : as $R$ is destructor-only, $c$ is introduced by a replacement $C[y \theta] \Downarrow$ and because $\operatorname{proj}_{i}\left(\left\langle x_{1}, x_{2}\right\rangle\right) \Rightarrow x_{i}, c$ would have been reduced.
- If $d=\operatorname{dec}$ and $c$ is in plaintext position of $d:$ if $c$ is not reduced, $\left(R_{n_{0}} \theta\right) \phi \downarrow$ is not a message, then $\left(R_{n_{0}} \theta\right) \phi \downarrow=R \phi \downarrow$, by Lemma A.1.4, implies $R \phi \downarrow$ is not a message either, and thus not $\phi$-precompact.
- Else, if $d=\operatorname{dec}$ and $c$ is in key position of $d$ : the key is not atomic, and similarly $R \phi \downarrow$ is not a message, and thus not $\phi$-precompact.
- if $p>\epsilon$ and $c=\operatorname{enc}\left(,, \_\right)$: the same reasoning as the previous case can be applied (interverting the first two subcases).

Hence $R_{n_{0}}$ cannot contain constructors if $R$ is $\phi$-precompact.
Lemma A.1.7. Let $R^{\text {init }}$ be a destructor-only recipe and $R=\mathcal{T}_{\phi}^{n}\left(R^{\text {init }}\right)$. If $R=C\left[R^{\prime}\right]_{p}, R$ is destructor-only, $\left(R^{\prime} \theta\right) \phi \downarrow$ is a message and $p$ is lesser w.r.t. $<$ than the next position where $\mathcal{T}_{\phi}$ is applied on $R$, then $\left.R\right|_{q} \phi_{S} \downarrow$ is a message for any $q \ll p$ or $q=p$.

Proof. We prove by induction that $\left.R\right|_{q} \phi_{S} \downarrow$ is a message.

- if $\left.R\right|_{q}=\mathrm{w}, \mathrm{w} \phi_{S}$ is a message,
- if $\left.R\right|_{q}=x, x \phi_{S}=x$ is a message,
- if $\left.R\right|_{q}=\operatorname{enc}\left(R_{1}, R_{2}\right)$ or $\left.R\right|_{q}=\left\langle R_{1}, R_{2}\right\rangle, R_{1} \phi_{S} \downarrow$ and $R_{2} \phi_{S} \downarrow$ are messages by induction hypothesis, then $\left.R\right|_{q} \phi_{S} \downarrow$ is a message too,
- if $\left.R\right|_{q}=\operatorname{proj}_{i}\left(R^{\prime \prime}\right)$ and $R^{\prime \prime} \phi_{S} \downarrow$ is a message:
- if $R^{\prime \prime} \phi_{S} \downarrow=x$ for some variable $x$ : a variable in $R^{\prime \prime}$ can only be introduced in key position of a dec, not a proj $_{i}$, impossible.
- if $R^{\prime \prime} \phi_{S} \downarrow=\left\langle R_{1}, R_{2}\right\rangle$ : then $\operatorname{proj}_{i}\left(\left\langle R_{1}, R_{2}\right\rangle\right) \phi_{S} \downarrow$ is a message,
- if $R^{\prime \prime} \phi_{S} \downarrow=\operatorname{enc}(u, v)$ : as $\left(R^{\prime \prime} \theta\right)\left(\phi_{S} \lambda_{P}\right) \downarrow=\left(R^{\prime \prime} \theta\right) \phi \downarrow$, there exist $u^{\prime}, v^{\prime}$ two terms such that $\left(R^{\prime \prime} \theta\right) \phi \downarrow=$ enc $\left(u^{\prime}, v^{\prime}\right)$. Thus $\left(\operatorname{proj}_{i}\left(R^{\prime \prime}\right) \theta\right) \phi \downarrow$ is not a message, and $\left(R^{\prime} \theta\right) \phi \downarrow$ is not a message either, by Lemma A.1.3 as $R$ is destructor-only. Contradiction.
- if $\left.R\right|_{q}=\operatorname{dec}\left(R_{1}, R_{2}\right), R_{1} \phi_{S} \downarrow$ and $R_{2} \phi_{S} \downarrow$ are messages:
- if $R_{1} \phi_{S} \downarrow=x$ for some variable $x$ : a variable can only occur in a key position, impossible. Either $R_{1}=x$, which can only occur in a key position, impossible; or $R_{1} \neq x$ and $R_{1} \phi_{S} \downarrow=x$, in which case $\mathcal{T}$ would be applied at position $q .1<p$
- if $R_{1} \phi_{S} \downarrow=\langle u, v\rangle$ : see the third point of the previous case.
- if $R_{1} \phi_{S} \downarrow=\operatorname{enc}(u, x)$ for some term $u$ and some variable $x$. By Definition A.1.4, as $\mathcal{T}$ was applied at position $q, R_{2}=x$ and $\operatorname{dec}\left(R_{1}, x\right) \phi_{S} \downarrow$ is a message.
- if $R_{1} \phi_{S} \downarrow=\operatorname{enc}(u, k)$ for some term $u$ and some non-variable atom $k$ : then $R_{2} \phi_{S} \downarrow \neq x$ for any variable $x$, as $R_{2}$ is a position lesser than $p$. Thus $R_{2} \phi_{S} \downarrow=k^{\prime}$ for some atom $k^{\prime}$, and $R_{2} \phi \downarrow=k^{\prime}$ as $k^{\prime}$ is not a variable. Similarly $R_{1} \phi \downarrow=\operatorname{enc}\left(u^{\prime}, k\right)$ for some term $u^{\prime}$. (R $) \phi \downarrow$ is a message implies (as $R$ is destructor-only and by Lemma A.1.3) $k=k^{\prime}$ and that $\operatorname{dec}\left(R_{1}, R_{2}\right) \phi_{S} \downarrow$ is a message too.

Corollary A.1.1. Let $R^{\text {init }}$ be a destructor-only recipe and $R=\mathcal{T}_{\phi}^{n}\left(R^{\text {init }}\right)$. If $R=C\left[R^{\prime}\right]_{p}, R$ is destructor-only, $\left(R^{\prime} \theta\right) \phi \downarrow$ is a message and $\mathcal{T}_{\phi}(R)=(R, \mathcal{R})$ then $\left.R\right|_{q} \phi_{S} \downarrow$ is a message for any $q \ll p$ or $q=p$.

Proof. Same proof as Lemma A.1.7, except we invoke the fact the transformation does not alter $R$ any more in cases where we derive an impossibility.

The following lemma intends to show that equalities between transformed test $\mathcal{T}^{*}(R)$ actually correspond to the unification performed by the algorithm at step 2. Indeed, the normal forms of $\phi_{S}$-compact recipes are encrypted subterms that can be unified in this step.

Lemma A.1.8 (compacification effect of $\left.\mathcal{T}^{*}\right)$. With previous notations, if $\mathcal{T}^{*}(R)=\left(R^{*}, \mathcal{R}\right)$ : if $R$ is $\phi$-precompact then $R^{*}$ is $\phi_{S}$-compact.

Proof. As $R$ is $\phi$-precompact, by Lemma A.1.6, any (iterated) application of $\mathcal{T}_{\phi}$ to $R$ yields a destructor-only recipe. We then use Lemma A.1.7 repeatedly and finally Corollary A.1.1 with $p=\epsilon$ (the root position) and for $q=p$ to conclude $R^{*} \phi_{S} \downarrow$ is a message. Invoking Lemma A.1.4 at each step finally gets us $R \phi \downarrow=\left(R^{*} \theta\right) \phi \downarrow$. As $\left(R^{*} \theta\right) \phi \downarrow=$ $R^{*} \phi_{S} \downarrow \lambda_{P}$, we can conclude that $R^{*} \phi_{S} \downarrow$ is not a pair nor an encryption with a deducible key (for the latter, consider the case where $R^{*} \phi_{S} \downarrow=\operatorname{enc}\left(u_{1}, u_{2}\right)$ : as $R$ is $\phi$-precompact, $u_{2} \lambda_{P}$ is not deducible in $\phi$; but if $u_{2}$ were deducible in $\phi_{S}, u_{2} \lambda_{P}$ would be in $\phi \cup \lambda_{P}$, and thus in $\phi$. Contradiction).

Lemma A.1.9 (uniformity of $\mathcal{T}$ ). Let $\phi, \phi_{S}, \psi, \psi_{S}$ be as introduced, $R$ be a destructor-only recipe, $\mathcal{T}_{\phi}^{*}(R)=\left(R_{1}^{*}, \mathcal{R}_{1}\right)$ and $\mathcal{T}_{\psi}^{*}(R)=\left(R_{2}^{*}, \mathcal{R}_{2}\right)$. If $\psi_{S} \models \mathcal{R}_{1}$ and $\phi_{S} \models \mathcal{R}_{2}$, then $R_{1}^{*}=R_{2}^{*}$.

Proof. Let $\left(R_{1}^{k}, \mathcal{R}_{1}^{k}\right)=\mathcal{T}_{\phi}^{k}(R)$ and $\left(R_{2}^{k}, \mathcal{R}_{2}^{k}\right)=\mathcal{T}_{\psi}^{k}(R)$ be the iterated application of $\mathcal{T}$ with both symbolic frames. We will prove inductively that $R_{1}^{k}=R_{2}^{k}$ and $\mathcal{R}_{1}^{k}=\mathcal{R}_{2}^{k}$.

- for $k=0$, the initial recipe, $R$, is identical in both cases and $\mathcal{R}_{1}^{0}=\emptyset=\mathcal{R}_{2}^{0}$.
- Let us assume we obtained the result up to some $k$ : $R_{1}^{k}=R_{2}^{k}=R^{k}$. Note that $\mathcal{R}_{i}^{k} \subseteq \mathcal{R}_{i}$ for $i \in\{1,2\}$ implies $\phi_{S} \models \mathcal{R}_{2}^{k}$ and $\psi_{S} \models \mathcal{R}_{1}^{k}$. Suppose now that $R^{k}=\left.C\left[R^{\prime}\right]\right|_{p}$ and $p$ is the lowest position w.r.t. $<$ such that any of the two rules in Definition A.1.4 can apply with either $\phi_{S}$ or $\psi_{S}$. For instance, suppose it is true for $\phi_{S}$ :

1. if $R^{\prime}=\operatorname{dec}\left(R_{1}, R_{2}\right)$, there exist a variable $x$ and a term $t$ such that $R_{1} \phi_{S} \downarrow=\operatorname{enc}(t, x), R_{2} \neq x$, then $R_{1}^{k+1}=C\left[\operatorname{dec}\left(R_{1}, x\right)\right]_{p}$ and $\mathcal{R}_{1}^{k+1}=\mathcal{R}^{k} \cup\left\{\operatorname{msg}\left(\operatorname{dec}\left(R_{1}, x\right)\right)\right\}$. As $\psi_{S} \models \mathcal{R}_{1}$ and $\mathcal{R}_{1}^{k+1} \subseteq \mathcal{R}_{1}$, $\psi_{S} \vDash \operatorname{msg}\left(\operatorname{dec}\left(R_{1}, x\right)\right)$. Hence $R_{1} \psi_{S} \downarrow=\operatorname{enc}(s, x)$ for some term $s$ and the same rule of $\mathcal{T}_{\psi}$ can be applied at the same position, and will, as $p$ is the lowest position where a rule of $\mathcal{T}$ is applicable for both symbolic frames, and then: $R_{2}^{k+1}=R_{1}^{k+1}$ and $\mathcal{R}_{2}^{k+1}=\mathcal{R}_{1}^{k+1}$.
2. If there exists a variable $y$ such that $R^{\prime} \phi_{S} \downarrow=y$ and $R^{\prime} \neq y$, then $R_{1}^{k+1}=C[y \theta] \Downarrow$ and $\mathcal{R}_{1}^{k+1}=$ $\mathcal{R}^{k} \cup\left\{R^{\prime}=y\right\}$. As $\psi_{S} \models \mathcal{R}_{1}$ and $\mathcal{R}_{1}^{k+1} \subseteq \mathcal{R}_{1}, \psi_{S} \models R^{\prime}=y$, i.e. $R^{\prime} \psi_{S} \downarrow=y$. The same rule of $\mathcal{T}_{\psi}$ can thus be applied at the same position, and will, as $p$ is the lowest position where a rule of $\mathcal{T}$ is applicable for both symbolic frames, and then: $R_{2}^{k+1}=R_{1}^{k+1}$ and $\mathcal{R}_{2}^{k+1}=\mathcal{R}_{1}^{k+1}$.

The case where $p$ corresponds to a position w.r.t. $\psi_{S}$ is handled symmetrically.
Applying that result for $n$ such that $\mathcal{T}_{\phi}^{*}(R)=\mathcal{T}_{\phi}^{n}(R)$ leads to the final result.
The next two lemmas finally ensure $\mathcal{T}^{*}$ does not alter the equalities in any nefarious way. Together they demonstrate that if a test holds in a concrete concrete frame, the transformed equality, up to a unification performed at step 2 of the algorithm, will hold in the symbolic frame.

Lemma A.1.10 (soundness of $\mathcal{T}^{*}$ ). Let $R_{1}, R_{2}$ be two destructor-only recipes, $\psi, \psi_{S}, \lambda_{Q}$ be as expected, $\left(R_{1}^{*}, \mathcal{R}_{1}\right)=$ $\mathcal{T}_{\psi}^{*}\left(R_{1}\right)$ and $\left(R_{2}^{*}, \mathcal{R}_{2}\right)=\mathcal{T}_{\psi}^{*}\left(R_{2}\right)$. Then, for any $i \in\{1,2\}, R_{i} \psi \downarrow=R_{i}^{*} \psi_{S} \lambda_{Q} \downarrow$; and thus $R_{1}^{*} \psi_{S} \downarrow=R_{2}^{*} \psi_{S} \downarrow$ implies $R_{1} \psi \downarrow=R_{2} \psi \downarrow$.

Proof. Iteration of Lemma A.1.4 gives $R_{i} \psi \downarrow=\left(R_{i}^{*} \theta\right) \psi \downarrow$; and we assumed $\psi=\psi_{S} \lambda_{Q}$ with $\lambda_{Q}=(\theta \psi) \downarrow$. Hence, $R_{i}^{*} \psi_{S} \lambda_{Q} \downarrow=\left(R_{i}^{*} \theta\right) \psi_{S}(\theta \psi) \downarrow=\left(R_{i}^{*} \theta\right) \psi \downarrow=R_{i} \psi \downarrow$.

Lemma A.1.11 (completeness of $\mathcal{T}^{*}$ ). Let $R_{1}, R_{2}$ be two $\phi$-precompact recipes, $\phi, \phi_{S}, \lambda_{P}$ be as expected, $\left(R_{1}^{*}, \mathcal{R}_{1}\right)=$ $\mathcal{T}_{\phi}^{*}\left(R_{1}\right)$ and $\left(R_{2}^{*}, \mathcal{R}_{2}\right)=\mathcal{T}_{\phi}^{*}\left(R_{2}\right)$. Then: $R_{1} \phi \downarrow=R_{2} \phi \downarrow$ implies there exists $\sigma$ which is a mgu of two $\phi_{S}$-compact recipes in $\phi_{S}$ such that $R_{1}^{*} \phi_{S} \sigma \downarrow=R_{2}^{*} \phi_{S} \sigma \downarrow$.

Proof. Iteration of Lemma A.1.4 gives $R_{i} \phi \downarrow=R_{i}^{*} \phi \downarrow$; and we assumed that $\phi=\phi_{S} \lambda_{P}$. Then, $R_{1} \phi \downarrow=R_{2} \phi \downarrow$ is the same as $R_{1}^{*} \phi_{S} \lambda_{P} \downarrow=R_{2}^{*} \phi_{S} \lambda_{P} \downarrow$. Thus $\sigma=m g u\left(R_{1}^{*} \phi_{S}, R_{2}^{*} \phi_{S}\right) \neq \perp$. As $R_{1}^{*}$ and $R_{2}^{*}$ are $\phi_{S}$-compact (Lemma A.1.8), we are done.

Unfortunately, the transformation $\mathcal{T}$ may, in some cases, transform a recipe reducing to a term which was not a message into a new recipe reducing to a symbolic message. The next lemma ensures these special case can be handled in the main proof of completeness of the algorithm.

Lemma A.1.12 (preservation of messages). Let $\phi, \phi_{S}, \psi, \psi_{S}$ be as expected, $R$ a $\phi$-precompact recipe such that $\mathcal{T}_{\phi}^{*}(R)=\left(R^{*}, \mathcal{R}_{1}\right), \psi_{S} \models \mathcal{R}_{1}, \mathcal{T}_{\psi}^{*}(R)=\left(R^{*}, \mathcal{R}_{2}\right)$ and $\phi_{S} \models \mathcal{R}_{2}$. If $R \phi \downarrow, R^{*} \phi_{S} \downarrow, R^{*} \psi_{S} \downarrow$ are messages but $R \psi \downarrow$ is not, then there either exist $R_{1}^{0}$ and $R_{2}^{0}$ two $\phi$-precompact recipes such that $R_{1}^{0} \phi \downarrow=R_{2}^{0} \phi \downarrow$ and $R_{1}^{0} \psi \downarrow \neq R_{2}^{0} \psi \downarrow$ or there exists a $\phi_{S}$-compact recipe $R_{0}$ such that $R_{0} \phi_{S} \downarrow$ is a message but $R_{0} \psi_{S} \downarrow$ is not.

Proof. Let $p$ be the minimal position in $R$ of a destructor $d$ which is not reduced in $R \psi \downarrow$. Suppose $\mathcal{T}^{*}(R)=\mathcal{T}^{n}(R)$ (note that Lemma A.1.9 guarantees that $\mathcal{T}_{\psi}=\mathcal{T}_{\phi}$ when applied on $R$ ). Let $R_{i}$ be a shortcut for the first argument of $\mathcal{T}^{i}(R)$. Let $q_{1}, q_{2}, \ldots, q_{n}$ be the successive positions where $\mathcal{T}$ is applied; and $i_{0} \in\{1, \ldots, n\}$ such that $\forall 0 \leq j<$ $i_{0},\left(R_{j} \theta\right) \psi \downarrow$ contains $d$ at position $p$ and $\left(R_{i_{0}} \theta\right) \psi \downarrow$ does not. Let $\mathcal{P}$ be the set of positions in $R$. We define a partition of $\mathcal{P}$ as follows:

$$
\mathcal{P}=\{p\} \cup \mathcal{P}_{1} \cup \mathcal{P}_{2} \cup \mathcal{P}_{3} \cup \mathcal{P}_{4} \cup \mathcal{P}_{5}
$$

where:

- $\mathcal{P}_{1}$ is the set of positions on the "plaintext line" of $p$ (always-leftmost children of $p$ ),
- $\mathcal{P}_{2}$ is the set of positions $q$ such that $q<p$ and $q \notin \mathcal{P}_{1}$,
- $\mathcal{P}_{3}$ is the set of strict parents of $p$,
- $\mathcal{P}_{4}$ is the set of always-leftmost children of elements of $\mathcal{P}_{3}$ which are not in $\mathcal{P}_{3} \cup \mathcal{P}_{1} \cup\{p\}$,
- $\mathcal{P}_{5}$ is the set of positions greater than $p$ w.r.t. $<$ which are not in $\mathcal{P}_{3}$ nor $\mathcal{P}_{4}$.

The core argument of this proof relies on a disjunction on the nature of $q_{i_{0}}$ :

- if $q_{i_{0}} \in \mathcal{P}_{2} \cup \mathcal{P}_{5}$ : impossible, as any transformation by $\mathcal{T}$ at these positions cannot affect anything at position $p$. Indeed all these elements appears below a key position, i.e. a position which is the key of some dec.
- $q_{i_{0}}=p$ : impossible, as if $\mathcal{T}$ were applied at this position, it would require $\left.R_{i_{0}-1}\right|_{p} \psi_{S} \downarrow$ to be some variable $x$, and thus $\left(R_{i_{0}-1} \theta\right) \psi \downarrow$ would not contain $d$ (as $\psi=\psi_{S} \lambda_{Q}$ ).
- $q_{i_{0}} \in \mathcal{P}_{1}$ : by definition of $i_{0},\left(R_{i_{0}-1} \theta\right) \psi \downarrow$ contains $d$ at position $p$ while $\left(R_{i_{0}} \theta\right) \psi \downarrow$ does not and $q_{i_{0}}<p$ (by definition of $\mathcal{P}_{1}$ ). Let $R_{i_{0}-1}=C\left[R^{\prime}\right]_{q_{0}}$. Because $\mathcal{T}$ is applied at $q_{i_{0}}$ and $d$ deleted at this step, necessarily $R^{\prime} \psi_{S} \downarrow=x$ for some variable $x$ and $R_{i_{0}}=C[x \theta]_{q_{i_{0}}} \Downarrow$; and $d$ is deleted through the $\Downarrow$-reduction. Two cases can occur a priori:
- $d=\operatorname{proj}_{i}$. In that case, the same reductions appear with $\phi$ : hence $x \theta$ has to contain the pair which is deleted by $d$, and as recipes are the same no matter the frame we consider, the same reduction could occur in $\psi$, hence $d$ would not occur in $R \psi \downarrow$ (We use Lemma A.1.4 to get the preservation of normal forms through the process). Impossibility.
$-d=$ dec. Then there exists a recipe in the key position of $d$ at position $p .2<p: R_{2}^{\prime 0}$. Because $\left(R_{2}^{\prime 0} \theta\right) \psi \downarrow$ is a message (minimality of $p$ ) and Lemma A.1.7 (third item, $p .2<q_{i_{0}}$ ), $R_{2}^{\prime 0} \psi_{S} \downarrow$ is a message. As $R$ is $\phi$-precompact and by Lemma A.1.6, $R_{2}^{\prime 0}$ is destructor-only. Note that $R_{2}^{\prime 0}$ may contain variables in key positions, due to the first item of Definition A.1.4. Because keys are atomic, for each variable in key position $x, x \lambda_{P}$ and $x \lambda_{Q}$ are atomic, thus there exist destructor-only recipe $R_{x}$ for each of them. So we define $R_{2}^{0}=R_{2}^{\prime 0}\left[R_{x} / x\right]$. $R_{2}^{0}$ is now $\phi$-precompact, $\left(R_{2}^{\prime 0} \theta\right) \psi \downarrow=R_{2}^{0} \downarrow \psi$ and $\left(R_{2}^{\prime 0} \theta\right) \phi \downarrow=R_{2}^{0} \downarrow \phi$. As $\Downarrow$-reduction only occurs at recipe level, there also exists a recipe $R_{1}^{0}$ for the encryption key used by the constructor reduced by $d$. Because keys are atomic, we also can always assume $R_{1}^{0}$ to be $\phi$-precompact in this setting. We now show that $R_{1}^{0} \psi \downarrow \neq R_{2}^{0} \psi \downarrow$ and $R_{1}^{0} \phi \downarrow=R_{2}^{0} \phi \downarrow$. These equalities are derived from the fact that $R \psi \downarrow$ still contains $d$ but $R \phi \downarrow$ is a message. Hence we obtain two recipes as in the statement of the lemma.
- $q_{i_{0}} \in \mathcal{P}_{3}$ : then $\left.R_{i_{0}-1}\right|_{q_{i_{0}} .1} \psi_{S} \downarrow=\operatorname{enc}(t, x)$ for some term $t$ and variable $x$, and $p \ll q_{i_{0}} .2$ (or else $\left.R_{i_{0}-1}\right|_{q_{i_{0}} .1} \psi_{S} \downarrow$ would not reduce if it included $d$ ). We get that $R_{i_{0}}=C\left[\operatorname{dec}\left(\left.R_{i_{0}-1}\right|_{q_{i_{0}} .1}, x\right)\right]_{q_{i_{0}}}$. Let $R_{0}=\left.R_{i_{0}-1}\right|_{q_{i_{0}} .2}$. In particular, $p$ is a position of $R_{0}$. As $q_{i_{0}} .2<q_{i_{0}}, R_{0}$ is $\phi_{S}$-compact (Lemmas A.1.6 and A.1.7). We now want to show that $R_{0} \psi_{S} \downarrow$ is not a message: as $\left(R_{0} \theta\right) \psi \downarrow$ contains $d$ by definition, if $R_{0} \psi_{S} \downarrow$ did not, $R_{0} \psi_{S} \downarrow \lambda_{Q \downarrow}=\left(R_{0} \theta\right) \psi \downarrow$ would not either, which contradicts our hypothesis. Hence we get our recipe $R_{0}$ as in the second case of the statement of the lemma.
- $q_{i_{0}} \in \mathcal{P}_{4}$ : we apply the same reasoning as if $q_{i_{0}} \in \mathcal{P}_{3}$, except for the fact it is now the second rule of Definition A.1.4 which is applied at $q_{j_{0}}$, where $q_{j_{0}}$ the longest common prefix of $q_{i_{0}}$ and $p$, and necessarily $\left.R_{i_{0}-1}\right|_{q_{j_{0}}}=\operatorname{dec}\left(R_{l}, R_{r}\right)$. If it were a $\operatorname{proj}_{i}, j_{0}$ would not be the longest common prefix.

