Caractérisation Phénotypique et Fonctionnelle des trois Sous Populations de Monocytes dans le Cadre de l'Obésité chez l'Homme

Par Estelle Pécheux Devêvre

Thèse de doctorat

Dirigée par le Prof. I. Cremer et le Dr. C. Poitou Bernert

Présentée et soutenue publiquement le 30/11/2015

Devant un jury composé de :

Prof. F. Berenbaum Dr. S. Ledoux Dr. A. Lehuen Dr. E. Gautier Dr. L. Yvan-Charvet Prof. I. Cremer Dr. C. Poitou Bernert

(PU-PH)	Président
(MCU-PH)	Rapporteur
(DR)	Rapporteur
(CR)	Examinateur
(DR)	Examinateur
(PU)	Directeur
(MCU-PU)	Directeur

REMERCIEMENTS

J'adresse mes plus sincères remerciements :

à Isabelle Cremer et Christine Poitou pour leur encadrement rigoureux et leur patience ;

à Martine Lelièvre-Pégorier et Catherine Fridman pour avoir soutenu mon projet de thèse ;

à Hélène Fohrer-Ting et Christophe Klein pour leur soutien et leur compréhension ;

à l'ensemble des collègues du Centre de Recherche des Cordeliers et de la Pitié-Salpêtrière ;

à ma famille, et plus particulièrement à Louis et Olivier.

RESUME

Les monocytes détectent des signaux métaboliques circulants qu'ils traduisent en signaux immunologiques. ils infiltrent les tissus inflamés et sont également les précurseurs des macrophages. Dans l'obésité, la fréquence, le nombre, le phénotype et la fonctionnalité des sous populations de monocytes (CD14⁺⁺CD16⁻ [CM], CD14⁺⁺CD16⁺ [IM] et CD14⁺CD16⁺⁺ [NCM]) sont spécifiquement modulés. Le phénotype des monocytes est pro-inflammatoire avec une plus forte réponse à la stimulation de TLR4 et de TLR8. Nos travaux suggèrent une capacité migratoire accrue des CM et des IM. La comparaison du transcriptome des sous populations chez des sujets obèses et des témoins, révèle une signature spécifique de chaque sous population montrant un plus fort impact de l'obésité sur les CM. Ils soutiendraient l'inflammation en modulant des gènes impliqués dans la signalisation cellulaire. Ils migreraient avec les IM vers les tissus inflamés. Les NCM resteraient plus longtemps dans la circulation où leur fonction de « patrouilleurs » serait accrue. Les gènes les plus modulés par les CM et les IM, respectivement Clusterine et CDGSH iron sulfur domain 1 sont des ponts entre la réponse immunitaire, le métabolisme et la réponse au stress. L'étude des « tops » gènes dont l'expression est la plus fortement modulée et des fonctions les plus probablement modulées révèle que le métabolisme des monocytes serait modifié dans l'obésité. Ce travail ouvre des perspectives concernant : 1) une éventuelle composante auto-immune de l'inflammation de bas grade et 2) des relations entre des modifications du métabolisme des monocytes et leur fonctionnalité.

PRRs : Récepteurs de reconnaissance de motifs moléculaires conservés
PSCGL-1 : Ligand de la sélectine P
RIN : Valeur d'intégrité de l'ARN
ROS : Dérivés réactifs de l'oxygène
IRS-1 ou 2 : Substrat 1 ou 2 du récepteur de l'insuline
SP : Substance P
MetS : Syndrome métablique
Th1 : Lymphocytes T CD4 auxiliaires Th1
Th17 : Lymphocytes T CD4 auxiliaires Th17
Th2 : Lymphocytes T CD4 auxiliaires Th2
TLR : Récepteur Toll Like
TNF-α : « Tumor necrosis factor »-α
Treg : Lymphocyte T CD4 régulateur

I. INTRODUCTION

L'organisation mondiale pour la santé (OMS) estime que chaque année l'obésité est responsable de 3,4 millions de décès. Caractérisée par un indice de masse corporel (IMC) supérieur ou égal à 30 kg/m², ce phénomène est en augmentation constante depuis les années 1980 pour atteindre 13% de la population mondiale en 2013 (1). Les derniers chiffres de projection de l'OMS communiqués au congrès européen de Prague en mai 2015 sont alarmants puisqu'il est estimé que dans tous les pays européens, l'obésité aura augmenté de façon majeure avec par exemple en France, une proportion de 25% d'hommes et 29% de femmes en obésité en 2030. Des études menées aux Etats-Unis suggèrent que si l'augmentation de l'obésité n'était pas enrayée cela conduirait au recul de l'espérance de vie (2).

L'obésité se définit médicalement comme une augmentation de la masse grasse entraînant des conséquences sur le bien être physique, psychologique et social. L'obésité humaine témoigne d'une mise en échec du système de régulation des réserves énergétiques par des facteurs externes (modes de vie, environnement) et/ou internes (psychologiques ou biologiques). Elle est considérée comme une maladie chronique et évolutive (3). En effet, l'obésité est impliquée dans des modifications métaboliques comme l'hyperglycémie et les dyslipidémies qui conduisent à des complications cliniques parmi lesquelles nous pouvons citer le diabète de type II, l'athérosclérose et les maladies cardiovasculaires, la maladie du foie gras non alcoolique (Non-Alcoholic Fatty Liver Disease, NAFLD), les pathologies inflammatoires articulaires, des problèmes respiratoires et enfin certains cancers (4) (5) (6). Concernant les complications métaboliques, l'impact de l'obésité sur le risque de diabète de type II est majeur : 75% des patients diabétiques de type 2 sont obèses. Pour une valeur d'IMC supérieure ou égale à 30 comparée à un IMC < 30, le risque de diabète de type II est multiplié par 10 chez la femme et 8 chez l'homme. Sont également facteurs de risque de diabète de type II, le gain de poids à l'âge adulte, l'adiposité abdominale, la durée de l'obésité, l'âge et les antécédents familiaux de diabète de type II (3). Les dyslipidémies les plus fréquentes dans l'obésité sont l'augmentation des triglycérides et la diminution du cholestérol-HDL (HDL-c), deux facteurs augmentant le risque de maladies cardivasculaires (7). Il existe une relation étroite entre l'obésité, le développement de la résistance à l'insuline, les dyslipidémies et le NAFLD. A la fois un IMC excessif et l'obésité viscérale sont des facteurs de risque reconnus de NAFLD (8).

Dans la majorité des cas, l'augmentation excessive du tissu adipeux est due à une

incapacité à faire face à un excès d'apport alimentaire et à une insuffisance des dépenses énergétiques. Ce déséquilibre peut être accentué par une augmentation des capacités de stockage. Il y a quatre acteurs physiopathologiques intervenant dans l'obésité : l'alimentation, les dépenses énergétiques, le tissu adipeux et le dialogue entre les organes impliqués dans le contrôle du bilan d'énergie. Ces dernières décennies, la recherche d'un mécanisme commun à la base des pathologies associées à l'obésité et au surpoids ont mis en avant une relation étroite entre l'excès de nutriments et des perturbations de l'équilibre des médiateurs cellulaires et moléculaires de l'immunité et plus particulièrement de l'inflammation (5). L'obésité est donc maintenant reconnue comme une maladie inflammatoire de basgrade et chronique (9) qui de part ce caractère favorise le développement des complications métaboliques et cardiovasculaires (10) (11).

D'un extrême à l'autre, les situations cliniques de l'obésité sont très diverses puisqu'il existe des formes d'obésité purement biologiques, généralement génétiques, et des formes purement comportementales. La réalité clinique est celle d'un continuum. Les stratégies thérapeutiques sont donc elles aussi très diverses et se construisent au cas par cas. Mais dans tous les cas l'objectif est d'aider le patient à perdre du poids et ainsi limiter les complications métaboliques (7). Parmi les traitements de l'obésité, certains consistent en une modification du mode vie par un changement de régime alimentaire et une augmentation de l'activité physique, d'autres sont médicamenteux ou encore chirurgicaux. Ces traitements sont le plus souvent prescrits simultanément (revue dans 12). La chirurgie bariatrique modifie l'anatomie de l'appareil digestif afin de conduire à une restriction de l'absorption des aliments. Cette chirurgie est une thérapie efficace dans la durée (13) qui conduit à l'amélioration de l'état inflammatoire des patients (14) (15) (16) (17) (18) et des complications de l'obésité (13) (15) (16) (17) (19).

Parce que l'inflammation, qu'elle soit systémique ou tissulaire, est au cœur des complications de l'obésité il est important de mieux la comprendre afin d'identifier de nouvelles thérapies visant à améliorer l'état inflammatoire des patients sur le long terme. Ces nouvelles thérapies pourraient être utilisées soit en complément d'une chirurgie bariatrique ou bien comme une alternative lorsque la chirurgie n'est pas envisageable.

A. Obésité et inflammation bas grade

L'inflammation est une réponse coordonnée de l'organisme à un signal de danger qui a pour vocation de revenir à son état basal une fois le danger écarté. La réponse inflammatoire existant dans l'obésité est comparable à une réponse inflammatoire classique. Elle est par conséquent caractérisée par une augmentation systémique des marqueurs moléculaires de l'inflammation, par une activation des cellules mononuclées circulantes, par le recrutement de cellules immunitaires activées vers les tissus inflammés et enfin par une réponse réparatrice des tissus. Par contre dans l'obésité, l'inflammation est chronique, créant une activation de bas grade de l'immunité innée et adaptative qui influe sur l'homéostasie métabolique dans la durée. Dans l'obésité, co-existent une inflammation systémique et une inflammation tissulaire, retrouvée au niveau du tissu adipeux, du foie et des muscles, du pancréas, de l'intestin et de l'hypothalamus (figure 1).

1. L'inflammation systémique

a. Les marqueurs moléculaires

L'inflammation systémique se manifeste par une augmentation modérée mais chronique dans la circulation de nombreux marqueurs de l'inflammation parmi lesquels les protéines de la phase aigüe (la protéine C réactive [CRP] x2,5 (18) et le sérum amyloïde A [SAA] x3,5 (20)), certaines cytokines (IL-6 x1,3 (18), IL-8 x6,7 (18), IL-9 x8,8 (18), IL-10 x68,3 (18), IL-1Ra x25,5 (18) et TNF-α x3,2 (21)) et certaines chimiokines (CCL2 x1,8 (18) et CCL5 x8 (18)), des endotoxines (lipopolysaccharide [LPS] x1,3 (22) ainsi que des neuropeptides (substance P [SP] (23)). Le nombre des molécules contribuant à caractériser l'inflammation bas grade chez l'obèse ne cesse d'augmenter depuis plusieurs années et elles sont répertoriées dans le tableau 1 (3). L'origine précise et la contribution relative notamment du tissu hépatique, du tissu adipeux, et des cellules immuno-inflammatoires circulantes dans la production de molécules inflammatoires circulantes ne sont pas encore complètement caractérisées dans l'obésité humaine. Le foie participe largement d'une part par la synthèse accrue de molécules de la phase aiguë (CRP, SAA, haptoglobine, orosomucoïde, ferritine, etc.) et d'autre part par la sécrétion d'IL-6, de TNF-α, et d'IL-1β (24). Celles-ci sont augmentés par deux mécanismes complémentaires : 1) la stéatose, définie par une accumulation de lipides dans le foie au cours de la prise de poids qui peut avoir un effet

Figure 1. Modification de l'homéostasie immunitaire dans l'obésité et ses conséquences. L'obésité active des réponses inflammatoires dans le tissu adipeux qui se propagent dans le foie, les muscles du squelette, le pancréas et l'hypothalamus entrainant une résistance à l'insuline systémique. Des modifications fonctionnelles au niveau de l'épithélium intestinal pourraient être la source de ces dérèglements immuno/ métaboliques avec notamment une augmentation de sa perméabilité. inducteur local de la réaction inflammatoire au sein du tissu hépatique, 2) la libération d'acides gras provenant du tissu adipeux *via* la circulation portale (revue dans 25). Parmi ces différents acteurs, le tissu adipeux est considéré comme ayant un rôle central en secrétant des adipokines et des cytokines. Celles ci exercent leurs fonctions dans le tissu adipeux lui même, mais aussi dans les autres organes métaboliques par l'intermédiaire de la circulation. En effet, le tissu adipeux contribue à l'augmentation plasmatique des marqueurs moléculaires de l'inflammation (26).

b. Les cellules immunitaires circulantes

La contribution des cellules immunitaires circulantes est révélée dans de nombreuses études, indiquant que le nombre ou le pourcentage de monocytes, de neutrophiles, de basophiles, d'eosinophiles et de lymphocytes T et B corrèle de façon positive avec l'IMC (27) et avec d'autres phénotypes associés à l'obésité tels que le syndrome métabolique (MetS) et la résistance à l'insuline. Le syndrome métabolique est un ensemble de facteurs de risque qui conduisent au développement des maladies cardiovasculaires et au diabète de type II. Ces facteurs comprennent : l'obésité, l'hypertension artérielle, un taux de triglycéride élevé, un taux de HDL-c bas et une forte glycémie. A la suite d'une thérapie aboutissant à une perte de poids, il est observé une diminution du pourcentage ou de nombre de monocytes, de neutrophiles, des lymphocytes totaux et des lymphocytes T. Enfin le nombre de monocytes corrèle avec l'inflammation du tissu adipeux (27). La modulation des monocytes dans l'obésité fera l'objet du dernier chapitre de l'introduction.

Les granulocytes

Les neutrophiles représentent la majorité des cellules immunitaires circulantes (50-70%) (27), ils interviennent rapidement dans la réponse immunitaire innée, ainsi l'activation potentielle des neutrophiles par l'obésité pourrait être fondamentale. De plus, il est maintenant démontré que les neutrophiles infiltrent le tissu adipeux de souris obèses, par conséquent il est important d'étudier l'état d'activation des neutrophiles circulants dans l'obésité. En effet, ils contribuent potentiellement aux complications métaboliques (28) (29) (30). Le nombre de neutrophiles circulants corrèle avec l'IMC dans la plupart des études (31), il est augmenté chez des patients présentant un MetS par rapport à des sujets témoins sans MetS (31) (32) et corrèle avec les marqueurs de la résistance à l'insuline (31) (32) et ceux de l'inflammation

Tableau 1. Modifications systémiques de marqueurs inflammatoires ou d'adhésions circulants au cours de l'obésité et de la perte de poids. Adapté de Clément et al. (Physiologie et physiopathologie du tissu adipeux, Chapitre : Inflammation du tissu adipeux au cours de l'obésité, Springer Paris, 2013)

systémique (CRP élevée) (32). Des modifications du mode de vie (régime alimentaire hypocalorique et/ou activité physique accrue) et la chirurgie bariatrique conduisant à une perte de poids chez des sujets obèses diminuent le nombre de neutrophiles circulant de 11,7% (31). De nombreuses études montrent que l'activité de certaines fonctions des neutrophiles est modulée par l'obésité. Par exemple les neutrophiles de patients sévèrement obèses (IMC > 40 kg/m²) présentent une plus faible expression de CD62L (sélectine-L), une molécule responsable de l'adhésion à la surface de l'endothélium. Cette perte est corrigée six mois après une perte de poids par chirurgie bariatrique (14). A l'inverse l'expression de CD66b, qui est considéré comme un marqueur d'activation des neutrophiles, est plus élevée chez des patients sévèrement obèses comparés à des témoins (33). En accord avec l'idée d'une activation accrue des neutrophiles dans l'obésité, les travaux de *Brandau et al.* (34) montrent *in vitro* que les neutrophiles de sujets obèses ou en surpoids produisent plus d'IL-8 après stimulation par LPS que des sujets minces. De plus, l'adiponectine (qui est diminuée dans le sérum des patients obèses) inhibe *in vitro* la production d'IL-8 par les neutrophiles et un taux élévé d'adiponectine dans le sérum corrèle avec une faible production d'IL-8 *in vitro*. Des études fonctionnelles ont montré que les neutrophiles de patients sévèrement obèses (IMC > 40 kg/m²) ont une capacité réduite à phagocyter *Echerichia Coli* et une production significativement réduite des dérivés réactifs de l'oxygène (ROS) après stimulation par la PMA (phorbol myristate acétate), avec cependant une production basale de ROS significativement plus élevée chez les patients obèses présentent une réponse accrue à une faible dose d'endotoxine (LPS), concomitante avec une diminution de l'apopotose et l'augmentation de leur durée de vie. Ce qui pourrait expliquer l'augmentation du nombre de neutrophiles par une durée de vie plus élevée et ceci tout particulièrement à la lumière de l'endotoxémie qui est suspectée dans l'obésité (36) (37) (38).

L'obésité est de plus en plus associée à des problèmes allergiques et respiratoires (39), ce qui conduit naturellement à chercher des associations avec les basophiles et les éosinophiles. Les basophiles sont les leucocytes les plus rares dans la circulation (0,4%) (27) mais ils sont des modulateurs de la réponse immunitaire et sont les effecteurs de l'inflammation allergique. Certaines études montrent une corrélation positive entre l'IMC et le nombre de basophiles (40) (41) (42) alors qu'une étude chez des adolescentes montre une corrélation négative (43). La leptine, une adipokine augmentée dans le sérum de patients obèses, en intéragissant avec son récepteur à la surface des basophiles, est responsable d'une augmentation de leur capacité à migrer, à dégranuler et à synthétiser de cytokines. La leptine augmente aussi leur survie et leur activation, révélée par une up-régulation de CD63. Ceci suggère un effet de l'hyper-leptinémie sur l'état d'activation des basophiles circulants dans l'obésité (44). Les éosinophiles représentent de 1-4% (27) des cellules immunitaires circulantes et comme les basophiles ils interviennent dans la réponse allergique. Il existe des études contradictoires concernant l'existence ou non d'une corrélation entre le nombre d'éosinophiles circulants et l'obésité (revue dans 27). Néanmoins, comme pour les basophiles, la leptine augmente les fonctions et la survie des éosinophiles, ce qui ouvre des voies en ce qui concerne la compréhension des mécanismes reliant l'obésité et l'exacerbation de l'asthme (45).

Les lymphocytes T et B

Les lymphocytes qui représentent de 20-40% (27) des cellules immunitaires circulantes sont des cellules de l'immunité adaptative. On distingue deux populations qui répondent spécifiquement aux antigènes grâce à leurs récepteurs hautement spécifiques : le BCR pour les lymphocytes B et le TCR pour les lymphocytes T. Le nombre de lymphocytes totaux corrèle avec l'IMC dans de nombreuses études (31) (41) (42) (46), même après un ajustement de l'age, du sexe (41) (46), du statut de fumeur (46) ou de l'origine ethnique (41). De plus le nombre total de lymphocytes corrèle avec la prévalence du MetS (42) et avec différents facteurs du MetS pris individuellement ou avec au taux d'insuline à jeun élevé (31) (47). Une perte de poids induite par une chirurgie bariatrique est associée à une dimunition du nombre de lymphocytes totaux dans la circulation (31).

Les lymphocytes T CD8 cytotoxiques (CD8) qui représentent de 19-48% (48) des lymphocytes totaux sont diminués en nombre absolu et en pourcentage dans la circulation avec l'obésité (49), ainsi que la proportion relative de CD8 par rapport aux lymphocytes totaux (50). Malgré toutes ces observations cohérentes entre elles aucun changement n'est observé en ce qui concerne le nombre absolu ou la proportion de CD8 dans les lymphocytes totaux après une perte de poids induite par une chirurgie bariatrique ou un régime pauvre en calories (49). Ce qui suggère que leur rôle dans les complications de l'obésité n'est pas critique. A l'opposé de très nombreuses publications ont montré que le nombre absolu de lymphocytes T auxiliaires CD4 (CD4), qui représente de 28-58% (48) des lymphocytes totaux, était plus élevé chez des patients obèses (51) (52) (49) (53) et sévèrement obèses (IMC > 40 kg/m2) (41) (54) (50) (53) comparé à des sujets minces. Les CD4 participent à la coordination et à la régulation de la réponse immunitaire. Parmi les CD4 on distingue notamment les CD4 Th1 (Th1) des CD4 Th2 (Th2). Les Th1 sont pro-inflammatoires et sécrètent préférentiellement l'IFN-y et l'IL-12 alors que les Th2 sont anti-inflammatoires, ils sécrètent les cytokines IL-4, IL-5, IL-9, IL-10 et IL-13 et favorisent la réponse humorale. Le ratio Th1/Th2, utilisé comme index de polarisation des lymphocytes d'un phénotype pro- vers un phénotype anti-inflammatoire, a été rapporté comme étant plus élevé chez des sujets obèses comparé à celui de sujets non obèses. Ce ratio corrèle aussi avec l'IMC, le degré de résistance à l'insuline mesuré par le modèle d'estimation de la résistance à l'insuline (HOMA-IR) (55). Une perte de poids induite par un régime hypocalorique suivit d'une chirurgie bariatrique ou par un régime seul entraine une diminution du ratio Th1/Th2 (56). Les lymphocytes T CD4 régulateurs (Treg) sont des cellules au caractère anti-inflammatoire connues pour leur rôle dans la tolérance immunitaire et dont la prolifération est controlée par la leptine (57). Leur description dans la circulation de patients obèses ne sont pas nombreuses et présentent des résultats contradictoires (58) que nous ne décrirons donc pas ici.