Thus the result for any position $q_{i_{0}}$, and the existence of such recipes in general.

## A.1.2 Decision for bounded protocols

Here we detail how symbolic traces can be formally linked to the concrete executions of the protocol so as to properly prove Proposition 4.2.3.

First, rather than deal with the usual notion of static equivalence or inclusion (i.e. only the direct implications in Definition 2.4.1), we use a variation which we prove to be equivalent in the next lemma.

Lemma A.1.13 (alternative definition of static inclusion). We say that $\phi_{1} \sqsubseteq^{\prime} \phi_{2}$ if:

- for every $\phi_{1}$-precompact recipe $M$, if $M \phi_{1} \downarrow$ is an atom, then $M \phi_{2} \downarrow$ is an atom,
- for every $\phi_{1}$-precompact recipe $M, M \phi_{2} \downarrow$ is a message,
- for every $\phi_{1}$-precompact recipe $M$ and $N$, if $M \phi_{1} \downarrow=N \phi_{1} \downarrow$ then $M \phi_{2} \downarrow=N \phi_{2} \downarrow$.
and similarly, $\phi_{1} \sim^{\prime} \phi_{2}$ if $\phi_{1} \sqsubseteq^{\prime} \phi_{2}$ and $\phi_{2} \sqsubseteq^{\prime} \phi_{1}$.
Then $\phi_{S} \sqsubseteq \phi_{2}$ if, and only if, $\phi_{1} \sqsubseteq^{\prime} \phi_{2}$.
Proof. We need to show that $\phi_{1} \sqsubseteq \phi_{2}$ if, and only if, $\phi_{1} \sqsubseteq^{\prime} \phi_{2}$, where $\sqsubseteq$ denotes the static inclusion, i.e. only the direct implications in Definition 2.4.1. The implication $\phi_{1} \sqsubseteq \phi_{2} \Rightarrow \phi_{1} \sqsubseteq^{\prime} \phi_{2}$ is direct, as this definition only examine fewer tests than the original one and the ability for the attacker to test whether a recipe $R$ reduces to an atom is already ensured by tests of the form $\operatorname{dec}\left(\operatorname{enc}\left(\mathrm{w}_{1}, R\right)\right)=\mathrm{w}_{1}$. So let us consider the converse implication, and assume that
$\phi_{1} \sqsubseteq^{\prime} \phi_{2}$ and suppose $\phi_{1} \nsubseteq \phi_{2}$. We proceed by induction on recipes, proving our transformation of a single recipe or a pair of recipes strictly decreases the number of constructors (in the single recipe or the sum for pairs). We claim that if we have a witness of static non-inclusion, there is a recipe or a pair of recipes which are destructor-only witnessing that. In the following, $M$ will denote a recipe such that $M \phi_{1} \downarrow$ is a message but $M \phi_{2} \downarrow$ is not; $M_{1}$ and $M_{2}$ will denote two recipes such that $M_{i} \phi_{j} \downarrow$ is a message for $i, j \in\{1,2\}, M_{1} \phi_{1} \downarrow=M_{2} \phi_{2} \downarrow$ but $M_{1} \phi_{2} \downarrow \neq M_{2} \phi_{2} \downarrow$; and $C$ will be a linear destructor-only context. Let $n$ be the number of constructors in $M$ or the sum of the number of constructors in $M_{1}$ and $M_{2}$.
- If $n=0: M$ (resp. $M_{1}$ and $M_{2}$ ) is destructor-only,
- $M$ contains pairing:

1. $M=C\left[\operatorname{dec}\left(\left\langle M_{1}^{0}, M_{2}^{0}\right\rangle, M_{3}^{0}\right)\right]$ : impossible, as $M \phi_{1} \downarrow$ would not be a message,
2. $M=C\left[\operatorname{proj}_{i}\left(\left\langle M_{1}^{0}, M_{2}^{0}\right\rangle\right)\right]$ : then $M^{\prime}=C\left[M_{i}^{0}\right]$ has strictly less than $n$ constructors, is a message in $\phi_{1}$ but still not in $\phi_{2}$,
3. $M=\left\langle M_{1}^{0}, M_{2}^{0}\right\rangle$ : then there exists $i \in\{1,2\}$ such that $M_{i}^{0}$ is a message in $\phi_{1}$ while not in $\phi_{2}$; and $M_{i}^{0}$ contains strictly less than $n$ constructors,

- $M$ contains encryption:

1. $M=\operatorname{enc}\left(M_{1}^{0}, M_{2}^{0}\right)$ : three subcases must be examined:
(a) if $M_{2}^{0} \phi_{2} \downarrow$ is a message and is not an atom: then $M_{2}^{0}$ contains strictly less than $n$ constructors; and $M_{2}^{0} \phi_{1} \downarrow$ is an atom (as $M$ reduces to a message in $\phi_{1}$ ),
(b) else, if $M_{2}^{0} \phi_{2} \downarrow$ is not a message: $M_{2}^{0}$ contains strictly less than that $n$ constructors,
(c) else, if $M_{2}^{0} \phi_{2} \downarrow$ is an atom: then $M_{1}^{0}$ is a message in $\phi_{1}$ but not in $\phi_{2}$ and contains strictly less than $n$ constructors,
2. $M=C\left[\operatorname{proj}_{i}\left(\operatorname{enc}\left(M_{1}^{0}, M_{2}^{0}\right)\right)\right]$ : impossible, as $M \phi_{1} \downarrow$ would not be a message,
3. $M=C\left[\operatorname{dec}\left(\operatorname{enc}\left(M_{1}^{0}, M_{2}^{0}\right), M_{3}^{0}\right)\right]$ : in particular, $M_{2}^{0} \phi_{1} \downarrow=M_{3}^{0} \phi_{1} \downarrow$. If $M_{2}^{0}$ and $M_{3}^{0}$ are both messages in $\phi_{2}$ and $M_{2}^{0} \phi_{2} \downarrow \neq M_{2}^{0} \phi_{2} \downarrow$ : the pair $\left(M_{2}^{0}, M_{3}^{0}\right)$ contains $n-1$ constructors and is a witness of noninclusion. Else, if $M_{i}^{0} \phi_{2} \downarrow$ is not a message for some $i \in\{2,3\}$, then it contains strictly less than $n$ constructors. In the remaining case, $M_{1}^{0} \phi_{2} \downarrow$ is not a message, and contains strictly less than $n$ constructors,

- $M_{1}$ contains pairing (or symmetrically, $M_{2}$ contains pairing), using the same numbering as the case where $M$ did contain pairing:

1. this case cannot happen,
2. $C\left[M_{i}^{0}\right] \phi_{j} \downarrow=M_{1} \phi_{j} \downarrow$ for $j \in\{1,2\}$, and $C\left[M_{i}^{0}\right]$ contains strictly less than $n$ constructors,
3. $M_{i}^{0} \phi_{2} \downarrow=\operatorname{proj}_{i}\left(M_{1}\right) \phi_{2} \downarrow$ and $M_{1} \phi_{2} \downarrow \neq M_{2} \phi_{2} \downarrow$ implies that either $\operatorname{proj}_{i}\left(M_{2}\right) \phi_{2} \downarrow$ is not a message, or $M_{i}^{0} \phi_{2} \downarrow \neq \operatorname{proj}_{i}\left(M_{2}\right) \phi_{2} \downarrow$; which in both cases counts strictly less than $n$ constructors,

- $M_{1}$ contains encryption (or symmetrically, $M_{2}$ contains encryption), using the same numbering as the case where $M$ did contain encryption:

1. $M_{2}^{0} \phi_{1} \downarrow$ and $M_{2}^{0} \phi_{2} \downarrow$ are both messages and atom and $M_{1} \phi_{2} \downarrow \neq M_{2} \phi_{2} \downarrow$ implies that either $\operatorname{dec}\left(M_{2}, M_{2}^{0}\right) \phi_{2} \downarrow$ is not a message or that $M_{1}^{0} \phi_{2} \downarrow \neq \operatorname{dec}\left(M_{2}, M_{2}^{0}\right) \phi_{2} \downarrow$; which in both cases counts strictly less than $n$ constructors,
2. this case cannot happen,
3. $M_{1} \phi_{2} \downarrow$ is a message implies $M_{2}^{0} \phi_{2} \downarrow=M_{3}^{0} \phi_{2} \downarrow$ and $M_{1}^{0} \phi_{2} \downarrow$ is a message. Then $M_{1}^{0}$ contains strictly less constructors than $M_{1}$, and we get $M_{1}^{0} \phi_{1} \downarrow=M_{2} \phi_{1} \downarrow$ while $M_{1}^{0} \phi_{2} \downarrow \neq M_{2} \phi_{2} \downarrow$.

At this point, we proved that we can only consider destructor-only witnesses of $\phi_{1} \nsubseteq \phi_{2}$. Suppose now $M, M_{1}$ and $M_{2}$ are destructor-only: we need to prove they are $\phi_{1}$-precompact, i.e. we show they do not reduce to a pair or an encryption with a deducible key.

- if $M \phi_{1} \downarrow=\langle s, t\rangle$ : there exists $i \in\{1,2\}$ such that $\operatorname{proj}_{i}(M)$ is still a message in $\phi_{1}$ but not in $\phi_{2}$,
- if $M \phi_{1} \downarrow=$ enc $(s, k)$ and $k$ is deducible in $\phi_{1}$, which implies there exists a destructor-only recipe $R$ such that $R \phi_{1} \downarrow=k$ (consider the $\Downarrow$ normalisation of any recipe reducing to $k$ ). $\operatorname{dec}(M, R)$ is a message in $\phi_{1}$ while not in $\phi_{2}$,
- if $M_{1} \phi_{1} \downarrow=\langle s, t\rangle=M_{2} \phi_{1} \downarrow$ : there exists $i \in\{1,2\}$ such that $\operatorname{proj}_{i}\left(M_{1}\right) \phi_{1} \downarrow=\operatorname{proj}_{i}\left(M_{2}\right) \phi_{1} \downarrow$ but $\operatorname{proj}_{i}\left(M_{1}\right) \phi_{2} \downarrow \neq$ $\operatorname{proj}_{i}\left(M_{2}\right) \phi_{2} \downarrow$ or $\operatorname{proj}_{i}\left(M_{j}\right) \phi_{2} \downarrow$ is not a message for some $j \in\{1,2\}$.
- if $M_{1} \phi_{1} \downarrow=\operatorname{enc}(s, k)=M_{2} \phi_{1} \downarrow$, and $k$ is deducible: as previously, there exists a destructor-only recipe $R$ such that $R \phi_{1} \downarrow=k$. In that case $\operatorname{dec}\left(M_{1}, R\right) \phi_{1} \downarrow=\operatorname{dec}\left(M_{2}, R\right) \phi_{1} \downarrow$. Then either $\operatorname{dec}\left(M_{i}, R\right) \phi_{2} \downarrow$ is not a message for some $i \in\{1,2\}$ or $\operatorname{dec}\left(M_{1}, R\right) \phi_{2} \downarrow \neq \operatorname{dec}\left(M_{2}, R\right) \phi_{2} \downarrow$.

Note that this last transformation does not introduce any constructor and strictly decreases the normal forms of $M$, $M_{1}$ and $M_{2}$ in $\phi_{1}$. Hence, if $\phi_{1} \nsubseteq \phi_{2}$, then $\phi_{1} \not \Phi^{\prime} \phi_{2}$.

Lemmas A.1.14 and A.1.16 provide the link between any concrete second-order trace, as the attacker can build, and the second-order traces which are generated at step 3 of our algorithm. They also provide the relations between concrete and symbolic frames we needed at the beginning of Section A.1.1.

Step 3 in the algorithm induces a renaming $\rho$. As this renaming is bijective, and only meant to provide concrete traces of $P$ and $Q$, in the following statements and proofs, we will omit it and refer to the non-renamed trace in the algorithm by $\left(\operatorname{tr}_{S}, \phi_{S}\right)$, which will then by symbolic.

Lemma A.1.14 (existence of a symbolic trace). For any $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$, there exists a symbolic second-order trace $\left(\operatorname{tr}_{S}, \phi_{S}\right)$ of $P$ generated by $\mathcal{A}_{\mathcal{B}}(P, Q)$, a first-order substitution $\lambda_{P}$ and a second-order substitution $\theta$ such that $\operatorname{tr} \phi \downarrow=\operatorname{tr}_{S} \phi_{S} \lambda_{P} \downarrow$ (in particular: $\phi=\phi_{S} \lambda_{P}$ ), $\operatorname{tr}_{S} \theta \phi \downarrow=\operatorname{tr} \phi \downarrow$ (the first-order input terms are identical), and such that for every $x \mapsto R_{x} \in \theta, R_{x}$ is built from the initial knowledge of the attacker and the outputs which preceded the introduction of $x$ in $\operatorname{tr}_{S}, R_{x} \phi_{S} \downarrow$ is a message and for every variable $x$ occurring in key position in $\operatorname{tr}_{S} \phi_{S} \downarrow, R_{x} \phi_{S} \downarrow$ is an atom,

Proof. For ( $\operatorname{tr}, \phi$ ) we can derive the existence of $\operatorname{tr}_{0} \in \operatorname{trace}_{s}(P)$ and a substitution $\sigma$ such that $\operatorname{tr} \phi \downarrow=\operatorname{tr}_{0} \sigma$ (Lemma 4.1.1). Using Definition 4.2.3 we get there exists a first-order substitution $\sigma_{1}$ generated by $\mathcal{B}$ applied to $\operatorname{tr}_{0}$ and a first-order substitution $\tau$ such that $\operatorname{tr}_{0} \sigma=\operatorname{tr}_{1} \tau$, where $\operatorname{tr}_{1}=\operatorname{tr}_{0} \sigma_{1} .\left(\operatorname{tr}_{S}, \phi_{S}\right)$ is obtained by lifting tr $\operatorname{tr}_{1}$ to second-order with arbitrary valid recipes (i.e progressively constructible by the attacker) and storing the outputs of $\operatorname{tr}_{1}$ in $\phi_{S}$. A fortiori then, $\phi_{S} \tau=\phi$. Let $\lambda_{P}=\tau$. To define $\theta$ we choose for every $x \in \operatorname{vars}\left(\operatorname{tr}_{S}\right)$ a recipe $R_{x}$ of $x \lambda_{P}$, then $\theta=\left\{x \mapsto R_{x}\right.$ for $\left.x \in \operatorname{vars}\left(\operatorname{tr}_{S}\right)\right\}$. Finding such a recipe is always possible thanks to Definition 4.2.3. We can moreover assume $R_{x} \phi_{S} \downarrow$ is a symbolic message and if $x$ appears in key position inside $\operatorname{tr}_{S} \phi_{S} \downarrow$, then $x \theta \phi_{S} \downarrow$ is an atom. Indeed, let us order variables in $\operatorname{tr}_{S}$ with their order of apparition (variables introduced simultaneously in an input can be ordered arbitrarily) in $\operatorname{tr}_{S}$, and define $\theta_{k}$ inductively. If no variables was introduced, $\theta_{0}=i d$. By induction, suppose $\theta_{k}$ defined up to the $k$ first variables in $\operatorname{tr}_{S}$ such that $y \theta_{k} \phi_{S} \downarrow$ is a message if $y$ is one of these $k$ first variables. Let us prove that $R_{x} \phi_{S} \downarrow$ can be chosen so that $R_{x} \phi_{S} \downarrow$ is a message. Without loss of generality, as keys are atomic, we can choose a recipe $R$ of $x \lambda_{P}$ such that $R=C\left[R_{1}, \ldots, R_{m}\right], C$ is a constructor-only context and for every $i \in\{1, \ldots, m\}, R_{i}$ is destructor-only. As both $\downarrow$-reduction and $\Downarrow$-reduction contain only rules with destructors on top, we get that $\mathcal{T}_{\phi}^{*}(R)=C\left[\mathcal{T}_{\phi}^{*}\left(R_{1}\right), \ldots, \mathcal{T}_{\phi}^{*}\left(R_{m}\right)\right]$. As $R \phi \downarrow$ and $C$ is constructor-only, for any $i, R_{i} \phi \downarrow$ is a message. By Lemmas A.1.4 and A.1.7 and Corollary A.1.1, if $\mathcal{T}_{\phi}^{*}\left(R_{i}\right)=\left(R_{i}^{*}, \mathcal{R}_{i}\right), R_{i} \phi \downarrow=\left(R_{i}^{*} \theta_{k}\right) \phi \downarrow$ and $R_{i}^{*} \phi_{S} \downarrow$ is a message. By induction hypothesis, we deduce $\left(R_{i}^{*} \theta_{k}\right) \phi_{S} \downarrow$ is a message. Taking $R_{x}=C\left[R_{1}^{*} \theta_{k}, \ldots, R_{m}^{*} \theta_{k}\right]$ ensures the result, and $\theta_{k+1}=\theta_{k} \cup\left\{x \mapsto R_{x}\right\}$. Then, suppose $x$ appears in a key position inside $\operatorname{tr}_{S} \phi_{S} \downarrow$ but $x \theta \phi_{S} \downarrow$
is not an atom. As $\phi=\phi_{S} \lambda_{P}$, we would get that $x \lambda_{P}$ would appear in key position inside $\operatorname{tr} \phi \downarrow$ and $x \lambda_{P}$ would not be atomic, absurd as $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ and keys are atomic. Finally: $\left(\operatorname{tr}_{S} \theta\right) \phi \downarrow=\left(\operatorname{tr}_{S} \phi\right) \downarrow \lambda_{P} \downarrow$, as $\operatorname{tr}_{S} \phi=\operatorname{tr}_{1}$, $\left(\operatorname{tr}_{S} \theta\right) \phi \downarrow=\operatorname{tr}_{1} \lambda_{P}=\operatorname{tr}_{1} \tau=\operatorname{tr}_{0} \sigma$ and finally $\left(\operatorname{tr}_{S} \theta\right) \phi \downarrow=\operatorname{tr} \phi \downarrow$.

Lemma A.1.14 aimed at linking any concrete second-order trace of $P$ to the valid second-order trace generated by the algorithm. The next ones, Lemmas A.1.15 and A.1.16 ensure similar properties for $\left(\operatorname{tr}_{S}, \psi_{S}\right)$ when it exists.
Lemma A.1.15 (instances of valid symbolic traces). If $\left(\operatorname{tr}_{S}, \psi_{S}\right)$ is a symbolic second-order trace of $Q$, then for every valid second-order substitution $\theta$, i.e. such that for every $x \mapsto R_{x} \in \theta, R_{x}$ is built from the initial knowledge of the attacker and the outputs which preceded the introduction of $x$ in $\operatorname{tr}_{S}, R_{x} \psi_{S} \downarrow$ is a message and for every variable $x$ occurring in key position in $\operatorname{tr}_{S} \psi_{S} \downarrow, R_{x} \psi_{S} \downarrow$ is an atom, then there exists $\psi^{\prime}$ such that $\left(\operatorname{tr}_{S} \theta, \psi^{\prime}\right) \in \operatorname{trace}(Q)$ and $\operatorname{tr}_{S} \theta \psi^{\prime} \downarrow=\operatorname{tr}_{S} \psi_{S} \downarrow\left(\theta \psi^{\prime}\right) \downarrow$ and $\psi^{\prime}=\psi_{S}\left(\theta \psi^{\prime}\right) \downarrow$.