Il existe aussi des cellules T invariantes associées aux muqueuses (MAIT) qui reconnaissent des ligands bactériens. Elles sont présentes dans la circulation où elles représentent de 1-10% (59) des lymphocytes T et sont augmentées dans les muqueuses et les tissus inflammés. Leur fréquence est diminuée dans la circulation de patients diabétiques et/ou sévèrement obèses jusqu'à parfois devenir indétectables. Elles présentent un phénotype associé à la production de cytokines de type Th1 et Th17 (IL-17, IL-21 et IL-22) dans la circulation. Trois mois après une chirurgie bariatrique la fréquence des MAIT dans la circulation augmente et leur production de cytokines diminue (60). Les MAIT sont donc modulés chez des patients diabétiques et/ou sévèrement obèses ce qui suggère leur implication dans le développement de ces pathologies.

Les lymphocytes B qui interviennent dans la réponse humorale, représentent 7-23% des lymphocytes, et comme les Tregs, ils restent peu étudiés dans la circulation de patients obèses. Néanmoins leur nombre et/ou leur pourcentage est rapporté comme étant augmenté dans la circulation de patients obèses comparé à des sujets minces (51) (61) (62) et corrèlent avec l'IMC (51). Chez des hommes, tous vétérants de l'armée américaine et de diverses origines ethniques, le nombre de lymphocyte B a été corrélé avec un les facteurs de risque du MetS (obesité, hypertension, fort taux de triglycérides et faible taux d'HDL-c) (62). Par contre, une autre étude montre, quant à elle chez des étudiantes originaires d'Arabie Saoudite, que le nombre de lymphocytes B et leur pourcentage parmi les leucocytes circulants ne corrèlent pas avec l'IMC chez des sujets obèses (52).

2. L'Inflammation tissulaire

a. Le tissu adipeux

Il reste difficile d'établir clairement le ou les événements responsables de l'inflammation dans le tissu adipeux. Les adipocytes eux-mêmes sont capables de produire de nombreuses biomolécules pro- ou anti-inflammatoires. L'accroissement de la taille des adipocytes, qui caractérise l'état obèse, altère leur profil de sécrétion et induit un statut proinflammatoire, sans que les signaux impliqués soient clairement définis. La répartition caractéristique des macrophages en couronne autour d'adipocytes présentant des signes de mort cellulaire (63) suggère l'intervention de facteurs attractants spécifiques. Des signaux exogènes comme les acides gras ou le LPS d'origine bactérienne induisent une réponse inflammatoire en activant leur récepteur Toll-like (TLR)-4 exprimé à la surface des adipocytes et des macrophages et les voies de signalisation intracellulaires associées, principalement la voie NF κ B (64). Localement, les adipocytes inflammatoires, dont l'activité lipolytique est élevée, libèrent des acides gras qui stimulent la voie NF κ B dans les macrophages, contribuant ainsi à une boucle paracrine délétère entre les deux types cellulaires. Parmi d'autres facteurs, l'hypoxie tissulaire, cause classique d'attraction des macrophages dans certaines tumeurs et dans la plaque d'athérome, pourrait aussi intervenir dans le déclenchement de l'inflammation du tissu adipeux et des autres tissus chez les sujets obèses (65). Le stress du réticulum endoplasmique et le stress oxydant seraient également susceptibles d'intervenir dans l'inflammation locale.

Le rôle du tissu adipeux dans la production de molécules inflammatoires circulantes est central puisqu'un des aspects fondamentaux de l'obésité est l'hypertrophie des adipocytes qui est associée à un profil sécrétoire pro-inflammatoire (Figure 1). Si l'accumulation globale de dépôt de tissu adipeux dans tout l'organisme contribue aux complications de l'obésité, la distribution des adipocytes hypertrophiés dans l'organisme est fondamentale. Notre équipe a montré que l'abondance des macrophages infiltrant le tissu adipeux était deux fois plus importante dans le tissu adipeux visceral que dans le sous cutané. De plus il existe une association entre l'augmentation des macrophages dans le tissu adipeux viscéral et la stéatose hépatique non alcoolique et/ou les lésions fribro/inflammatoires du foie (66). L'hypertrophie des adipocytes conduit à terme à leur mort et au relargage de leur contenu dans l'espace extracellulaire. Ce phénomène, par la libération d'acides gras ou d'autres facteurs, déclencherait une réponse inflammatoire des cellules immunitaires environnantes et plus particulièrement des macrophages (67) (68). D'autres facteurs, tels que l'hypoxie, le stress du réticulum endoplasmique ou la production de chimiokines par les adipocytes hypertrophiés, interviendraient également dans l'activation des cellules immunitaires (69) (70). La sécrétion de cytokines pro-inflammatoires qui en résulte amplifie cet état pathologique en conduisant au recrutement de plus de cellules immunitaires. Ainsi, toutes les populations de cellules immunitaires du tissu adipeux sont augmentées dans l'obésité (71).

Les macrophages

En 2003, deux équipes américaines décrivent l'accumulation de macrophages dans le tissu adipeux de souris obèses de même que chez l'homme en relation avec l'augmentation de l'IMC (70) (72). L'infiltration macrophagique n'est que partiellement réversible avec la perte de poids induite par la chirurgie gastrique (73) (74). Les macrophages se disposent typiquement en couronne autour d'un adipocyte présentant des signes de mort cellulaire (67) (73). Cette disposition est spécifique du tissu adipeux obèse et plus fréquente dans le territoire viscéral. Ces observations suggèrent que les macrophages exercent leur rôle « classique » de phagocytose et d'élimination des adipocytes métaboliquement déficients chez le sujet obèse, en particulier ceux ayant atteint une taille critique provoquant la mort cellulaire. L'injection d'un marqueur spécifique des monocytes chez la souris a permis de montrer que l'obésité induite par un régime riche en graisse dans le modèle murin DIO (Diet Induced Obesity) provoque le recrutement de macrophages de type M1 ayant un phénotype pro-inflammatoire caractérisé par l'expression de CD11c, d'oxides nitriques (NO), de TNF-α et d'IL-6 (75). Ces macrophages sont chargés en gouttelettes lipidiques en accord avec une activité de phagocytose des lipides (67) (76). En l'absence d'obésité, des macrophages « résidents » sont également détectés dans le tissu adipeux. Ils présentent un phénotype anti-inflammatoire de type M2, produisent des médiateurs anti-inflammatoires tels que l'IL-10 et jouent un rôle important dans le maintien de la sensibilité à l'insuline. Leur abondance n'est pas ou peu modifiée dans l'obésité (74) (75). Une étude cinétique dans le modèle DIO suggère une situation plus complexe. En effet, l'apparition et l'accumulation de macrophages de type M1 augmente jusqu'à seize semaines de régime puis diminue au profit de macrophages de type M2, sans que l'on sache s'il s'agit d'un recrutement ou d'une repolarisation in situ des macrophages M1 en macrophages M2 (68). De plus, une troisième population de phénotype intermédiaire M1-M2 a été identifiée dans le tissu adipeux de souris DIO, qui pourrait constituer un groupe de cellules en cours de repolarisation (77). Chez l'homme, ce sont principalement des macrophages de phénotype mixte, intermédiaire entre la polarisation M1 et M2 qui ont été décrits (78) (79). Leur abondance est augmentée en relation avec le degré d'adiposité. Ils favorisent la fibrose du tissu adipeux et la résistance à l'insuline. Dans une population de sujets massivement obèses, notre équipe a observé une augmentation du nombre des cellules positives pour un marqueur de type M1 (CD40), face à un nombre constant de cellules exprimant des marqueurs de type M2 (CD206 et CD163) par rapport à des sujets témoins, suggérant que l'obésité favorise l'accumulation de macrophages de type M1 (74). Une caractérisation plus précise montre que, comme chez la souris, les macrophages en couronne présentent un phénotype orienté M1, alors que les macrophages interstitiels ont un phénotype orienté M2 (80) (81).

Les neutrophiles, les mastocytes et les éosinophiles

Chez la souris DIO, les neutrophiles sont recrutés dans le tissu adipeux dès la première semaine d'un régime riche en graisse. Bien qu'en petit nombre, ils interviennent dans le contrôle de la tolérance au glucose, de la sensibilité à l'insuline et dans le maintien de l'inflammation (82) (30) (28). Les mastocytes qui sécrètent l'IL-6 et l'IFN- γ semblent également jouer un rôle dans les maladies métaboliques (83). Les cellules éosinophiles, quant à elles, participent à la réduction de l'inflammation en favorisant la polarisation de type M2 des macrophages dépendant de la sécrétion d'IL-4 et d'IL-13 (84).

Les cellules NK-T, NK-T invariantes (iNK-T) et NK

Chez la souris, des cellules NKT capables de reconnaître des antigènes glycolipidiques, colonisent également le tissu adipeux dans les premières phases de l'obésité induite par un régime riche en graisse, et cette étape semble être nécessaire à l'infiltration macrophagique. En effet, Ohmura *et al.* (85) ont montré que l'infiltration macrophagique du tissu adipeux et l'intolérance au glucose, observées lorsque des souris sont soumises à un régime riche en graisse, sont respectivement réduites et améliorées chez des souris déficientes en β 2 microglobulin qui ne possèdent pas de cellules NKT comparées à des souris sauvages. De plus, lorsque les souris sauvages sont traitées avec un activateur spécifique des cellules NKT (α -galactosylcéramide) après 13 semaines d'un régime riche en graisse, l'intolérance au glucose, l'infiltration macrophagique du tissu adipeux ainsi que l'expression au niveau des ARN messagers de CCL2 (MCP-1), de CCL5 (RANTES), TNF- α et IFN- γ dans le tissu adipeux sont augmentés.

Les cellules NK-T invariantes (iNK-T) sont des cellules qui reconnaissent des antigènes lipidiques présentés par CD1d. Chez la souris et chez l'homme le tissu adipeux viscéral est enrichi en cellules iNK-T. Ces cellules représentent 15 à 20% des cellules T et produisent l'IL-2 et l'IL-10. Elles induisent un phénotype anti-inflammatoire des macrophages et, par l'intermédiaire de la production d'IL-2, contrôlent le nombre et la prolifération des Tregs dans le tissu adipeux (86).

Les cellules NK sont des sentinelles de l'organisme qui surveillent les tissus à la recherche de cellules infectées, transformées ou stressées. Elles sont équipées de récepteurs qui leur permettent de détecter des cellules pathologiques. Parmi ceux-là, NKp46 (NCR1 chez la souris) est un récepteur impliqué dans le développement du diabète de type I (87). Une étude récente a montré son implication dans les complications métaboliques de l'obésité. En effet, Wensveen et al. (88) ont montré chez la souris obèse DIO que les cellules NK résidentes du tissu adipeux visceral sont des éléments déterminants qui permettent de faire le lien entre le stress du tissu adipeux qui est en hypoxie et dont l'accès aux nutriments est limité (89) (90), l'activation des macrophages et le développement de la résistance à l'insuline. Dans le modèle murin DIO, un régime riche en graisse provoque l'up-régulation du ligand de NC1R à la surface des adipocytes, ce qui entraine l'activation des cellules NK et induit leur prolifération. L'IFN-γ produite par ces cellules en réponse à la signalisation induite par NC1R provoque la polarisation M1 des macrophages. A l'inverse lorsque l'activation des cellules NK est empêchée, la polarisation M1 des macrophages est fortement réduite et la tolérance au glucose ainsi que la sensibilité à l'insuline sont améliorées. Les cellules NK sont donc des éléments clefs de régulation de la polarisation des macrophages en réponse au stress des adipocytes dans l'obésité.

Les lymphocytes T

L'activation des macrophages est modifiée par les lymphocytes T. En effet, les lymphocytes Th1 qui sécrètent l'IFN- γ ainsi que les lymphocytes T auxilliaires CD4 Th17 (Th17) qui sécrètent l'IL-17 augmentent les fonctions pro-inflammatoires des macrophages en induisant la sécrétion d'IL-1, d'IL-6 et de TNF- α . A l'inverse, les lymphocytes antiinflammatoires Th2 qui sécrètent l'IL-4 et l'IL-13 ainsi que les Tregs modifient les fonctions des macrophages en induisant leur différentiation en macrophages de type M2 qui sécrètent IL-10 ou encore en macrophage de type intermédiaire M1-M2 (91) (92). L'étude de la fraction stroma-vasculaire du tissu adipeux chez l'homme a révélé que les lymphocytes représentent 6 ± 0,5% des cellules immunitaires CD45+ et que la majorité d'entre-eux sont des lymphocytes T CD3+ (CD3). Ils sont organisés en grappe autour des adipocytes, quelques CD3+ isolés sont identifiés dans le stroma et très peu dans les capillaires. Les CD4 et les CD8 forment la majorité des CD3. Le nombre de CD3, de CD4 et de CD8 dans le tissu adipeux augmente avec l'IMC et ce nombre est statistiquement plus élevé chez les sujets obèses que chez les sujets minces (93) (94). De plus, le nombre de CD3 dans le tissu adipeux viscéral des patients obèses est plus élevé que dans le tissu adipeux sous cutané avec une augmentation accrue du nombre de CD8 par rapport au nombre CD4 (93). Des expériences de culture d' adipocytes en présence de milieu de culture de lymphocytes du tissu adipeux ont montré que les lymphocytes T du tissu adipeux avaient un effet médié par l'insuline sur l'expression d'enzyme lipogéniques et que cet effet nécessitait l'action de l'IFN-y. A l'inverse, la culture d'apocytes en présence de milieu de culture de macrophages n'a pas montré d'effet comparable (93). Chez la souris non obèse les lymphocytes T représentent environ 10% de la fraction stroma-vasculaire du tissu adipeux, 50% d'entres eux sont des CD3, avec un nombre plus important de CD4 que de CD8 (ratio de 3/1). Environ 50% des CD4 sont des Treg, ce qui est bien plus que dans les autres organes, qu'ils soient lymphoïdes (rates et ganglions) ou non (foie, poumon). De plus, les Treg s'accumulent préférentiellement dans le tissu adipeux viscéral. Concernant le ratio Th1/Th2, les lymphocytes Th1 et Th2 sont en nombres équivalents (95). Chez la souris durant le développement d'une obésité induite le nombre de lymphocytes T augmente ainsi que le ratio CD8/CD4 alors que la proportion de Treg diminue (94) (95) (96) (97). Par un suivi cinétique des populations de cellules immunitaires infiltrant le tissu adipeux dans le modèle murin d'obésité induite par un régime riche en graisse, il a été montré que l'accumulation des CD8 dans le tissu adipeux précède celle des macrophages. De plus la déplétion des CD8 par un traitement à l'aide d'anticorps neutralisants a montré que l'absence de CD8 réduisait l'infiltration des macrophages de type M1 sans affecter les macrophages de type M2. Des expériences de co-cultures de CD8 provenant du tissu adipeux de souris non obèse ou de souris obèses avec des monocytes (en présence de tissu adipeux non obèse) ont montré que les CD8 de tissu adipeux obèse généraient plus de macrophages que ceux de tissu adipeux non obèse. Des expériences de culture in vitro ont également montré que les CD8 de tissu adipeux obèse comparés à ceux de tissu adipeux non obèse sécrétaient plus des chimiokines (C-C motif) ligand MCP-1 (CCL2), MCP-3 (CCL7), RANTES (CCL5) (94) et de protéine-10 inductible par l'INF- y (IP-10). Ces molécules sont connues pour leur capacité à induire la migration des macrophages/monocytes. Des expériences de migration *in vitro* ont confirmé la migration accrue des macrophages en milieu de culture conditionné par les CD8 provenant de tissu adipeux obèse vs non obèse et le traitement du milieu par un anti-CCL2 montre l'importance de cette chimiokine pour la migration des macrophages. Chez la souris la déplétion des CD8 réduit l'inflammation et améliore la résistance à l'insuline (94) mais au côté des CD8, les CD4 interviennent aussi dans les dysfonctionnements métaboliques liés à l'obésité. Dans le tissu adipeux les CD4 sont polarisés Th1 et leur déplétion chez la souris améliore l'inflammation en réduisant l'influx de lymphocytes T et de macrophages et en réduisant la résistance à l'insuline (96). Les Treg du tissu adipeux jouent également un rôle en prévenant l'apparition de la résistance à l'insuline liée à l'obésité. Ceci a été démontré par des expériences de déplétion chez la souris où l'absence de Treg entraînait l'inflammation du tissu adipeux et l'installation de la résistance à l'insuline (98). Des observations similaires ont été faites dans le tissu adipeux humain avec, dans le tissu adipeux visceral, la présence de lymphocytes Th1 douze fois plus nombreux que les Treg Foxp3+. La proportion relative de Th1 par rapport aux Treg Foxp3+ corrèle avec l'IMC. Les Treg Foxp3+ sont le plus souvent à proximité des monocytes et des macrophages ce qui laisse entrevoir une interaction entre ces types cellulaires (95). La dernière souspopulation de lymphocytes impliquée dans la résistance à l'insuline est celle des lymphocytes T CD4 auxiliaires Th17 (Th17). Les CD4 Th17 sont des cellules importantes dans l'inflammation locale par leur sécrétion de cytokines pro-inflammatoires telles que l'IL-17, l'IL-21 et l'IL-22. Chez l'homme, les CD4 Th17 sont augmentés 3 fois dans le tissu adipeux de sujets obèses présentant une résistance à l'insuline par rapport au tissu adipeux de sujets obèses encore sensibles à l'insuline, et 10 fois par rapport au tissu adipeux de sujets non obèses. La concentration en IL-22 et en IL-6 dans le sérum de ces patients est également augmentée. Sachant que les cellules musculaires du squelette et les hépatocytes de sujets obèses expriment les récepteurs de l'IL-17 et de l'IL-22, des expériences de culture in vitro ont été réalisées afin de tester l'effet des ces deux cytokines. Ces expériences ont montré que l'IL-22 et l'IL'17 avaient la capacité à réduire l'absorption du glucose par les cellules musculaires du squelette et à réduire la sensibilité à l'insuline des hépatocytes (99). Les MAIT dont la fréquence est diminuée dans la circulation de patients diabétiques est inversement augmentés dans le tissu adipeux. Ils présentent un phénotype associé à la production de cytokines de type Th1 et Th17 dans la circulation et fortement de type Th17 dans le tissu adipeux. Trois mois après une chirurgie bariatrique, la fréquence des MAIT dans la circulation augmente et leur production de cytokine diminue (60). Les MAIT sont donc modulés chez des patients diabétiques et/ou sévèrement obèses ce qui suggère leur implication dans le développement de ces pathologies.

Les lymphocytes B

Les travaux de *Winer et al.* (100) ont montré que les lymphocytes B sont recrutés dans le tissu adipeux visceral au cours de l'obésité induite par un régime riche en graisse dans le modèle murin DIO. Ils ont également montré que des souris DIO déplétées de leur lymphocytes B à l'aide d'un anticorps anti-CD20 sont protégées des complications de l'obésité, et cela, en dépit d'une prise de poids. L'effet des lymphocytes B sur le métabolisme du glucose est mécanistiquement associé à l'activation pro-inflammatoire des macrophages et des lymphocytes T et à la production d'IgG pathogéniques. Le traitement avec l'anti-CD20 diminue l'intolérance au glucose alors que le transfert d'IgG provenant de souris DIO induit rapidement la résistance à l'insuline et l'intolérance au glucose. Pour compléter ces observations, Winer et al. ont aussi montré que l'obésité humaine associée à la résistance à l'insuline possède un profil spécifique d'auto-anticorps circulants. En effet, en utilisant la technologie ProtoArray comprenant 9000 antigènes, les auto-anticorps ont été dosé dans le sérum de 32 individus minces, en surpoids ou obèses, et identifiés comme resistants ou non à l'insuline. Ils ont mis en évidence 122 IgGs spécifiquement augmentés par la résistance à l'insuline. Les 10 auto-anticorps les plus présents dans le sérum des sujets obèses de sexe masculin sont essentiellement des anticorps dirigés contre des protéines intracellulaires, la plupart d'entres elles étant ubiquitaires. On les retrouve au niveau des cellules immunitaires, du pancréas, du système nerveux, des muscles ou du tissu adipeux. Trois de ces autoanticorps ont été confirmés par western-blot. Les cibles des ces auto-anticorps sont : GOSR1 (golgi SNAP receptor complex member 1, transcript variant 1), BTK (Bruton agammaglobulinemia tyrosine kinase) and GFAP (glial fibrillary acidic protein). Des études expérimentales (101) ont montré que les lymphocytes B de souris obèses sécrètent plus de cytokines pro-inflammatoires (IFN- γ , IL-6 et IL-8) et moins de cytokines anti-inflammatoires (IL-5 et IL-10). De plus, au cours de l'obésité, les lymphocytes B sont 1) directement activés par le biais de l'induction par des lipides des voies de signalisation dépendantes des TLRs, des récepteurs transmembranaires jouant un rôle important dans l'immunité innée et dans l'induction de la réponse inflammatoire, ou 2) indirectement activés par le biais de mécanismes dépendant des lymphocytes T pour produire des (auto)anticorps qui favorisent l'inflammation du tissu adipeux et la résistance à l'insuline. L'ensemble de ces travaux montre l'importance des lymphocytes B et de l'immunité adaptative dans le développement de la résistance à l'insuline associée à l'obésité et suggère de nouvelles modalités diagnostiques et thérapeutiques applicables à cette pathologie.

L'accumulation de toutes ces preuves renforce l'idée d'une implication coordonnée de l'immunité adaptative et de l'immunité innée dans l'inflammation de bas grade qui caractérise le tissu adipeux au cours de l'obésité.

b. Le foie et les muscles

De nombreuses voies de signalisation impliquées dans l'inflammation et le métabolisme sont activées en cas de NAFLD. De la même façon que dans le tissu adipeux la stéatose hépatique non alcoolique est associée à une augmentation des cytokines associée à une polarisation M1/Th1 et une augmentation du nombre de cellules immunitaires infiltrant le foie (102) (103). Les muscles du squelette de personnes obèses ont un phénotype métabolique anormal dans le sens où même si ils sont exposés à un taux de lipides élevé à jeun, le glucose a tendance à être préféré comme substrat pour la production d'ATP conduisant à l'accumulation de lipides dans les muscles (104) (105) et contribue à l'établissement de la résistance à l'insuline (106) (107). TLR4, connu pour être le récepteur du LPS, en plus d'être exprimé à la surface des cellules immunitaires, est aussi exprimé à la surface des hépatocytes et des myocytes (108) (109). Son expression par ces différents types cellulaires suggère que TLR4 n'est pas seulement un récepteur de l'immunité innée mais peut-être aussi un régulateur du métabolisme. En effet, l'activation in vitro de TLR4 avec une faible dose de LPS, comparable à celle de l'endotoxémie métabolique (50 pg/mL) (22), dans des cultures de myocytes humains primaires résulte en une augmentation de l'oxidation du glucose et à une diminution de l'oxidation des acides gras (110). De plus, il existe des preuves d'une inflammation accrue des cellules musculaires du squelette qui s'accompagne d'une production accrue de cytokines. L'inflammation des muscles pourrait être due à un recrutement de macrophages polarisés M1(111) (112).

c. L'intestin

Dans l'intestin, la barrière mucosale, qui sépare le milieu intérieur de la lumière intestinale, est constituée de cellules épithéliales, de cellules immunitaires et d'une couche de mucus. Toutes ces cellules ainsi que leurs produits (*e.g.* mucus, défensines et cytokines) permettent l'absorption des nutriments mais prévient aussi le passage des microbes et des virus. De plus, l'intestin des mammifères renferme environ 10¹⁴ bactéries qui vivent en symbiose avec leur hôte et qui contribuent aussi au maintien de l'homéostasie. Elles influent directement sur le métabolisme et la résistance à l'insuline (113). Dans l'obésité humaine les modifications fonctionnelles de l'intestin sont encore peu étudiées. Pourtant, une étude chez l'homme montre une corrélation positive entre le taux d'endotoxines (LPS) et le développement du diabète de Type II chez des sujets obèses (114). Ce qui pourrait s'expliquer

par une augmentation de la perméabilité de la barrière intestinale induite par l'obésité. De plus, il a été montré chez la souris que l'obésité induite par un régime riche en graisse facilite la translocation des bactéries intestinales et de leurs sous produits comme le LPS par une dégradation des jonctions serrées de l'épithélium intestinal (115) (116). Il est par conséquent possible que des mécanismes comparables à ceux observés chez la souris existent aussi chez l'homme (117) (118). Ainsi, le microbiote intestinal jouerait un rôle prépondérant dans l'installation de l'inflammation par le biais du LPS qui, associé à un régime hypercalorique, pourraient induire au long-terme une endotoxémie métabolique. Celle-ci participerait activement au maintien de l'inflammation de bas grade relative à l'obésité (117) (118). Ceci d'autant plus que le LPS peut interagir avec TLR4 qui est exprimé aussi bien au niveau des cellules immunitaires circulantes et tissulaires, qu'au niveau des adipocytes, des hépatocytes et des myocytes (119) (108) (109). Enfin, des travaux récents, toujours chez l'homme démontrent que l'obésité provoque une inflammation du jéjunum par le biais des lymphocytes T et une résistance à l'insuline des entérocytes, les cellules absorbantes de la muqueuse intestinale (120).

d. Le pancréas

Comme dans le tissu adipeux, les macrophages s'accumulent dans les îlots au cours de l'installation de l'obésité induite par l'alimentation, et ils sont probablement à l'origine de cytokines pro-inflammatoires dont IL1- β qui entravent le fonctionnement des cellules β du pancréas. L'inflammation peut réduire la sécrétion d'insuline et déclencher l'apoptose des cellules β des îlots de Langerhans qui conduit la diminution de la taille des ilots, un événement majeur dans l'installation du diabète de type II (121) (122).

e. L'hypothalamus

Chez la souris et le rat, des expériences de comparaison entre une alimentation riche ou pauvre en graisse, ainsi que des expériences de perfusions intra-cérébroventriculaires de lipides montrent que les acides gras saturés provoquent une activation des voies de signalisation de l'inflammation dans l'hypothalamus qui aboutit à une augmentation de la prise de nourriture et au stockage des nutriments. Avec une alimentation riche en graisse, des métabolites comme les diacylglycérols et les céramides s'accumulent dans l'hypothalamus et provoque des résistances à la leptine et l'insuline au niveau du système nerveux central (123) (124) (125).

3. Les mécanismes de l'inflammation au cours de l'obésité

Les lipides sont des signaux importants de la réponse immunitaire et du contrôle de la régulation du métabolisme. De nombreux mécanismes ont été appréhendés pour comprendre les conséquences de l'interaction entre des signaux lipidiques et des récepteurs de l'immunité innée et des récepteurs nucléaires. Il existe aussi d'autres mécanismes intervenant dans l'inflammation ne faisant pas appel directement aux signaux lipidiques, c'est le cas de l'hypoxie et du stress du reticulum endoplasmique (Figure 2).

a. Les conséquences de la sécrétion des cytokines induite par l'obésité

L'activation des tissus et des cellules immunitaires circulantes déclenche la sécrétion de cytokines, qui peuvent induire des dysfonctionnements métaboliques dont la résistance à l'insuline. Parmi les cytokines pro-inflammatoires, TNF-α est la cytokine la plus étudiée et est toujours associée à la résistance à l'insuline. Par exemple, le TNF- α peut stimuler des sérines kinases dont les kinases inhibitrices du facteur nucléaire kappa (IKK) et les kinases C-Jun Nterminales (JNK) qui entrainent la phosphorylation du substrat 1 du recepteur de l'insuline (IRS-1) (126) (127), modulant ainsi sa capacité à propager les signaux en aval de la voie de signalisation de l'insuline. L'augmentation des acides gras par une alimentation riche en graisse active l'inflammasome résultant en la sécrétion d'IL-1ß, une diminution de la tolérance au glucose et de la sensibilité à l'insuline (128). Le taux d'IL-6 corrèle également avec la résistance à l'insuline induite par l'obésité, et de nombreux travaux montrent que l'IL-6 a un effet pro-inflammatoire (130) (131). Les cytokines pro-inflammatoires peuvent également avoir un effet sur l'expression de certains gènes. Par exemple, le traitement des adipocytes par le TNF- α induit une baisse de l'expression des transporteurs du glucose GLUT4 et PPAR-γ (132) (133). Un autre mécanisme, intéressant, serait que les cytokines proinflammatoires et les acides gras saturés pourraient up-réguler des gènes impliqués dans la synthèse des céramides (123).

En plus des cytokines pro-inflammatoires, certaines cytokines anti-inflammatoires sont augmentées dans l'obésité (IL-1Ra, SFRP5 et IL-10). L'équilibre entre les cytokines pro-

et anti-inflammatoires définit l'amplitude de l'inflammation et de son effet sur la résistance à l'insuline (135) (136) (112).

Pour conclure, les cytokines dans l'obésité ont un effet paracrine local avec un taux dans les tissus suffisamment élevé pour qu'elles puissent se propager dans la circulation systémique. Néanmoins la concentration de cytokines dans les tissus est certainement plus élevée que dans la circulation, et il reste encore à montrer que le niveau de cytokines circulantes dans l'obésité est suffisant pour exercer un effet endocrine sur la sensibilité systémique à l'insuline.

b. Les acides gras comme inducteurs des voies de signalisation de

l'inflammation

Les TLR et l'inflammasome

Les PRRs, composants de l'immunité innée, détectent des molécules étrangères notamment les motifs moléculaires associés aux pathogènes (PAMPs) tels que le LPS, le pepitoglycane (PGN), et les acides nucléiques des micro-organismes. Mais ils détectent aussi des signaux endogènes de stress comme les motifs moléculaires associés aux dommages cellulaires (DAMPs). Une quantité accrue de DAMPs libérés par des cellules nécrotiques dans l'obésité (des acides gras saturés libres, des protéines « Heat-shock » [HSP60], des protéines « calcium-binding » [S100A8 et S100A9] etc...) pourraient participer à l'inflammation chronique de bas grade en partie *via* les PRRs par exemple dans le tissu adipeux et les îlots pancréatiques (122).

Parmi les PRRs, la famille des TLRs comprend au moins 10 membres chez l'homme et leur stimulation entraîne l'activation du facteur nucléaire (NF- κ B) et des protéines kinases MAPKs ce qui induit la sécrétion de protéines pro-inflammatoires. Les récepteurs TLR2, et TLR4 sont certainement les plus étudiés dans l'obésité (138). En effet, il a été montré que les acides gras modulaient les voies de signalisation induites par TLR4 et la quantité d'acides gras libres présents dans le sérum après relargage par les adipocytes, est augmentée dans l'obésité (139). Par exemple des acides gras saturés tels que l'acide laurique, l'acide palmitique et l'acide stéarique induisent et/ou modulent une réponse inflammatoire *via* TLR4 (140) (141) (142). Concernant les protéines sécrétées par le tissu adipeux nous pouvons illustrer leur action par l'exemple de la résistine. Elle est augmentée dans le sérum des patients obèses (tableau 1) et se fixe directement à TLR4 ce qui induit la résistance à

l'insuline (143). TLR2 reconnaît une large gamme de dérivés bactériens tels que des lipopeptides ou le PGN. Il a été montré que l'acide laurique induit l'activation de NF- κ B *via* la dimérisation de TLR2 avec TLR1 et TLR6 (144) (145) (146). D'autres travaux ont montré que la stimulation de lignées de myoblastes par l'acide palmitique active NF- κ B par la voie TLR2-MyD88, et que cette réponse inflammatoire entraine la résistance à l'insuline (146) (Figure 2).

D'autres PRRs sont représentés par la famille des récepteurs Nod (Nucleotide-Binding Oligomerization Domain)-like (NLR). Ce sont des récepteurs intracellulaires qui reconnaissent des PGN bactériens. Les recepteurs NOD1 reconnaissent des dérivés des bactéries Gram+ et les récepteurs NOD2 reconnaissent des dérivés des bactéries Gram+ et Gram-. Il existe de nombreux travaux montrant que l'activation de NOD1 et NOD2 est associée à la résistance à l'insuline. Par exemple Schertzer et al. (147) ont montré que des souris double KO NOD1 et NOD2 sont protégées de l'inflammation induite par un régime riche en graisse, de l'accumulation de lipides dans le foie et du développement de la résistance à l'insuline dans le tissu adipeux et le foie. De plus, l'acide laurique peut activer la voie NF- κB par le biais de NOD1/2 ce qui suggère que les acides gras saturés pourraient être des ligands endogènes de NOD1 et NOD2 (148) (149). Un autre récepteur NLR est impliqué dans l'obésité, il s'agit de NLRP3 (NOD-Like Receptor Family, Pyrin Domain Containing 3). NLRP3 est exprimé par les cellules dentritiques, les monocytes, les macrophages et les neutrophiles, et son expression est augmentée suite à une réponse aux PAMPs et aux DAMPs (150). La signalisation par NLRP3 se fait en deux étapes. La première implique l'induction de l'expression de NLRP3 et du pro-IL-1 β ce qui se fait grâce à l'activation de NF- κ B par les TLRs et l'IL-1R. La seconde étape est l'assemblage de l'inflammasome NLRP3, un complexe protéique oligomérique comprenant NLRP3 et pro-caspase-1, dont la résultante est l'activation de la caspase 1 qui permet le clivage du pro-IL-1ß et ainsi la libération d'IL-1ß. L'inflammasome a un rôle critique dans le développement de l'inflammation du tissu adipeux et de la résistance à l'insuline chez la souris et chez l'homme. En effet, chez des patients souffrants de diabète de type II, la perte de poids corrèle avec l'amélioration de la sensibilité à l'insuline, une diminution de l'expression de NLRP3 et d'IL-1 β dans le tissu adipeux (151). L'IL-1ß sécrétée active les voies NF-kB et MAPK par son interaction avec le récepteur IL-1R et perturbe la voie de signalisation de l'insuline (Figure 3). Au cours de l'obésité, la quantité d'acides gras libres est augmentée (139). Ces acides gras peuvent être phagocytés par les macrophages qui les utiliseront pour générer des céramides (152). Par conséquent, les céramides, composés de shingoside et d'acides gras, pourraient être des DAMPs responsables

de l'activation de l'inflammasome NLRP3 dans l'obésité car elles induisent l'activation de la caspase-1 et la sécrétion d'IL-1 β d'une manière dépendante de NLRP3. Un autre acide gras, l'acide palmitique, est aussi capable d'activer l'inflammasome (128). Parallèlement, le polypeptide amyloïde des îlots pancréatiques (IAPP), qui s'accumule chez les patients souffrant de diabète de type II, est également un inducteur de NLRP3 (153). En ce qui concerne les monocytes, l'activation de l'inflammasome NLRP3 se fait par l'intermédiaire de l'activation de TLR2, et elle est modulée par les acides gras provenant de l'alimentation (154). Certains acides gras insaturés préviennent l'activation de l'inflammasome NLRP3 alors que des acides gras saturés tels que l'acide palmitique l'activent (155) (Figure 2).

Dans l'obésité il existe une quantité accrue de DAMPs libérés par les cellules nécrotiques. Ces DAMPs se retrouvent dans la circulation et dans les tissus et, parce que des cellules très diverses telles que les cellules immunitaires, les cellules musculaires, les cellules hépatiques, les adipocytes et les cellules des îlots pancréatiques expriment différents types de PRRs. l'effet de ces ligands endogènes est donc global au niveau de l'organisme dans l'inflammation chronique induite par l'obésité. De plus les modifications au niveau de la barrière intestinale (115) (116) (117) (118) et le taux plus élevé de ligands exogènes dans le sérum de patients obèses comme par exemple le LPS (22), indiquent que des ligands endogènes et exogènes peuvent déclencher et maintenir l'inflammation dans l'obésité.

Les récepteurs activés par les proliférateurs de péroxysome (PPAR)

Les PPAR sont des récepteurs nucléaires qui transmettent les effets des acides gras et de leurs dérivés sur l'expression des gènes, ils comprennent PPAR- α , PPAR- δ et PPAR- γ . Ils sont exprimés par les monocytes, les macrophages et les adipocytes et sont des modulateurs clefs de la polarisation des macrophages et de l'inflammation du tissu adipeux. PPAR- α aurait un effet anti-inflammatoire. Sa déplétion chez la souris conduit à l'up-régulation de cytokines, de chimiokines et de marqueurs de l'inflammation des macrophages chez des souris soumises à un régime riche en graisse (156). De la même façon PPAR- δ et PPAR- γ réduisent l'inflammation du tissu adipeux, favorisent la polarisation M2 des macrophages, et améliorent la sensibilité à l'insuline (157) (158) (133) (159). Les PPARs suppriment l'inflammation par de nombreux mécanismes. Ainsi PPAR- α et PPAR- γ inhibent l'expression de gènes pro-

inflammatoires en interférant avec l'activité des facteurs de transcription NF-kB, AP-1 et STATs (160) (161).

Les céramides et les lipides intracellulaires dans l'inflammation

Un autre dénominateur commun entre le métabolisme et l'inflammation est l'équilibre entre les différentes espèces de lipides intracellulaires comme les céramides et les sphingolipides. Il est intéressant de prendre en considération le fait que dans de nombreux tissus métaboliques la synthèse de céramides par le LPS et les acides gras saturés dépend de TLR4 (123) et que l'inhibition de la production de céramide bloque la capacité des acides gras à induire la résistance à l'insuline. L'effet bénéfique de l'adiponectine en tant que désactivatrice des voies pro-inflammatoires et promotrice de la sensibilité à l'insuline pourrait être du en partie à sa capacité à stimuler les céramidases et donc à moduler l'équilibre entre les céramides et les sphingolipides (162).

c/ Autres mécanismes intervenant dans l'inflammation de bas grade caractérisant l'obésité

Le stress du réticulum endoplasmique et les kinases C-Jun Nterminales activées par le stress (JNK)

On observe une activation globale du stress du reticulum endoplasmique dans l'obésité qui est intimement liée aux deux voies JNK1 et IKK/NF-κB dans les tissus métaboliques (163). Par exemple, la kinase dépendante des ARN double brins (PKR) est un PRR qui se situe à l'interface entre le stress du réticulum endoplasmique et les nutriments. En effet, Nakamura *et al.* ont montré à l'aide du modèle murin DIO, d'un modèle de souris génétiquement obèse, de souris sauvages perfusées avec des acides gras libres, et à l'aide de lignées de fibroblastes de souris cultivées en présence d'acide palmitique, que l'activité de PKR était régulée par les lipides. Ils ont montré aussi qu'elle était régulée par le stress du réticulum endoplasmique et que PKR coordonne l'activité d'autres kinases inflammatoires comme les JNKs pour réguler l'action de l'insuline (164). Plus généralement, l'obésité active JNK dans les tissus répondant à l'insuline certainement en réponse à des signaux de stress tels que les acides gras, l'insuline, l'hyperglycémie et les cytokines pro-inflammatoires par le biais de voies de signalisations communes à IKK/NF- κ B et situées en aval de JNK (131). Les effets de JNK1 sur les cellules non hématopiétiques jouent sur le contrôle de la masse corporelle, la dépense énergétique et le métabolisme du glucose (166) (167).

L'hypoxie

Au cours du développement de l'obésité, l'approvisionnement en oxygène du tissu adipeux devient insuffisante ; il se forme des zones de « microhypoxie ». Ce phénomène d'abord observé chez la souris est aussi présent chez l'homme (168). Cela entraîne l'activation du facteur de transcription 1 α inductible par l'hypoxie (HIF-1 α) qui lui-même entraine l'expression de cytokines pro-inflammatoires. Par ailleurs, le syndrome d'apnée du sommeil, responsable d'épisodes d'hypoxie nocturnes est très fréquent dans l'obésité et participe à l'activation de l'inflammation systémique et tissulaire (170) (171)

Pour conclure la figure 3 présente un modèle hypothétique de l'initiation et du maintien de l'inflammation dans l'obésité.

Figure 3. Modèle hypothétique de l'initiation et du maintien de l'inflammation dans l'obésité. Des signaux tels que les acides gras saturés, le lipopolysaccharide (LPS) ou le « tumor necrosis factor » (TNF) stimulent les voies proinflammatoires par leur interaction avec les récepteurs membranaires TLRs ou le récepteur au TNF entrainant l'activation de signaux pro-inflammatoires des voies NF-kB et JNK ou l'activation de l'inflammasome qui conduit à la sécrétion de cytokines pro-inflammatoire et à la libération d'interleukine-1β (IL-1β). Au niveau intracellulaire, les acides gras peuvent promouvoir le stress du réticulum endoplasmique. Ce phénomène avec l'hypoxie et la modification de l'équilibre entre les céramides et les sphingolipides activent également les signaux pro-inflammatoires. L'ensemble conduit à l'installation de la résistance à l'insuline. L'interleukine-10 (IL-10) en interagissant avec son récepteur membranaire module l'inflammation. Les récepteurs nucléaires PPAR peuvent également moduler l'inflammation par leur capacité à répondre aux acides gras.