Proof. Let us proceed by induction on $n$ the length of $\operatorname{tr}_{S}^{n}$ and prove the following statements: $\left(\operatorname{tr}_{S}^{n} \theta, \psi^{n}\right) \in \operatorname{trace}(Q)$, $\operatorname{tr}_{S}^{n} \theta \psi^{n} \downarrow=\operatorname{tr}_{S}^{n} \psi_{S}^{n} \downarrow\left(\theta \psi^{n}\right) \downarrow, \psi^{n}=\psi_{S}^{n}\left(\theta \psi^{n}\right) \downarrow\left(\right.$ which is a particular case of the previous item) and $\sigma^{n}=\sigma_{S}^{n}\left(\theta \psi^{n}\right) \downarrow ;$ where

$$
\begin{aligned}
& \sigma^{n}=\operatorname{mgu}\left(\left(R_{1} \theta \psi^{n-1} \downarrow, u_{1} \rho_{1}\right), \ldots,\left(R_{m} \theta \psi^{n-1} \downarrow, u_{m} \rho_{m}\right)\right) \\
& \sigma_{S}^{n}=\operatorname{mgu}\left(\left(R_{1} \psi_{S}^{n-1} \downarrow, u_{1} \rho_{1}\right) \ldots,\left(R_{m} \psi_{S}^{n-1} \downarrow, u_{m} \rho_{m}\right)\right)
\end{aligned}
$$

and:

- $\operatorname{tr}^{n}$ denotes the truncation of $\operatorname{tr}$ at length $n, m$ corresponds to the number of inputs in $\operatorname{tr}^{n}$ and $\psi^{n}$ is the adequate subframe of $\psi$.
- the $u_{i}$ are the input patterns of $Q$ filtering the inputs of $\operatorname{tr}_{S}$,
- $\rho_{i}$ is the substitution applied to the remaining process after an input ( $\theta$ in the description of our semantics rules). In particular, $\rho_{1}=i d$ and

$$
\rho_{k+1}=m g u\left(\left(R_{1} \theta \psi^{n-1} \downarrow, u_{1} \rho_{1}\right), \ldots,\left(R_{k} \theta \psi^{n-1} \downarrow, u_{k} \rho_{k}\right)\right)
$$

We can first note that

$$
\begin{aligned}
\sigma^{n} & =\operatorname{mgu}\left(\left(R_{1} \theta \psi^{n-1} \downarrow, u_{1} \rho_{1}\right), \ldots,\left(R_{m} \theta \psi^{n-1} \downarrow, u_{m} \rho_{m}\right)\right) \\
& =\operatorname{mgu}\left(\left(R_{1} \theta \psi^{n-1} \downarrow, u_{1}\right), \ldots,\left(R_{m} \theta \psi^{n-1} \downarrow, u_{m}\right)\right)
\end{aligned}
$$

by defining of the $\rho_{i}$ and the unification algorithms for sets of pairs. Similarly,

$$
\begin{aligned}
\sigma_{S}^{n} & =m g u\left(\left(R_{1} \psi_{S}^{n-1} \downarrow, u_{1} \rho_{1}\right) \ldots,\left(R_{m} \psi_{S}^{n-1} \downarrow, u_{m} \rho_{m}\right)\right) \\
& =m g u\left(\left(R_{1} \psi_{S}^{n-1} \downarrow, u_{1}\right) \ldots,\left(R_{m} \psi_{S}^{n-1} \downarrow, u_{m}\right)\right)
\end{aligned}
$$

The induction itself:

- $\mathrm{n}=0$ : We consider only the initial knowledge of the attacker. As initial frames contain no variables, $\psi^{0}=\psi_{S}^{0}$; because no input has been made, $\sigma^{0}=\sigma_{S}^{0}=\emptyset ; \operatorname{tr}_{S}^{0} \theta \psi^{0} \downarrow=\operatorname{tr}_{S}^{0} \psi_{S}^{0} \downarrow\left(\theta \psi^{0}\right) \downarrow$; and finally, $\left(\operatorname{tr}^{0} \theta, \psi^{0}\right) \in \operatorname{trace}(Q)$ as it has length zero.
- Suppose we get the result up to some $n$ : we make a disjunction on the $n+1$-th action in $\operatorname{tr}_{S}$.
- If $\operatorname{tr}_{S}^{n+1}$ ends by an output w (stored in $\psi_{S}^{n+1}$ ) on some channel $c$. As $\operatorname{tr}_{S}$ is a valid symbolic trace, any variable occurring in $w \psi_{S}^{n}$ was first introduced in former inputs. $\left(\operatorname{tr}_{S}^{n} \theta, \psi^{n}\right) \in \operatorname{trace}(Q)$ by induction hypothesis; $\sigma^{n+1}=\sigma^{n}$ and $\sigma_{S}^{n+1}=\sigma_{S}^{n}$ as there is no new input; and finally, according to the input rule in our semantics, if $v_{n+1}$ is the output pattern of the protocol specification being instantiated, $\mathrm{w} \psi_{S}^{n+1}=v_{n+1} \sigma_{S}^{n}$ and $\mathrm{w} \psi^{n+1}=v_{n+1} \sigma^{n}$. Hence $\mathrm{w} \psi_{S}^{n+1}\left(\theta \psi^{n} \downarrow\right)=\mathrm{w} \psi^{n+1}$, and $\psi^{n+1}=\psi_{S}^{n+1}\left(\theta \psi^{n}\right) \downarrow=$ $\psi_{S}^{n+1}\left(\theta \psi^{n+1}\right) \downarrow$ by induction hypothesis (and as the output does not introduce new variables in $\psi^{n+1}$ ). And thus $\operatorname{tr}_{S}^{n+1} \theta \psi^{n+1} \downarrow=\operatorname{tr}_{S}^{n+1} \psi_{S}^{n+1} \downarrow\left(\theta \psi^{n+1}\right) \downarrow$, as the new action of the trace is the output for which the equality has been proved with the new frames $\psi_{S}^{n+1}$ and $\psi^{n+1}$.
- If $\operatorname{tr}_{S}^{n+1}$ ends by an output of a channel $c: c$ does not contain any variable and its value only depends on the number of channel outputted so far. As $\operatorname{tr}_{S}^{n} \theta \psi^{n} \downarrow=\operatorname{tr}_{S}^{n} \psi_{S}^{n} \downarrow\left(\theta \psi^{n}\right) \downarrow$ by induction hypothesis, no substitution is computed in the semantics nor any element added to the frame, we directly derive $\operatorname{tr}_{S}^{n+1} \theta \psi^{n+1} \downarrow=\operatorname{tr}_{S}^{n+1} \psi_{S}^{n+1} \downarrow\left(\theta \psi^{n+1}\right) \downarrow, \psi^{n+1}=\psi^{n}, \sigma^{n+1}=\sigma^{n}$ (and similarly with their symbolic counterparts).
- If $\operatorname{tr}_{S}^{n+1}$ ends by an input with recipe $R_{n+1}$ on some channel $c$. According to the input rule semantics, let $u_{m+1}$ be the pattern to be match against $R_{m+1}\left(\operatorname{in~}_{\operatorname{tr}_{S}^{n+1}}\right.$ ) and against $R_{m+1} \theta\left(\operatorname{in} \operatorname{tr}_{S}^{n+1} \theta\right.$ ). Let $\sigma_{S}^{n+1}$ (resp. $\sigma^{n+1}$ ) be the substitution introduced by the rule for $\operatorname{tr}_{S}^{n+1}\left(\right.$ resp. $\left.\operatorname{tr}_{S}^{n+1} \theta\right)$. We have that:

$$
\begin{array}{r}
\sigma_{S}^{n+1}=\operatorname{mgu}\left(\left(R_{1} \psi_{S}^{n} \downarrow, u_{1}\right) \ldots,\left(R_{m} \psi_{S}^{n} \downarrow, u_{m}\right),\right. \\
\\
\left.\left(R_{m+1} \psi_{S}^{n} \downarrow, u_{m+1}\right)\right) \\
\sigma^{n+1}=\operatorname{mgu}\left(\left(R_{1} \theta \psi^{n} \downarrow, u_{1}\right) \ldots,\left(R_{m} \theta \psi^{n} \downarrow, u_{m}\right),\right. \\
\left.\left(R_{m+1} \theta \psi^{n} \downarrow, u_{m+1}\right)\right)
\end{array}
$$

These equalities can be rewritten as:

$$
\begin{aligned}
& \sigma_{S}^{n+1}=m g u\left(m g u \left(\left(R_{1} \psi_{S}^{n} \downarrow, u_{1}\right) \ldots,\right.\right. \\
& \left.\left.\left(R_{m} \psi_{S}^{n} \downarrow, u_{m}\right)\right),\left(R_{m+1} \psi_{S}^{n} \downarrow, u_{m+1}\right)\right) \\
& \sigma^{n+1}=m g u\left(m g u \left(\left(R_{1} \theta \psi^{n} \downarrow, u_{1}\right) \ldots,\right.\right. \\
& \left.\left.\left(R_{m} \theta \psi^{n} \downarrow, u_{m}\right)\right),\left(R_{m+1} \theta \psi^{n} \downarrow, u_{m+1}\right)\right)
\end{aligned}
$$

Note that $\psi^{n}$ is actually equal to $\psi^{n-1}$ on their common domain. Hence we get:

$$
\begin{aligned}
& \sigma_{S}^{n+1}=\operatorname{mgu}\left(\sigma_{S}^{n}, \operatorname{mgu}\left(R_{m+1} \psi_{S}^{n} \downarrow, u_{m+1}\right)\right) \\
& \sigma^{n+1}=\operatorname{mgu}\left(\sigma^{n}, \operatorname{mgu}\left(R_{m+1} \theta \psi^{n} \downarrow, u_{m+1}\right)\right)
\end{aligned}
$$

We now need to show that:

$$
m g u\left(R_{m+1} \theta \psi^{n} \downarrow, u_{m+1}\right)=m g u\left(R_{m+1} \psi_{S}^{n} \downarrow, u_{m+1}\right)\left(\theta \psi^{n} \downarrow\right)
$$

Indeed, $R_{m+1} \theta \psi^{n} \downarrow=\left(R_{m+1} \psi^{n}\right) \downarrow\left(\theta \psi^{n}\right) \downarrow$ and as $\operatorname{dom}\left(u_{m+1}\right) \cap \operatorname{dom}(\theta)=\emptyset$ :

$$
\begin{aligned}
& m g u\left(\left(R_{m+1} \psi_{S}^{n}\right) \downarrow\left(\theta \psi^{n}\right) \downarrow, u_{m+1}\right) \\
= & m g u\left(R_{m+1} \psi_{S}^{n} \downarrow, u_{m+1}\right)\left(\theta \psi^{n} \downarrow\right)
\end{aligned}
$$

Hence, as $\sigma^{n}=\sigma_{S}^{n}\left(\theta \psi^{n}\right) \downarrow$, we end up with $\sigma^{n+1}=\sigma_{S}^{n+1}\left(\theta \psi^{n}\right) \downarrow$, and because the last action of $\operatorname{tr}_{S}$ is an input, $\psi^{n}=\psi^{n+1}$, we get that $\sigma^{n+1}=\sigma_{S}^{n+1}\left(\theta \psi^{n+1}\right) \downarrow$, as intended. Thus $\operatorname{tr}_{S}^{n+1} \theta \psi^{n+1} \downarrow=$ $\operatorname{tr}_{S}^{n+1} \psi_{S}^{n+1} \downarrow\left(\theta \psi^{n+1}\right) \downarrow$. In particular, $m g u\left(R_{m+1} \theta \psi^{n} \downarrow, u_{m+1}\right) \neq \perp$, so $\left(\operatorname{tr}_{S}^{n+1} \theta, \psi^{n+1}\right) \in \operatorname{trace}(Q)$ and $\psi^{n+1}=\psi_{S}^{n+1}\left(\theta \psi^{n+1}\right) \downarrow$.

Thus our induction is complete, and for $n$ equal to the length of $\operatorname{tr}_{S}$, naming $\psi^{\prime}=\psi^{n}$, we prove the desired result.
Let $\sqsubseteq_{k}$ denotes the trace inclusion up to length $k$ i.e.: $P \sqsubseteq_{k} Q$ if for any trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ of length (in term of number of actions) lesser than or equal to $k$, there exits $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ such that $\phi \sim^{\prime} \psi$.

Lemma A.1.16 (from $\phi$ to $\psi$ ). Let $n \in \mathbb{N}^{*}$. If $P \sqsubseteq_{n-1} Q$, given $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ of length $k \leq n,(\operatorname{tr}, \psi) \in$ $\operatorname{trace}(Q), \operatorname{tr}_{S}$ and $\theta$ as defined in Lemma A.1.14 and $\psi_{S}$ such that $\left(\operatorname{tr}_{S}, \psi_{S}\right)$ is a symbolic second-order trace, then $\operatorname{tr} \psi \downarrow=\operatorname{tr}_{S} \psi_{S} \lambda_{Q} \downarrow$ and $\psi=\psi_{S} \lambda_{Q}$ where $\lambda_{Q}=(\theta \psi) \downarrow$.

Proof. By definition of $\theta$, for every recipe $R$ of tr and its corresponding recipe $R_{S}$ in $\operatorname{tr}_{S}, R \phi \downarrow=R_{S} \theta \phi \downarrow$. As $P \sqsubseteq_{n-1} Q$, it implies $R \psi \downarrow=R_{S} \theta \psi \downarrow$ (if the last action is an output of a term, the variables are identical, if the last action is an input, their recipes are built on recipes from the frame generated from tr minus its last action, if the last
action is the output of a channel, the channels are identical). By induction on $\operatorname{tr}$ and $\mathrm{tr}_{S}$, we show both traces can share the same execution, thus leading to $\operatorname{tr}_{S} \theta \psi \downarrow=\operatorname{tr} \psi \downarrow$. From Lemma A.1.15, as there exists $\psi^{\prime}$ such that $\left(\operatorname{tr}_{S} \theta, \psi^{\prime}\right)$ is also a second-order trace of $Q$ and by induction on $\operatorname{tr}$ and $\operatorname{tr}_{S}$, we show both traces can share the same execution, thus leading to $\psi=\psi^{\prime}$; and setting $\lambda_{Q}=\theta \psi \downarrow$, we get that $\psi=\psi_{S} \lambda_{Q}$. Hence we finally get that $\operatorname{tr} \psi \downarrow=\operatorname{tr}_{S} \psi_{S} \lambda_{Q} \downarrow$.

We are now able to prove Proposition 4.2.3 as stated in Section 4.2.3.
Proposition 4.2.3 (completeness). Let $P$ and $Q$ be two bounded protocols such that $P \not \approx Q$. The algorithm $\mathcal{A}_{\mathcal{B}}$ applied on $P$ and $Q$ returns a minimal (in term of number of actions) witness tr of non-equivalence.

Proof. The proof is by induction on the length of traces. We suppose trace equivalence has been proved up to some length $n-1$ and consider a witness $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ of $P \not \chi_{t} Q$ of length $n$. Then we consider for instance the case where $P \not \mathbb{Z}_{t} Q$, i.e. $(\operatorname{tr}, \psi)$ cannot belong in trace $(Q)$ and the case where $\phi \not \chi^{\prime} \psi$. The other cases are handled symmetrically.

From Lemma A.1.14, we get the existence of $\left(\operatorname{tr}_{S}, \phi_{S}\right)$ a symbolic second-order trace of $P$ along with their substitutions $\lambda_{P}$ and $\theta$.

In the first case, suppose that $(\operatorname{tr}, \psi) \notin \operatorname{trace}(Q)$. If for every frame $\psi_{S},\left(\operatorname{tr}_{S}, \psi_{S}\right)$ is not a symbolic trace of $Q$ we have a witness. Otherwise let us assume that there exists $\psi_{S}$ such that $\left(\operatorname{tr}_{S}, \psi_{S}\right)$ is a valid second-order symbolic trace of $Q$. For every $x \in \operatorname{dom}(\theta), x \theta \phi_{S} \downarrow$ is a message implies that $x \theta \psi_{S} \downarrow$ is a message, as equivalence between $P$ and $Q$ has been proved up to length $n-1$ (and $x \theta$ must be a recipe built from the frame after $\operatorname{tr}_{S}^{-1}$ ). Now, if $\theta$ does not satisfy the property that for every variable $x$ occurring in key position in $\operatorname{tr}_{S} \psi_{S} \downarrow, x \theta \psi_{S} \downarrow$ is an atom and thus there would exist a variable $x$ such that $x$ appears in key position in $\operatorname{tr}_{S} \psi_{S} \downarrow$ while $x \theta \psi_{S} \downarrow$ is not an atom. Equivalence up to length $n-1$ ensures $x \theta \phi_{S} \downarrow$ is not an atom. Thus, $x$ should not occur in a key position in $\operatorname{tr}_{S} \phi_{S} \downarrow$, meaning $x \in K_{\psi_{S}} \backslash K_{\phi_{S}}$. Step 5 in the algorithm would then ensures that if $\lambda=\{\langle\omega, \omega\rangle / x\}, \operatorname{tr}_{S} \lambda$ is a witness of $P \nsubseteq Q$, as $\left(\operatorname{tr}_{S} \lambda, \phi_{S} \lambda\right)$ is valid symbolic trace of $P$ but not of $Q$, as $\langle\omega, \omega\rangle$ would appear in key position in $\left(\operatorname{tr}_{S} \lambda\right)\left(\psi_{S} \lambda\right) \downarrow$. In the following we will then assume $\theta$ satisfy this property. Using Lemma A.1.15, we get that $\left(\operatorname{tr}_{S} \theta, \psi^{\prime}\right) \in \operatorname{trace}(Q)$ and $\operatorname{tr}_{S} \theta \psi^{\prime} \downarrow=\operatorname{tr}_{S} \psi_{S} \downarrow\left(\theta \psi^{\prime} \downarrow\right)$. Because $P \sqsubseteq_{n-1} Q$, there exists $\psi^{\prime \prime}$ such that $\left(\operatorname{tr}^{-1}, \psi^{\prime \prime}\right) \in \operatorname{trace}(Q)$ and $\operatorname{tr}_{S}^{-1} \theta \psi^{\prime \prime} \downarrow=$ $\operatorname{tr}^{-1} \psi^{\prime \prime} \downarrow$. Indeed, by definition of $\theta$, for every recipe $R$ of $\operatorname{tr}$ and its corresponding recipe $R_{S}$ in $\operatorname{tr}_{S}, R \phi \downarrow=R_{S} \theta \phi \downarrow$. As $P \sqsubseteq_{n-1} Q$, it implies $R \psi^{\prime \prime} \downarrow=R_{S} \theta \psi^{\prime \prime} \downarrow$ (if the last action is an output of a term, the variables are identical, if the last action is an input, their recipes are built on recipes from the frame generated from tr minus its last action, if the last action is the output of a channel, the channels are identical). By induction on $\operatorname{tr}^{-1}$ and $\operatorname{tr}_{S}^{-1}$, we show both traces can share the same execution, thus leading to $\operatorname{tr}_{S}^{-1} \theta \psi^{\prime \prime} \downarrow=\operatorname{tr}^{-1} \psi^{\prime \prime} \downarrow$. Moreover after executing $\operatorname{tr}_{S}^{-1} \theta$ and $\operatorname{tr}^{-1}$, $Q$ ends up in the same configuration (by following the same execution). Then, if tr's last action is an output of a term, because $\left(\operatorname{tr}_{S} \theta, \psi^{\prime}\right) \in \operatorname{trace}(Q)$, there exists $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$, contradiction. If its last action is an input on some channel $c$ with a recipe $R$, as we already established that $R_{S} \theta \psi^{\prime \prime} \downarrow=R \psi^{\prime \prime} \downarrow$ and their configurations are identical, there exists $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$, also reaching a contradiction. If the last action is an output of channel, $\left(\operatorname{tr}_{S}, \theta^{\prime}\right) \in \operatorname{trace}(Q)$ directly implies $\left(\operatorname{tr}, \psi^{\prime \prime}\right) \in \operatorname{trace}(Q)$, which is also a contradiction. Hence $\left(\operatorname{tr}_{S}, \psi_{S}\right)$ is not a valid second-order trace of $Q$ if $(\operatorname{tr}, \psi) \notin \operatorname{trace}(Q)$ for any frame $\psi$.

Assume $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ for some $\psi$ and $\phi \not \chi^{\prime} \psi$ for any such $\psi$. In the second case, we need to prove either that if there is a recipe leading to a message in $P$ but not in $Q$ the algorithm will yield an attack; or that if an equality holds in $P$ but not in $Q$, the algorithm can derive two equalities which will hold in $P$ and not in $Q$; or that if a recipe leads to an atom in $\phi$ but not in $\psi$, the algorithm witnesses it. As $\left(\operatorname{tr}_{S}, \psi_{S}\right) \in \operatorname{trace}(Q)$ in this case, from Lemma A.1.16 and because $Q$ is determinate, we can derive the existence of $\lambda_{Q}$ such that $\psi=\psi_{S} \lambda_{Q}$, which is a required hypothesis of Lemma A.1.10.

In the first subcase, let $R$ be a $\phi$-precompact recipe such that $R \phi \downarrow$ is a message but $R \psi \downarrow$ is not. Let us then define $\left(R^{*}, \mathcal{R}_{1}\right)=\mathcal{T}_{\phi}^{*}(R)$ and $\left(R^{* *}, \mathcal{R}_{2}\right)=\mathcal{T}_{\psi}^{*}(R)$. We operate the following disjunction:

1. $\psi_{S} \not \vDash \mathcal{R}_{1}$ or $\phi_{S} \not \vDash \mathcal{R}_{2}$. By Lemma A.1.1, $\phi_{S} \models \mathcal{R}_{1}$. Consider for example an equality in $\mathcal{R}_{1}$ witnessing $\psi_{S} \notin \mathcal{R}_{1}$ : this equality is captured by the algorithm at step 6 , hence leading to a witness of non-equivalence. The other case is treated symmetrically.
2. else, if $\psi_{S} \models \mathcal{R}_{1}$ and $\phi_{S} \models \mathcal{R}_{2}$ : we can apply Lemma A.1.9, thus $R^{*}=R^{*}$. If $R^{*} \psi_{S} \downarrow$ is not a message, as $R^{*}$ is $\phi_{S}$-compact (because $R$ is $\phi$-precompact and of Lemma A.1.8), we have a witness of non-inclusion provided by the algorithm. So let us assume that $R^{*} \psi_{S} \downarrow$ is a message. We can now apply Lemma A.1.12. With the same notations, either there exists a $\phi_{S}$-compact recipe $R_{0}$ such that $R_{0} \phi_{S} \downarrow$ is a message while $R_{0} \psi_{S} \downarrow$ is not, in which case we directly get a witness of non-inclusion; or we can consider the next case.

We now deal with the subcase where an equality holds in $\phi$ but not in $\psi$. Let $R_{1}$ and $R_{2}$ be two $\phi$-precompact recipes such that $R_{1} \phi \downarrow=R_{2} \phi \downarrow$ and $R_{1} \psi \downarrow \neq R_{2} \psi \downarrow$. Let us define $\left(R_{1}^{*}, \mathcal{R}_{1}\right)=\mathcal{T}_{\phi}^{*}\left(R_{1}\right),\left(R_{2}^{*}, \mathcal{R}_{2}\right)=\mathcal{T}_{\phi}^{*}\left(R_{2}\right)$, $\left(R_{1}^{* *}, \mathcal{R}_{1}^{\prime}\right)=\mathcal{T}_{\psi}^{*}\left(R_{1}\right)$ and $\left(R_{2}^{\prime *}, \mathcal{R}_{2}^{\prime}\right)=\mathcal{T}_{\psi}^{*}\left(R_{2}\right)$. As previously, we can operate the following disjunction:

1. $\psi_{S} \not \vDash \mathcal{R}_{1}$ or $\psi_{S} \not \vDash \mathcal{R}_{2}$ or $\phi_{S} \not \vDash \mathcal{R}_{1}^{\prime}$ or $\phi_{S} \not \vDash \mathcal{R}_{2}^{\prime}$ : see the previous subcase, we can directly create a witness of non-equivalence.
2. $\psi_{S} \models \mathcal{R}_{1}, \psi_{S} \models \mathcal{R}_{2}, \phi_{S} \models \mathcal{R}_{1}^{\prime}$ and $\phi_{S} \models \mathcal{R}_{2}^{\prime}$ : we can now apply Lemma A.1.9 twice and get that $R_{1}^{* *}=R_{1}^{*}$ and $R_{2}^{* *}=R_{2}^{*}$. From that we apply Lemma A.1.11 and get that there exists $\sigma m g u$ of two $\phi_{S}$-compact recipes such that such that $R_{1}^{*} \phi_{S} \sigma \downarrow=R_{2}^{*} \phi_{S} \sigma \downarrow$. Thus we can choose $\sigma_{1}=\sigma$ at step 2 in the algorithm. And if, for the sake of clarity, we name $\operatorname{tr}_{E}, \phi_{E}$ and $\psi_{E}$ the trace and frames (respectively) introduced at step 3 of the algorithm, it ensures that $R_{1}^{*} \phi_{E} \downarrow=R_{2}^{*} \phi_{E} \downarrow$. From Lemmas A.1.14 and A.1.16, we get new first-order substitutions $\lambda_{P}^{\prime}$ (for $\left(\operatorname{tr}_{E}, \phi_{E}\right)$ ) and $\lambda_{Q}^{\prime}\left(\right.$ for $\left(\operatorname{tr}_{E}, \psi_{E}\right)$ ). From there, we apply the same reasoning as before, as an equality still holds in $\phi$ but not in $\psi$, using $\mathcal{T}^{*}$ and making three separate cases. The first two are identical. In the third one, we now have that we can once again apply Lemma $A .1 .9$, followed by Lemma $A .1 .11$. In this case, $\sigma=i d$ (by construction of $\phi_{E}$, and thus we get an equality $R_{1}^{*}=R_{2}^{*}$ of compact recipes in $\phi_{E}$ and an inequality in $\psi_{E}$ (Lemma A.1.10).

We finally deal with the case of testing atomicity of a term: suppose there exists $R$ a $\phi$-precompact recipe such that $R \phi \downarrow$ is an atom while $R \psi \downarrow$ is not. Let $\left(R^{*}, \mathcal{R}_{1}\right)=\mathcal{T}_{\phi}^{*}(R)$ and $\left(R^{\prime *}, \mathcal{R}_{2}\right)=\mathcal{T}_{\psi}^{*}(R)$.

- if $\phi_{S} \not \vDash \mathcal{R}_{2}$ or $\psi_{S} \not \vDash \mathcal{R}_{1}$ : as before, we get a witness of non-equivalence in our algorithm,
- else, if $\phi_{S} \models \mathcal{R}_{2}$ and $\psi_{S} \models \mathcal{R}_{1}$, by Lemma A.1.9, $R^{*}=R^{* *}$. As $R^{*}$ is $\phi_{S}$-compact (Lemma A.1.8), $R \phi_{S} \downarrow$ is not a variable, and in particular $R^{*} \phi_{S} \downarrow=R \phi \downarrow$ (by Lemma A.1.4). Hence $R^{*} \phi_{S} \downarrow$ is an atom. Now, if $R^{*} \psi_{S} \downarrow$ is a variable, $R^{*}=x$ holds in $\psi_{S}$ for some variable $x$ but not in $\phi_{S}$, yielding a witness of non static equivalence. Else, if $R^{*} \psi_{S} \downarrow$ is a composed term, we get a witness of non static inclusion as $R^{*} \psi_{S} \downarrow$ would not be an atom. Finally, if $R \psi_{S} \downarrow$ is an ground atom, as in that case $R^{*} \psi_{S} \downarrow=R \psi \downarrow$ (by Lemma A.1.4), but $R \psi \downarrow$ is not an atom which cannot happen as it would contradict our hypothesis.

In conclusion, we found a witness of length $n$ of $P \not \approx t Q$ assuming trace equivalence up to length $n-1$ : hence we the algorithm derived a shortest witness in terms of number of actions.

## A. 2 Proofs of Theorem 4.1.1 and Proposition 4.1.1

In Section A.1, we proved the completeness of the procedure described in Section 4.2. To prove Theorem 4.2.1, and thus Proposition 4.1.1, we still need to prove this algorithm actually preserves types. Once done, we will be able to finally prove Theorem 4.1.1.

A stronger version of Proposition 4.1.1 is actually proven with Theorem 4.2.1: not only there exists such an algorithm, but the algorithm described in Section 4.2.2 does satisfy all the necessary conditions.

Theorem 4.2.1. Let $P$ and $Q$ be two bounded protocols type-compliant w.r.t. ( $\left.\mathcal{T}_{1}, \delta_{1}\right)$ and $\left(\mathcal{T}_{2}, \delta_{2}\right)$ respectively, and such that $P \not \approx Q$. Assume the algorithm $\mathcal{A}_{\mathcal{B}}$ uses a type-preserving reachability blackbox $\mathcal{B}$ and a well-typed renaming $\rho$ at step 3. Then $\mathcal{A}_{\mathcal{B}}(P, Q)$ returns a trace tr such that

- either $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ for some $\phi$ and $(\operatorname{tr}, \phi)$ is pseudo-well-typed w.r.t. $\left(\mathcal{T}_{1}, \delta_{1}\right)$;
- or $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ for some $\psi$ and $(\operatorname{tr}, \psi)$ is pseudo-well-typed w.r.t. $\left(\mathcal{T}_{2}, \delta_{2}\right)$.

Proof. Assume here the witness of non-equivalence is a trace of $P$. Because the reachability blackbox preserves types, the trace $\operatorname{tr}_{1}$ at step 1 is well-typed. At step 2 , unification can only happen on a pair $(s, t)$ of ciphertexts with variables: $s, t \in E S t\left(\operatorname{tr}_{1}\right) \subseteq E S t(\operatorname{tr}) \sigma_{1}$. Thus there exists two terms $s^{\prime}, t^{\prime} \in E S t(P)$ such that $s=s^{\prime} \sigma_{1}$ and $t=t^{\prime} \sigma_{1}$. Since $P$ is type-compliant w.r.t. $\left(\mathcal{T}_{1}, \delta_{1}\right), \delta_{1}\left(s^{\prime}\right)=\delta_{1}\left(t^{\prime}\right)$. By definition of a typing system, $\sigma_{1}$ is well-typed and then $\delta_{1}(t)=\delta_{1}(s)$ and thus their unifier is well-typed. Hence $\operatorname{tr}_{1} \sigma_{1}$ is well-typed, and applying the reachability blackbox and a well-typed renaming leads to $(\operatorname{tr}, \phi)$ being well-typed. If $\mathcal{A}_{\mathcal{B}}(P, Q)$ outputs a witness tr at step 5 and $\mathrm{c}_{0}$ is the constant replaced by $\langle\omega, \omega\rangle$, as $(\operatorname{tr}, \phi)$ is well-typed and thus $(\operatorname{tr} \lambda, \phi \lambda) \in \operatorname{trace}(P)$, where $\lambda=\left\{\langle\omega, \omega\rangle / c_{0}\right\}$ is pseudo-well-typed. The symmetric case with traces of $Q$ is handled similarly, as $Q$ is type-compliant w.r.t. ( $\mathcal{T}_{2}, \delta_{2}$ ).

The proof of Proposition 4.1.1 is then a direct consequence of Theorem 4.2.1.
Theorem 4.1.1. Let $P$ and $Q$ be two determinate protocols type-compliant w.r.t. $\left(\mathcal{T}_{1}, \delta_{1}\right)$ and $\left(\mathcal{T}_{2}, \delta_{2}\right)$ respectively. We have that $P \not \approx Q$ if, and only if, there exists a witness of non-equivalence $t r$ such that:

- either $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ for some $\phi$ and $(\operatorname{tr}, \phi)$ is pseudo-well-typed w.r.t. $\left(\mathcal{T}_{1}, \delta_{1}\right)$;
- or $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ for some $\psi$ and $(\operatorname{tr}, \psi)$ is pseudo-well-typed w.r.t. $\left(\mathcal{T}_{2}, \delta_{2}\right)$.

Proof. If $P$ or $Q$ contain replication and $P \not \chi_{t} Q$, there exists a minimal witness tr of length $n$ of this non-equivalence. Consider $P^{\prime}$ (resp. $Q^{\prime}$ ) the unfolding of $P$ where every occurrence of a subprocess ! $R$ is replaced by $R|\ldots| R(n+1$ times), with $\alpha$-renaming to avoid name and variable capture. Because tr is of length $n, \mathcal{A}\left(P^{\prime}, Q^{\prime}\right)$ or $\mathcal{A}\left(Q^{\prime}, P^{\prime}\right)$ would yield a witness of $P^{\prime} \not \boldsymbol{z}_{t} Q^{\prime}$ of length lesser than $n$, as Proposition 4.2.3 ensures the algorithm returns the shortest witness of non-equivalence. Then, as $P^{\prime}$ and $Q^{\prime}$ were unfolded $n+1$ times, this witness is also a witness of $P \not \boldsymbol{\not}_{t} Q$. We now need to prove that $P^{\prime}$ is type-compliant w.r.t. $\left(\mathcal{T}_{1}, \delta_{1}\right)$ and $Q^{\prime}$ is type-compliant w.r.t. $\left(\mathcal{T}_{2}, \delta_{2}\right)$. For instance, let $s^{\prime}, t^{\prime} \in E S t\left(P^{\prime}\right)$ and $\sigma^{\prime}$ such that $t^{\prime} \sigma^{\prime}=s^{\prime} \sigma^{\prime}$. Because $P^{\prime}$ can be $\alpha$-renamed so as to use common variable and names with unfold ${ }^{2}(P)$, there exist $s, t \in E S t\left(\right.$ unfold $\left.^{2}(P)\right)$, renamings of $s^{\prime}$ and $t^{\prime}$ respectively, and $\sigma$, renaming of $\sigma^{\prime}$, such that $s \sigma=t \sigma, \delta_{1}(s)=\delta_{1}\left(s^{\prime}\right)$ and $\delta_{1}(t)=\delta_{1}\left(t^{\prime}\right)$ (as $\alpha$-renaming preserves types). By definition of type-compliant we can conclude that $\delta_{1}(t)=\delta_{1}(s)$ and thus $P^{\prime}$ is type-compliant w.r.t. $\left(\mathcal{T}_{1}, \delta_{1}\right)$. The same reasoning also applies to $Q^{\prime}$ w.r.t. $\left(\mathcal{T}_{2}, \delta_{2}\right)$. Hence $P^{\prime}$ and $Q^{\prime}$ are both type-compliant w.r.t. to their respective typing systems and without replication. Hence we only need to deal with the case where $P$ and $Q$ do not use replication. Theorem 4.2.2 and Proposition 4.2.3 ensure that $P \not \not \approx t Q$ if, and only if, $\mathcal{A}(P, Q)$ yields a witness, which is well-typed for at least one of these protocols according to Theorem 4.2.1.

## Appendix B

## Decidability of trace equivalence for ping-pong protocols

## B. 1 Undecidability of trace inclusion

The purpose of this section is to establish the following result.
Theorem 7.1.2. The following problem is undecidable.
Input $P$ and $Q$ two protocols in $\mathcal{C}_{\mathrm{pp}}$.
Output Whether $P$ is trace included in $Q$, i.e. $P \sqsubseteq Q$.
An instance of the PCP over the alphabet $A$ is given by two sets of tiles $U=\left\{u_{i} \mid 1 \leq i \leq n\right\}$ and $V=\left\{v_{i} \mid 1 \leq\right.$ $i \leq n\}$ where $u_{i}, v_{i} \in A^{*}$. The problem consists of deciding whether there exists a non-empty sequence $i_{1}, \ldots, i_{p}$ over $\{1, \ldots, n\}$ such that $u_{i_{1}} \ldots u_{i_{p}}=v_{i_{1}} \ldots v_{i_{p}}$.

To prove the undecidability of trace inclusion in $\mathcal{C}_{\mathrm{pp}}$, we show it is possible to encode the Post Correspondence Problem into an inclusion of two protocols of this class. Given a word, one protocol will be meant to unstack the first set of tiles while the other will try as much as possible to unstack the second set of tiles. While an empty word is not "simultaneously" reached by the two processes, their traces appear to be equivalent. Conversely, if a solution to the Post Correspondence Problem does exit, it will lead the second process to react in a distinct way (by stopping its execution), breaking the trace inclusion property.

For each $i \in\{1, \ldots, n\}$, we define two (possibly empty) sets of words over $A$, namely $W_{i} \stackrel{\text { def }}{=} A^{\left|v_{i}\right|} \backslash\left\{v_{i}\right\}$, and $W_{i}^{\prime} \stackrel{\text { def }}{=} A^{0} \cup A^{1} \cup \ldots \cup A^{\left|v_{i}\right|-1}$ where $\left|v_{i}\right|$ denote the length of the word $v_{i}$.

Example B.1.1. Let $A=\{a, b\}$ and consider the following pairs of tiles $(b, \epsilon),(b, a)$, and $(a, b a)$. This instance of PCP admits a solution. Indeed, the non-empty sequence 13 leads to the word $u_{1} u_{3}=v_{1} v_{3}=b a$. We have $W_{1}=W_{1}^{\prime}=\emptyset, W_{2}=\{b\}$ and $W_{2}^{\prime}=\{\epsilon\}$, and lastly $W_{3}=\{a a, a b, b b\}$ and $W_{3}^{\prime}=\{a, b, \epsilon\}$.

Words in $A^{*}$ will be represented through nested symmetric encryption with private keys representing their counterparts in $A$. For the sake of brevity, given a word $u=\alpha_{1} \ldots \alpha_{p}$ of $A^{*}$, we denote by:

- $\bar{u}$ the term $\operatorname{senc}\left(\ldots \operatorname{senc}\left(\epsilon, \alpha_{1}, z_{1}\right) \ldots, \alpha_{p}, z_{p}\right)$; and
- $\overline{x . u}$ the term senc $\left(\ldots \operatorname{senc}\left(x, \alpha_{1}, z_{1}\right) \ldots, \alpha_{p}, z_{p}\right)$
where $z_{1}, \ldots, z_{p}$ are variables of sort rand. Note that if $u=\epsilon$ then $\bar{u}=\epsilon$, and $\overline{x \cdot u}=x$.
Below, $\mathrm{k}_{i}, \mathrm{k}_{i}^{\prime}$ with $i \in\{0,1,2,3\}$ are constants in $\Sigma_{0}$ of sort SymKey, and for each $\alpha \in A$, we denote also by $\alpha$ its counterpart in $\Sigma_{0}$ (constants of sort SymKey). We denote $\epsilon$ a constant in $\Sigma_{0}$ of sort msg. These constants are initially unknown by the attacker and actually it is quite easy to see that they will be never revealed. Lastly, $c, c_{\alpha}, c_{i}, c^{\prime}$ with $\alpha \in A$ and $i \in\{1, \ldots, n\}$ are constant symbols of sort channel in $\mathcal{C} h$.

Let $P_{U}$ and $P_{V}$ be the following protocols.

$$
\begin{align*}
P_{U}:=\quad & !\operatorname{in}(c, \operatorname{start}) . \text { new } r \text {.out }\left(c, \operatorname{senc}\left(\epsilon, \mathrm{k}_{0}, r\right)\right)  \tag{start}\\
& !\operatorname{in}\left(c_{\alpha}, \operatorname{senc}\left(x, \mathrm{k}_{0}, z\right)\right) . \text { new } r_{1}, r_{2} . \operatorname{out}\left(c_{\alpha}, \operatorname{senc}\left(\operatorname{senc}\left(x, \alpha, r_{2}\right), \mathrm{k}_{0}, r_{1}\right)\right)  \tag{1}\\
& !\operatorname{in}\left(c_{i}, \operatorname{senc}\left(\overline{x . u_{i}}, \mathrm{k}_{0}, z\right)\right) \text {.new } r . \operatorname{out}\left(c_{i}, \operatorname{senc}\left(x, \mathrm{k}_{1}, r\right)\right)  \tag{2}\\
& !\operatorname{in}\left(c_{i}, \operatorname{senc}\left(\overline{x . u_{i}}, \mathrm{k}_{1}, z\right)\right) \text {.new } r . \operatorname{out}\left(c_{i}, \operatorname{senc}\left(x, \mathrm{k}_{1}, r\right)\right)  \tag{3}\\
& !\operatorname{in}\left(c^{\prime}, \operatorname{senc}\left(\epsilon, \mathrm{k}_{1}, z\right)\right) . \text { new } r . \operatorname{out}\left(c^{\prime}, \operatorname{senc}\left(\epsilon, \mathrm{k}_{2}, r\right)\right) \tag{4}
\end{align*}
$$

where $i$ ranges in $\{1, \ldots, n\}$ and $\alpha$ in $A$.
The branch (start) is the only way to start an execution, then branches (1) are used to build a word $\alpha_{1} \ldots \alpha_{n}$ (that could be a Post word in case we consider a positive instance of PCP). This word will be represented through the term $\operatorname{senc}\left(\ldots \operatorname{senc}\left(\epsilon, \alpha_{1}, r_{1}\right), \ldots, \alpha_{n}, r_{n}\right)$ up to the choice of randoms. Then, branches (2) and (3) are used to unstack the different tiles $u_{1}, \ldots, u_{n}$. Note that the purpose of having two similar branches (but using different keys) for this task is to ensure that we will unstack at least one tile, and thus the sequence $i_{1} \ldots i_{p}$ of indices is not empty. Then, reaching the empty word when unstacking these tiles will allow us to perform input/output on channel $c^{\prime}$ (branch (4)).

$$
\begin{align*}
& P_{V}:=\quad!\text { in }(c, \text { start }) \text {.new } r \text {.out }\left(c, \operatorname{senc}\left(\epsilon, \mathrm{k}_{0}^{\prime}, r\right)\right) \quad \text { (start) } \\
& \text { | !in }\left(c_{\alpha}, \operatorname{senc}\left(x, \mathrm{k}_{0}^{\prime}, z\right)\right) \text {.new } r_{1}, r_{2} \text {. out }\left(c_{\alpha}, \operatorname{senc}\left(\operatorname{senc}\left(x, \alpha, r_{2}\right), \mathrm{k}_{0}^{\prime}, r_{1}\right)\right)  \tag{1}\\
& \mid \quad!\operatorname{in}\left(c_{i}, \operatorname{senc}\left(\overline{x . v_{i}}, \mathrm{k}_{0}^{\prime}, z\right)\right) \text {.new } r \text {.out }\left(c_{i}, \operatorname{senc}\left(x, \mathrm{k}_{1}^{\prime}, r\right)\right) \\
& \text { | ! in }\left(c_{i}, \operatorname{senc}\left(\overline{x . w}, \mathrm{k}_{0}^{\prime}, z\right)\right) \text {.new } r \text {.out }\left(c_{i}, \operatorname{senc}\left(\epsilon, \mathrm{k}_{3}^{\prime}, r\right)\right) \\
& \text { | !in }\left(c_{i}, \operatorname{senc}\left(\overline{w^{\prime}}, \mathrm{k}_{0}^{\prime}, z\right)\right) \text {.new } r \text {.out }\left(c_{i}, \operatorname{senc}\left(\epsilon, \mathrm{k}_{3}^{\prime}, r\right)\right) \\
& \text { | ! in }\left(c_{i}, \operatorname{senc}\left(\overline{x . v_{i}}, \mathrm{k}_{1}^{\prime}, z\right)\right) \text {.new } r \text {.out }\left(c_{i}, \operatorname{senc}\left(x, \mathrm{k}_{1}^{\prime}, r\right)\right) \\
& \mid \quad!\operatorname{in}\left(c_{i}, \operatorname{senc}\left(\overline{x . w}, \mathrm{k}_{1}^{\prime}, z\right)\right) \text {.new } r \text {.out }\left(c_{i}, \operatorname{senc}\left(\epsilon, \mathrm{k}_{3}^{\prime}, r\right)\right) \\
& \mid \quad \operatorname{in}\left(c_{i}, \operatorname{senc}\left(\overline{w^{\prime}}, \mathrm{k}_{1}^{\prime}, z\right)\right) \text {.new } r \text {.out }\left(c_{i}, \operatorname{senc}\left(\epsilon, \mathrm{k}_{3}^{\prime}, r\right)\right) \\
& \mid \quad!\operatorname{in}\left(c^{\prime}, \operatorname{senc}\left(\overline{x . \beta}, \mathrm{k}_{1}^{\prime}, z\right)\right) \text {.new } r \text {.out }\left(c^{\prime}, \operatorname{senc}\left(\epsilon, \mathrm{k}_{2}^{\prime}, r\right)\right) \\
& \mid \quad!\operatorname{in}\left(c^{\prime}, \operatorname{senc}\left(\epsilon, \mathrm{k}_{3}^{\prime}, z\right)\right) \text {.new } r \text {.out }\left(c^{\prime}, \operatorname{senc}\left(\epsilon, \mathrm{k}_{2}^{\prime}, r\right)\right) \\
& \mid \quad!\operatorname{in}\left(c_{i}, \operatorname{senc}\left(\epsilon, \mathrm{k}_{3}^{\prime}, z\right)\right) \text {.new } r \text {.out }\left(c_{i}, \operatorname{senc}\left(\epsilon, \mathrm{k}_{3}^{\prime}, r\right)\right)
\end{align*}
$$

where $i$ ranges in $\{1, \ldots, n\}, \alpha$ and $\beta$ in $A$, and for each $i \in\{1, \ldots, n\}, w$ in $W_{i}$ and $w^{\prime}$ in $W_{i}^{\prime}$.
The protocol $P_{V}$ has the same structure as $P_{U}$. However, it is more complex since we want $P_{V}$ to follow the execution of $P_{U}$ as soon as the execution does not correspond to a solution of the PCP problem. In particular, we do not want $P_{V}$ to block in case it is not able to unstack a tile $v_{i}$. To achieve this, some additional branches are added (namely $\left(2^{\prime} a\right)$ and $\left(2^{\prime} b\right)$, as well as $\left(3^{\prime} a\right)$ and $\left(3^{\prime} b\right)$ ). Intuitively, those branches are triggered when ( $2^{\prime}$ ) and $\left(3^{\prime}\right)$ can not, and the resulting term is encrypted with a special key $k_{3}^{\prime}$ that will allow $P_{V}$ to mimic the remaining of the execution using branch $\left(5^{\prime}\right)$. Now, regarding the branches on channel $c^{\prime}$, the idea is to allow $P_{V}$ to mimic the behaviour of $P_{U}$ only when the trace tr does not correspond to a solution of the PCP. To achieve this, we allow $P_{V}$ to follow $P_{U}$ only when the term given in input on channel $c^{\prime}$ is not a legal encoding of the empty word. Such a term will go through $\left(4^{\prime} a\right)$ or $\left(4^{\prime} b\right)$.