B. Le rôle des monocytes dans l'obésité

1. Monocytes humains : généralités

Les monocytes sont des cellules mononuclées faisant partie du système immunitaire inné, représentant environ 6% des globules blancs chez l'homme. Les monocytes sont issus des cellules progénitrices des monocytes (cMoPs) de la moelle osseuse. Ils circulent dans le sang quelques jours puis meurent où bien infiltrent les tissus et se différencient en macrophages ou en cellules dendritiques, dont les fonctions variées dépendent du microenvironnement dans lequel ils résident. Ils peuvent également dans certaines conditions garder leur phénotype de monocyte lorsqu'ils entrent dans des tissus comme la peau ou les poumons où ils acquièrent des antigènes puis is retournent dans la circulation en direction des ganglions lymphatiques sans s'être différentiés en macrophages ou en cellules dendritiques (172) (173). Chez la souris, il a été montré qu'il existe des macrophages qui ne proviennent pas des monocytes circulants mais qui sont différenciés dans les tissus au cours de l'embryogénèse. Ils sont génétiquement différents des macrophages dérivant des monocytes circulants (174) (175). Le besoin en monocytes est augmenté pendant l'inflammation, ils sont alors rapidement remplacés grâce à leur mobilisation depuis la moelle osseuse ce qui résulte en une augmentation de leur nombre dans la circulation que l'on appelle monocytose. Ce phénomène est à associer avec un influx important de monocytes dans les tissus durant l'inflammation (176) (169) (178). Chez l'homme, où l'étude de l'ontogénèse n'est pas facilitée comme chez la souris, les populations de cellules phagocytaires mononuclées qui dériveraient directement des monocytes ne sont pas aussi bien définies. Il existe néanmoins des analyses transcriptomiques suggérant une origine monocytaires de certaines populations de cellules dendritiques du derme et de l'intestin ainsi que dans des tissus inflammés (179). Ainsi, les monocytes ne sont pas seulement les précurseurs de cellules phagocytaires mononuclées infiltrant les tissus inflammés, ils sont aussi des cellules multifonctionnelles jouant un rôle essentiel dans l'homéostasie, la défense immunitaire et la réparation des tissus. La nomenclature officielle de l'Union Internationale des Sociétés d'Immunologies distingue trois sous populations de monocytes humains en fonction du niveau d'expression des récepteurs FCRyIII (CD16) et CD14 : les monocytes classiques CD14++CD16- (CM), les monocytes intermédiaires CD14++CD16+ (IM) et, les monocytes non classiques CD14+CD16++ (NCM) (180) (Figure 4). Ces sous populations présentent des profils chimiokines d'expression des récepteurs de différents qui reflètent

	Marqueurs principaux	Fonctions principales
Π., 🏊 🔲		Monocytes Classiques
CD14++CD16- (80%-90%)	CCR2 CD93 CD64 CD11b CD36 CXCR2 CD62L CCR1 CXCR1 CD99 CLEC4d CLEC5A IL13RA1	 Fort potentiel de phagocytose Production d'agents antimicrobien Production de CCL2 et d'IL-10 après stimulation par LPS
		Monocytes Intermédiaires
CD14 ⁺ CD16 ⁺	CCR5 CD74 HLA-DR CD105 VEGFR2 HLA-ABC CD301 GFRA2	 Présentation de l'antigène par les MHCII; stimulation de la prolifération des lymphocytes T CD4 Forte production basale de dérivés réactifs de l'oxygène Production de TNF et d'IL-1β après stimulation par LPS Mobilisation du pool marginal par l'exercice Déplétion par les glucocorticoïdes Pouvoir angiogénique
		Monocytes Non Classiques
CD14+CD16++	CX3CR1 CD31 CD43 CD11a CD47 CD115 CD294 SIGLEC10 CD162	 Patrouille les endothélium de manière dépendante de LFA-1 Détecte les virus et les acides nucléiques via TLR7 et TLR8 Télomères courts Mobilisation du pool marginal par l'exercice Déplétion par les glucocorticoïdes

Figure 4. Principaux marqueurs et principales fonctions caractérisant les trois sous population de monocytes humains tirés de plusieurs publications. D'après A.M. Zawada et al., *Immunobiology*, 2012

probablement des capacités à être recrutées différentes. Les CM CD14++CD16- sont CCR2++CX3CR1-/+CCR5-, les IM sont CCR2-/+CX3CR1+CCR5++ et enfin les NCM sont

CCR2-CX3CR1++CCR5-. Wong et al. (181) et Zawada et al. (182) ont décrit en 2011 les trois sous populations de monocytes chez des sujets sains par des analyses transcriptomiques, cytométrie en flux et par des tests fonctionnels de production de cytokines. Leurs travaux ont montré chez l'homme que les CM qui représentent la population majoritaire (environ 90%), sont les plus versatiles. Ils expriment le plus large panel de récepteurs membranaires, de gènes impliqués dans une grande diversité de fonctions comprenant la réparation des tissus et la réponse immunitaire et produisent le plus grand nombre de cytokines et de chimiokines (G-CSF, IL-10, CCL2, CCL5 et IL-6) en réponse à la stimulation par LPS. Ces données complètent les travaux de Cros et al. (183) montrant qu'ils produisent CCL2 et IL-10 consécutivement à une stimulation par LPS. De plus, ils entretiendraient l'inflammation par la surexpression de gènes pro-inflammatoires tels que les gènes codant pour les protéines S100 fixant le calcium (S100) A12 et A8/9 (181). S100A12 et S100A8/9 sont des marqueurs important jouant un rôle dans le maintien de l'inflammation. Elles sont sécrétées en autres par les granulocytes et les monocytes suite à une activation de l'immunité innée par exemple par le biais de l'interaction entre TLR4 et LPS. Elles peuvent être sécrétées par des cellules activées ou bien relarguées par des cellules en nécrose. Fonctionellement, elles sont considérées comme des DAMPs. Elles ont la capacité à activer les cellules endothéliales par les voies de TLR4 et du récepteur des produits avancés de la glycation (RAGE) conduisant via l'action de NF-KB à 1) l'expression de molécules d'adhésion à la surface de l'endothélium, les molécules d'adhésion intercellulaires et vasculaires (ICAM et VCAM) et la sélectine et 2) à la sécrétion de chimiokines comme l'IL-8 (CXCL8) qui attirent les monocytes vers l'endothélium (184). Les IM et NCM représentent 10% des monocytes restant, sont très proches phénotypiquement mais possèdent néanmoins des caractéristiques fonctionnelles qui leur sont propres (183). Ainsi les IM seraient plus impliqués dans la présentation des antigènes. Ils possèdent un fort potentiel inflammatoire puisqu'ils sont les principaux producteurs des dérivés réactifs de l'oxygène à l'état basal (185) et qu'ils produisent spécifiquement IL-1 β et TNF- α suite à une stimulation par LPS. A l'opposé, les NCM produisent IL-1 β , TNF- α et CCL3 après stimulation par des acides nucléiques via la voie TLR7-TLR8-MyD88-MEK plutôt que par une stimulation avec LPS (183). Enfin, les NCM humains patrouillent les endothéliums des vaisseaux sanguins de souris après un transfert adoptif par un mécanisme dépendant de la fonction lymphocytaire associée à l'antigène-1 (LEAF-1) (183). Une analyse comparant les données de cinq études transcriptomiques des sous populations de monocytes confirme que les CM soutiennent les
réponses anti-bactériennes et inflammatoires alors que les NCM ont une activité métabolique et du cytosquelette en accord avec celui de cellules patrouilleuses motiles (186).

Les trois sous populations de monocytes sont différentiellement impliquées dans diverses pathologies dont voici quelques illustrations. Le nombre de NCM et IM est significativement augmenté chez des patients atteints de psoriasis, une maladie inflammatoire et chronique de la peau. La proportion de monocytes CD16+ est augmentée chez des patients souffrant de la maladie de Crohn, une maladie inflammatoire et chronique de l'intestin, et curieusement, il a été montré dans cette pathologie qu'un traitement efficace par des anticorps anti-TNF- α augmentait encore plus la proportion d'IM (187). Dans le cas de l'arthrite rhumatoïde, une maladie inflammatoire chronique touchant les articulations, il a été montré qu'un nombre plus important de CM et d'IM dans la circulation des patients est un mauvais indicateur pronostic de la réponse clinique à un traitement par méthotrexate (acide (N-[4-[[(2,4-diamino-6-pteridinyl)méthyl]méthylamino]benzoyl]-L-glutamique) (188). Des travaux sur la pré-éclampsie, une complication de la grossesse associée à une hypertension artérielle et dont l'obésité est un facteur de risque ont montré l'implication spécifique des IM (189). Enfin, une étude comparative montre que les phénotypes des sous populations de monocytes de patients infectés par le virus HIV-1 et de patients présentant un syndrome coronarien aigü mais non infectés par le virus HIV-1 présentaient des similitudes. Il existe donc des mécanismes communs faisant intervenir les monocytes dans ces deux pathologies (190). Pour conclure, si l'on cherche des points communs à toutes ces pathologies où il a été montré une implication des monocytes et plus précisément une implication différentielle des trois sous populations, ce sont les caractères inflammatoires et chroniques qui émergent. Par conséquent, nous nous sommes naturellement intérrogés sur le rôle de chacune des trois sous populations de monocyte dans l'obésité et ses pathologies métaboliques associées.

2. Monocytes et obésité

Des études visant à quantifier les cellules immunitaires dans le cadre de l'obésité chez l'homme montrent une corrélation positive entre le nombre de monocytes et l'IMC (191) (192) (14). De plus, la quantité de monocytes est positivement corrélé au taux de triglycérides et négativement aux taux de HDL-cholestérol (HDL-c) (14), deux anomalies métaboliques classiquement observées au cours de l'obésité. Une première étude portant plus spécifiquement sur les monocytes a montré que l'augmentation du nombre de monocytes avec l'IMC corrélait avec une augmentation de la sous-population exprimant à la fois CD14 et CD16 avec un retour à l'état basal après une perte de poids induite par chirurgie gastrique (14). Prenant en compte l'évolution de la nomenclature officielle de l'Union Internationale des Sociétés d'Immunologie, notre équipe est allée plus loin en considérant séparément les trois sous populations de monocytes. Elle a montré une augmentation de la proportion et du nombre absolu des IM et des NCM chez des patients obèses par rapport aux sujets non obèses et une corrélation entre le pourcentage de monocytes non classiques et la glycémie qui est indépendante de la masse grasse. De plus, une perte de poids importante induite par une chirurgie bariatrique s'accompagne d'une diminution de la fréquence de cette sous-population et ces variations sont fortement corrélées aux variations de masse grasse (193). D'autres études portant sur le phénotype des monocytes révèlent des corrélations positives entre les marqueurs de l'activation de patients obèses a été mis en évidence par une augmentation des dérivés réactifs de l'oxygène (ROS) ainsi que par l'activation du stress du réticulum endoplasmique (190).

De ces observations découlent des interrogations concernant le rôle et l'origine des monocytes dont le nombre et le phénotype sont modifiés par l'obésité. Les premières idées furent qu'ils étaient les précurseurs des macrophages du tissu adipeux. En effet, des expériences in vitro laissent penser que CCL5 qui est augmenté dans le sérum et le tissu adipeux de patients obèses par rapport à ceux de sujets sains, participerait à l'inflammation du tissu adipeux en recrutant des monocytes et en ayant une fonction anti-apoptotique sur les macrophages du tissu adipeux (196). Dans le même ordre d'idée, l'haptoglogine qui est une protéine de la réaction inflammatoire ayant des propriétés anti-oxydantes et qui est up-régulée par le tissu adipeux de sujets obèses, est capable d'attirer par chimiotactisme les monocytes grâce à son interaction avec CCR2 (197). Une autre étude, qui confirme une augmentation du pourcentage de monocytes exprimant à la fois CD14 et CD16 dans l'obésité, révèle une modulation par l'obésité du profil d'expression des récepteurs de chimiokine C-C (CCR) des monocytes et plus particulièrement de CCR2 qui est up-régulé. Ces mêmes travaux, par des essais de migration in vitro, ont montré une plus grande activité chimiotactique des monocytes de patientes obèses en corrélation avec l'expression de CCR2 et la résistance à l'insuline (198). Concernant l'explication de l'origine des monocytes surnuméraires dans la circulation de patients obèses, des pistes sont apportées par des travaux sur des modèles murins d'obésité. Ils ont montré une monocytose importante associée à une expansion des progéniteurs myéloïdes de la moelle osseuse. Ils ont également montré que par l'intermédiaire des protéines S100A8/A9 produites par les adipocytes, les macrophages du tissu adipeux produisent IL-1β notamment par la voie TLR4/MyD88. IL-1β interagit avec le récepteur IL-1 (IL-1R) des progéniteurs myéloïdes entraînant la stimulation de la production de monocytes. Les macrophages du tissu adipeux favorisent ainsi la myélopoiëse et la monocytose dans l'obésité (199).

3. Le rôle des monocytes circulants dans les pathologies métaboliques associées à l'obésité

a. Monocytes et dyslipidémie

Les dyslipidémies sont des maladies du métabolisme des lipoprotéines. Dans l'obésité elles se manifestent par un taux élevé à jeun et également post-prandial des triglycérides, des acides gras libres, un taux réduit de HDL-c, et une composition anormale des LDL avec notamment un nombre plus important de LDL petites et denses. Le faible taux de HDL-c est dû à son catabolisme accru et peut être relié à l'enrichissement en triglycérides. Il existe donc un lien entre le nombre de monocytes dans la circulation et les dyslipidémies de l'obésité puisque la quantité de monocytes est positivement corrélé au taux de triglycérides et négativement aux taux de HDL-c (201). Il faut noter qu'un traitement à la pravastatine, un médicament de la classe des statines qui a pour objectif de réduire le taux de cholestérol et de triglycérides sanguins, induit également une réduction du nombre de monocytes (201). Chez l'homme, des taux élevés de cholestérol et de LDL corrèlent avec une plus forte expression de CCR2 à la surface des monocytes (203) or CCR2 est notamment utilisé par les monocytes pour quitter la moelle osseuse (204) et est préférentiellement exprimé par les CM. D'autres études ont montré que l'hyperlipidémie altérait le phénotype des monocytes. Non seulement l'hyperlipidémie provoque l'up-régulation de molécules d'adhérence cellulaire (CAM) à la surface des cellules endothéliales mais également à la surface des monocytes humains. Ainsi, l'expression de CD18 (integrin \beta2) et CD54 (ICAM-1) est plus élevée à la surface des monocytes de patients présentant de l'hypertriglycéridémie que chez des sujets contrôles (203). Concernant l'implication des différentes sous populations de monocytes dans les dyslipidémies, il a été observé chez des patients ayant (familialement) un taux de cholestérol élevé que les monocytes CD16+ étaient plus spécialisés dans l'ingestion des oxLDL à la surface des endothéliums activés que les CM CD16- qui ingèrent les LDL natifs (204). Une

étude de 2013 portant sur l'analyse spécifique des trois sous populations de monocytes humains en relation avec le taux de HDL-c met en évidence, grâce à une cohorte de sujets sélectionnés de façon aléatoire, une corrélation négative entre le pourcentage de CM et le taux de HDL-c et une corrélation directe entre le pourcentage de NCM et ce même taux alors qu'aucune corrélation n'a été observée avec le pourcentage des IM. Ensuite, dans cette même étude et grâce à une autre cohorte, des sujets sains ont été comparés à des patients présentant une dyslypidémie avec un faible taux de HDL-c. Ces derniers présentent une augmentation significative du pourcentage de CM et une diminution significative des NCM. De plus, les monocytes isolés des sujets sains et des patients ont montré une expression accrue chez les patients des ARNm codant pour une série de chimiokines et de cytokines en relation avec l'activation des monocytes telles que : CD40L, MCP1, TNF-α, IFN-γ, IL-6 et IL-10 (205).

b. Monocytes et athérosclerose

Des dysfonctionnements de l'endothélium vasculaire ainsi que l'inflammation chronique des parois artérielles entraînent le développement de plaques d'athérome. Ces événements sont causés par des facteurs de risque qui comprennent non seulement l'obésité mais aussi la consommation de cigarettes, l'hypercholestérolémie et l'hypertension. Ces facteurs de risque par l'intermédiaire de stimuli pro-inflammatoires tels que le TNF-a, l'IL-1β, l'ox-LDL et l'angiotensine II (206) (207) (208) (209) (210), induisent l'expression de molécules d'adhésion, dont notamment le ligand de l'intégrine et la sélectine, à la surface des cellules endothéliales, ce qui permet le recrutement de monocytes circulants (208) (211). Les monocytes sont les premières cellules immunitaires à infiltrer les plaques d'athéromes en formation et, de nombreuses études indiquent qu'ils sont essentiels au développement de l'athérosclérose (212). Les efforts de recherche ont essentiellement porté sur les molécules responsables de leur recrutement et leur maintien dans les plaques d'athérome. Ils ont mis en évidence chez la souris, grâce à des études impliquant du transfert adoptif de cellules marquées avec des molécules fluorescentes, la déplétion de sous populations ou l'utilisation de souris KO, le rôle essentiel de trois récepteurs de chimiokines et de leurs ligands respectifs : CCR2, CCR5 et CX3CR1. Ces molécules sont importantes de par leur fonction migratoire et, en plus, pour CX3CR1 par leur rôle dans le contrôle de la survie cellulaire (213). Des études de suivi des sous populations de monocytes ont montré chez la souris que les monocytes classiques (CCR2⁺CX3CR1⁺Ly-6C^{hi}) et les non classiques (CCR2⁻ CX3CR1⁺⁺Ly-6C^{lo}) peuvent entrer dans les plaques d'athéromes mais les non classiques avec une fréquence moindre. Ces deux types cellulaires ne dépendent pas des mêmes récepteurs de chimiokine pour migrer dans les plaques. Les monocytes non classiques ne sont pas dépendant de CX3CR1 pour migrer mais ont besoin de CCR2 et CCR5 alors que étonnamment, les monocytes CCR2(+)CX3CR1(+)Ly-6C(hi) que l'on peut comparer aux CM humains ont besoin de CX3CR1 en plus de CCR2 et CCR5 (214). Chez l'homme des études mécanistiques sur la mobilisation différentielle des sous populations de monocytes n'est pas possible in vivo et par conséquent l'appréhension des ces questions est essentiellement corrélative. Il existe des preuves expérimentales et cliniques laissant entrevoir une contribution spécifique des sous populations de monocytes dans l'athérosclérose. Plus précisément, une étude de 2012 portant sur une cohorte de 951 patients sélectionnés pour subir une angiographie coronaire a montré que parmi les trois sous populations de monocytes ce serait principalement le nombre de IM qui seraient indicateur du risque cardiovasculaire (215). Ceci est d'autant plus intéressant que les monocytes intermédiaires expriment sélectivement CCR5, un marqueur qui a été associé à l'athérosclérose dans plusieurs études épidémiologiques à grande échelle (216). Ces résultats sont à rapprocher de nos travaux qui montrent une diminution des NCM et des IM durant la perte de poids avec en plus une association entre la diminution des IM et la diminution de l'épaisseur de l'intima média mesurée à l'aorte (193). Néanmoins, une autre étude portant cette fois-ci non pas sur une cohorte de patients mais sur une cohorte de 700 sujets choisis aléatoirement, présente des résultats contradictoires. En effet, une augmentation des CM en nombre et en proportion serait indicatrice du risque d'évènements cardiovasculaires indépendamment du sexe, de l'âge, du statut de fumeur ou non, du taux de HDL-c, de la présence de diabète ou d'hypertension. Cette même étude montre une corrélation négative entre l'épaisseur de l'intima média mesurée à l'aorte et le pourcentage de monocytes exprimant CD16 (217). Deux aspects différencient cette dernière étude de la notre et de celle effectuée par Rogacev et al. (215) : 1) Elle a été effectuée à partir d'échantillons congelés et non à partir d'échantillons analysés le jour du prélèvement et 2) La cohorte est constituée de sujets sélectionnés aléatoirement alors que pour l'étude de Rogacev et al. et la notre deux cohortes de patients ont été étudiées, respectivement des patients éligibles pour une angiographie coronaire et des patients obèses avec ou non un diabète de type II, éligibles pour une chirurgie bariatrique.

c. Monocytes et diabète de type II

L'inflammation chronique qui caractérise l'obésité est une composante clef dans le

développement de la résistance à l'insuline, une des caractéristiques du diabète de type II. Les cytokines pro-inflammatoires sont en partie la cause de la résistance à l'insuline dans le tissu adipeux, les muscles du squelette et le foie en inhibant les signaux de transduction de l'insuline (figure 3). Ces cytokines sont produites par les tissus cibles de l'insuline eux même, en particulier le tissu adipeux et le foie avec un rôle important des macrophages et des autres cellules immunitaires les infiltrants et notamment des lymphocytes T les infiltrants. C'est ainsi que les macrophages du tissu adipeux de patients présentant un diabète de type II ont une signature pro-inflammatoire très marquée conduite par une production accrue d'IL-1ß dépendante de NLRP3. Cette augmentation est positivement corrélée avec une détérioration de la glycémie et diminue après une chirurgie gastrique. A cela s'ajoute un enrichissement spécifique en lymphocytes T CD4 produisant l'IL-17 et l'IL-22 (218). Parallèlement, dans la circulation de patients présentant un diabète de type II, le taux d'IL-6, d'IL-1 β et de TGF- β est élevé, or ces trois cytokines sont connues pour induire la différentiation des lymphocytes T vers un profil Th17 (219). Effectivement, le pourcentage de lymphocytes T mémoires Th17 est plus plus élevé dans la circulation de donneurs diabétiques comparés à des donneurs non diabétiques. In vitro les monocytes sont nécessaires au maintien du phénotype proinflammatoire des lymphocytes T provenant du sang de patients (220). Nous pouvons donc en déduire un rôle important des monocytes circulants dans l'installation mais aussi dans le maintien de l'inflammation systémique liée au diabète de type II. De plus, les monocytes de patients présentant un diabète de type II sécrètent de façon constitutive un taux élevé d'IL-6, d'IL-8, de TNF- α et d'IL-1 β (221).

II. Objectifs de la thèse

A. Investigation du rôle des différentes populations de monocytes dans l'obésité

Il existe donc une relation étroite entre l'augmentation excessive de la masse grasse qui caractérise l'obésité et les perturbations de l'équilibre des médiateurs cellulaires et moléculaires de l'immunité et plus particulièrement de l'inflammation. Cela se manifeste notamment par une activation des cellules mononuclée circulantes et par leur recrutement actif vers les tissus. L'inflammation systémique, centrale dans l'établissement et le maintien de l'état inflammatoire chronique, rend primordiale l'étude des monocytes circulants en tant que détecteurs de signaux métaboliques circulants qu'ils traduisent en signaux immunologiques mais aussi en tant que précurseur des macrophages. Nous savons déjà que le nombre et le phénotype des monocytes est modifié dans l'obésité avec notamment une modulation des proportions de chacune des trois sous populations (193). C'est pourquoi nous avions pour premier objectif de poursuivre la caractérisation phénotypique et fonctionnelle des trois sous populations de monocytes afin de mieux comprendre leur participation dans l'inflammation de bas grade qui caractérise l'obésité. Pour cela, nous avons comparé dans les 3 sous populations de monocytes, l'expression de « gènes candidats » impliqués dans la migration, la phagocytose et l'inflammation chez des sujets sains et des sujets obèses. Nous avons ensuite testé leur capacité à sécréter des cytokines et des chimiokines inflammatoires en réponse à une stimulation de TLR4 ou de TLR8 et mesuré l'expression protéique des gènes surexprimés. Enfin nous avons examiné les corrélations existant entre le degré d'expression protéique de ces récepteurs surexprimés et des marqueurs cliniques de l'obésité. Les résultats de ces travaux sont présentés en première partie des résultats de la thèse sous la forme d'un article publié dans « The Journal of Immunology ». Notre second objectif était de découvrir des voies de signalisation qui seraient différentiellement modulées par les trois sous populations de monocytes afin de mieux comprendre l'implication de chacune des trois sous populations dans les comorbiditées de l'obésité. Nous avons donc décidé de comparer l'expression au niveau du génome complet des trois sous populations de monocytes à partir de cellules triées par « Fluorescence Activated Cell Sorting » FACS chez des sujets témoins et chez des sujets obèses en utilisant la technique « Agilent Whole Human Genome Oligo Microarrays ». L'analyse de ces données est présentée en deuxième partie des résultats de la thèse sous la forme d'un article à soumettre.

B. Méthodologie

Pour l'ensemble de ces travaux de thèse nous disposions d'une cohorte de 45 patients obèses non diabétiques, éligibles pour un programme de chirurgie bariatrique et recrutés dans le service de nutrition de l'Hôpital de la Pitié-Sâlpétrière à Paris et d'un groupe de 26 sujets sains également non diabétiques. Les deux groupes étaient d'un âge moyen comparable. Afin de préserver au mieux la viabilité des monocytes, chacun des échantillons a été immédiatement traité après le prélèvement. Pour réduire le temps de tri par (FACS), il était impératif d'enrichir les échantillons par une première étape de centrifugation sur un gradient de Ficoll Hypaque suivit d'une deuxième étape par centrifugation sur un gradient de Percoll. Nous ne disposions que d'un maximum de 10 ml de sang par patient ou par donneur ce qui ajouté aux limitations techniques (présentées dans le paragraphe suivant) a rendu le recrutement d'un grand nombre de patients et de témoins dans l'étude difficile. L'ensemble de l'organisation expérimentale est présenté figure 5.

Pour la première partie de ce travail, nous avons mis au point une méthode de tri cellulaire par FACS impliquant le tri de pouplations rares. Pour l'expérience d'expression au niveau du génome complet les cellules étaient marquées avec CD14-APC et CD16-FITC. Après élimination des doublets et des cellules mortes, les monocytes ont été sélectionnés sur la base de leur morphologie, définie à l'aide d'un Dot-Plot représentant l'intensité de la lumière diffractée contre celle de la lumière réfractée par les cellules (FSC vs SSC), et de leur expression de CD14. Les trois sous populations de monocytes ont été sélectionnées ensuite en fonction de l'intensité d'expression de CD14 et CD16: CD14++CD16- pour les CM, CD14++CD16+ pour les IM et CD14+CD16++ pour les NCM. En raison du faible volume de sang disponible pour certains sujets et pour les sous populations les moins représentées (IM et NCM) nous avions parfois moins de 9000 cellules à notre disposition. La rareté du matériel biologique nous a conduit à optimiser l'extration des ARNs pour la réalisation des PCR quantitatives. Nous avons donc décidé de trier les cellules directement dans le tampon de lyse cellulaire et de les congeler immédiatement dans l'azote liquide. Les cellules triées étaient conservées à -80°C avant l'extraction de l'ARN. La vérification de la pureté des populations était faite immédiatement après le tri par répétition du tri dans du PBS afin de pouvoir ré-analyser par cytométrie en flux les populations triées. Les tris dont la pureté était supérieure à 95% étaient validés et les échantillons inclus dans l'étude. 9000 cellules correspond au nombre minimal de cellules triées à partir desquelles nous optenons suffisamment d'ARN (5124 pg) de qualité, avec une valeur d'intégrité (RIN) supérieure ou égale à 7, pour effectuer les analyses d'expression des gènes par PCR quantitative. Après une transciption réverse les mêmes quantités d'ADNc ont été pré-amplifiées à l'aide d'un Taqman Master Mix PreAmp (Applied Biosystem) puis amplifiées à l'aide d'un Low Density Array System (LDA) réalisé à façon et enfin, analysées par le Biosystem Applied 7900HT. Le LDA a été conçu pour mesurer les variation d'expression des gènes de : CX3CR1, CSF-1R, SELPLG, TNF-α, CCR2, CCR5, CD3, ICAM1, IL-10, IL-8, IL-1β, CCL2, CCL3, TLR2, TLR4, TLR7, TLR8, PPAR- Y. L'actine a été utilisée comme gène de référence. L'analyse de l'expression des gènes au niveau protéique à été faite par cytométrie en flux sur des PBMC enrichis en monocytes par un gradient de Percoll, à l'aide d'un panel comprenant CD14-APC, CD16-APC-H7, CD3-V450 CD19-V450, CD56-V450, CSF-1R-FITC, CCR5-PE/CF594, CCR2-PerCP-Cy5.5 et CX3CR1-PE-Cy7 afin de confirmer la modulation par l'obésité de l'expression de CFS-1R, CCR5, CCR2 et CX3CR1 au niveau de chaque sous population de monocytes. Un autre panel comprenant CD14-APC, CD16-APC-H7, CD3-V450 CD19-V450, CD56-V450 et TLR4-PE ou TLR8-PE a été conçu pour mesurer l'expression de TLR4 et de TLR8 à partir de sang complet.

Pour la réalisation des tests fonctionnels de production de cytokines par stimulation de TLR4 ou de TLR8, nous avons fixé le nombre minimal de cellules acceptables à 10000 cellules triées. Pour la sélection des monocytes nous avons ajouté au panel d'anticorps CD3-PE, CD19-PE et CD56-PE afin de créer un canal d'exclusion permettant d'éliminer les contaminations potentielles par des lymphocytes T et B et des cellules NK. Les cellules étaient triées dans du milieu de culture (RPMI 1640) supplémenté par 10% de sérum fœtal bovin (RPMI 10% FBS). Après centrigugation des cellules triées, le milieu a été remplacé par du RPMI 10% FBS incluant du LPS (10 ng/ml), de l'ARN simple brin (ssRNA) (10 ug/ml) ou dans du milieu seul afin de tester la capacité différentielle des trois sous populations à répondre à une stimulation de TLR4 ou de TLR8. Après 18 heures de culture les surnageants ont été prélevés et congelés à -80°C pour un dosage ultérieur de 10 cytokines et chimiokines pro-inflammatoires : TNF- α , IL-1 β , IL-6, IL-12p70, CCL2 (MCP-1), CCL5 (RANTES), CXCL10 (IP10) et CXCL8 (IL-8) par la technique « Cytometry Bead Array » de la société Becton Dickinson. Pour le dosage, 20 µl de chaque surnageant ont été utilisé.

Toutes les analyses statistiques de comparaison des moyennes entre le groupe de patients et le groupe de témoins ont été faites à l'aide du test U non paramétrique de Mann-

Whitney sauf pour les comparaisons d'expressions de gènes des microarrays où nous avons utilisé le test *t* de Student. La détermination des corrélations entre les différentes variables quantitatives mesurées a été faite par le calcul du coefficient de correlation de Spearman. Pour chacune des analyses une valeur de p < 0,05 était considérée comme significative.

La deuxième partie de ce travail qui consistait à rechercher des voies de signalisation qui seraient différentiellement modulées par l'obésité au niveau des trois sous populations de monocytes. Nous avons opté pour une étude au niveau du génome complet, et en raison notamment de son coût, nous n'avions la possibilité d'analyser le transcriptome que d'un très petit nombre d'échantillons. En effet, l'analyse du transcriptome d'un sujet implique le tri des trois sous populations et consécutivement l'hybridation de 3 microarrays. Nous avions donc pour 5 sujets obèses et 5 sujets sains, 30 échantillons à traiter. Brièvement, nous avons trié 2000 cellules de chacune des sous populations directement dans du tampon de lyse, vérifié la pureté des tris et congelé les échantillons. L'ensemble de la réalisation des microarray a été assuré par la société Miltenyi Biotec. Après extraction, les ARNs messagers ont été convertis en ADNc puis amplifiés et quantifiés. L'intégrité des ARNs a été vérifiée et 250 ng de chaque ADNc a été étiqueté avec la molécule fluorescente Cy3 et hybridé à un microarray « Agilent Whole Human Genome Microarray ». La fluorescence des signaux émis par les microarray hybridés a été scannée et convertie en valeur d'intensité du signal qui est proportionnelle à l'expression de chacune des sondes constituant le microarray. La démarche que nous avons adoptée pour le filtrage des données ainsi que la méthode d'analyse de ces données seront présentées dans la deuxième partie des résultats.

Figure 5. Organisation expérimentale. Comparaison des sous populations de monocytes chez des sujets sains et chez des sujets obèses non diabétiques

III. RESULTATS

A. Les monocytes dans l'obésité humaine : sous populations et fonctions

Nos travaux visant à caractériser phénotypiquement et fonctionellement les monocytes dans l'obésité humaine sont exposés dans un un article intitulé : « Profiling of the three circulating monocyte subpopulations in the contexte of human obesity » et publié en mars 2015 dans la revue « The Journal of Immunology ».

1. Introduction

Dans un article précédent nous avions observé une augmentation de la fréquence des IM et des NCM chez des patients obèses comparés à des sujets témoins non obèses avec une augmentation significative des NCM chez les patients obèses et diabétiques. Par une analyse multivariée nous avions montré une corrélation entre le pourcentage de NCM et la glycémie indépendante de la masse grasse. Nous avions aussi montré qu'une perte de poids drastique obtenue après une chirurgie bariatrique entraine une diminution de la fréquence de ces deux sous populations et que l'amplitude de cette dimunition corrèle avec la perte de masse grasse. De plus, une diminution d'au moins 5% de la masse grasse est suffisante pour observer une diminution significative du pourcentage des NCM. Nous avions également observé une diminution des IM après perte de poids corrélée avec une diminution de l'épaisseur de l'intima média mesurée à l'artère carotide. L'objectif de cette première partie a été de décrire les modifications phénotypiques et fonctionnelles des sous populations de monocytes dans l'obésité et de relier ces modifications aux fonctions métaboliques dans le but de mieux comprendre le rôle des monocytes dans l'inflammation de bas grade caractéristique de l'obésité. L'hypothèse de départ a reposée sur la modulation de l'expression de certains gènes dont les produits impliqués dans l'inflammation sont essentiels aux différentes fonctions des monocytes directement ou indirectement. Le point de départ de ce travail de caractérisation a éte le choix de 18 gènes candidats qui pourraient être différentiellement modulés par l'obésité dans chacune des trois sous populations de monocytes. Nous avons donc sélectionné en premier lieu des gènes impliqués dans la fonction de migration avec les récepteurs de chimiokines : CCR2, CCR5 et CX3CR1 (138) (139) (140) (141) (142) (143) (144) (145) (146) (222), en postulant qu'une expression différentielle de ces récepteurs expliquerait le recrutement préférentiel de l'une ou l'autre des sous populations dans les tissus inflammés. Une expression différentielle de CX3CR1 expliquerait également une meilleure résistance à l'apotose de l'une ou l'autre des sous populations et par conséquent pourrait expliquer les variations de proportion de chacune des sous populations entre des sujets obèses et des témoins (223). Toujours concernant la fonction migratoire nous avons recherché des modulations d'expression des chimiokines CCL2 (MCP-1) et CCL3 (MIP-1a). Ces deux molécules sont produites en abondance par les macrophages du tissu adipeux. L'idée était de définir laquelle des trois sous populations avait un profil sécrétoire s'approchant de celui des macrophages du tissu adipeux (78) (79). Afin de définir laquelle des trois sous populations infiltre préférentiellement le tissu adipeux inflammé dans l'obésité et plus largement les autres tissus métaboliques inflammé (e.g. le foie, le pancréas, les muscles), nous avons mesuré le niveau d'expression de molécules d'adhésion indispensables à la transmigration dans les tissus, le ligand de la sélectine P (PSCGL-1) et la molécule d'adhesion intercellulaire-1 (ICAM). Enfin, pour terminer avec le rôle des monocytes en tant que précurseur des macrophages, nous avons mesuré l'expression de CSF1-R, un gène impliqué dans la différentiation des macrophages. Ensuite, nous nous sommes intéressés aux PPRs, comme médiateurs des signaux métaboliques en signaux inflammatoires. Nous avons évidemment choisi de mesurer l'expression différentielle de TLR2 et TLR4, deux récepteurs déjà largement étudiés dans l'obesité (138) (139) (140) (141) (142) (143) (144) (145) (146) (222) auxquels nous avons ajouté l'étude des récepteurs intracellulaires TLR7 et TLR8 comme détecteurs des acides nucléiques (ssRNA) ou de complexes contenant des acides nucléiques qui pourraient ête libérés dans le milieu extracellulaire par des cellules en nécroses ou des cellules activées (137). Ceci d'autant plus que les NCM répondent spécifiquement aux virus et aux complexes contenant des acides nucléiques via la voie TLR7-TLR8-MyD88-MEK en sécrétant TNF-α, IL-1β et CCL3 (MIP-1α) (183). Une expression différentielle de ces PPRs impliquerait plus ou moins l'une ou l'autre des sous populations dans l'initiation et l'entretien de l'état inflammatoire de bas grade qui caractérise l'obésité. Avec toujours en tête la fonction de détecteur des signaux métaboliques nous avons ajouté à la liste de gènes, CD36 pour sa capacité à fixer les oxLDL (224), les lipoprotéines natives (225), les phospholipides et certaines acides gras libres (226). Concernant les récepteurs impliqués dans les grandes voies de signalisation nous avons sélectionné PPAR-y parce que c'est un récepteur nucléaire qui transmet les effets des acides gras et de leurs dérivés sur l'expression des gènes et parce qu'il est impliqué dans de nombreuses fonctions modulées par l'obésité comme par exemple la polarisation des macrophages, le developpement de la résistance à l'insuline et le transport du glucose (160) (161). Pour conclure notre exploration nous nous sommes intéressés aux cytokines IL-1 β , TNF- α et IL-10 en tant qu'effectrices de la traduction inflammatoire des signaux métaboliques (128) (132) (133) (136) afin de savoir laquelle des sous populations était le plus directement impliquée dans le développement des maladies métaboliques associées à l'obésité. La suite de notre travail a été de confirmer au niveau protéique et fonctionnel les résultats de l'analyse transcriptomique.

2. Résultats

L'analyse de la modulation de la transcription par l'obésité des 18 gènes sélectionnés a montré que 7 gènes étaient modulés (Article 1, Figure 2). Le fait que ces gènes soient différentiellement modulés par les trois sous populations de monocytes nous ouvre des pistes dans la compréhension du rôle de chacune des sous populations de monocytes dans l'obésité. Il apparaît en première analyse que les CM et les IM up-régulent les récepteurs CCR2, CX3CR1 et CCR5 impliqués dans la migration, tandis que les IM up-régulent plutôt la sécrétion de molécules effectrices avec la chimiokine CCL2 et la cytokine IL-1 β et que les NCM up-régulent le récepteur PPAR- γ . Ces résultats feraientt des CM, les précurseurs des macrophages dans les tissus des IM, les effecteurs de la réponse inflammatoire et des NCM, des « réparateurs » par l'up-régulation d'un récepteur nucléaire ayant des propriétés anti-inflammatoires et favorisant la polarisation M2 des macrophages. En accord avec la littérature TLR4 (138) est up-régulé par tous les monocytes et pour la première fois nous montrons une up-régulation de TLR8, un PPR intracellulaire, également par chacune des sous populations.

Nous avons pu confirmer au niveau protéique la surexpression de CCR2 et CCR5 par les CM et les IM indiquant une augmentation de leur potentiel migratoire dans l'obésité. En revanche CX3CR1 serait up-régulé par l'ensemble des monocytes (Article 1, Figure 4). Concernant l'up-régulation de TLR4 et de TLR8, nous la retrouvons au niveau protéique même si les différences ne sont pas statistiquement différentes. Au niveau fonctionnel nous avons montré que toutes les sous populations répondent plus fortement à la stimulation de TLR4 ou de TLR8 bien que pas toujours de façon significative (Article 1, Figure 3). Ces résultats renforcent l'idée de l'importance des TLRs comme médiateurs de l'inflammation dans l'obésité par leur fonctionalité accrue dans les monocytes circulants de patients obèses comparés à ceux de donneurs non obèses. L'étude des corrélations existantes entre le degré d'expression protéique des récepteurs surexprimés et des marqueurs cliniques de l'obésité ont montré une corrélation négative entre le degré d'expression de CCR2 et de CX3CR1 et le taux de HDL-c alors que le degré d'expression de CCR5 est positivement corrélé avec la glycémie, le taux de triglycérides et l'HOMA-IR, tous trois sont des marqueurs sanguins métaboliques de l'obésité (Article 1, Figure 5).

3. Conclusion

Nos résultats confirment le phénotype pro-inflammatoire des monocytes dans l'obésité avec notamment l'up-régulation de TLR4 et TLR8 par les trois sous populations et une plus forte réponse à la stimulation de TLR4 ou de TLR8. Il existe cependant des différences entre les sous populations en ce qui concerne l'intensité de la réponse à ces stimulations. Les CM de patients obèses comparés à ceux de témoins non obèses répondent plus fortement à la stimulation par LPS en produisant significativement plus d'IL-1 β et, de TNF- α et d'IL-10 suite à la stimulation par ssRNA. Parmi les trois sous populations c'est donc celle dont la réponse fonctionnelle via TLR4 ou TLR8 est la plus fortement augmentée ches les sujets obèses, quantitativement et qualitativement, puisqu'elle implique le plus grand nombre de cytokines. Nous avons aussi montré que la fonction migratoire était différentiellement modulée par les trois sous populations avec une intensité d'expression significativement plus forte chez les sujets obèses des trois récepteurs de chimiokines étudiés : CCR2, CCR5 et CX3CR1 par les CM et les IM. Les NCM ne surexpriment significativement que CX3CR1. Les corrélations observées entre le degré d'expression de CCR2 et de CX3CR1 et le taux de HDL-c et celles observées entre le degré d'expression de CCR5 avec la glycémie, le taux de triglycérides et l'HOMA-IR varient en fonction des sous populations. Elles sont significativement plus fortes pour les NCM comparées à celles des CM et des IM. Il en est de même pour la corrélation entre le degré d'expression de CSF-1R et l'insulinémie et l'HOMA-IR. Ce qui suggère que l'augmentation des NCM en proportion et en nombre absolu dans l'obésité pourrait être un indicateur de risque des maladies cardiovasculaires et métaboliques.

Profiling of the Three Circulating Monocyte Subpopulations in Human Obesity

Estelle F. Devêvre,*^{,†,‡,§,¶,1} Mariana Renovato-Martins,^{*,†,‡,§,1} Karine Clément,^{†,‡,§,∥,#,**} Catherine Sautès-Fridman,^{*,‡,§} Isabelle Cremer,^{*,‡,§,1} and Christine Poitou^{†,‡,§,∥,#,**,1}

Three subpopulations of circulating monocytes have been described: $CD14^{2+}CD16^{-}$ (classical monocytes [CM]), $CD14^{2+}CD16^{+}$ (intermediate monocytes [IM]), and $CD14^{+}CD16^{2+}$ (nonclassical monocytes [NCM]). We previously showed that obesity is associated with an increased proportion of IM and NCM. Our objective is to decipher the migratory and inflammatory functions of each monocyte subset in obesity-related low-grade inflammation. Twenty-six healthy, normal-weight and nondiabetic volunteers (C) and 40 obese nondiabetic (Ob) individuals were included in this study. We explored the gene expression profile of 18 inflammatory genes in each subset of C and Ob subjects and measured protein expression of the upregulated genes. We then tested their functional response to TLR signaling in both groups. We showed an increased expression of CX3CR1 in all monocyte subpopulations and of CCR2 and CCR5 in CM and IM in the Ob group. We found negative correlation between CCR2 and CX3CR1 expressions and high-density lipoprotein-cholesterol, whereas CCR5 expression was positively linked to obesity-related metabolic traits. Production of inflammatory proteins upon bacterial LPS and viral ssRNA stimulation was higher in CM and NCM of the Ob group compared with the C group. Our work highlights an enhanced inflammatory phenotype of monocytes with a higher response to TLR4 stimulations in obesity. Moreover, it suggests an increased migration capacity of CM and IM subpopulations. *The Journal of Immunology*, 2015, 194: 3917–3923.

besity is an ongoing worldwide epidemic now recognized as a low-grade inflammatory disease characterized by increased concentrations of a large panel of cytokines, chemokines, and acute-phase proteins in the circulation (1, 2). Obesity-related inflammation favors the development of metabolic and cardiovascular complications (3), (4). This systemic inflammation results, at least in part, from activation of circulating immune cells (5), vascular endothelium (6), and excessive accumulation of inflammatory cells in adipose tissue (7). Monocytes, acting critically in several inflammatory diseases, have been recently categorized in three subsets according to the expression of LPS (CD14) and the $Fc\gamma$ RIII (CD16) receptors (8, 9). CD14²⁺CD16⁻ classical monocytes (CM) express high levels of CCR2, the chemokine receptor of CCL2 also known as MCP-1, and low levels of CCR5, receptor of CCL3 and CCL5, and of CX3CR1, the fractalkine (CX3CL1) receptor. In contrast, CD14²⁴ CD16⁺ intermediate monocytes (IM) and CD14⁺CD16²⁺ nonclassical monocytes (NCM) express high levels of CX3CR1 and CCR5 but do not express CCR2 (10, 11). We and others have described an increased proportion of circulating NCM and IM subsets in human chronic pathologies associated with low-grade inflammation, including obesity (12, 13). In addition, we demonstrated a decrease in proportion of NCM and IM during weight loss, a clinical situation characterized by a major improvement of systemic inflammation (12). In healthy subjects, transcriptomic approaches revealed major differences among CM, IM, and NCM subsets. Classical CD16⁻ monocytes were described as the main antimicrobial monocytes (14, 15), whereas the two CD16⁺ monocyte subsets were linked to Ag processing and presentation, and inflammation (16, 17). The three monocyte subsets can be polarized by the cytokine environment to acquire their functions and migration properties (10). Interestingly, it has been demonstrated that the NCM subset, known as "patrolling" monocytes, has the capacity to be stimulated by TLR7 and TLR8 ligands, implicating them in local surveillance of damaged or virus-infected tissues (15).