Note that, on both protocols, the terms that are outputted look like fresh random numbers due to fresh nonces occurring in every output and ignorance of the keys. In other words, the two frames resulting from the execution
of respectively $P_{U}$ and $P_{V}$ always remain in static equivalence. Therefore, checking trace equivalence amounts into checking that any execution trace of $P_{U}$ is a trace of $P_{V}$, and conversely.

Lemma B.1.1. The protocols $P_{U}$ and $P_{V}$ described above are in $\mathcal{C}_{\mathrm{pp}}$.
Proof. The only non-trivial point is to ensure that condition (2) stated in Definition 7.1.1 is satisfied, i.e. to ensure that pattern matching operated by inputs taking place on the same channel is exclusive. Regarding protocol $P_{U}$, when two inputs occur on the same channel $c_{i}$, we have that the outermost key is different. Regarding protocol $P_{V}$, the result also holds thanks to the exclusivity of the pattern matching obtained through a careful definition of sets $W_{i}$ and $W_{i}^{\prime}$. For instance, note that when $v_{i}=\epsilon, W_{i}=W_{i}^{\prime}=\emptyset$, and thus there is no branch $\left(2^{\prime} a\right) /\left(2^{\prime} b\right)$ (resp. $\left(3^{\prime} a\right) /\left(3^{\prime} b\right)$ ).

Proposition B.1.1. Let $U / V$ be an instance of PCP. We have that $P_{U} \sqsubseteq P_{V}$ if, and only if, $U / V$ is a negative instance of PCP (i.e. an instance with no solution).

Proof. We prove successively the two implications.
$(\Rightarrow)$ If $U / V$ is a positive instance of $P C P$ then $P_{U} \nsubseteq P_{V}$. If $U / V$ is a positive instance of PCP, there exists a non-empty sequence $i_{1} \ldots i_{p}$ over $\{1, \ldots, n\}$ such that $u_{i_{1}} \cdot \ldots \cdot u_{i_{p}}=v_{i_{1}} \cdot \ldots \cdot v_{i_{p}}$.

Let $u=\alpha_{1} \ldots \alpha_{m}$ be the resulting word over $A$. From this word and the sequence $i_{1}, \ldots, i_{p}$, the attacker playing with $P_{u}$ can build the term senc $\left(\bar{u}, \mathrm{k}_{0}, r\right)$ representing the word $u$ with branches (1) and then remove one by one the tiles $u_{i_{p}}$ to $u_{i_{1}}$ using (2) and (3). Let tr be the resulting trace of the protocol $P_{U}$ :

$$
\begin{aligned}
\mathrm{tr} \stackrel{\text { def }}{=} & \mathrm{io}\left(c, \text { start, } \mathrm{w}_{1}\right) \cdot \mathrm{io}\left(c_{\alpha_{1}}, \mathrm{w}_{1}, \mathrm{w}_{2}\right) \ldots \text { io }\left(c_{\alpha_{m}}, \mathrm{w}_{m}, \mathrm{w}_{m+1}\right) \\
& \text { io }\left(c_{i_{p}}, \mathrm{w}_{m+1}, \mathrm{w}_{m+2}\right) \ldots \mathrm{io}\left(c_{i_{1}}, \mathrm{w}_{p+m}, \mathrm{w}_{p+m+1}\right) \cdot \operatorname{in}\left(c^{\prime}, \mathrm{w}_{m+p+1}\right)
\end{aligned}
$$

where $\mathrm{io}(c, R, \mathrm{w}) \stackrel{\text { def }}{=} \mathrm{in}(c, R)$. out $(c, \mathrm{w})$.
The trace tr models the fact that, given senc $\left(\bar{u}, \mathrm{k}_{0}, r\right)$ (stored in $\left.\mathrm{w}_{m+1}\right), P_{U}$ can remove one by one the tiles $u_{i_{p}}$ to $u_{i_{1}}$ to reach the empty word and hence output the message $\operatorname{senc}\left(\epsilon, \mathrm{k}_{1}, r\right)$ (stored in $\mathrm{w}_{m+p+1}$ ) that can then be accepted as input on $c^{\prime}$. In this execution, no equality holds in the resulting frame $\phi$, as the attacker ignores the keys that are used to encrypt, and all outputted message use different random seeds; thus all messages look fresh.

We claim that this trace does exist in $P_{V}$, i.e. there exists no $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}\left(P_{V}\right)$. Indeed, the pattern matching operated by $P_{V}$ is exclusive once the term and the channel is fixed. Thus, $P_{V}$ has no choice but to remove tiles $v_{i_{p}}$ to $v_{i_{1}}$ using $\left(2^{\prime}\right)$ and $\left(3^{\prime}\right)$ leading to the term $\operatorname{senc}\left(\epsilon, \mathrm{k}_{1}^{\prime}, r\right)$ (stored in $\left.\mathrm{w}_{m+p+1}\right)$ as $\alpha_{1} \ldots \alpha_{m}$ is a Post word. Any other trace would either lead to a mismatch on the channels or an improper filtering in $P_{V}$. Then the action $\operatorname{in}\left(c^{\prime}, \mathrm{w}_{m+p+1}\right)$ will have no counterpart on $P_{V}$. So $(\operatorname{tr}, \phi)$ has no equivalent trace in $P_{V}$, i.e. $P_{U} \nsubseteq P_{V}$.
$(\Leftarrow)$ If $U / V$ is a negative instance of $P C P$ then $P_{U} \sqsubseteq P_{V}$. Let $(\operatorname{tr}, \phi) \in \operatorname{trace}\left(P_{U}\right)$, we aim at showing that there exists an equivalent trace $(\operatorname{tr}, \psi) \in \operatorname{trace}\left(P_{V}\right)$. Actually, since terms that are outputted by $P_{U}$ and $P_{V}$ look like fresh random numbers, we simply have to show that there exists $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}\left(P_{V}\right)$. Two cases can occur for any trace $(\operatorname{tr}, \phi) \in \operatorname{trace}\left(P_{U}\right)$ :

- tr contains no input on channel $c^{\prime}$. In such a case, by construction of $P_{V}$, the frame $\psi$ can be built by following the sequence of channels used in tr and choosing the adequate filtering. It is always possible to do so, as the definition of sets $W_{i}$ and $W_{i}^{\prime}$ ensure that every term built by the attacker can be handled on any channel $c_{i}$. Note that when the term given in input is of the form $\operatorname{senc}\left(\epsilon, \mathrm{k}_{3}^{\prime}, r\right)$ for some $r$, it would be accepted on any channel.
- tr contains an input on channel $c^{\prime}$. In such a case, this means that the associated term senc $\left(\overline{\alpha_{1} \ldots \alpha_{m}}, \mathrm{k}_{0}, r\right)$ that has been built using channels $c_{\alpha}$ with $\alpha \in A$ is a word made of tiles in $\left\{u_{1}, \ldots, u_{n}\right\}$. Indeed, the only way to activate an input on $c^{\prime}$ is to go through the branches (2) and (3) by unstacking the said tiles. Then, because this particular instance of $P C P$ has no solution, such a word $\alpha_{1} \ldots \alpha_{m}$ cannot be a Post word and thus it cannot
be decomposed using tiles in $\left\{v_{1}, \ldots, v_{n}\right\}$ following the same sequence of indices: because the filtering in $P_{V}$ is also exhaustive, messages outputted by $P_{V}$ from a certain point will be either encrypted by $\mathrm{k}_{3}^{\prime}$ or will reach the end of the sequence with a term of the form $\operatorname{senc}\left(u, \mathrm{k}_{1}^{\prime}, r\right)$ with $u$ different from the constant $\epsilon$. Thanks to branches $\left(4^{\prime} a\right),\left(4^{\prime} b\right)$, and $\left(5^{\prime}\right), P_{V}$ will be able to follow $P_{U}$.

Hence, for any trace $(\operatorname{tr}, \phi) \in \operatorname{trace}\left(P_{U}\right)$ there exists a trace $(\operatorname{tr}, \psi) \in \operatorname{trace}\left(P_{V}\right)$. It remains to show that $\phi \sim \psi$. This is due to the fact that both $\phi$ and $\psi$ are of the form $\left\{\mathrm{w}_{1} \triangleright \operatorname{senc}\left(m_{1}, k_{1}, r_{1}\right), \ldots, \mathrm{w}_{n} \triangleright \operatorname{senc}\left(m_{n}, k_{n}, r_{n}\right)\right\}$ where the $k_{i}$ are non deducible and the $r_{i}$ are "fresh" in the sense that they are all distinct and non deducible. We therefore conclude that $P_{U} \sqsubseteq P_{V}$.

Theorem 7.1.2 directly follows from Proposition B.1.1 and the undecidability of the Post Correspondence Problem.

## B. 2 Getting rid of the attacker

Lemma 7.2.1. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}, \mathcal{K}_{P}$ (resp. $\mathcal{K}_{Q}$ ) be the set of deducible constants of sort key that occur in $P$ (resp. $Q$ ), if $P \approx Q$ then there exists a unique bijection $\alpha$ from $\mathcal{K}_{P}$ to $\mathcal{K}_{Q}$ such that for every trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ there exists a trace $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ such that for any recipe $R$ and any $\mathrm{k} \in \mathcal{K}_{P}$ :

- $R \phi \downarrow$ is of sort s if, and only if, $R \psi \downarrow$ is of sort s;
where $s \in\{$ SymKey, PubKey, PrivKey $\}$.
- $R \phi \downarrow=\mathrm{k}$ if, and only if, $R \psi \downarrow=\alpha(\mathrm{k})$;
- $R \phi \downarrow=\mathrm{k}^{-1}$ if, and only if, $R \psi \downarrow=(\alpha(\mathrm{k}))^{-1}$;
and conversely, for every $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ there exists a trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ satisfying the same properties.
Proof. We can describe $\alpha$ as a relation in the following way:
for every $\mathrm{k} \in \mathcal{K}_{P}$ of sort s , and every trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ and recipe $R$ such that $R \phi \downarrow=\mathrm{k}$, we define $\alpha(\mathrm{k})=R \psi \downarrow$ where $\psi$ is the only frame such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$.

The existence of such a frame comes from the fact that $P \approx Q$, whereas its unicity is a consequence of the determinism of protocols in $\mathcal{C}_{\mathrm{pp}}$.

We now need to prove that our definition of $\alpha$ is sound and unambiguous. To do so, we show that:

- $R \psi \downarrow$ is a constant of sort s . We have that there exists a trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ such that $R \phi \downarrow=\mathrm{k} \in K_{P}$. Since $P \approx Q$ and $Q$ is in $\mathcal{C}_{\mathrm{pp}}$, we consider the trace $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$. By definition of static equivalence, we have that $R \psi \downarrow$ is a constant of sort s. Otherwise, we would have that senc $\left(\operatorname{start}, R, r_{i}\right) \phi \in \mathcal{T}(\Sigma, \mathcal{N})$ whereas $\operatorname{senc}\left(\right.$ start $\left., R, r_{i}\right) \psi \notin \mathcal{T}(\Sigma, \mathcal{N})$ if $\mathrm{s}=$ SymKey (the resulting term is not properly sorted). The same argument applies with raenc and sign for s equal to PubKey and PrivKey respectively.
- We have that $\left|\mathcal{K}_{P}\right|=\left|\mathcal{K}_{Q}\right|$. Suppose ad absurdum that, for instance, $\left|\mathcal{K}_{P}\right|<\left|\mathcal{K}_{Q}\right|$. Since every element of $\mathcal{K}_{Q}$ is deducible (and due to the shape of the protocols under study), there exists $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ such that for all $\mathrm{k} \in \mathcal{K}_{Q}$, there exists a recipe $R_{\mathrm{k}}$ such that $R_{\mathrm{k}} \psi \downarrow=\mathrm{k}$. In particular, when $k \neq k^{\prime}$, we have that $R_{k} \psi \downarrow \neq R_{k^{\prime}} \psi \downarrow$. Since $P \approx Q$, there exists a frame $\phi$ such that $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$. Thanks to previous item, we know that $R_{k} \phi \downarrow$ (resp $R_{k^{\prime}} \phi \downarrow$ ) has the same sort as $R_{k} \psi \downarrow$ (resp. $R_{k^{\prime}} \psi \downarrow$ ), i.e. sort key. As $\left|\mathcal{K}_{P}\right|<\left|\mathcal{K}_{Q}\right|$, there exist two distinct keys k and $\mathrm{k}^{\prime}$ such that $R_{\mathrm{k}} \phi \downarrow=R_{\mathrm{k}^{\prime}} \phi \downarrow$. Hence $\phi$ and $\psi$ are not statically equivalent, contradicting the fact that $P \approx Q$. The case where $\left|\mathcal{K}_{Q}\right|<\left|\mathcal{K}_{P}\right|$ can be handle similarly.
- $\alpha$ is a function. Suppose there exist a trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$, a recipe $R_{i}$ and a corresponding equivalence $\operatorname{trace}(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ such that $R_{i} \phi \downarrow=\mathrm{k}$ and $R_{i} \psi \downarrow=\mathrm{k}^{\prime}$; a trace $\left(\operatorname{tr}^{\prime}, \phi^{\prime}\right) \in \operatorname{trace}(P)$, a recipe $R_{j}$ and a corresponding equivalence trace $\left(\operatorname{tr}^{\prime}, \psi^{\prime}\right) \in \operatorname{trace}(Q)$ such that $R_{j} \phi^{\prime} \downarrow=\mathrm{k}$ but $R_{j} \psi^{\prime} \downarrow=\mathrm{k}^{\prime \prime}$ with $\mathrm{k}^{\prime} \neq \mathrm{k}^{\prime \prime}$. Considering the trace made up of the trace $\operatorname{tr}$ followed by $\operatorname{tr}^{\prime}$, it is then possible to exhibit a witness of nonequivalence. More precisely, relying on $R_{i}$ and $R_{j}$ we can build a test that holds in the resulting frame when executing $P$, whereas this test will not hold on the frame resulting from the execution of $Q$.

Now we show that $\alpha$ is an injection, i.e. $\alpha(\mathrm{k}) \neq \alpha\left(\mathrm{k}^{\prime}\right)$ as soon as $\mathrm{k}, \mathrm{k}^{\prime}$ are two distinct elements of $\mathcal{K}_{P}$. Suppose, as previously, there exist a trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$, a recipe $R_{i}$ and a corresponding equivalence trace $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ such that $R_{i} \phi \downarrow=\mathrm{k}$ and $R_{i} \psi \downarrow=\alpha(\mathrm{k})$; a trace $\left(\operatorname{tr}^{\prime}, \phi^{\prime}\right) \in \operatorname{trace}(P)$, a recipe $R_{j}$ and a corresponding equivalence trace $\left(\operatorname{tr}^{\prime}, \psi^{\prime}\right) \in \operatorname{trace}(Q)$ such that $R_{j} \phi^{\prime} \downarrow=\mathrm{k}^{\prime}$ but $R_{j} \psi^{\prime} \downarrow=\alpha(\mathrm{k})$ with $\mathrm{k} \neq \mathrm{k}^{\prime}$. Considering the trace made up of the trace $\operatorname{tr}$ followed by $\mathrm{tr}^{\prime}$, it is then possible to exhibit a witness of non-equivalence. More precisely, relying on $R_{i}$ and $R_{j}$ we can build a test that holds in the frame resulting from the execution of $P$ and that does not hold when executing $Q$. Thus, we have now prove that $\alpha$ is a bijection.

Note that we have already proved that: $R \phi \downarrow=\mathrm{k}$ if, and only, if $R \psi \downarrow=\alpha(\mathrm{k})$.
To show that $\alpha$ satisfies the last condition (item 3), suppose that $\mathrm{k} \in \mathcal{K}_{P}$, and $R \phi \downarrow=\mathrm{k}^{-1}$. As previously shown, $R \psi \downarrow=\alpha\left(\mathrm{k}^{-1}\right)$. We want to prove that $\alpha\left(\mathrm{k}^{-1}\right)=(\alpha(\mathrm{k}))^{-1}$. If k is of sort SymKey, the result is obvious as $\mathrm{k}^{-1}=\mathrm{k}$ for any such key. Suppose k is of sort PubKey. We have now that there exists a trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ and a recipe $R^{\prime}$ such that $R^{\prime} \phi \downarrow=\mathrm{k} \in K_{P}$. Since $P \approx Q$, consider the corresponding equivalence trace $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$. Consider the recipes $R_{1}=\operatorname{raenc}\left(\operatorname{start}, R^{\prime}, n\right)$ and $R_{2}=\operatorname{radec}\left(R_{1}, R\right)$. Then $R_{2} \phi \downarrow=\operatorname{start}$ and $R_{2} \psi \downarrow=\operatorname{start}$ if, and only if, $R \psi \downarrow=\left(R^{\prime} \psi\right)^{-1}$. As we have already proved that $\alpha$ preserves sorts, we get that $R_{2} \psi \downarrow$ is of sort msg if, and only if, $\alpha\left(\mathrm{k}^{-1}\right)=R \psi \downarrow=\left(R^{\prime} \psi \downarrow\right)^{-1}=(\alpha(\mathrm{k}))^{-1}$. Hence $\alpha$ is compatible with the inverse function. The same argument can be used if $k$ is of sort PrivKey with sign and check.

Finally we prove the unicity of such a bijection: suppose there were $\alpha^{\prime}$ an adequate bijection and $\mathrm{k} \in \mathcal{K}_{P}$ such that $\alpha(\mathrm{k}) \neq \alpha^{\prime}(\mathrm{k})$. By definition of $\alpha$, for every trace $(\operatorname{tr}, \phi) \in \operatorname{trace}(P)$ and every recipe $R$ such that $R \phi \downarrow=\mathrm{k}$, $\alpha(\mathrm{k})=R \psi \downarrow$. But as $\alpha^{\prime}$ satisfy a similar property, we get that $R \psi \downarrow=\alpha^{\prime}(\mathrm{k})$, contradicting our hypothesis. Hence $\alpha$ is unique. Determinism of $P$ and $Q$ then ensures that traces of $P$ and $Q$ are uniquely matched (as $P \approx Q$ ), thus guaranteeing the converse part of the Lemma.

Lemma 7.2.3. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}$ respectively disclosing two sets of keys $K$ and $K^{\prime}$ as in Lemma 7.2.2. Then $P \approx Q$ if, and only if, $\bar{P} \approx_{\text {fwd }} \bar{Q}$ where:

$$
\begin{aligned}
& \bar{Q}=Q \quad|\quad| \quad \mid \quad \operatorname{lin}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {senc }}, x\right) \text {.new } n \text {.out }\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {senc }}, \operatorname{senc}(x, \alpha(\mathrm{k}), n)\right)
\end{aligned}
$$

where $K^{\text {s }}$ denotes the keys of sort s of $K$. We call $\mathcal{T}_{\text {oracle }}$ the transformation taking a pair of protocols $(P, Q)$ satisfying the aforementioned condition and returning the pair $(\bar{P}, \bar{Q})$ presently defined.

Proof. Let $\mathcal{K}_{P}\left(\right.$ resp. $\left.\mathcal{K}_{Q}\right)$ be the set of deducible constants of sort key that occur in $P$ (resp. $Q$ ). We recall, that, as a consequence of Lemma 7.2.2, we necessarily have that $\mathcal{K}_{P} \subseteq K$ and $\mathcal{K}_{Q} \subseteq K^{\prime}$. Because protocols $P$ and $\bar{P}$ (resp. $Q$ and $\bar{Q})$ disclose all their deducible keys, their exists a trace $\left(\operatorname{tr}_{0}, \phi_{0}\right)$ of $P$ and $\bar{P}\left(\right.$ resp. $\left(\operatorname{tr}_{0}, \psi_{0}\right)$ a trace of $Q$ and $\left.\bar{Q}\right)$ defined as follows:

$$
\operatorname{tr}_{0}=\operatorname{in}\left(c_{\mathrm{k}_{1}, \alpha\left(\mathrm{k}_{1}\right)}, \operatorname{start}\right) \cdot \operatorname{out}\left(c_{\mathrm{k}_{1}, \alpha\left(\mathrm{k}_{1}\right)}, \mathrm{w}_{1}^{0}\right) \ldots \operatorname{in}\left(c_{\mathrm{k}_{n}, \alpha\left(\mathrm{k}_{n}\right)}, \operatorname{start}\right) \cdot \operatorname{out}\left(c_{\mathrm{k}_{n}, \alpha\left(\mathrm{k}_{n}\right)}, \mathrm{w}_{n}^{0}\right)
$$

for $\mathrm{k}_{1}, \ldots, \mathrm{k}_{n} \in \mathcal{K}_{P}$, and $\phi_{0}=\left\{\mathrm{w}_{1}^{0} \triangleright \mathrm{k}_{1}, \ldots \mathrm{w}_{n}^{0} \triangleright \mathrm{k}_{n}\right\}$, and symmetrically for $Q$ and $\bar{Q}$. In the following, we will assume that a trace of $P$ or $\bar{P}$ (resp. of $Q$ or $\bar{Q}$ ) starts with the prefix $\operatorname{tr}_{0}$ and contains the frame $\phi_{0}$.