To date, there is no available information on the migratory and inflammatory functions of each monocyte subset in human obesity. Therefore, we performed array analysis to compare gene expression of 18 candidate genes related to migration, phagocytosis, and inflammatory processes in normal-weight and obese subjects before and after surgery-induced weight loss. We then tested their functional response to TLR signalings, and measured surface and intracellular protein expression of the upregulated genes (TLR4, TLR8, CCR2, CCR5, CX3CR1, and CSF-1R). Finally, we examined the correlation between protein expression of the upregulated receptors and common obesity-related clinical markers.

Materials and Methods

Subjects

3918

Two groups of subjects were included in this study (Table I). The first group included 40 obese nondiabetic (Ob) individuals involved in a bariatric surgery program and recruited to the nutrition division of Pitié-Salpêtrière Hospital (Reference Center for the Medical and Surgery Care of Obesity, Institute of Cardiometabolism and Nutrition, ICAN La Pitié-Salpêtrière Hospital, Paris, France). Patients met the criteria for bariatric surgery as described earlier (12). The second group comprised 26 healthy normalweight and nondiabetic volunteers (C), living in the same region as the Ob subjects. The Ethics Committee (CPP IIe de France 1) approved the clinical investigations for both Ob and C individuals. All subjects gave written informed consent. The study was conducted in accordance with the Declaration of Helsinki and was registered in a public trial registry (NCT00476658 and NCT01655017).

For each of the experiments, we used fasting blood samples from only part of the two groups. For ethical reasons, blood withdrawal for monocyte isolation was restricted to a maximum of 10 ml per patient. This resulted in isolation of 1×10^6 to 4×10^6 monocytes per patient, which limited the number of IM and NCM after FACS sorting, and experimental design was adapted accordingly (Supplemental Fig. 1).

Mononuclear cell isolation and FACS sorting of monocyte subpopulations

PBMCs were isolated from blood by centrifugation on a Ficoll-Hypaque gradient (PAA Laboratories). Monocytes were then enriched by a centrifugation on a Hyper-osmotic Percoll^{Plus} Gradient (GE Healthcare) (18). Monocyte-enriched cell fraction was further subdivided by FACS. For the gene expression experiment, cells were stained with allophycocyanin-CD14 and FITC-CD16. Doublets and dead cells were excluded, monocytes were selected based on their light scatters and CD14 and CD16 expressions, and sorted into CD14⁺CD16²⁺, CD14²⁺CD16⁺, and CD16⁺Cells directly in RNeasy Lysis Buffer (Qiagen) using a FACS Vantage cell sorter (BD Biosciences). Sorted cells were kept at -80°C before RNA isolation. For cytokine production, we added a PE-elimination channel with PE-CD3, PE-CD19, and PE-CD56 to exclude potential contaminant from the monocyte gate. A total of 10,000 monocytes pr subset were sorted using a FACSAria III (BD Biosciences) into RPMI 1640 medium. Sorted monocytes were cultivated immediately. Supplemental Table I describes Abs used for these studies.

RNA extraction, reverse transcription, and cDNA preamplification

Total RNA was isolated from 9000 to 90,000 sorted monocytes. RNeasy Mini Kit (Qiagen) was used according to manufacturer's instructions including DNase treatment. RNA quality and quantity were analyzed by capillary electrophoresis (BioAnalyzer; Agilent). Equal amounts of cDNA were preamplified using the TaqMan PreAmp Master Mix (Applied Biosystems).

Real-time PCR

Preamplified cDNA samples were amplified using Made-to-Order Low Density Array System according to manufacturers' instructions. The arrays were carried out on the Applied Biosystems 7900HT. TaqMan Low Density Array was designed to screen for changes in gene expression of CX3CR1, CSF-1R, SELPLG, TNF, CCR2, CCR5, CD36, ICAM1, IL-10, IL-8, IL-1 β , CCL2, CCL3, TLR2, TLR4, TLR7, TLR8, peroxisome proliferator-activated receptor γ genes, and actin as endogenous controls. A detailed list of probes is given in Supplemental Table 1. Each sample was run in duplicate, and the results were analyzed with the RQ Manager software (Applied Biosystems) and expressed as relative gene expression ($2^{-\Delta\Delta Ct}$ method) using β -actin expression as endogenous control.

Cytokine production

To analyze cytokine production, we cultivated 1 \times 10⁴ FACS-sorted CM, IM, or NCM in 100 μ l RPMI 1640 and 10% FBS. Each subset was stimulated with 10 ng/ml LPS, 10 μ g/ml viral ssRNAs (ssRNA40/LyoVect; Invivogen), or media alone. After 18 h, supernatants were harvested and kept at -80° C for cytokine quantification. Monocyte supernatants were quantified for TNF, IL-1β, IL-6, IL-10, IL-12p70, CCL2 (MCP-1), CCL5 (RANTES), CXCL10 (IP10), and IL-8 (CXCL8) by the human 9-flex cytometric bead array. Details about each flex set are given in Supplemental Table I. Samples were processed according to the manufacturer's instructions; acquisition was performed on an LSRII and quantification calculated with FCAP array v3 software (all from Becton Dickinson).

MONOCYTES IN HUMAN OBESITY: SUBSETS AND FUNCTIONS

Protein expression

Flow cytometry using 8-fluorophores was performed on monocyte-enriched PBMCs. To prevent nonspecific binding, we blocked FcRs using 2% human serum PBS (2% HS) for 10 min. Abs were diluted in the same buffer and incubated 30 min in the dark at 4°C. Monocyte subsets were selected as described earlier. Fluorescence minus one (FMO) was used to determine the cutoff between cells expressing FITC-CSF-1R, PE/CF594-CCR5, PerCP/ Cy5.5-CCR2, or PE/Cy7-CX3CR1 and negative cells (Supplemental Fig. 2). Expression of TLR4 and TLR8 was performed separately on whole blood. Whole blood was FcR blocked in 2% HS for 15 min. Anti-TLR4 Ab or matching isotype control was added to cells before a mix of allophycocyanin-CD14, allophycocyanin/H7-CD16, V450-CD3, V450-CD19, V450-CD56, and a fixable dead cell marker. After 30 min of surface staining, RBC lysis and fixation were performed simultaneously using Versafix (Beckman Coulter). TLR8 intracellular staining was performed after surface staining; cells were permeabilized with 0.1% saponin 2% HS for 10 min at 4°C. Anti-TLR8 or matching isotype was diluted in this buffer and incubated 30 min in the dark at 4°C. Monocyte subsets were selected as described earlier, and FMO, including PE-isotype, was used to determine the cutoff between cells expressing TLR4 or TLR8 and negative cells. Labeled cells were washed and analyzed using FACSAria III (8-fluorophore flow cytometry) or LSRII (TLR4 and TLR8) (both instruments from BD Biosciences). Acquisitions were standardized over time by the use of both BD Cytometer Setup and Tracking software and the application setting functions available in BD FACSDiva software. We used the mean fluorescence intensity (MFI) to evaluate the expression of CSF1R, CCR5, CCR2, CX3CR1, TLR4, and TLR8. Abs description and dead cell markers are given in Supplemental Table I.

Statistical analyses

Data are expressed as means \pm SEM. Comparisons of mean for quantitative variables between groups were performed using the nonparametric Mann–Whitney *U* test. Relationship among the different quantitative variables was determined by calculating the Spearman correlation coefficient. For all analyses, a *p* value < 0.05 was considered statistically significant. Statistical analyses were done with GraphPad Prism 5.0 (GraphPad Software).

Results

Specific gene expression profile in monocyte subsets in obesity

In accordance with previous findings (12), monocyte absolute numbers were increased in each subset of the obese subject group, as well as the proportion of IM and NCM (Fig. 1). To unravel the molecular signature of monocytes in obesity, we compared expression of 18 candidate genes related to monocyte functions in 3 monocyte subpopulations isolated from C and Ob subjects before and after gastric surgery-induced weight loss (Fig. 2). We found that each monocyte subset displayed a specific gene expression signature. Regarding molecules involved in chemotaxis, mRNA expression of CX3CR1 was significantly increased (2- to 2.5fold) in the Ob group compared with the C group in the CM and IM, and with a trend in the NCM. After weight loss, the expression of CX3CR1 decreased in all monocyte subsets. In obese CM and IM, CCR2 and CCR5 were significantly 2- to 2.5-fold overexpressed. Decreased mRNA expression was observed after weight loss for CCR5 in the CM and for CCR2 in the IM. The expression of CCL2 chemokine was increased by 3.6-fold in the IM of Ob subjects and decreased to levels comparable with C group after weight loss. We found no difference in CCL3 expression in Ob group. Peroxisome proliferator-activated receptor γ , which regulates fatty acid storage and glucose metabolism, was increased in the NCM of Ob individuals and in the CM after weight loss.

For genes involved with the pathogen recognition function, we found a 2- to 4-fold increased expression of TLR4 and TLR8 in all monocyte subsets of the Ob group. Conversely, the expression of TLR2 and TLR7 was similar in both groups. After weight loss, the expression profiles of these TLRs was not significantly modified.

FIGURE 1. Quantification of monocyte subsets of obese and control subjects. (**A**) Absolute numbers and (**B**) percentages of each subset. Normal-weight control group is represented by clear dots (n = 22) and obese group by black dots (n = 24). Statistical comparisons between each group were obtained by the nonparametric Mann–Whitney U test.

For genes involved in cytokine production, we found increased expression of IL-1 β in NCM and of TNF in IM in Ob individuals. No significant difference in NCM expression level of IL-1 β was observed after weight loss, whereas IM expression level of TNF tended to return to normal value.

Taken together, these results show modified mRNA expression of gene related to monocyte functions in obesity. We observed specific characteristics for each monocyte subset for genes involved in cytokines production, chemotaxis, fatty acid storage and glucose metabolism, and pathogen recognition. Indeed, TLR4 and TLR8 overexpression could be considered as a molecular signature of monocytes in obese patients.

Monocyte subsets are characterized by stronger responses upon TLR4 and TLR8 stimulation in obesity

While observing only a slight increase, however not statistically significant, in TLR4 and TLR8 expressions at the protein level in monocytes of obese patients compared with lean subjects (Fig. 3A, 3B), we demonstrated that monocyte subsets from obese patients compared with lean subjects have increased ability to secrete inflammatory molecules upon stimulation with LPS or viral ssRNA respective ligands of TLR4 and TLR8.

We found that some cytokines involved in the inflammatory response were increased in the monocyte subsets (Fig. 3C). CMs were characterized by an increased production of IL-1 β in response to LPS and an increased production of TNF and IL-10 upon ssRNA stimulation in the Ob group compared with C. The IM subset did not differ in terms of cytokine production in response to LPS or ssRNA. Finally, the NCM subset displayed higher production of IL- β upon ssRNA stimulation.

Chemokine production analysis (Fig. 3D) revealed an increased CM production of CCL5 when stimulated by LPS in the Ob group compared with C. The IM subset did not differ in terms of chemokine production in response to LPS or ssRNA. Finally, the NCM subset of Ob subjects displayed higher secretion of CCL5 upon ssRNA stimulation.

We present in this article convincing evidence that CM and NCM are characterized by a higher response upon TLR4 and TLR8 activation in obese patients compared with lean subjects.

Monocyte subsets are characterized by changes in chemokine receptor expression related to obesity-related bioclinical features

The analysis of gene expression signatures revealed specificities between monocyte subsets regarding chemotaxis. The heat-map representation of CCR2, CCR5, CX3CR1, and CSF-1R protein expression revealed a general overexpression of these receptors in

FIGURE 2. Heat-map gene expression of 18 candidate genes related to migration, phagocytosis, and inflammatory processes in the CM, IM, and NCM purified from seven normal-weight and nondiabetic volunteers (C) and seven obese nondiabetic (Ob) subjects before and after surgery-induced weight loss (Ob/AC). Data are means relative gene expression in arbitrary unit (a.u.) \pm SEM. Statistical comparisons between each group were obtained by the nonparametric Mann–Whitney *U* test (*p < 0.05, **p < 0.01).

MONOCYTES IN HUMAN OBESITY: SUBSETS AND FUNCTIONS

FIGURE 3. Comparison of inflammatory molecule secretion by monocyte subsets upon TLR4 and TLR8 stimulation. (**A**) Protein expression of TLR4 and TLR8 measured by flow cytometry. n = 12 normal-weight and nondiabetic volunteers (C), n = 10 obese nondiabetic subjects (Ob). (**B**) Representative examples of TLR4 surface staining and TLR8 intracellular staining of one C and one Ob. Black histogram represents obese patient, gray histogram represents lean subject, and clear histogram represents FMO, with matching isotype control for TLR8. (**C**) Cytokines TNF, IL-16, IL-10, and IL-12p70, and (**D**) chemokines MCP-1 (CCL2), RANTES (CCL5), IP-10 (CXCL10), and IL-8 (CXCL8) measured by cytometric bead array upon 18-h LPS (10 ng/ml) or ssRNA (10 µg/ml) stimulation. C is represented by clear bar and Ob by black bar. n = 5 C, n = 5 Ob. Statistical comparisons between each group were obtained by the nonparametric Mann–Whitney U test (*p < 0.05, **p < 0.01).

all subsets of the Ob group (Fig. 4). Thus, the overexpression is significant only for CCR2, CCR5, and CX3CR1 in the CM and IM subsets and for CX3CR1 at the surface of NCM subset (Fig. 4 and

Supplemental Fig. 2). Taken together, these findings suggest higher migration ability and increased survival of monocytes in Ob compared with C subjects. Indeed, the highest increased

expression of CCR5 and CCR2 in the CM and the IM imply that those two cell subpopulations could have higher migration capacity than the NCM (19).

To evaluate the clinical relevance of increased expression of chemokine receptors, we performed correlation analysis between protein expression of CCR2, CCR5, CX3CR1, and CSF-1R and phenotypes related to corpulence (body mass index [BMI]) and metabolic status (lipid and diabetes-related traits) listed in Table I. The complete linkage clustering of correlation coefficients of obese clinical outcomes and protein expression levels of CCR2, CCR5, CX3CR1, and CSF-1R showed that for each receptor the expression level of CM and IM segregated from the one of NCM (Fig. 5). We found that monocyte surface expression of CX3CR1 and CCR2 was negatively correlated with high-density lipoproteincholesterol (HDL-c), a protective marker of cardiovascular risk. The strength of the negative correlation was particularly strong for NCM subset. This suggests that increased NCM subpopulation in obesity could be linked to cardiovascular risk. The expression of CCR5 was positively correlated with BMI and metabolic traits (glycemia and triglycerides) in the three subsets. Furthermore, expression of CCR5 and CSF-1R in NCM correlated with homeostasis model assessment-estimated insulin resistance, an index of insulin resistance. Overexpression of CCR5 and CSF-1R in NCM could therefore be considered a hallmark of metabolic alteration, especially insulin resistance, in Ob subjects. Fig. 6 proposes a model of the presumed functions of monocyte subsets in obesity-related low-grade inflammation.

Discussion

Recent studies in healthy individuals have characterized gene expression profiles of the three monocyte subsets (11, 16, 17). However, little is known about these different subpopulations in inflammatory-related diseases. In this study, we show that the three subsets display specific modified gene expression and protein expression profiles of inflammatory molecules, as well as differential functional response to the TLR signaling in obesity, a well-known low-grade (sterile) inflammatory pathology.

It is well established that monocytes migrate into sites of inflammation in response to several chemokines and obesity is closely associated with an enhanced number of adipose tissue macrophages (7). We showed that a common characteristic of the three subsets of monocytes in obesity is the overexpression of CX3CR1, suggesting their increased potential to migrate in response to CX3CL1, the chemokine ligand for CX3CR1. This result is consistent with the demonstration by Shah et al. (20) that CX3CL1 is secreted by adipose tissue and mediates monocyte adhesion to human adipocytes. They concluded that CX3CL1 is a novel adipose tissue chemokine in humans and may modulate the recruitment of monocytes into adipose tissue. Consistently, Polyák et al. (21) demonstrated that the CX3CL1-CX3CR1 chemokine system is implicated in the development of metabolic visceral adipose tissue inflammation in obese mice. This is further supported by several studies performed in murine models (22, 23) and clinical investigations in humans (24-26) that suggest a role

of CX3CR1–CX3CL1 axis in the development of atherosclerosis and cardiovascular events. In this scenario, CX3CL1 functions as chemoattractant or as an adhesion molecule, facilitating monocyte and T cell transmigration in atherosclerotic lesion areas (27–29) and is also able to regulate monocyte differentiation and survival (30).

We also observed increased expression of CCR2 and CCR5, which have been involved in the recruitment of monocytes in atherosclerotic plaques in murine models (31, 32), in CM and IM of obese subjects. We previously observed that conditioned medium from visceral adipose tissue of obese subjects or the addition of CCL5 induced adhesion and transmigration of human blood monocytes through adipose tissue endothelium (33). A recent study on obese women demonstrated higher chemotactic activity of monocytes from obese subjects in response to CCL2 and CCL5 (19). These findings together with our data suggest that higher levels of macrophages found among adipose tissue during obesity could be a result of increased migration of monocytes expressing high levels of CX3CR1, CCR2, or CCR5 in response to chemokines secreted by activated endothelium and adipose tissue. Furthermore, our results suggest higher chemotactic ability specifically

FIGURE 6. Presumed functions of monocyte subsets in obesity-related low-grade inflammation. We propose a model where proinflammatory monocytes of obese subjects would sense circulating factors through TLR4 and TLR8. In response, the CM and NCM subsets secrete more inflammatory cytokines. Expressing more CCR5 and CCR2, the IM and CM could be able to migrate more toward tissues where they could differentiate into macrophages. Both phenomena contribute to sustain low-grade inflammation associated with obesity, whereas NCM could stay longer in the circulation and assume "patrolling" function.

of the CM and IM subsets. It suggests that the NCM would be less involved than the two other subsets in recruiting monocytes to atherosclerotic plaques and decreased migration toward the adipose tissue.

Interestingly, we found a strong negative correlation between HDL-c serum level and CX3CR1 and CCR2 expression. On the same line, others reported that in vitro incubation of monocytes with reconstituted high density lipoprotein reduces CCR2 and CX3CR1 expression (34). These data suggest that decreased HDL, a common abnormality observed in obesity, could be directly linked to changes in monocyte phenotype and function.

We observed that CSF-1R was overexpressed in the NCM of obese subjects, however not at a significant level. CSF-1R (also known as CD115, c-fms, and M-CSF receptor) is a tyrosine kinase protein high-affinity receptor for CSF-1 and IL-34. Its ligands, IL-34 and CSF-1, have a pivotal role in regulating survival, proliferation, and differentiation of mononuclear phagocytes (9, 35, 36). CSF-1R is notably expressed by adipose tissue in obese subjects (37, 38). The highest expression of CSF-1R in the NCM could reflect a longer life span compared with the other subsets. Interestingly, we found a positive association between overexpression of CSF-1R in NCM and homeostasis model assessment–estimated insulin resistance, a surrogate of insulin resistance, suggesting that CSF-1R could be considered as characteristic of metabolic alteration, especially insulin resistance, in obese subjects.

TLRs are members of a family of pattern-recognition receptors that detect components of microorganisms, playing a critical role in the innate immune system by activating inflammatory signaling pathways (39). Studies highlighted the involvement of TLR2 and TLR4 in metabolic functions, as well as in innate immune responses, in obesity (40, 41). An interesting finding from this study is a higher activation of TLR4 signaling in response to LPS of CM subset. TLR4 could be stimulated by circulating bacterial LPS or fatty acids, whose levels are commonly increased in obesity (40). We demonstrate for the first time, to our knowledge. a higher activation of TLR8 signaling in response to ssRNA in NCM and CM from obese patients compared with lean subjects. TLR8 is an endosomal TLR that binds viral ssRNAs (17). Although there are no evidences showing increased levels of circulating nucleic acids in obesity, we can suggest that TLR8 present in monocytes from obese subjects could detect circulating nucleic acids or some not yet known ligands other than viral ssRNAs. Moreover, in accordance with increased TLR8 overexpression and stimulation, we found that monocytes display high levels of proinflammatory cytokines in obese patients, particularly IL-1β for NCM.

The Journal of Immunology

In conclusion, our findings demonstrate that the three monocyte subsets from obese patients display a more inflammatory phenotype with a higher response to TLR4 and TLR8 stimulation, and a chemokine receptor expression profile that suggests a higher capacity to migrate for CM and IM and increased survival for NCM (Fig. 6). Indeed, therapeutic strategies targeting inflammatory processes or TLR signaling could be a promising approach to reduce inflammatory, metabolic, and cardiovascular complications linked to obesity.

Acknowledgments

We thank Rohia Alili, Valentine Lemoine, and Dr. Florence Marchelli (Center for Research on Human Nutrition, Pitié-Salpêtrière Hospital) who were involved in patient recruitment and sampling. We thank Dr. Sarah Church for English proofreading and helpful comments on the manuscript. B. Analyse comparative du transcriptome de chacune des sous populations de monocytes chez des sujets obèses *vs* non obèses

Ces travaux visant à comparer le transcriptome de chacune des trois sous populations de monocytes chez des sujets obèses et chez des sujets non obèses sont présentés sous la forme d'un article et intitulé «Transcriptomic comparative analysis of each monocyte subset from obese and lean subject: classical monocytes (CD14⁺⁺CD16⁻) sustain obesity low grade inflammation » à soumettre au journal Plos Biology. La soumission se fera après confirmation par PCR quantitative de la modulation de l'expression des gènes intéressants.