For sake of clarity of the construction explained below, we actually show that:

$$
\bar{P} \approx_{\mathrm{fwd}} \bar{Q} \text { if, and only if } P^{+} \approx Q^{+}
$$

where $P^{+}=P \mid!\operatorname{in}(c, x)$.out $(c, x)$ and $Q^{+}=Q \mid!\operatorname{in}(c, x)$.out $(c, x)$ for some fresh channel name $c$. Then, it is easy to conclude at the expected result relying on the fact that $P \approx Q$ is equivalent to $P^{+} \approx Q^{+}$.
$(\Rightarrow)$ First, suppose $\bar{P} \not \nsim f w d ~^{\text {fw }}$. Assume that there exists $(\operatorname{tr}, \phi) \in \operatorname{trace}_{\mathrm{fwd}}(\bar{P})$ such that there is no equivalent frame $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}_{\mathrm{fwd}}(\bar{Q})$. We define $\left(\operatorname{tr}^{\prime}, \phi\right) \in \operatorname{trace}\left(P^{+}\right)$as follows:

- every sequence $\operatorname{in}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {senc }}, R\right) \cdot \operatorname{out}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {senc }}, \mathrm{w}^{\prime}\right) \quad$ in $\quad \operatorname{tr} \quad$ is replaced by the sequence $\operatorname{in}\left(c, \operatorname{senc}\left(R, \mathrm{w}_{k}^{0}, n\right)\right) \operatorname{out}\left(c, \mathrm{w}^{\prime}\right)$ in $\operatorname{tr}^{\prime}$ where $n$ is a fresh name.
- every sequence $\operatorname{in}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {sdec }}, R\right) . \operatorname{out}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {sdec }}, \mathrm{w}^{\prime}\right) \quad$ in $\quad \operatorname{tr} \quad$ is replaced by the sequence in $\left(c, \operatorname{sdec}\left(R, \mathrm{w}_{k}^{0}\right)\right)$.out $\left(c, \mathrm{w}^{\prime}\right)$ in $\operatorname{tr}^{\prime}$.
- every sequence $\operatorname{in}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {raen }}, R\right)$.out $\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {raenc }}, \mathrm{w}^{\prime}\right) \quad$ in $\quad \operatorname{tr} \quad$ is replaced by the sequence $\operatorname{in}\left(c, \operatorname{raenc}\left(R, \mathrm{w}_{k}^{0}, n\right)\right)$.out $\left(c, \mathrm{w}^{\prime}\right)$ in $\operatorname{tr}^{\prime}$ where $n$ is a fresh name.
- every sequence $\operatorname{in}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {radec }}, R\right) \cdot \operatorname{out}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\mathrm{radec}}, \mathrm{w}^{\prime}\right) \quad$ in $\quad \mathrm{tr}$ is replaced by the sequence in $\left(c, \operatorname{radec}\left(R, \mathrm{w}_{k}^{0}\right)\right)$.out $\left(c, \mathrm{w}^{\prime}\right)$ in $\mathrm{tr}^{\prime}$.
- every sequence $\operatorname{in}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {sign }}, R\right) \cdot \operatorname{out}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {sign }}, \mathrm{w}^{\prime}\right) \quad$ in $\quad \mathrm{tr}$ is replaced by the sequence $\operatorname{in}\left(c, \operatorname{sign}\left(R, \mathrm{w}_{k}^{0}, n\right)\right)$.out $\left(c, \mathrm{w}^{\prime}\right)$ in $\operatorname{tr}^{\prime}$ where $n$ is a fresh name.
- every sequence $\operatorname{in}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\text {check }}, R\right) . \operatorname{out}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\mathrm{check}}, \mathrm{w}^{\prime}\right)$ in $\operatorname{tr}$ is replaced by the sequence in $\left(c, \operatorname{check}\left(R, \mathrm{w}_{k}^{0}\right)\right)$.out $\left(c, \mathrm{w}^{\prime}\right)$ in $\operatorname{tr}^{\prime}$.

Note that by definition of a trace being in $\operatorname{trace}_{\mathrm{fwd}}(\bar{P})$, we have that $R$ is either a variable w or the constant start. We claim that there exists no frame $\psi$ such that $\left(\operatorname{tr}^{\prime}, \psi\right) \in \operatorname{trace}\left(Q^{+}\right)$with $\phi \sim \psi$. Indeed, because the frame are left unchanged, the input recipes match the same input patterns, and recipes holding true and false keep their truth values. So if such a frame $\psi$ existed, $(\operatorname{tr}, \psi)$ would belong to $\operatorname{trace}_{f \mathrm{fwd}}(\bar{Q})$ and be equivalent to $(\operatorname{tr}, \phi)$.
$(\Leftarrow)$ Now, suppose $P \not \approx Q$. We have that $P^{+} \not \approx Q^{+}$, and we can even assume that $P^{+} \not \chi^{\text {io* }} Q^{+}$. We consider a witness of this non-equivalence, i.e. a trace $\operatorname{tr}$ such that $(\operatorname{tr}, \phi) \in \operatorname{trace}^{\mathrm{i} 0 *}\left(P^{+}\right)$and for which there exists no equivalent frame $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}^{\mathrm{i} 0 *}\left(Q^{+}\right)$. Actually, we can even assume w.l.o.g. that:

- every input recipe in tr on a channel different from $c$ is either a variable $w$ or the constant start;
- every input recipe in $\operatorname{tr}$ on channel $c$ involves at most one function symbol in $\Sigma_{\text {pub }}$;
- $\phi \chi_{\text {fwd }} \psi$, i.e. we consider recipes that are either variables or the constant start.

We consider the shortest trace $(\operatorname{tr}, \phi) \in \operatorname{trace}^{\mathrm{io} *}(P)$, in terms of number of transitions, such that there is no equivalent frame $\psi$ satisfying $(\operatorname{tr}, \psi) \in \operatorname{trace}^{\mathrm{io*}}(Q)$, and for which all the requirements listed above are satisfied.

Through recipes of the form $\operatorname{senc}(u, v, w)$ on channel $c$, the attacker has the ability to use the same random seed more that once. Let us first show that we can always assume tr uses nonces at most once. If it is not the case, we build a new trace ( $\tilde{\operatorname{tr}}, \tilde{\phi}$ ), such that $\phi$ is statically equivalent to $\tilde{\phi}$ for which it is the case.

First, if we consider the case where there exists no $\psi$ such that $(\operatorname{tr}, \psi) \notin \operatorname{trace}{ }^{\mathrm{i} * *}(Q)$. Because random seeds are not filtered in protocols of $\mathcal{C}_{\mathrm{pp}}$ (every input pattern contains distinct variables as third argument), we can rename some occurrences of the random seeds of the attacker (i.e. the random seeds appearing in the recipes on channel $c$ ) by fresh random seeds without changing the status of the trace (i.e. the fact that the trace is executable or not). Given $\operatorname{tr}_{\rho}$ such a trace obtained by renaming, we have that $\left(\operatorname{tr}_{\rho}, \phi_{\rho}\right) \in \operatorname{trace}{ }^{\mathrm{io} *}(P)$ for some frame $\phi_{\rho}$ whereas $\left(\operatorname{tr}_{\rho}, \psi_{\rho}\right) \notin \operatorname{trace}^{\mathrm{io} *}(Q)$ for any frame $\psi_{\rho}$. And it particular, if we choose $\operatorname{tr}_{\rho}$ such that there are no two identical nonces in its image, we get a witness of non-equivalence with pairwise distinct random seeds for the attacker.

Now, we consider the case where $(\operatorname{tr}, \psi) \in \operatorname{trace}^{\mathrm{i} 0 *}(Q)$ but $\phi \chi_{\text {fwd }} \psi$. Suppose $r$ is a random seed which appears twice in tr , in two contexts $\mathrm{f}\left(\mathrm{w}_{i}, \mathrm{w}_{j}, r\right)$ and $\mathrm{f}\left(\mathrm{w}_{i}^{\prime}, \mathrm{w}_{j}^{\prime}, r\right)$ for some $\mathrm{f} \in \Sigma_{\mathrm{pub}}$ with $\mathrm{w}_{i} \phi=\mathrm{w}_{i}^{\prime} \phi$ and $\mathrm{w}_{j} \phi=\mathrm{w}_{j}^{\prime} \phi$. Because tr is a minimal witness of non-equivalence, $\phi_{-1} \sim_{\text {fwd }} \psi_{-1}$ where $\phi_{-1}$ (resp. $\psi_{-1}$ ) denotes $\phi$ (resp. $\psi$ ) minus its last element. Consequently we also have that $\mathrm{w}_{i} \psi=\mathrm{w}_{i}^{\prime} \psi$ and $\mathrm{w}_{j} \psi=\mathrm{w}_{j}^{\prime} \psi$, as $\mathrm{w}_{i}, \mathrm{w}_{j}, \mathrm{w}_{i}^{\prime}, \mathrm{w}_{j}^{\prime} \in \operatorname{dom}\left(\phi_{-1}\right)$ (they are used in input recipes). Let w and $\mathrm{w}^{\prime}$ be the corresponding outputs of the recipes $\mathrm{f}\left(\mathrm{w}_{i}, \mathrm{w}_{j}, r\right)$ and $\mathrm{f}\left(\mathrm{w}_{i}^{\prime}, \mathrm{w}_{j}^{\prime}, r\right)$ and assume w appears before $\mathrm{w}^{\prime}$ in tr: we now have that $\mathrm{w}=\mathrm{w}^{\prime}$ in both $\phi$ and $\psi$, and we can safely replace any occurrence of $\mathrm{w}^{\prime}$ in $\operatorname{tr}$ by w . The resulting trace is still a witness of non-equivalence as the substitution replace identical terms in $\psi$.

Thus, it remains only to consider the case where a random seed appears twice in tr but such that either the function symbol, the plaintext or the keys are different. Formally, consider the two contexts $\mathrm{f}\left(\mathrm{w}_{i}, \mathrm{w}_{j}, r\right)$ and $\mathrm{g}\left(\mathrm{w}_{i}^{\prime}, \mathrm{w}_{j}^{\prime}, r\right)$ with $\mathrm{f}, \mathrm{g} \in \Sigma_{\mathrm{pub}}, \mathrm{w}$ and $\mathrm{w}^{\prime}$ their respective outputs variables as before; and either $\mathrm{w}_{i} \phi \neq \mathrm{w}_{i}^{\prime} \phi, \mathrm{w}_{j} \phi \neq \mathrm{w}_{j}^{\prime} \phi$ or $\mathrm{f} \neq \mathrm{g}$. Following the same reasoning as before, as $\phi_{-1} \sim_{f w d} \psi_{-1}$, the same inequality has to hold in $\psi$. Consider the test $\mathrm{w}_{k}=\mathrm{w}_{k}^{\prime}$ which distinguishes between $\phi$ and $\psi$ : suppose $\mathrm{w}_{k} \phi=\mathrm{w}_{k}^{\prime} \phi$ but $\mathrm{w}_{k} \psi \neq \mathrm{w}_{k}^{\prime} \psi$. Replacing $r$ by $r^{\prime}$ in $\mathrm{g}\left(\mathrm{w}_{i}^{\prime}, \mathrm{w}_{j}^{\prime}, r\right)$ will still lead to $\mathrm{w}_{k} \psi \neq \mathrm{w}_{k}^{\prime} \psi$ (after replacement) as no equality between subterms is added. But if $\mathrm{w}_{k} \phi \neq \mathrm{w}_{k}^{\prime} \phi$ (after replacement), it would imply that there were two subterms which became different, and were identical before: but, because the first step already took care of recipes introducing the same random seed twice in the same context, and the protocols in $\mathcal{C}_{\mathrm{pp}}$ cannot use a random seed from an input to use it in another encryption, it is impossible.

Hence, we showed that modifying tr into $\tilde{t r}$ is a symmetric operation which preserves equalities in the two protocols: identical plaintexts and keys in $(\operatorname{tr}, \phi)$ correspond to identical plaintexts and keys in $(\operatorname{tr}, \psi)$, whereas adding fresh nonces does not create any equality in $\tilde{\phi}$ or $\tilde{\psi}$. If $(\operatorname{tr}, \phi)$ does not have any equivalent $\tilde{\tau}^{\operatorname{trace}}$ in $Q$, neither has $(\tilde{\operatorname{tr}}, \tilde{\phi})$. If there exists no frame $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$, then there will exist no frame $\tilde{\psi}$ such that $(\tilde{\operatorname{tr}}, \tilde{\psi}) \in \operatorname{trace}(Q)$ as input filtering is not affected by our transformation. Else, if there exists $\psi$ such that $(\operatorname{tr}, \psi) \in \operatorname{trace}(Q)$ but $\phi$ and $\psi$ are not statically equivalent, because our transformation preserves the terms in the frame, any pair of recipes which
distinguishes between the two of them, will distinguish $\tilde{\phi}$ and $\tilde{\psi}$. So we can always assume than the random seeds occurring in the recipes $\mathrm{f}(u, v, w)$ in $(\operatorname{tr}, \phi)$ are distinct.

Let us now define a corresponding trace $(\overline{\operatorname{tr}}, \bar{\phi}) \in \operatorname{trace}_{f w d}(\bar{P})$.

- each sequence $\operatorname{in}\left(c_{i}, R\right)$.out $\left(c_{i}, \mathrm{w}^{\prime}\right)$, where $c_{i} \neq c$, is left unchanged;
- each sequence $\operatorname{in}\left(c, \mathrm{f}\left(R, R_{k}, n\right)\right)$.out $\left(c, \mathrm{w}^{\prime}\right)$, where $R_{k} \phi \downarrow=\mathrm{k}$ and $\mathrm{f} \in\{$ senc, raenc, sign $\}$, is replaced by $\operatorname{in}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\mathrm{f}}, R\right) \cdot \operatorname{out}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\mathrm{f}}, \mathrm{w}^{\prime}\right)$;
- each sequence $\operatorname{in}\left(c, \mathrm{~g}\left(R, R_{k}\right)\right)$.out $\left(c, \mathrm{w}^{\prime}\right)$, where $R_{k} \phi \downarrow=\mathrm{k}$ and $\mathrm{g} \in\{\mathrm{sdec}$, radec, check $\}$, is replaced by $\operatorname{in}\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\mathrm{g}}, R\right)$.out $\left(c_{\mathrm{k}, \alpha(\mathrm{k})}^{\mathrm{g}}, \mathrm{w}^{\prime}\right)$.

Note that each recipe $R$ and $R_{k}$ above is a variable w or the constant start. The corresponding frame $\bar{\phi}$ is then defined according to our semantics. Since we have assume that the random seed occurring in the recipes in tr are distinct, we have that $\bar{\phi}=\phi$.

Finally, because $(\operatorname{tr}, \phi) \in \operatorname{trace}^{\mathrm{io*}}(P)$ has no equivalent in $Q$, and the definition of $(\overline{\operatorname{tr}}, \bar{\phi})$ does not alter the filtering on inputs nor equalities between terms in the frame, $(\overline{\operatorname{tr}}, \bar{\phi}) \in \operatorname{trace}_{\mathrm{fwd}}(\bar{P})$ has no equivalent in $\bar{Q}$.

## B. 3 Encoding a protocol into a real-time GPDA

## B.3.1 Characterisation of trace equivalence

Lemma B.3.1. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}$, if $P \approx_{\mathrm{fwd}} Q$ then for every trace $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace} \mathrm{e}_{\mathrm{fwd}}(P)$ and every $\mathrm{w}, \mathrm{w}^{\prime} \in \operatorname{dom}\left(\sigma_{P}\right)$, if $\mathrm{w} \sigma_{P}=\mathrm{w}^{\prime} \sigma_{P}=\mathrm{c}$ for some constant c , then $\mathrm{w} \sigma_{Q}=\mathrm{w}^{\prime} \sigma_{Q}=\mathrm{c}^{\prime}$ for some constant $\mathrm{c}^{\prime}$ where $\sigma_{Q}$ is the frame such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in \operatorname{trace}(Q)$.

Proof. First, note that the frame $\sigma_{Q}$ mentioned in the lemma is unique up to some alpha-renaming of the randoms that occur in $\sigma_{P}$. Thus, the choice of the frame $\sigma_{Q}$ does not change anything regarding the result that we want to prove.

Actually, the only non-trivial point to prove is that if $\mathrm{w} \sigma_{P}=\mathrm{c}$, then $\mathrm{w} \sigma_{Q}$ is necessarily a constant too. Since protocols in $\mathcal{C}_{\mathrm{pp}}$ have a replication for every branch, consider the trace obtained by "playing twice" the trace $\operatorname{tr}$ in $P$ and $Q$, i.e. given $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace}_{\mathrm{fwd}}(P)$ with

$$
\operatorname{tr}=\operatorname{in}\left(c_{i_{1}}, \operatorname{start}\right) . \operatorname{out}\left(c_{i_{1}}, \mathrm{w}_{1}\right) \ldots \operatorname{in}\left(c_{i_{l}}, \mathrm{w}_{l-1}\right) . \operatorname{out}\left(c_{i_{l}}, \mathrm{w}_{l}\right)
$$

build $\left(\operatorname{tr}^{\prime}, \sigma_{P}^{\prime}\right) \in \operatorname{trace}_{\mathrm{fwd}}(P)$ where:

$$
\left\{\begin{array}{l}
\operatorname{tr}^{\prime} \stackrel{\text { def }}{=} \operatorname{tr} . \overline{\operatorname{tr}} \\
\overline{\operatorname{tr} r} \stackrel{\text { def }}{=} \operatorname{in}\left(c_{i_{1}}, \operatorname{start}\right) . \operatorname{out}\left(c_{i_{1}}, \mathrm{w}_{|\phi|+1}\right) \ldots \operatorname{in}\left(c_{i_{l}}, \mathrm{w}_{|\phi|+l}\right) \cdot \operatorname{out}\left(c_{i_{l}}, \mathrm{w}_{|\phi|+l}\right)
\end{array}\right.
$$

where every occurrence of start in tr is kept in tr but occurrences of $\mathrm{w}_{k}$ are replaced by $\mathrm{w}_{\left|\sigma_{P}\right|+k},\left|\sigma_{P}\right|$ being the cardinal of $\operatorname{dom}\left(\sigma_{P}\right)$; and tr.tr denotes the concatenation of the two sequences of labels, which is a valid trace, i.e. $\left(\operatorname{tr}^{\prime}, \sigma_{P}^{\prime}\right) \in \operatorname{trace} \mathrm{f}_{\mathrm{fwd}}(P)$. We get symmetrically $\left(\operatorname{tr}^{\prime}, \sigma_{Q}^{\prime}\right) \in \operatorname{trace}_{\mathrm{fwd}}(Q)$. In particular, there exists $\mathrm{w}_{*} \in \operatorname{dom}\left(\sigma_{P}^{\prime}\right)$ with $l<*$ such that $\mathrm{w} \sigma_{P}^{\prime}=\mathrm{w}_{*} \sigma_{P}^{\prime}=\mathrm{c}$ and the test $\mathrm{w}=\mathrm{w}_{*}$ is disjoint, i.e. $\mathrm{seq}_{\mathrm{tr}^{\prime}}(\mathrm{w})$ and $\mathrm{seq}_{\mathrm{tr}^{\prime}}\left(\mathrm{w}_{*}\right)$ share no common prefix. As $P \approx_{\text {fwd }} Q$, necessarily $\mathrm{w} \sigma_{Q}^{\prime}=\mathrm{w}_{*} \sigma_{Q}^{\prime}$. Now, because the test is disjoint, $\mathrm{w} \sigma_{Q}^{\prime}$ and $\mathrm{w}_{*} \sigma_{Q}^{\prime}$ could not share any random nonces. Hence, $w \sigma_{Q}$ is a constant.

Lemma B.3.2. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}$ such that $P \approx_{\mathrm{fwd}} Q$. For every trace $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace} \mathrm{f}_{\mathrm{fwd}}(P)$, every $\mathrm{w}, \mathrm{w}^{\prime} \in \operatorname{dom}\left(\sigma_{P}\right)$ such that the test $\mathrm{w}=\mathrm{w}^{\prime}$ is $\sigma_{P}$-valid, $\sigma_{P}$-guarded, and pulled-up in $\left(\operatorname{tr}, \sigma_{P}\right)$, we have that $\mathrm{w}=\mathrm{w}^{\prime}$ is $\sigma_{Q}$-valid, $\sigma_{Q}$-guarded, and pulled-up in $\left(\operatorname{tr}, \sigma_{Q}\right)$ where $\sigma_{Q}$ is the frame such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in \operatorname{trace} \mathrm{f}_{\mathrm{fwd}}(Q)$

Proof. First, note that the frame $\sigma_{Q}$ mentioned in the lemma is unique up to some alpha-renaming of the randoms that occur in $\sigma_{P}$. Thus, the choice of the frame $\sigma_{Q}$ does not change anything regarding the result that we want to prove.

The only non-trivial point to prove is that if the test $\mathrm{w}=\mathrm{w}^{\prime}$ is $\sigma_{P}$-valid, $\sigma_{P}$-guarded, and pulled-up in ( $\mathrm{tr}, \sigma_{P}$ ) then it is also $\sigma_{Q}$-guarded and pulled-up in $\left(\operatorname{tr}, \sigma_{Q}\right)$. Note that it is necessarily $\sigma_{Q}$-valid since $P \approx_{\text {fwd }} Q$. Actually, we can still assume that the test $\mathrm{w}=\mathrm{w}^{\prime}$ is $\sigma_{Q}$-guarded (it would otherwise contradict Lemma B.3.1).

Let pref $=\mathrm{io}\left(c_{i_{0}}\right.$, start, $\left.\mathrm{w}_{j_{0}}\right) \ldots$ io $\left(c_{i_{p}}, \mathrm{w}_{j_{p-1}}, \mathrm{w}_{j_{p}}\right)$ be the maximal common prefix of seq $\mathrm{tr}_{\mathrm{tr}}(\mathrm{w})$ and seq $\mathrm{t}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)$. Now, it remains to show that $\mathrm{w}=\mathrm{w}^{\prime}$ is pulled-up in $\left(\mathrm{tr}, \sigma_{Q}\right)$, i.e. $\mathrm{w} \sigma_{Q}$ does not occur as a subterm in $\mathrm{w}_{j_{-1}} \sigma_{Q}, \mathrm{w}_{j_{0}} \sigma_{Q}, \ldots \mathrm{w}_{j_{p-1}} \sigma_{Q}$ where $\mathrm{w}_{j_{-1}} \sigma_{Q}=$ start.

Assume that this is not the case, we will show that there exists a trace $\left(\operatorname{tr}^{*}, \sigma_{Q}^{*}\right) \in \operatorname{trace}_{\mathrm{fwd}}(Q), \mathrm{w}_{*}, \mathrm{w}_{*}^{\prime} \in \operatorname{dom}\left(\sigma_{Q}^{*}\right)$ such that $\mathrm{w}_{*} \sigma_{Q}^{*}=\mathrm{w}_{*}^{\prime} \sigma_{Q}^{*}$ whereas $\mathrm{w}_{*} \sigma_{P}^{*} \neq \mathrm{w}_{*}^{\prime} \sigma_{P}^{*}$, where $\sigma_{P}^{*}$ is the frame such that $\left(\operatorname{tr}^{*}, \sigma_{P}^{*}\right) \in \operatorname{trace} \mathrm{f}_{\mathrm{fwd}}(P)$. Note that such a frame necessarily exists since otherwise it trivially contradicts our hypothesis.

Let $p^{\prime} \in\{0, \ldots, p-1\}$ be the smallest index such that $\mathrm{w} \sigma_{Q}$ occurs as a subterm in $\mathrm{w}_{j_{p^{\prime}}} \sigma_{Q}$. We have that:

$$
\text { pref }=s_{1} \cdot \mathrm{io}\left(c_{i_{p^{\prime}}}, \mathrm{w}_{j_{p^{\prime}-1}}, \mathrm{w}_{j_{p^{\prime}}}\right) \cdot s_{2} \quad \text { and } \quad\left\{\begin{aligned}
\operatorname{seq}_{\mathrm{tr}}(\mathrm{w}) & =\text { pref. } s_{3} \\
\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right) & =\text { pref. } s_{3}^{\prime}
\end{aligned}\right.
$$

for some sequence $s_{1}, s_{2}, s_{3}$, and $s_{3}^{\prime}$.
From these sequences we can define $\left(\operatorname{tr}^{*}, \sigma_{Q}^{*}\right)$ with $\operatorname{tr}^{*}=\operatorname{tr} . \overline{\mathrm{tr}}$. Intuitively, the trace $\overline{\operatorname{tr}}$ is obtained relying on the sequence of channels as indicated in the sequence $s_{2} \cdot s_{3}^{\prime}$ using systematically the last generated recipe to feed the following input, and $\mathrm{w}_{j_{p^{\prime}}}$ to start. More precisely, assuming that

$$
\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)=s_{1} \cdot \operatorname{io}\left(c_{i_{p^{\prime}}}, \mathrm{w}_{j_{p^{\prime}-1}}, \mathrm{w}_{j_{p^{\prime}}}\right) \cdot \operatorname{io}\left(c_{k_{1}}, \mathrm{w}_{j_{p^{\prime}}}, \mathrm{w}_{l_{1}}\right) \cdot \operatorname{io}\left(c_{k_{2}}, \mathrm{w}_{l_{1}}, \mathrm{w}_{l_{2}}\right) \ldots \operatorname{io}\left(c_{k_{\ell}}, \mathrm{w}_{l_{\ell-1}}, \mathrm{w}_{l_{\ell}}\right)
$$

we have that:

$$
\overline{\operatorname{tr}}=\mathrm{io}\left(c_{k_{1}}, \mathrm{w}_{j_{p^{\prime}}}, \mathrm{w}_{\left|\sigma_{P}\right|+1}\right) \cdot \mathrm{io}\left(c_{k_{2}}, \mathrm{w}_{\left|\sigma_{P}\right|+1}, \mathrm{w}_{\left|\sigma_{P}\right|+2}\right) \ldots \mathrm{io}\left(c_{k_{\ell}}, \mathrm{w}_{\left|\sigma_{P}\right|+l-1}, \mathrm{w}_{\left|\sigma_{P}\right|+\ell}\right)
$$

and $\sigma_{Q}^{*}$ defined as expected relying on our semantics. Let $\mathrm{w}_{*}=\mathrm{w}$ and $\mathrm{w}_{*}^{\prime}=\mathrm{w}_{\left|\sigma_{P}\right|+\ell}$. We can now show that:

1. The test $\mathrm{w}_{*}=\mathrm{w}_{*}^{\prime}$ is $\sigma_{Q}^{*}$-valid and $\sigma_{Q}^{*}$-guarded. Indeed, by definition of $\mathrm{tr}^{*}, \mathrm{w}_{*}^{\prime} \sigma_{Q}^{*}$ and $\mathrm{w}^{\prime} \sigma_{Q}$ are already equal up to a renaming of random seeds, as the channel components of $\operatorname{seq}_{\operatorname{tr}}\left(w^{\prime}\right)$ and $\operatorname{seq}_{\mathrm{tr}_{*}}\left(\mathrm{w}_{*}^{\prime}\right)$ match. As $\mathrm{w}_{*} \sigma_{Q}^{*}=\mathrm{w} \sigma_{Q}=\mathrm{w}^{\prime} \sigma_{Q}, \mathrm{w}_{*} \sigma_{Q}^{*}$ and $\mathrm{w}_{*}^{\prime} \sigma_{Q}^{*}$ are equal up to a renaming of their random seeds. Lastly, we have that $\mathrm{w}_{*} \sigma_{Q}^{*}$ and $\mathrm{w}_{*}^{\prime} \sigma_{Q}^{*}$ are both subterms of $\mathrm{w}_{j_{p^{\prime}}} \sigma_{Q}^{*}$, hence $\mathrm{w}_{*} \sigma_{Q}^{*}=\mathrm{w}_{*}^{\prime} \sigma_{Q}^{*}$.
2. The test $\mathrm{w}_{*}=\mathrm{w}_{*}^{\prime}$ is pulled-up in $\left(\mathrm{tr}^{*}, \sigma_{Q}^{*}\right)$. This is by construction of $\operatorname{tr}^{*}$.

Finally, as $P \approx_{\mathrm{fwd}} Q$, there exists $\sigma_{P}^{*}$ such that $\left(\operatorname{tr}^{*}, \sigma_{P}^{*}\right) \in \operatorname{trace} \mathrm{e}_{\mathrm{fwd}}(P)$. But now $\mathrm{w}_{*}=\mathrm{w}_{*}^{\prime}$ is $\sigma_{Q}^{*}$-valid, $\sigma_{Q}^{*}$-guarded and pulled-up in $\left(\operatorname{tr}^{*}, \sigma_{Q}^{*}\right)$. Moreover, we are now in a situation where the top-level random seeds of $\mathrm{w}_{*} \sigma_{P}^{*}$ and $\mathrm{w}_{*}^{\prime} \sigma_{P}^{*}$ are generated outside the common prefix of $\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}_{*}\right)$ and $\mathrm{seq}_{\mathrm{tr}}\left(\mathrm{w}_{*}^{\prime}\right)$, and thus it implies that $\mathrm{w}_{*} \sigma_{P}^{*} \neq \mathrm{w}_{*}^{\prime} \sigma_{P}^{*}$, contradicting the equivalence $P \approx_{\text {fwd }} Q$.

Lemma 7.3.1. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}$, then $P \approx_{\mathrm{fwd}} Q$ if, and only if, the following four conditions are satisfied:

- $\operatorname{Const}_{P}$ : For all $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace}_{\mathrm{fwd}}(P)$, there exists a frame $\sigma_{Q}$ such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in \operatorname{trace}_{\mathrm{fwd}}(Q)$ and for every $\mathrm{w}, \mathrm{w}^{\prime} \in \operatorname{dom}\left(\sigma_{P}\right)$ and for every constant $\mathrm{c} \in \Sigma_{0} \cup\{\mathrm{start}\}, \mathrm{w} \sigma_{P}=\mathrm{w}^{\prime} \sigma_{Q}=\mathrm{c}$ if, and only if, there exists a constant $\mathrm{c}^{\prime} \in \Sigma_{0} \cup\{$ start $\}$ such that $\mathrm{w} \sigma_{Q}=\mathrm{w}^{\prime} \sigma_{Q}=\mathrm{c}^{\prime}$.
- $\operatorname{Const}_{Q}$ : Similarly swapping the roles of $P$ and $Q$.
- $\operatorname{GuARDED}_{P}$ : For all $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace}_{\mathrm{fwd}}(P)$, there exists a frame $\sigma_{Q}$ such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in \operatorname{trace}_{\mathrm{fwd}}(Q)$ and every test that is $\sigma_{P}$-valid, $\sigma_{P}$-guarded, and pulled-up in $\left(\operatorname{tr}, \sigma_{P}\right)$ is also $\sigma_{Q^{-}}$-valid, $\sigma_{Q^{-}}$-guarded, and pulled-up in $\left(\operatorname{tr}, \sigma_{Q}\right)$.
- Guarded ${ }_{Q}$ : Similarly swapping the roles of $P$ and $Q$.

Proof. We prove the two directions separately.
$(\Rightarrow)$ This implication is a direct consequence of Lemma B.3.1 and Lemma B.3.2.
$(\Leftarrow)$ Suppose that $P \not \overbrace{\mathrm{fwd}} Q$. This means that there exists for instance $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace}_{\mathrm{fwd}}(P)$ such that either there exists no frame $\sigma_{Q}$ such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in \operatorname{trace} \mathrm{f}_{\mathrm{fwd}}(Q)$, in which case conditions $\operatorname{Const}_{P}$ and GuARDED ${ }_{P}$ fail, or $\sigma_{Q}$ is indeed defined and there exists a test $\mathrm{w}=\mathrm{w}^{\prime}$ such that $\mathrm{w} \sigma_{P}=\mathrm{w}^{\prime} \sigma_{P}$ but $\mathrm{w} \sigma_{Q} \neq \mathrm{w}^{\prime} \sigma_{Q}$ (or the converse). Let us assume that $\mathrm{w} \sigma_{P}=\mathrm{w}^{\prime} \sigma_{P}$ but $\mathrm{w} \sigma_{Q} \neq \mathrm{w}^{\prime} \sigma_{Q}$.

If $\mathrm{w} \sigma_{P}=\mathrm{w}^{\prime} \sigma_{P}=\mathrm{c}$ for some constant c , then condition $\operatorname{CoNST}_{P}$ is false.
Otherwise, we have that the test $\mathrm{w}=\mathrm{w}^{\prime}$ is $\sigma_{P}$-valid and $\sigma_{P}$-guarded. From tr and $\mathrm{w}=\mathrm{w}^{\prime}$, we will build a new trace $\left(\operatorname{tr}^{*}, \sigma_{P}^{*}\right)$ and a new test $\mathrm{w}_{*}=\mathrm{w}_{*}^{\prime}$ which is $\sigma_{P}^{*}$-valid, $\sigma_{P}^{*}$-guarded, and also pulled-up in $\left(\operatorname{tr}^{*}, \sigma_{P}^{*}\right)$. Actually, we proceed as in the proof of the previous lemma.

Let pref $=\mathrm{io}\left(c_{i_{0}}\right.$, start, $\left.\mathrm{w}_{j_{0}}\right) \ldots$ io $\left(c_{i_{p}}, \mathrm{w}_{j_{p-1}}, \mathrm{w}_{j_{p}}\right)$ be the maximal common prefix of $\operatorname{seq}_{\mathrm{tr}}(\mathrm{w})$ and seq $\mathrm{s}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)$. Let $p^{\prime} \in\{0, \ldots, p-1\}$ be the smallest index such that $\mathrm{w} \sigma_{P}$ occurs as a subterm in $\mathrm{w}_{j_{p^{\prime}}} \sigma_{P}$. Note that if this index does not exist then the test $\mathrm{w}=\mathrm{w}^{\prime}$ is already pulled-up in $\left(\operatorname{tr}, \sigma_{P}\right)$ and we are done.

We have that:

$$
\text { pref }=s_{1} \cdot \mathrm{io}\left(c_{i_{p^{\prime}}}, \mathrm{w}_{j_{p^{\prime}-1}}, \mathrm{w}_{j_{p^{\prime}}}\right) \cdot s_{2} \quad \text { and } \quad\left\{\begin{aligned}
\operatorname{seq}_{\mathrm{tr}}(\mathrm{w}) & =\text { pref. } s_{3} \\
\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right) & =\text { pref. } s_{3}^{\prime}
\end{aligned}\right.
$$

for some sequence $s_{1}, s_{2}, s_{3}$, and $s_{3}^{\prime}$.
From these sequences, we can define $\left(\operatorname{tr}^{*}, \sigma_{P}^{*}\right)$ with $\operatorname{tr}^{*}=\operatorname{tr}$, $\overline{\mathrm{r}}$. Intuitively, the trace $\overline{\mathrm{tr}}$ is obtained relying on the sequence of channels as indicated in the sequence $s_{2} \cdot s_{3}^{\prime}$ using systematically the last generated recipe to feed the following input, and $\mathrm{w}_{j_{p^{\prime}}}$ to start. More precisely, assuming that

$$
\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)=s_{1} \cdot \operatorname{io}\left(c_{i_{p^{\prime}}}, \mathrm{w}_{j_{p^{\prime}-1}}, \mathrm{w}_{j_{p^{\prime}}}\right) \cdot \operatorname{io}\left(c_{k_{1}}, \mathrm{w}_{j_{p^{\prime}}}, \mathrm{w}_{l_{1}}\right) \cdot \operatorname{io}\left(c_{k_{2}}, \mathrm{w}_{l_{1}}, \mathrm{w}_{l_{2}}\right) \ldots \operatorname{io}\left(c_{k_{\ell}}, \mathrm{w}_{l_{\ell-1}}, \mathrm{w}_{l_{\ell}}\right)
$$

we have that:

$$
\overline{\operatorname{tr}}=\mathrm{io}\left(c_{k_{1}}, \mathrm{w}_{j_{p^{\prime}}}, \mathrm{w}_{\left|\sigma_{P}\right|+1}\right) \cdot \mathrm{io}\left(c_{k_{2}}, \mathrm{w}_{\left|\sigma_{P}\right|+1}, \mathrm{w}_{\left|\sigma_{P}\right|+2}\right) \ldots \mathrm{io}\left(c_{k_{\ell}}, \mathrm{w}_{\left|\sigma_{P}\right|+l-1}, \mathrm{w}_{\left|\sigma_{P}\right|+\ell}\right)
$$

and $\sigma_{P}^{*}$ defined as expected relying on our semantics. Let $\mathrm{w}_{*}=\mathrm{w}$ and $\mathrm{w}_{*}^{\prime}=\mathrm{w}_{\left|\sigma_{P}\right|+\ell}$.
Now, either there exists no frame $\sigma_{Q}^{*}$ such that $\left(\operatorname{tr}^{*}, \sigma_{Q}^{*}\right) \in \operatorname{trace}(Q)$, in which case condition GuARDED ${ }_{P}$ fails obviously, or such a frame exists. In this case, by construction of $\operatorname{tr}^{*}$, we have that the test $\mathrm{w}_{*}=\mathrm{w}_{*}^{\prime}$ is $\sigma_{P}^{*}$-valid, $\sigma_{P}^{*}$-guarded, and pulled-up in $\left(\operatorname{tr}^{*}, \sigma_{P}^{*}\right)$.

In order to conclude, it remains to show that $\mathrm{w}_{*} \sigma_{Q}^{*} \neq \mathrm{w}_{*}^{\prime} \sigma_{Q}^{*}$. We already know that $\mathrm{w} \sigma_{Q}=\mathrm{w}_{*} \sigma_{Q}^{*}$. Suppose $a d$ absurdum that $\mathrm{w}_{*} \sigma_{Q}^{*}=\mathrm{w}_{*}^{\prime} \sigma_{Q}^{*}$. Because the sequences of channels that occur in $\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)$ and $\operatorname{seq}_{\mathrm{tr}^{*}}\left(\mathrm{w}_{*}^{\prime}\right)$ are the same, $\mathrm{w}^{\prime} \sigma_{Q}$ and $\mathrm{w}_{*}^{\prime} \sigma_{Q}^{*}$ are either constant and equal or of the form $\mathrm{f}(u, \mathrm{k}, r)$ with $\mathrm{f} \in\{$ senc, raenc, sign $\}$ and equal up to a renaming of their random seeds. In the first case, it is enough to conclude that $\mathrm{w} \sigma_{Q}=\mathrm{w}^{\prime} \sigma_{Q}$, which is absurd. In the second case, $\mathrm{w}_{*} \sigma_{Q}^{*}$ and $\mathrm{w}_{*}^{\prime} \sigma_{Q}^{*}$ being randomised, must have equal top-level random seeds, implying that this nonce was introduced before io $\left(c_{i_{p^{\prime}}}, \mathrm{w}_{j_{p^{\prime}-1}}, \mathrm{w}_{j_{p^{\prime}}}\right)$ in the common prefix of their respective sequences. As the said prefix is also common to w and $\mathrm{w}^{\prime}$ in $\operatorname{tr}, \mathrm{w} \sigma_{Q}$ and $\mathrm{w}^{\prime} \sigma_{Q}$ share the same top-level random seed and are thus equal, contradicting our hypothesis. Therefore: $\mathrm{w}_{*} \sigma_{Q}^{*} \neq \mathrm{w}_{*}^{\prime} \sigma_{Q}^{*}$. Hence $\operatorname{GUARDED}_{P}$ is false.

Finally, if $\mathrm{w} \sigma_{Q}=\mathrm{w}^{\prime} \sigma_{Q}$ but $\mathrm{w} \sigma_{P} \neq \mathrm{w}^{\prime} \sigma_{P}$, conditions $\operatorname{Const}_{Q}$ and $\operatorname{GUARDED}_{Q}$ will similarly fail.

## B.3.2 From trace equivalence to language equivalence

Lemma 7.3.2. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\mathrm{pp}}$, the two real-time GPDA $\mathcal{A}_{\mathrm{CONST}}^{P}$ and $A_{\mathrm{CONST}}^{Q}$ are such that:

$$
P \text { and } Q \text { satisfy conditions } \operatorname{CoNST}_{P} \text { and } \operatorname{CoNST}_{Q} \text { iff } \mathcal{L}\left(\mathcal{A}_{\mathrm{CONST}}^{P}\right)=\mathcal{L}\left(\mathcal{A}_{\mathrm{CONST}}^{Q}\right)
$$

Proof. We prove the two implications separately.
$(\Rightarrow)$ Assume that $\mathcal{L}\left(\mathcal{A}_{\text {CONST }}^{P}\right) \neq \mathcal{L}\left(\mathcal{A}_{\text {CONST }}^{Q}\right)$, and consider w.l.o.g. a word $u \in \mathcal{L}\left(\mathcal{A}_{\text {CONST }}^{P}\right) \backslash \mathcal{L}\left(\mathcal{A}_{\mathrm{CONST}}^{Q}\right)$. We distinguish two cases depending on whether $u$ is accepted in state $q_{0}$ or $q_{\mathrm{f}}$.
Case $u=c_{i_{1}} \cdot c_{i_{2}} \ldots c_{i_{l}}$ is accepted in $q_{0}$ : In such a case, we built ( $\left.\operatorname{tr}, \sigma_{P}\right)$ as follows:

$$
\operatorname{tr}=\operatorname{io}\left(c_{i_{1}}, \operatorname{start}, \mathrm{w}_{1}\right) \cdot \operatorname{io}\left(c_{i_{2}}, \mathrm{w}_{1}, \mathrm{w}_{2}\right) \ldots \mathrm{io}\left(c_{i_{l}}, \mathrm{w}_{l-1}, \mathrm{w}_{l}\right)
$$

with $\sigma_{P}$ the substitution defined uniquely as expected from our semantics. We have that $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace}_{\mathrm{fwd}}(P)$ as the transition function $\delta$ fully captures input filtering and output of terms for protocols in $\mathcal{C}_{\mathrm{pp}}$. Since $u \notin \mathcal{L}\left(\mathcal{A}_{\text {CONST }}^{Q}\right)$, we have that $\left(\operatorname{tr}, \sigma_{Q}\right) \notin \operatorname{trace}_{\mathrm{fwd}}(Q)$ for any substitution $\sigma_{Q}$, and thus the condition $\operatorname{CoNST}_{P}$ fails.
Case $u$ is accepted in $q_{\mathrm{f}}$ : In such a case, we also build a trace $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace}_{\mathrm{fwd}}(P)$ "corresponding" to $u$. The construction is a bit more involved. We have that $u$ is of the form $c_{i_{1}} c_{i_{2}} \ldots c_{i_{k}} c_{\text {test }} c_{j_{1}} c_{j_{2}} \ldots c_{j_{l}} c_{\text {end }}$. Let $\operatorname{tr}=\operatorname{tr}_{1} . \operatorname{tr}_{2}$ with $\operatorname{tr}_{1}$ and $\operatorname{tr}_{2}$ defined as follows:

- $\operatorname{tr}_{1}=\mathrm{io}\left(c_{i_{1}}\right.$, start, $\left.\mathrm{w}_{1}\right) \cdot \mathrm{io}\left(c_{i_{2}}, \mathrm{w}_{1}, \mathrm{w}_{2}\right) \ldots \mathrm{io}\left(c_{i_{k}}, \mathrm{w}_{k-1}, \mathrm{w}_{k}\right)$;
- $\operatorname{tr}_{2}=\mathrm{io}\left(c_{j_{1}}\right.$, start, $\left.\mathrm{w}_{k+1}\right) . \mathrm{io}\left(c_{j_{2}}, \mathrm{w}_{k+1}, \mathrm{w}_{k+2}\right) \ldots \mathrm{io}\left(c_{j_{l}}, \mathrm{w}_{k+l-1}, \mathrm{w}_{k+l}\right)$;
and $\sigma_{P}$ is defined uniquely as expected from our semantics, as $P$ is deterministic. We have that $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace} \mathrm{f}_{\mathrm{fwd}}(P)$ as the transition function $\delta$ fully captures input filtering and output of terms for protocols in $\mathcal{C}_{\mathrm{pp}}$. We can now define $\mathrm{w}=\mathrm{w}_{k}$ and $\mathrm{w}^{\prime}=\mathrm{w}_{k+l}$. Because the transitions from $q_{0}$ to $q_{\mathrm{c}}$ and then from $q_{\mathrm{c}}$ to $q_{\mathrm{f}}$ for some constant c were possible, we get that $\mathrm{w} \sigma_{P}=\mathrm{w}^{\prime} \sigma_{P}=\mathrm{c}$.

We know that $u=u_{1} c_{\text {test }} u_{2} c_{\text {end }} \notin \mathcal{L}\left(\mathcal{A}_{\text {CONST }}^{Q}\right)$, and we may assume that $u_{1}$ and $u_{2}$ are both in $\mathcal{L}\left(\mathcal{A}_{\text {CONST }}^{Q}\right)$. Indeed, otherwise, this means that there exists no substitution $\sigma_{Q}$ such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in \operatorname{trace} \mathrm{f}_{\mathrm{fwd}}(Q)$, and thus $\operatorname{CoNST}_{P}$ fails, and the result holds. From now one, we assume that there exists $\sigma_{Q}$ such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in \operatorname{trace} \mathrm{f}_{\mathrm{fwd}}(Q)$.

Now, let $q \xrightarrow{c ; \alpha / \beta} q^{\prime}$ be the first failing transition in the run of $u$ in $\mathcal{A}_{\text {Const }}^{Q}$. We distinguish several cases:

1. Case $q=q_{0}$ and $q^{\prime}=q_{\mathrm{c}}$ for some constant c . In such a case $\mathrm{w} \sigma_{Q} \neq \mathrm{c}$ for any constant c , and $\mathrm{w} \sigma_{Q}$ is thus a guarded term. The condition $\operatorname{CoNST}_{P}$ fails.
2. Case $q=q_{\mathrm{c}}$ and $q^{\prime}=q_{\mathrm{f}}$ for some constant c . In such a case $\mathrm{w} \sigma_{Q}=\mathrm{c}$ but $\mathrm{w} \sigma \neq \mathrm{c}$, making $\operatorname{Const}_{P}$ fail once again.