1. Introduction

Notre travail préalable a montré un phénotype pro-inflammatoire des monocytes dans l'obésité, qui se traduit par une plus forte réponse à la stimulation de TLR4 et de TLR8, avec une augmentation de la réponse moins importante pour les IM que pour les NCM et les CM. Il suggère également une capacité migratoire accrue des CM et des IM dans l'obésité. Ce travail était basé sur une sélection limitée de molécules, choisies en raison de leur implication dans la réponse inflammatoire. Il nous semblait indispensable de passer à l'échelle de l'analyse du génome complet afin d'aborder l'étude de l'implication des différentes sous populations de monocyte dans l'obésité et ses comorbiditées sous un grand angle. Grâce à cette analyse, nous avons recherché les gènes et les grandes fonctions les plus modulées afin de découvrir de nouvelles voies de signalisation activées dans le contexte de l'obésité, et ainsi mieux comprendre l'implication de chacune des sous populations.

2. Résultats

Nous retrouvons les variations de proportions des trois sous populations de monocytes lorsque l'on compare le sang de sujets obèses et non obèses. La fréquence des CM diminue, celles des IM et NCM augmentent (Article 2 Figure 1). Les données des microarrays se présentent sous la forme de listes de sondes. Chaque sonde est spécifique d'un gène, et elle est associée à une intensité de fluorescence proportionelle à l'expression du gène. Une liste composée 42405 sondes a été générée pour chacun des trente échantillons. Nous avons normalisé ces données à l'aide du logiciel Gene Spring Software (Agilent), puis chacune des valeurs a été comparée au bruit de fond, et nous avons extrait une liste « P50 » des gènes

exprimés dans au moins 50% des échantillons pour chaque sous population. Ces listes comprennent respectivement 30550, 30688 et 31036 sondes pour les CM, les IM et les NCM. Les listes « P50 » ont été utilisées pour la comparaison de l'expression des gènes entre les sujets obèses et les sujets non obèses. Les gènes dont la variation d'expression est statistiquement significative et \geq 1,5 ont été sélectionnés. Ensuite, l'analyse des listes de 670, 640 et 570 gènes respectivement modulés par l'obésité dans les CM, les IM et les NCM a été faite en trois étapes : 1/ vérification de l'existence de variations différentielles d'expression des gènes mesurées au niveau du génome complet entre le groupe obèse et le groupe témoin pour chacune des sous populations, 2/ analyse des gènes dont l'expression est la plus modulée par l'obésité et 3/ analyse intégrative grâce au logiciel Ingenuity Pathway Analysis (IPA) des voies de signalisation et des fonctions associées aux gènes modulés dans chaque sous population. La figure 2 de l'article 2 résume la stratégie d'analyse.

L'analyse de l'expression des gènes au niveau du génome complet confirme sa modulation par l'obésité qui est spécifique de chacune des sous populations (Article 2, Figures 3 et 4) avec une signature plus homogène pour les CM que pour les IM et les NCM (Article 2, Figure 5).

Parmi les gènes dont l'expression est la plus modulée par l'obésité dans les CM, se trouvent des gènes codant pour des molécules impliquées dans la migration cellulaire, l'adhésion, la réponse immunitaire et le métabolisme (Article 2, Tableau 2). Concernant la migration et l'adhésion cellulaire les CM up-régulent fortement CLU (Clusterin), PLXNA2 (plexin A2), FBLIM1 (filamin binding LIM protein 1) (Article 2, Tableau 2). Ils up-régulent aussi CCR5 (Rantes) et FPR2 (formyl-peptide receptor 2), un gène pro-inflammatoire récepteur du SAA. Le gène de la clusterine ou apolipoprotéine J est le plus up-regulé par l'obésité (114,89 fold change, p < 0001), c'est une molécule intervenant dans la réponse immunitaire et la régulation du métabolisme (Article 2, Tableau 2). L'analyse intégrative par IPA a révélé que les gènes dont l'expression est modulée par l'obésité sont impliqués entre autre dans la signalisation cellulaire et le transport de molécules (Article 2, Tableau 5 et Figure 6). Les gènes les plus différentiellement exprimés par les IM de sujets obèses vs non obèses jouent un rôle dans les grandes fonctions moléculaires et cellulaires suivantes : adhésion cellulaire, réponse immunitaire, métabolisme, réponse aux substances toxiques, apoptose, régulation de la prolifération cellulaire et régulation de la respiration (Article 2, Tableau 3). Ils up-régulent par exemple des molécules clefs (ATP2A1 [ATPase, Ca⁺⁺ transporting, cardiac muscle, fast twitch 1] et MAP3K13 [mitogen-activated protein kinase

13]) des voies de signalisation NF- κ B, JNK et de la réponse cellulaire au glucose. CISD1 (CDGSH iron sulfur domain 1), encore appelé MitoNEET, est le gène le plus fortement uprégulé par l'obésité dans les IM (353,78-fold change, p = 0,003). Il s'agit d'une molécule intervenant dans la réponse au stress et dans la tolérance au glucose. L'analyse intégrative par IPA met en évidence que les IM modulent 95 gènes impliqués dans la mort cellulaire (Article 2, Tableau 5 et figure 7) dont 25 sont impliqués dans la mort du tissu conjonctif.

Les gènes les plus différentiellement exprimés par les NCM de sujets obèses *vs* non obèses interviennent dans l'adhésion cellulaire, la réponse immunitaire, le métabolisme, la réponse aux dérivés réactifs de l'oxygène, l'apoptose et le contrôle de la prolifération cellulaire (Tableau 4 article 2). L'analyse intégrative par IPA met en évidence que le métabolisme des sucres et des lipides est modifié par l'obésité dans les NCM et notamment la régulation du taux de glycogène (Article 2, Tableau 5 et Figure 8). Les NCM chez les sujets obèses seraient responsables d'une augmentation de la quantité de mégacaryocytes (les cellules à l'origine des plaquettes sanguines), et favoriseraient également la migration des cellules dendritiques.

3. Conclusion

L'analyse au niveau du génome complet confirme partiellement nos hypothèses et ouvre de nouvelles perspectives dans la compréhension du rôle de chacune des sous populations de monocytes dans le développement des maladies associées à l'obésité. Notre hypothèse de base faisait des CM les médiateurs de l'inflammation, des IM ses effecteurs et des NMC les modulateurs. L'image est en réalité plus complexe. Nous confirmons l'impact de l'obésité sur le transcriptome des monocytes qui est spécifique à chacune des sous populations. Néanmoins, l'influence de l'obésité sur l'expression des gènes des CM est plus homogène que sur celles des IM et des NCM.

Chez les sujets obèses, les CM up-régulent des gènes impliqués dans la migration, dans l'adhésion cellulaire (CLU, PLXNA, FBLIM1, CCR5) et dans'inflammation (FPR2). Ces résultats confirment leur rôle dans le maintien de l'inflammation de bas grade qui caractérise l'obésité. Chez les sujets obèses, les IM par l'up-regulation de molécules clefs (ATP2A1 et MAP3K13) des voies de signalisation NF-κB, JNK et de la réponse cellulaire au glucose, pourraient effectivement être les effecteurs dans la circulation systémique de la réponse inflammatoire aux signaux métaboliques, comme l'hyperglycémie et la dyslipidémie, présents chez les patients obèses. Mais sans doute pour contre balancer la réponse proinflammatoire, ils up-régulent un gène tel que CISD1 ayant des fonctions protectrices dans l'obésité. L'analyse intégrative par IPA suggère que les IM chez les sujets obèses favorisent la fibrose et la mort et du tissu conjonctif ; ils seraient donc les précurseurs de macrophages tissulaires pro-fibrotiques, dont le phénotype ne favoriserait pas l'angiogénèse.

Les NCM chez les sujets obèses pourraient aussi être capables de stocker des lipoprotéines circulantes par l'up-régulation d'un gène comme PXN (paxillin) qui intervient la phagocytose des oxLDL et dans la motilité. De plus, l'analyse intégrative par IPA suggère qu'ils stockent moins de glycogène que les NCM de sujets non obèses. Enfin, les NCM joueraient également un rôle dans la régulation des différentes populations de cellules immunitaires circulantes chez les sujets obèses. Ceci est mis en évidence par la modulation de l'expression d'un ensemble de gènes dont CXCL12, qui pourraient augmenter entre autre la quantité de mégacaryocytes circulantes et la migration des cellules dendritiques.

Abstract

Monocytes as major actors of the innate immune response in the circulation are considered as a bridge between inflammation and metabolism alterations. Our previous studies showed that monocytes quantities and inflammatory and migratory phenotypes of their subsets (CD14⁺⁺CD16⁻ [CM, Classical], CD14⁺⁺CD16⁺ [IM, Intermediate] and CD14⁺CD16⁺⁺ [NCM, Non Classical]) were specifically altered in human obesity, a disease associated to metabolic disorders. The aim of the present study was to decipher more broadly their individual contribution to obesity by comparative microarray analysis of sorted CM, IM and NCM isolated from blood of non diabetic obese patients and healthy non obese subjects; monocytes from 5 subjects of each group were analyzed for a total of thirty microarrays processed. Our results demonstrate that monocytes display a signature of obesity specific to each monocyte subset. The obesity imprint on CM reveals that they sustain the obesity linkedinflammation by modulating genes involved in cell signaling and among those genes we found up-regulation of CCR5 and FPR2 (formyl-peptide receptor 2), a receptor of serum amyloid A (SAA). The top regulated genes by obese-CM and obese-IM, respectively clusterin (CLU) and CISD1 or MitoNEET (CDGSH iron sulfur domain 1), link the immune response to metabolism and response to stress; CSD1 has protective functions in obesity. The microarray analysis showed that IM modulate also genes involved in increased activation of cell death of connective tissue and NCM modulate genes implicated in hematological development.

Key words: monocyte-subsets, obesity, transcriptomic microarray

Introduction

Obesity is recognized as a low-grade inflammatory disease characterized by an increased concentration of a large panel of cytokines, chemokines and acute phase proteins in the circulation (1) (2). Obesity-related inflammation favors the development of comorbidities such as type II diabetes, atherosclerosis, cardiovascular diseases, non-alcoholic steatohepatitis and some cancers (3) (4) (5) (6). The last decades, research for shared mechanism between obesity related pathologies and overweight highlighted closed relationships between nutrient excess and immunological homeostasis (4). Monocytes as major actors of the innate immune response in the circulation are considered as a bridge between inflammation and metabolism alterations. Indeed, there is positive correlation between the body mass index (BMI) and absolute number of monocytes (7) (8) (9) and monocytes are involved in cardiovascular disease pathophysiologies (10) (11) (12) (13) (14) (15). Three subsets of circulating monocytes have been described: classical monocytes (CD14⁺⁺CD16⁻ [CM]), intermediate monocytes (CD14⁺⁺CD16⁺ [IM]) and non-classical monocytes (CD14⁺CD16⁺⁺ [NCM]). CM represent about 90% of total monocytes and IM and NCM about 10%, they express differentially chemokine receptors indicating specific migratory potential: CM are CCR2⁺⁺CX3CR1^{-/+}CCR5⁻, IM are CCR2^{-/+}CX3CR1⁺CCR5⁺⁺ and NCM are CCR2⁻ CX3CR1⁺⁺CCR5⁻. Wong et al. (16) and Zawada et al. (17) described the three subsets in healthy donors using transcriptomic analysis, flow cytometry and functional in vitro tests of cytokine production; they showed that the CM are the more versatile ones, expressing the broadest range of trans-membrane receptors, of gene involved in a wide diversity of functions from tissue repair to immune response and producing the most important number of cytokines (G-CSF, IL-10, CCL2, CCL5 et IL-6) and chemokines when stimulated by LPS. IM would be more implicated in antigen presentation with a high inflammatory potential. Indeed, they are the main producers at basal state of reactive oxygen species and they produce specifically IL-1 β and TNF- α upon LPS stimulation (18). Inversely, NCM produce IL-1 β , TNF- α and CCL3 upon nucleic acid stimulation via TLR7-TLR8-MyD88-MEK pathway (19) and human NCM patrol endothelium of murine blood vessels after adoptive transfer (19). Our group described the three monocyte-subsets in obesity and we previously showed that both IM and NCM were increased in obese compared to lean subjects, with a significant enrichment of the NCM subset in obese diabetic patients. Multivariate analysis demonstrated a link between the percentages of NCM and glycemia, independent of fat mass. Drastic weight loss led to a sharp decrease of this subset, the variations of which were strongly related to fat mass changes. A reduction of at least 5% of fat mass was sufficient to observe a significant decrease of NCM monocytes. A diminution of the NCM subset was also observed during weight loss and was associated with a decrease in intima-media thickness (20). Phenotypically, we showed an increased expression of CX3CR1 in all monocyte subsets and of CCR2 and CCR5 in CM and IM in the Ob group. We found negative correlation between CCR2 and CX3CR1 expressions and high-density lipoprotein cholesterol, whereas CCR5 expression was positively linked to carbohydrate and lipid metabolism. Functionally, production of inflammatory proteins upon bacterial LPS and viral ssRNA stimulation was higher in obese-CM and obese-NCM compared to lean ones. Therefore our work highlighted an enhanced inflammatory phenotype of monocytes with a higher response to TLR4 and TLR8 stimulations in obesity and it suggested an increased migration capacity of CM and IM subsets (21). Our objective here is to decipher their individual contribution in obesity-linked inflammation more broadly by characterizing the transcriptional signature of each subset. To this purpose, we compared gene expression profile at whole genome level of sorted CM, IM and NCM monocytes isolated from blood of non-diabetic obese patients and healthy non-obese subjects. We conducted our analysis in three steps: 1/ demonstration that obesity specifically modulates mRNA expression at whole genome level in each subset, 2/ Individual analysis of modulated genes in each subset selected among the top ten up- and down-modulated genes and 3/ Research of top obesity modulated functions in each subset.

Our results demonstrate that monocyte display at the whole genome level a specific gene expression signature of obesity. This signature is specific to each monocyte subset and the CM obesity imprint shows that they sustain the obesity linked-inflammation.

Materials and methods

Blood samples and cell sorting

We used fasting blood samples from a group of 5 obese (Ob) and 5 control lean subjects (C). The obese patients enrolled in this study were involved in a bariatric surgery program and recruited to the nutrition division of Pitié-Salpêtrière Hospital (Reference Center for the Medical and Surgery Care of Obesity, Institute of Cardiometabolism and Nutrition, ICAN La Pitié-Salpêtrière Hospital, Paris, France). Patients were non-diabetic and met the criteria for bariatric surgery *i.d.* BMI \geq 40 kg/m2 or \geq 35 kg/m2 with at least 1 of the following comorbidity (hypertension, dyslipidemia, or obstructive sleep apnea syndrome). The second group comprised healthy normal-weight and non-diabetic volunteers (C), living in the same region as the Ob subjects. The Ethics Committee (CPP IIe de France 1) approved the clinical investigations for both Ob and C individuals. All subjects gave written informed consent. The study was conducted in accordance with the Declaration of Helsinki and was registered in a public trial registry (NCT00476658).

Cell sorting

PBMCs were isolated from blood by centrifugation on a Ficoll-Hypaque gradient (PAA Laboratories). Monocytes were then enriched by a centrifugation on a Hyper-osmotic Percoll^{Plus} Gradient (GE Healthcare) (22). Monocyte-enriched cell fraction was stained with APC-CD14, FITC-CD16, PE-CD3, PE-CD19, and PE-CD56. Doublets, dead cells, CD3+ T-cells, CD19⁺ B-cells and CD56⁺ NK cells were excluded, finally monocytes were selected based on their light scatters, CD14 and CD16 expressions and sorted into CD14⁺CD16⁺⁺, CD14⁺⁺CD16⁺ and CD14⁺CD16⁺⁺ cells. 2000 Cells were directly sorted in SuperAmp lysisTM buffer (MACS molecular Miltenyi Biotec) using a FACS ARIA III cell sorter (BD Biosciences), incubated at 45°C for 10 minutes and kept at -20°C until shipping on dry ice to Miltenyi Biotec. Supplemental Table I describes antibodies used for this studies.

Isolation of total RNA and cDNA amplification

SuperAmp RNA amplification was performed according to miltenyi Biotec's undisclosed procedure. Message RNA was isolated *via* magnetic bead technology and amplification was made according to a global PCR protocol using mRNA-derived cDNA, Amplified cDNA samples were quantified using the ND-1000 Spectrophotometer (NanoDrop Technologies). The integrity of the cDNA was check *via* the Agilent 2100 Bioanalyzer platform (Agilent Technologies)

Whole genome experiment

250 ng of each of the cDNAs were used as template for Cy3 labeling which was performed according to Miltenyi Biotec's undisclosed protocol. The Cy3-labeled cDNA were hybridized to an Agilent Whole Human Genome Oligo Microarrays 8x60K. Fluorescence signals of the hybrized Agilent Microarrays were detected using Agilent's Microarray Scanner System (Agilent Technologies). The Agilent Feature Extraction Software (FES) was used to read out and process the microarray image files. The software determines features intensities, reject outliers and calculate statistical confidences. The output data includes gene probe list for each sample.

Statistical and data analysis analysis

For each probe and each monocyte subset we calculated the average fluorescence intensity of samples from obese subjects and lean controls. The ratio between obese and lean groups was calculated (fold-change). Three "P50" lists have been created by filtering probes flagged as "Present" for at least half of the chips involved in the study, and were used for the genome comparison. The group comparisons were done using Student's *t*-test. To estimate the false discovery rate the resulting *p*-values were filtered at 0.05. Cluster analysis was performed by hierarchical clustering, using the Spearman correlation similarity measure and ward linkage algorithm. Unsupervised analysis step were performed using clustering prior to any supervised statistical comparison to unveil natural groups among the tested samples. Probes lists were filtered by *p*-value < 0.05 reflecting the statistical validity and by 1.5 fold-change variation of the gene expression. A new clustering step was performed after supervised analysis in order to test the generated list by classifying the samples in expected groups. To visualize the gene expression we turn mean centered data into heat-maps built by hierarchical classification using the Spearman correlation similarity measure and ward linkage

in clustering algorithm. The data were computed with R and the graphic produced with TreeView. Volcano plots were constructed by plotting for each comparison the negative log of the *p*-value on the *y*-axis and the *x*-axis is the log of the fold-change between the two conditions. Data were subsequently used for Ingenuity Pathway Analysis (IPA), a knowledge and discovery tool allowing to relate the most recent literature findings to experimental data, to model relationships among genes and proteins and to determine putative relevant biological processes.
Results

Obese patients, lean controls and cell sorting

The Ob patients and C subjects enrolled in this study were all non-diabetic females, aged 44.1 ± 1.8 and 39.8 ± 3.4 years respectively. The mean body mass index (BMI) was 44.1 ± 8.9 for Ob group and 22.4 ± 1.7 for the C group (Table 1). As expected, metabolic traits (glycemia, insulinemia and HOMA-IR) were significantly altered in Ob compared C group. As already published (23) (21), percentage of CM was decreased in the Ob group compared to the C group whereas percentages of IM and NCM were increased (Figure 1). Absolute number of NCM was also significantly increased in Ob group. Sorted monocyte subpopulations containing more than 98% of CD14⁺C16⁺⁺ or CD14⁺⁺CD16⁺ or CD14⁺⁺CD16⁻ cells were considered acceptable to include in the study (supplemental figure 1). Total RNA from obese and lean monocyte subsets was used to analyze whole genome expression by microarray experiments.

Genome-wide expression reveals an impact of obesity on the three subsets of monocytes

Our previous study showed that monocyte phenotype and functions of each of the three subsets was specifically altered in human obesity (21). Here, gene expression profiling using Agilent Microarray technology was performed to characterize the transcriptional signature of each monocyte subset in obesity. Our aim was to discover new key pathways and molecules that would be specifically modulated by obesity in each monocyte subpopulation. The whole strategy of filtering and analysis of the microarray data sets is summarized in figure 2. Normalized signal values corresponding to the 42405 probe-sets representing the whole genome were imported from microarrays data files for each subset. Probes giving normalized signal values different from the background signal in at least half of the chips involved in the study of each subset were selected, which represents 30550, 30688 and 31036 probes respectively for the CM, the IM and NCM (Figure 2).

To determine whether obese monocyte displayed a specific transcriptomic signature, a non-supervised clustering analysis (Spearman correlation similarity measure and ward linkage algorithm) with normalized signal values of the 30550, 30688 and 31036 probes-sets was performed (Figure 3A) followed by an unpaired supervised clustering including probes showing a minimal 1.5 fold-change expression between monocytes from obese and lean subjects, with a minimal *p*-value of 0.05. Using these filters, lists of 670, 640 and 570 probes that were differentially and significantly expressed were obtained for the CM, IM and NCM

subjects was observed for each subset demonstrating that obesity is associated with significant modifications in molecular features of the three monocyte subpopulations.

To ascertain the specificity of the probes modulated in each subset of monocyte by human obesity we constructed a Venn diagram and we found 17 obesity-modulated probes shared by CM and IM, 25 by IM and NCM and 16 by NCM and CM and none shared by the three subsets together (Figure 4). A list of the genes shared by two of the three subsets is presented in supplemental tables 1 to 3. Taken together, these results clearly demonstrate that monocyte sorted from blood obese patient display a specific gene expression signature, different from that of monocyte sorted from blood of lean subjects and the signature is specific to each monocyte subset.