Hence $P$ and $Q$ do not satisfy $\operatorname{Const}_{P}$. Symmetrically, if $u \in \mathcal{L}\left(\mathcal{A}_{\text {CONST }}^{Q}\right) \backslash \mathcal{L}\left(\mathcal{A}_{\text {CONST }}^{P}\right)$, the condition $\operatorname{Const}_{Q}$ will fail.
$(\Leftarrow)$ If $P$ and $Q$ do not satisfy $\operatorname{Const}_{P}\left(\right.$ or $\left.\operatorname{Const}_{Q}\right)$, i.e. there exists a trace $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace} \mathrm{f}_{\mathrm{fwd}}(P)$ such that:

1. either there exists no $\sigma_{Q}$ such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in \operatorname{trace}_{\mathrm{fwd}}(Q)$;
2. or there exist $\mathrm{w}, \mathrm{w}^{\prime} \in \operatorname{dom}\left(\sigma_{P}\right)$ and a constant c such that $\mathrm{w} \sigma_{P}=\mathrm{w}^{\prime} \sigma_{P}=\mathrm{c}$ but: either $\mathrm{w} \sigma_{Q}$ is not a constant, or $\mathrm{w} \sigma_{Q}$ is a constant but $\mathrm{w} \sigma_{Q} \neq \mathrm{w}^{\prime} \sigma_{Q}$.

We consider such a trace of minimal length $\ell$.
In the first case, thanks to minimality, we have that $\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}_{\ell}\right)=\operatorname{tr}$. From tr we build a word $u \in \mathcal{L}\left(\mathcal{A}_{\text {CONST }}^{P}\right)$ by extracting the channels that occur in tr keeping the order. Since there does not exist $\sigma_{Q}$ such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in$ $\operatorname{trace}_{\mathrm{fwd}}(Q)$, and the transition function $\delta$ of the automaton fully captures input filtering and output of terms for protocols in $\mathcal{C}_{\mathrm{pp}}$, we have that $u \notin \mathcal{L}\left(\mathcal{A}_{\mathrm{CONST}}^{Q}\right)$.

In the second case, thanks to minimality, we have that $t r$ is actually made up of all the actions that occur in $\operatorname{seq}_{\mathrm{tr}}(\mathrm{w})$ and $\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)$ (note that these two sequences may share some actions). From tr, we built a word $u=u_{1} c_{\text {test }} u_{2} c_{\text {end }} \in$ $\mathcal{L}\left(\mathcal{A}_{\text {Const }}^{P}\right)$ as follows:

- $u_{1}$ is obtained by extracting the channels that occur in $\operatorname{seq}_{\mathrm{tr}}(\mathrm{w})$ preserving the order; and
- $u_{2}$ is obtained by extracting the channels that occur in $\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)$ preserving the order;,

As the transition function $\delta$ fully captures input filtering and output of terms for protocols in $\mathcal{C}_{\mathrm{pp}}$, we get that upon reading $c_{\text {test }}, \mathcal{A}_{\text {CONST }}^{P}$ is in $q_{0}$, the transition $q_{0} \xrightarrow{c_{\text {test }} ; \omega \mathrm{c} / \omega} q_{\mathrm{c}}$ is indeed possible as $\mathrm{w} \sigma_{P}=\mathrm{c}$; and similarly upon reading the $c_{\text {end }}, \mathcal{A}_{\text {Const }}^{P}$ is in $q_{\mathrm{c}}$, the transition $q_{\mathrm{c}} \xrightarrow{c_{\text {end }} ; \omega \mathrm{c} / \omega} q_{f}$ is indeed possible as $\mathrm{w}^{\prime} \sigma_{P}=\mathrm{c}$, hence $u \in \mathcal{L}\left(\mathcal{A}_{\text {CONST }}^{P}\right)$. What remains to show is that $u \notin \mathcal{L}\left(\mathcal{A}_{\text {CONST }}^{Q}\right)$. We distinguish two cases:

- Case $\mathrm{w} \sigma_{Q}$ is not a constant. In such a case, no transition $q_{0} \xrightarrow{c_{\text {test } ; \omega \mathrm{c}} / \omega} q_{\mathrm{c}}$ will be possible after $u_{1}$
- Case $\mathrm{w} \sigma_{Q}$ is a constant c but $\mathrm{w} \sigma_{Q} \neq \mathrm{w}^{\prime} \sigma_{Q}$. In such a case, the transition $q_{0} \xrightarrow{c_{\text {end }} ; \omega \mathrm{c} / \omega} q_{c}$ will not be possible after $u_{2}$.
Hence $u$ cannot belong to $\mathcal{L}\left(\mathcal{A}_{\mathrm{c}}^{Q}\right)$. This allows us to conclude.
Lemma 7.3.3. Let $P$ and $Q$ be two protocols in $\mathcal{C}_{\text {pp }}$, the two real-time GPDA $\mathcal{A}_{\text {GUarded }}^{P}$ and $A_{\text {GUarded }}^{Q}$ are such that: $P$ and $Q$ satisfy conditions $\operatorname{GuARDED}_{P}$ and $\operatorname{GUARDED}_{Q} \operatorname{iff} \mathcal{L}\left(\mathcal{A}_{\text {Guarded }}^{P}\right)=\mathcal{L}\left(\mathcal{A}_{\text {Guarded }}^{Q}\right)$.
Proof. We prove the two directions separately.
$(\Rightarrow)$ Assume that $\mathcal{L}\left(\mathcal{A}_{\text {GUarded }}^{P}\right) \neq \mathcal{L}\left(\mathcal{A}_{\text {Guarded }}^{Q}\right)$, and consider w.l.o.g. a word $u \in \mathcal{L}\left(\mathcal{A}_{\text {Guarded }}^{P}\right) \backslash \mathcal{L}\left(\mathcal{A}_{\text {Guarded }}^{Q}\right)$. We distinguish two cases depending on whether the word $u$ is accepted in state $q_{0}$ or $q_{\mathrm{f}}$.

Case $u=c_{i_{1}} c_{i_{2}} \ldots c_{i_{l}}$ is accepted in $q_{0}$ : In such a case, we built $\left(\operatorname{tr}, \sigma_{P}\right)$ as follows:

$$
\operatorname{tr}=\operatorname{io}\left(c_{i_{1}}, \operatorname{start}, \mathrm{w}_{1}\right) \cdot \operatorname{io}\left(c_{i_{2}}, \mathrm{w}_{1}, \mathrm{w}_{2}\right) \ldots \mathrm{io}\left(c_{i_{l}}, \mathrm{w}_{l-1}, \mathrm{w}_{l}\right)
$$

with $\sigma_{P}$ the substitution defined uniquely as expected from our semantics. We have that $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace}_{\mathrm{fwd}}(P)$ as the transition function $\delta$ fully captures input filtering and output of terms for protocols in $\mathcal{C}_{\mathrm{pp}}$. Since $u \notin \mathcal{L}\left(\mathcal{A}_{\text {CONST }}^{Q}\right)$, we have that $\left(\operatorname{tr}, \sigma_{Q}\right) \notin \operatorname{trace}_{\mathrm{fwd}}(Q)$ for any substitution $\sigma_{Q}$, and thus the condition $\operatorname{GUARDED}_{P}$ fails.

Case $u$ is accepted in $q_{\mathrm{f}}$ : In such a case, we also build a trace $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace}_{\mathrm{fwd}}(P)$ "corresponding" to $u$. The construction is a bit more involved. We have that $u$ is of the form: $c_{i_{1}} c_{i_{2}} \ldots c_{i_{k}} c_{\text {fork }}^{i_{0}} c_{j_{1}} c_{j_{2}} \ldots c_{j_{l}} c_{\text {test }} c_{p_{1}} c_{p_{2}} \ldots c_{p_{m}} c_{\text {end }}$. Let $t r=\operatorname{tr}_{0} \cdot \operatorname{tr}_{1} \cdot \operatorname{tr}_{2}$ with $\operatorname{tr}_{0}, \operatorname{tr}_{1}$ and $\operatorname{tr}_{2}$ defined as follows:

- $\operatorname{tr}_{0}=\mathrm{io}\left(c_{i_{1}}, \operatorname{start}, \mathrm{w}_{1}\right) \cdot \mathrm{io}\left(c_{i_{2}}, \mathrm{w}_{1}, \mathrm{w}_{2}\right) \ldots \mathrm{io}\left(c_{i_{k}}, \mathrm{w}_{k-1}, \mathrm{w}_{k}\right) \cdot \mathrm{io}\left(c_{i_{0}}, \mathrm{w}_{k}, \mathrm{w}_{k+1}\right)$;
- $\operatorname{tr}_{1}=\mathrm{io}\left(c_{j_{1}}, \mathrm{w}_{k+1}, \mathrm{w}_{k+2}\right) \cdot \mathrm{io}\left(c_{j_{2}}, \mathrm{w}_{k+2}, \mathrm{w}_{k+3}\right) \ldots \mathrm{io}\left(c_{j_{l}}, \mathrm{w}_{k+l}, \mathrm{w}_{k+l+1}\right)$;
- $\operatorname{tr}_{2}=\mathrm{io}\left(c_{p_{1}}, \mathrm{w}_{k+1}, \mathrm{w}_{k+l+2}\right) \cdot \mathrm{io}\left(c_{p_{2}}, \mathrm{w}_{k+l+2}, \mathrm{w}_{k+l+3}\right) \ldots \mathrm{io}\left(c_{p_{m}}, \mathrm{w}_{k+l+m}, \mathrm{w}_{k+l+m+1}\right)$.
and $\sigma_{P}$ is uniquely defined as expected from our semantics, as $P$ is deterministic. We have that $\left(\operatorname{tr}, \sigma_{P}\right) \in \operatorname{trace}_{\mathrm{fwd}}(P)$ as the transition function fully captures input filtering and output of terms for protocols in $\mathcal{C}_{\mathrm{pp}}$. We can now define $\mathrm{w}=\mathrm{w}_{k+l+1}$ and $\mathrm{w}^{\prime}=\mathrm{w}_{k+l+m+1}$. The test is $\sigma_{P}$-guarded (the index $k$ associated to the stack symbol (fork, $k$ ) is indeed strictly positive), $\sigma_{P}$-valid (since the last transition from $q_{2}$ to $q_{\mathrm{f}}$ requires the stack to be identical to the stack before reading $c_{\text {test }}$ ), and pulled-up in ( $\operatorname{tr}, \sigma_{P}$ ) (since the fork tiles allow us to control the first time the top-level random seed of $\mathrm{w} \sigma_{P}$ appears in the frame).

We know that $u=u_{0} c_{\text {fork }}^{i_{0}} u_{1} c_{\text {test }} u_{2} c_{\text {end }} \notin \mathcal{L}\left(\mathcal{A}_{\text {GUARDED }}^{Q}\right)$, and we may assume w.l.o.g. that $u_{0} c_{i_{0}} u_{1}$ and $u_{0} c_{i_{0}} u_{2}$ are both in $\mathcal{L}\left(\mathcal{A}_{\text {GUarded }}^{Q}\right)$. Indeed, otherwise this means that there exists no frame $\sigma_{Q}$ such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in \operatorname{trace} \mathrm{e}_{\text {fwd }}(Q)$, and thus GUARDED $P_{P}$ fails, and the result holds. From now on, we assume that there exists $\sigma_{Q}$ such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in$ $\operatorname{trace}_{f w d}(Q)$.

Now, let $q \xrightarrow{c ; \alpha / \beta} q^{\prime}$ be the first failing transition in the run of $u$ in $\mathcal{A}_{\text {GUARDED }}^{Q}$. We distinguish several cases:

1. Case $q=q_{0}$ and $q^{\prime}=q_{1}$. Since we have already assume that $u_{0} c_{i_{0}} u_{1}$ is in $\mathcal{L}\left(\mathcal{A}_{\text {GUARDED }}^{Q}\right)$, this means that the required transition does not exist because $\left\|v_{i}^{j}\right\|=0$. In such a case, the test $\mathrm{w}=\mathrm{w}^{\prime}$ (even if it was $\sigma_{Q}$-valid and $\sigma_{Q}$-guarded) can not be a pulled-up one in $\left(\operatorname{tr}, \sigma_{Q}\right)$. Thus the condition GUARDED $P_{P}$ fails.
2. Case $q=q_{1}$ and $q^{\prime}=q_{1}$. In such a case, this means that a fork tile cannot be unstacked, meaning that the corresponding test (even if it was $\sigma_{Q}$-valid and $\sigma_{Q}$-guarded) will not be pulled-up in ( $\operatorname{tr}, \sigma_{Q}$ ), and GuARDED ${ }_{P}$ is false.
3. Case $q=q_{1}$ and $q^{\prime}=q_{2}$. In such a case, the problem occurs due to the fact that the fork tile is not at the top of the stack upon becoming test. The corresponding test $\mathrm{w}=\mathrm{w}^{\prime}$ will not be $\sigma_{Q}$-valid since $\mathrm{w} \sigma_{Q}$ will contain a random seed that has been generated after the "forking point", and thus this random seed can not occur in w' $\sigma_{Q}$. Thus, the condition $\operatorname{GuARDED}_{P}$ fails.
4. Case $q=q_{2}$ and $q^{\prime}=q_{\mathrm{f}}$. In such a case, the test tile is not at the top of the stack upon reading the last letter of the word. The test is not $\sigma_{Q}$-valid. The stack at this point, without the test tile, is not identical to the stack before the fork tile turning test, making $\operatorname{GUARDED}_{Q}$ fail.

Hence $\operatorname{GuARDED}_{Q}$ fails as soon as $u \notin \mathcal{L}\left(\mathcal{A}_{\text {Guarded }}^{Q}\right)$.
$(\Leftarrow)$ If $P$ and $Q$ do not satisfy conditions $\operatorname{GuARDED}_{P}\left(\right.$ or $\left.\operatorname{GUARDED}_{Q}\right)$, i.e. there exists a trace $\left(\operatorname{tr}, \sigma_{P}\right) \in$ $\operatorname{trace}_{\mathrm{fwd}}(P)$ such that:

1. either there exists no $\sigma_{Q}$ such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in \operatorname{trace} \mathrm{e}_{\mathrm{fwd}}(Q)$;
2. or (such a $\sigma_{Q}$ exists) and there exists $\mathrm{w}, \mathrm{w}^{\prime} \in \operatorname{dom}\left(\sigma_{P}\right)$ such that the test $\mathrm{w}=\mathrm{w}^{\prime}$ is $\sigma_{P}$-guarded and $\sigma_{P}$-valid, and pulled-up in ( $\mathrm{tr}, \sigma_{P}$ ), and

- either $\mathrm{w}=\mathrm{w}^{\prime}$ is not $\sigma_{Q^{-}}$-valid,
- or $\mathrm{w}=\mathrm{w}^{\prime}$ is not $\sigma_{Q}$-guarded,
- or $w=w^{\prime}$ is not pulled-up in $\left(\operatorname{tr}, \sigma_{Q}\right)$.

We consider such a trace of minimal length $\ell$.
In the first case, thanks to the minimality, we have that $\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}_{\ell}\right)=\operatorname{tr}$. From tr we build a word $u \in \mathcal{L}\left(\mathcal{A}_{\text {Guarded }}^{P}\right)$ by extracting the channels that occur in $\operatorname{tr}$ keeping the order. Since there does not exist $\sigma_{Q}$ such that $\left(\operatorname{tr}, \sigma_{Q}\right) \in$ $\operatorname{trace}_{\mathrm{fwd}}(Q)$, and the transition function $\delta$ of the automaton fully captures input filtering and output of terms for protocols in $\mathcal{C}_{\mathrm{pp}}$, we have that $u \notin \mathcal{L}\left(\mathcal{A}_{\text {GUARDED }}^{Q}\right)$.

In the second case, thanks to minimality, we have that tr is actually made up of all the actions that occur in seq $\mathrm{q}_{\mathrm{tr}}(\mathrm{w})$ and $\operatorname{seq}_{t r}\left(\mathrm{w}^{\prime}\right)$. These two sequences have a maximal common prefix pref that is not empty. Actually, we have that:

$$
\text { pref }=\mathrm{io}\left(c_{i_{1}}, \text { start }, \mathrm{w}_{1}\right) \cdot \mathrm{io}\left(c_{i_{2}}, \mathrm{w}_{1}, \mathrm{w}_{2}\right) \ldots \text { io }\left(c_{i_{p}}, \mathrm{w}_{p-1}, \mathrm{w}_{p}\right) \text { for some } p \geq 1
$$

From tr, we build a word $u=c_{i_{1}} c_{i_{2}} \ldots c_{i_{p-1}} c_{\text {fork }}^{i_{p}} u_{1} c_{\text {test }} u_{2} c_{\text {end }} \in \mathcal{L}\left(\mathcal{A}_{\text {GUARDED }}^{P}\right)$ as follows:

- $u_{1}$ is obtained by extracting the channels that occur in $\operatorname{seq}_{\mathrm{tr}}(\mathrm{w})$ after the prefix $c_{i_{1}} c_{i_{2}} \ldots c_{i_{p-1}} c_{i_{p}}$; and
- $u_{2}$ is obtained by extracting the channels that occur in $\operatorname{seq}_{\mathrm{tr}}\left(\mathrm{w}^{\prime}\right)$ after the prefix $c_{i_{1}} c_{i_{2}} \ldots c_{i_{p-1}} c_{i_{p}}$.

As the transition function $\delta$ fully captures input filtering and output of terms for protocols in $\mathcal{C}_{\mathrm{pp}}$, and since $\mathrm{w}=\mathrm{w}^{\prime}$ is a test that is $\sigma_{P}$-guarded, $\sigma_{P}$-valid and pulled-up in $\left(\operatorname{tr}, \sigma_{P}\right)$, we get that $u \in \mathcal{L}\left(\mathcal{A}_{\text {GUARDED }}^{P}\right)$. What remains to show is that $u \notin \mathcal{L}\left(\mathcal{A}_{\text {Guarded }}^{Q}\right)$. We distinguish two cases:

- Case $\mathrm{w}=\mathrm{w}^{\prime}$ is not $\sigma_{Q^{-}}$-valid. In such a case, even if after reading the first part of $u$, i.e. $c_{i_{1}} c_{i_{2}} \ldots c_{i_{p-1}} c_{\text {fork }}^{i_{p}} u_{1} c_{\text {test }}$, we reach $q_{2}$, then we will fail to read the remaining of the word to end in $q_{\mathrm{f}}$.
- Case $\mathrm{w}=\mathrm{w}^{\prime}$ is $\sigma_{Q}$-valid but $\mathrm{w}=\mathrm{w}^{\prime}$ is not $\sigma_{Q}$-guarded. In such a case, this means that $\mathrm{w} \sigma_{Q}$ is a constant, and the run will stop in $q_{0}$ after reading $c_{i_{1}} c_{i_{2}} \ldots c_{i_{p-1}}$. This comes from the fact that it is not possible to go from $q_{0}$ to $q_{1}$ adding a tile (fork ${ }_{i}^{j}, k$ ) with $k=0$.
- Case $\mathrm{w}=\mathrm{w}^{\prime}$ is $\sigma_{Q}$-valid, $\sigma_{Q}$-guarded, but not pulled-up in $\left(\mathrm{tr}, \sigma_{Q}\right)$. The fact that the test is $\sigma_{Q}$-valid but not pulled-up means that the run will stop in $q_{1}$ after reading because of the presence of a tile (fork ${ }_{i}^{j}, k$ ) in the stack that can not go down anymore.

Hence $u$ cannot belong to $\mathcal{L}\left(\mathcal{A}_{\text {GUARDED }}^{Q}\right)$. This allows us to conclude.

Titre : Analyse automatique de propriétés d'équivalence pour les protocoles cryptographiques
Mots-clefs : sécurité, vérification, protocoles, équivalence, décidabilité

Résumé : À mesure que le nombre d'objets capables de communiquer croît, le besoin de sécuriser leurs interactions également. La conception des protocoles cryptographiques nécessaires pour cela est une tâche notoirement complexe et fréquemment sujette aux erreurs humaines. La vérification formelle de protocoles entend offrir des méthodes automatiques et exactes pour s'assurer de leur sécurité.

Nous nous intéressons en particulier aux méthodes de vérification automatique des propriétés d'équivalence pour de tels protocoles dans le modèle symbolique et pour un nombre non borné de sessions. Les propriétés d'équivalence sont naturellement employées pour s'assurer, par exemple, de l'anonymat du vote électronique ou de la non-traçabilité des passeports électroniques.

Parce que la vérification de propriétés d'équivalence est un problème complexe, nous proposons dans un premier temps deux méthodes pour en simplifier la vérification : tout d'abord une méthode pour supprimer l'utilisation des nonces dans un protocole tout en préservant la correction de la vérification automatique; puis nous démontrons un résultat de typage qui permet de restreindre l'espace de recherche d'attaques sans pour autant affecter le pouvoir de l'attaquant.

Dans un second temps nous exposons trois classes de protocoles pour lesquelles la vérification de l'équivalence dans le modèle symbolique est décidable. Ces classes bénéficient des méthodes de simplification présentées plus tôt et permettent d'étudier automatiquement des protocoles taggués, avec ou sans nonces, ou encore des protocoles ping-pong.

Title : Automated analysis of equivalence properties for cryptographic protocols
Keywords : security, verification, protocols, equivalence, decidability

#### Abstract

As the number of devices able to communicate grows, so does the need to secure their interactions. The design of cryptographic protocols is a difficult task and prone to human errors. Formal verification of such protocols offers a way to automatically and exactly prove their security.

In particular, we focus on automated verification methods to prove the equivalence of cryptographic protocols for a unbounded number of sessions. This kind of property naturally arises when dealing with the anonymity of electronic voting or the untracability of electronic passports.

Because the verification of equivalence properties is a

complex issue, we first propose two methods to simplify it: first we design a transformation on protocols to delete any nonce while maintaining the soundness of equivalence checking; then we prove a typing result which decreases the search space for attacks without affecting the power of the attacker.

Finally, we describe three classes of protocols for which equivalence is decidable in the symbolic model. These classes benefit from the simplication results stated earlier and enable us to automatically analyse tagged protocols with or without nonces, as well as ping-pong protocols.

[^0]:    ${ }^{1}$ i.e. there does not exist $\theta$ such that $u_{i}^{j_{1}} \theta=u_{i}^{j_{2}} \theta$.