To emphasis these observations, three heat maps including the 670, 640 and 570 differentially expressed probes between the two groups (fold-change > 1.5, *p*-value < 0.05)

were built. For the CM, all obese and lean samples are clustered in homogenous manner: on the upper part of the map are clustered the obese samples, the obesity-under expressed genes and the obesity-over-expressed genes segregate respectively on the left and the right side of the heat map; the inverse pattern was observed on the lower part of the heat map where are clustered the lean samples. These patterns were not observed for the IM and the NCM (Figure 5A) indicating a clearer signature of obesity for the CM compared to the two other subsets. Volcano plots showing probe expression variation in monocytes from obese and lean subjects revealed set of 314, 258 and 335 up-regulated probes and of 356, 382 and 235 down-regulated probes in obese CM, IM and NCM respectively (Figure 5B).

The top regulated genes in the three monocytes subsets link the immune response to metabolism and response to stress

We first performed without any functional filtering the analysis of the top regulated genes by obesity in the three monocytes subsets. Among the modulated probes in the CM, IM and NCM, 531, 491 and 458 unique and predicted probes were successfully mapped to a gene in Ingenuity Pathways Knowledge Base (IPKB). Complete lists of regulated genes are visible as supplementary data (Supplemental tables 4 to 6). The distribution of the different gene types is comparable between the three subsets with a maximum of 1% cytokines, 1% to 2% G-protein coupled receptors, less than 1% growth factors, 4% to 6% kinases, 1% to 3% peptidases, 1% to 2% phosphatases, less than 1% ligand-dependent nuclear factors, 2% to 3% trans-membrane receptors and 3% to 5% transporters. In Table 2 to 4 are presented top ten up- and top ten down-regulated genes in each monocyte subset in obesity.

Among the top 10 up- or down-regulated genes in obese-CM we found genes coding for molecules involved in: 1/ cell migration and adhesion (CLU [Clusterin], PLXNA2, FBLIM1 [filamin binding LIM protein 1]), 2/ immune response (ZP3 [zona pellucida glycoprotein 3 *sperm receptor*], SPON2 [spondin 2, extracellular matrix protein] and CLU) and 3/ metabolism (CLU, WDR35 [WD repeat domain 35], PINLYP [phospholipase A2 inhibitor and LY6/PLAUR domain containing] and BCKDHB [branched chain keto acid dehydrogenase E1, beta polypeptide]). We also found important up-regulation (51.64-fold change, p=0.02) of PEX11G (peroxisomal biogenesis factor 11 γ) a gene coding for a molecule involved in size regulation of the peroxisome, an organelle involved in oxidation reactions and in lipid biosynthesis. CLU or apolipoprotein J is the most regulated gene

Over expression in obesity

Table 3. Top up and down regulated genes in intermediate monocytes in obesity. "F50"-probes "present" at least in half of the chips involved in the study were analysed and filtered by 1.5-fold-change variation of the gene expression between obese and lean control groups and by *p*-value <0.05 reflecting the statistical validity. Resulting lists were analysed with Ingenuity Pathway IPA software and specific genes modulated in obese monocyte subsets were edited. We looked for gene functions and process in the NCBI gene database.

Table 4. Top up and down regulated genes in non classical monocytes in obesity. "F50"-probes "present" at least in half of the chips involved in the study were analysed and filtered by 1.5-fold-change variation of the gene expression between obese and lean control groups and by *p*-value <0.05 reflecting the statistical validity. Resulting lists were analysed with Ingenuity Pathway IPA software and specific genes modulated in obese monocyte subsets were edited. We looked for gene functions and process in the NCBI gene database.

Over-expression in obesity

(114.89-fold change, p < 0.001) in obese-CM. It is implicated in metabolic and immunological process. Which makes it interesting as a gene coding for a molecule linking the immune response with regulation of metabolism.

The top 10 up- or down-regulated genes in obese-IM are involved in many processes: 1/ cell adhesion (CD22), 2/ immune response (SFTPD [surfactant protein D], ATP2A1 [ATPase, Ca⁺⁺ transporting, cardiac muscle, fast twitch 1], MAP3K13 [mitogen-activated protein kinase 13], DOK4 [docking protein 4] and USP38 [ubiquitin specific peptidase 38]), 3/ metabolism (BPHL [biphenyl hydrolase-like - *serine hydrolase*], ARSD [arylsulfatase D] and ATP2A1), 4/ response to toxic substance (BPHL [biphenyl hydrolase-like - *serine hydrolase*]), 5/ apoptosis and regulation of cell proliferation (NAE1 [NEDD8 activating enzyme E1 subunit 1], TRIM35 [tripartite motif containing 35] and FANCA [Fanconi anemia, complementation group A]) and 6/ regulation of respiration (CISD1 [CDGSH iron sulfur domain 1] and SFTPD). Interestingly molecules like ATP2A and DOK4 binds the insulin receptors, and more particularly ATP2A is involved as well in metabolism process and in pathways of the inflammatory response. In the obese-IM, CISD1 is the most up-regulated gene (353,78-fold change, p = 0,003). CISD1 is also known as MitoNEET, a molecule already studied in obesity and acting on the oxidative stress and glucose intolerance (24).

The top modulated genes by obese-NCM are involved in: 1/ cell adhesion (DCHS1 [dachsous cadherin-related 1], PXN [paxillin) and CLASP2 [cytoplasmic linker associated protein 2]), 2/ immune response (NF1 [neurofibromin 1], CLEC1A [C-type lectin domain family 1, member A], PXN, PDXP [pyridoxal - *pyridoxine, vitamin B6* – phosphatase], LILRB5 [leukocyte immunoglobulin-like receptor, subfamily B - *with TM and ITIM domains*, member 5] and KLHL21 [kelch-like family member 21]), 3/ metabolism (CMPK2 [cytidine monophosphate (UMP-CMP) kinase 2, mitochondrial], NF1, IQCE [IQ motif containing E], FAHD2A [fumarylacetoacetate hydrolase domain containing 2A] and AACS [acetoacetyl-CoA synthetase], 4/ response to reactive oxygen species (PXN) and 5/ apoptosis and regulation of cell proliferation (NF1 and KLHL21). NF1 and PXN, because of their implication in processes of immune response, metabolism and response to stress are of interest in the comprehension of NCM functions in obesity. The top obesity modulated gene in the NCM is not as highly altered as the ones in the CM and IM, with a fold change of 33.96 and a *p* value of 0.031. The name of the molecule is methyltransferase like 24 (METTL24) and its functions are still unknown.

Top biological functions in which obesity modulated genes by each monocyte subset are implicated

To determine the link between the obesity-modulated genes in each monocyte subset and obesity related disorders we characterized the most relevant functions related to those genes using Ingenuity Pathway Analysis (IPA) application. Networks were then generated to determine top associated molecular and cellular functions. IPA calculates for each function an activation z-score. A positive activation z-score indicates an increase and, a negative one a decrease of the relevant function. When the absolute value of the activation z-score is ≥ 2 the increase or decrease is statistically significant (Table 5). We took into consideration functions relevant to obesity related disorders with z-score >1 and/or number of obesity modulated genes implicated > 6. We plotted the obesity-modulated genes implicated on those functions on heat-maps representing their level of expression in the obese and lean control groups (Figures 6, 7 and 8).

Top molecular and cellular group of functions modulated by obesity in the CM are: cell signaling, cellular compromise, DNA replication, recombination, and repair, molecular transport and nucleic acid metabolism. Cell signaling is the one that is the most likely to be modulated by obese-CM ($4.57 \times 10^{-4} 2.14 \times 10^{-2}$). It involves 39 genes implicated in immune cells recruitment, adhesion and migration and their modulation would lead to significant decrease of these functions (activation z-scores \leq -2,000). Five of the modulated genes (INRS [insulin receptor], NME1 [non-metastatic cells 1], PIKFYVE [phosphoinositide kinase, FYVE finger containing], PLAUR [plasminogen activator, urokinase receptor], ROCK2 [Rho-associated, coiled-coil containing protein kinase 2]) lead to an increase quantity of actin synthesis ($p = 1.12 \times 10^{-2}$, activation z-score = +2,000), a molecule involve in cell migration, by obese-CM (Figure 6A and table 5). Among the 19 genes involved in molecular transport, we found 10 genes involved as well in carbohydrate and lipid metabolism with 7 of them controlling the amount of glycogen (IGF1 [insulin-like growth factor 1], INPPL1 [inositol polyphosphate phosphatase-like 1], INSR, PDK4 [pyruvate dehydrogenase kinase, isozyme 4], RGL1 [ral guanine nucleotide dissociation stimulator-like 1], STK25 [serine/threonine kinase 25], STK40 [serine/threonine kinase 40]) though with a p value of $1,47 \times 10^{-3}$ and an null activation z- activation (Figure 6B and table 5).

Monocyte subsets	Molecular and cellular group of functions	# of genes involved in the group of functions	<i>p</i> -value	Functions within the group with absolute value z-score > 1 and/or number of genes implicated > 6
				Adhesion of granulocyte ($z = -2,102, \#$ genes = 10)
				Adhesion of immune cells (z = -2,243, # genes = 19)
				Adhesion of neutrophils $(z = -1, 477)$, # genes = 6)
				Adhesion of phagocyte $(z = -1,732, \# \text{ genes} = 8)$

	Carbohydrate and lipid Metabolism	17	3.69.10 ⁻² - 1.02.10 ⁻³	Quantity of glycogen (z = -1,133, # genes = 6)
	Cell Death and Survival	12	3.69.10 ⁻² - 1.02.10 ⁻³	
	Small Molecule Biochemistry	23	3.69.10 ⁻² - 1.02.10 ⁻³	
NCM	Cell Morphology	24	3.69.10 ⁻² - 1.24.10 ⁻³	Spreading of blood cells $(z = 1,452, \# \text{ genes} = 5)$
	Hematological system and development	17	3.69.10 ⁻² - 2.02.10 ⁻²	Quantity of megakaryocytes ($z = 1,000$, # genes = 4) Migration of dendritic cells ($z = 2,148$, # genes = 9)

Table 5. Top bio-functions in which obesity modulated genes are implicated. Analysis of genes presenting a 1.5 fold modulated expression in obesity were perform with Ingenuity Pathway IPA software to find their implication in bio-functions. Presented are group functions that are strongly associated with the up- and down-regulated molecules. The number of genes involved in each group of functions are indicated. *p* values reflect the less and the most probable function. Only functions with a *p* value < 0.05 were considered as relevant. Z-score (z) = activation score were calculated by IPA, positive or negative z indicates increase or decrease of the relevant function, absolute z-score > 2 is significant

Figure 6. Obese-classical monocytes (CM) modulate genes involved in cell signaling and in molecular transport and carbohydrate & lipid metabolism. Heat Maps representing gene expression by CM from obese (OB) subjects and lean controls (C) of genes involved A. in cell signaling and B. in molecular transport and carbohydrate & lipid metabolism. Hierarchical clustering was calculated using complete linkage.

Top molecular and cellular group of functions modulated by obesity in the IM are: cell morphology, gene expression, cell death and survival, cellular movement and molecular transport. Cell death and survival includes 95 modulated genes and among them 25 are implicated in cell death of connective tissue ($p = 1.13 \times 10^{-2}$, activation z-score = +1.621) (Figure 7A and table 5) and interestingly the down-regulation of VEGFA (Vascular endothelial growth factor A) could lead according to IPA prediction to increased activation of fibrosis of adipose tissue. Regarding molecular transport 13 molecules are implicated and, 5 of them control the release of glycerol ($p = 1.57 \times 10^{-3}$, activation z-score = -1.980) (Figure 7B and table 5).

Figure 7. Obese-intermediate monocytes (IM) modulate genes involved in cell death of connective tissue and in controlling the release of glycerol. Heat Maps representing gene expression by (IM) from obese (OB) subjects and lean controls (C) of genes involved A. in cell death of connective tissue and B. in controlling the release of glycerol. Hierarchical clustering was calculated using complete linkage.

Top molecular and cellular group of functions modulated by obesity in the NCM are: carbohydrate and lipid metabolism, cell death and survival, small molecule biochemistry, cell morphology and hematological system and development. The two groups, carbohydrate metabolism and lipid metabolism include 17 molecules; 13 belong only to the carbohydrate metabolism group of functions, 4 belong only to the lipid metabolism group of functions and 5 are shared by both of them. Seven molecules are involved in determining the quantity of glycogen (ACACB [acetyl-CoA carboxylase beta], PCYT1A [phosphate cytidylyltransferase 1, choline, alpha], PRKAB2 [protein kinase, AMP-activated, beta 2 non-catalytic subunit], RPS6KB1 [protein kinase, AMP-activated, beta 2 non-catalytic subunit], STK40 and ZBTB20 [zinc finger and BTB domain containing 20]) ($p = 1.15 \times 10^{-2}$, activation z-score = -1.133) (Figure 8A and table 5). Seventeen genes modulated by obesity in the NCM are related functions of hematological system and development with a p values between 3.69×10^{-2} and 2.02x10⁻². Four genes, C6orf25 (chromosome 6 open reading frame 25), CXCL12 (chemokine (C-X-C motif) ligand 12), FUT7 (fucosyltransferase 7 (alpha (1,3) fucosyltransferase)) and SPRED2 (sprouty-related, EVH1 domain containing 2) are implicated in regulating the quantity of megakaryocyte ($p = 1.29 \times 10^{-9}$, z-score = +1,000) and 6 are significantly ($p = 2.57 \times 10^{-2}$, activation z-score = +2.148) involved in increasing the migration of dendritic cells (CLEC1B [C-type lectin domain family 1, member B], CXCL12, FPR2, HCLS1 [hematopoietic cell-specific Lyn substrate 1], PLXNC1 [plexin C1], TRPV1 [transient receptor potential cation channel, subfamily V, member 1]) (Figure 8B and table 5). Among those genes, CXCL12 (fold increased OB *vs* C = 1,766, $p = 4.36 \times 10^{-2}$) is a central molecule that controls the amount of megakaryocytes together with SPRED2 and FUT7. IPA predicts its involvement in humoral immune response by acting with BCL6 (B-cell CLL/lymphoma 6) (fold increased OB *vs* C = 2,131, $p = 4.19 \times 10^{-2}$) on pro-B lymphocyte and development of plasma cells. It is also involved in chemotaxis of monocyte and migration of dendritic cells (z-score = + 2,148) (Table 5).

Figure 8. Obese-non classical monocytes (NCM) modulate genes involved in carbohydrate & lipid metabolism and in hematological system and development. Heat Maps representing gene expression by (NCM) from obese (OB) subjects and lean controls (C) of genes involved **A.** in carbohydrate & lipid metabolism and **B.** in hematological system and development. Hierarchical clustering was calculated using complete linkage.

Discussion

There are an increased proportion of circulating NCM and IM subsets in human obesity low-grade inflammation and an increased absolute number of each subsets including CM (23) (21). We previously showed that these modifications are associated with an enhanced inflammatory phenotype of monocytes in obesity (21). Therefore, the next step was to complete their description by a whole genome microarray analysis of sorted monocytes subsets from obese and lean subjects. The microarray results reinforce the role of CCR5 in CM previously described by Krinninger et al. (25) and our team (21). Here, we demonstrated specific characteristics for each monocyte subset at the whole genome level whereas, in our previous study, we showed specific modulation by obesity in each monocyte subset of only a selection of genes involved in the inflammatory response (21). More precisely, the microarray study reveals transcriptional modulations occurring specifically in monocyte present in the circulation of obese patient, with specific gene expression signature for each monocyte subset. This finding therefore shows clearer transcriptional modulation of the CM in obesity compared to the other subsets and brings them in front for their implication in obesity lowgrade inflammation. These results have to be put in line with the work of Wong et al. (16) defining circulating human monocyte subsets in healthy conditions. According to their microarray results, classical monocytes are the more versatile ones and they express the broadest range of sensing receptor genes, and also genes involved in a wide diversity of functions, including tissue repair and immune responses. Furthermore, the relatively high expression of pro-inflammatory genes may underlie the ability of classical monocytes to support inflammation.

In the obese-CM, CLU or apolipoprotein J is the most regulated gene. It has been shown by *Won et al.* (26) that plasma CLU levels were positively associated with indices of obesity and markers of systemic inflammation. Furthermore, plasma CLU levels showed an upward trend with increasing numbers of metabolic syndrome components. These findings suggest that fasting plasma CLU levels correlate with the parameters of adiposity and systemic inflammation in healthy adults. Therefore, the authors suggest that circulating CLU level may be a surrogate marker for obesity-associated systemic inflammation. By upregulating molecules like CLU, obese-CM could participate to increase circulating CLU levels. CLU circulates in plasma as a HDL complex (27) and recent proteomic analyses revealed that CLU is also bound to LDL and very-low density LDLs (28) (29) (30). It may

serve not only as an inhibitor of the lytic terminal complement cascade, but also as a regulator of lipid transport and local lipid redistribution (27). CLU is ubiquitously expressed in most cells and tissues, and is up-regulated under a variety of pathological conditions including ageing, diabetes, dyslipidemia, atherosclerosis, degenerative diseases (31) (32) (33). Whether increased CLU levels have beneficial or adverse effects on the cardiovascular system remains uncertain depending on its secreted or nuclear forms (34) (35) (36). The transcriptional regulation of CLU is very complex and controversial depending on the cytokines and tissues involved; it can be differentially regulated by various stimuli due to many distinct regulatory sites. As a matter of fact its promoter, highly conserved among the species, contains many potential regulatory elements including transforming growth factor (TGF)- β inhibitory element, activator protein-1 (AP-1), CLU-specific elements, and carbohydrate response element.

To get further inside on implication of CM in maintenance of inflammation, we studied the top biological functions in which CM obesity modulated genes are implicated. We found that cell signaling is the most modulated group of functions by obesity in the CM with a significant decreased activation of functions involved in immune cell recruitment, adhesion and migration. It shows that indeed CM are not responsible for the increased recruitment toward inflamed tissues, adhesion or migration of the other immune cells in obesity. Nevertheless, among the genes implicated in cell signaling over expression of CCR5 and FPR2 by obese-CM compare to lean-CM, indicate that the CM in obesity sustains the lowgrade inflammation and could be involved in obesity-related cardiovascular diseases. Undeniably there are now more evidences showing that CCR5 is implicated in monocyte attraction toward inflamed tissues (21) (25) (37). Furthermore CCR5 has been reported to be an active participant in the late stage of atherosclerosis and has the potential as a prognostic biomarker for plaque stability (38). FPR2 is activated by the acute phase reactant serum amyloid A (SAA), a marker of adiposity-induced low-grade inflammation (39) (40). SAA along with CRP are used clinically as inflammatory markers. Some studies have shown that SAA levels increase with higher degrees of inflammation, even in some non-cardiovascular inflammatory conditions, whereas CRP levels remain normal (41). Thus, SAA is considered more sensitive and useful than CRP as a marker of acute inflammatory response (41) (42). It was determined that SAA could potentiate atherogenesis at a number of stages. 1/ SAA is chemotactic for neutrophils and monocytes. 2/ SAA-carrying LDL may have greater proteoglycan-binding affinity leading to increased retention. 3/ SAA stimulates the synthesis of biglycan and increases its binding affinity for LDL. 4/ SAA can stimulate the production of other pro-inflammatory cytokines, exacerbating the vascular inflammation. 5/ SAA can induce matrix metalloproteinases (MMPs) that can lead to destabilization of the developing atherosclerotic plaque. Since SAA-1 allelic variant variant *via* FPR2 indirectly provokes monocyte chemotaxis by induction of cooperating CC and CXC chemokines (43) these new data suggest that SAA participate to the sustainability of obesity low-grade inflammation by interacting with the up-regulated receptor FPR2 at the surface of obese-CM. Furthermore, the significant increased activation of actin synthesis, a molecule involved in cell motility, by obese-CM consolidate the idea of an increased migratory potential of obese-CM. Interestingly among the gene participating to the increased activation of actin synthesis we found the insulin receptor, a key receptor in glucose metabolism, that is increased in obese-CM. Actually, this molecule is also implicated in function controlling the amount of glycogen together with IGF1, INPPL1, PDK4, RGL1, STK25, STK40 that are also modulated by obesity in CM.

Interestingly IM up-regulate with a very high magnitude a molecule (CISD1 or MitoNEET) that would make them actors of the organism protection against excess free fatty acid. A very complete work (24) performed on mouse models with altered adipocyte expression of mitoNEET shows that adipocyte overexpression of mitoNEET enhances lipid uptake and storage, leading to an expansion of the mass of adipose tissue. Nevertheless, despite the resulting massive obesity, benign aspects of adipose tissue expansion prevail, and insulin sensitivity is preserved. Mechanistically, they also found that mitoNEET inhibits mitochondrial iron transport into the matrix and, because iron is a rate-limiting component for electron transport, lowers the rate fatty acid degradation by β -oxidation. This effect is associated with lower mitochondrial membrane potential and lower levels of reactive oxygen species-induced damage, along with increased production of adiponectin. Conversely, a reduction in mitoNEET expression enhances mitochondrial respiratory capacity through enhanced iron content in the matrix, ultimately corresponding to less weight gain on a highfat diet. However, this reduction in mitoNEET expression also causes heightened oxidative stress and glucose intolerance. They found similar effect exerted by mitoNEET in hepatocytes indicating a common effect of mitoNEET on cellular physiology in different tissue types. Our whole genome microarray analysis is the first one showing increased expression of mitoNEET by a specific cell type in the context of human obesity. This finding suggests an adaptation of IM to obesity by becoming able to store and neutralize excess free fatty acid.

In the same line among top biological functions in which IM obesity modulated genes are implicated we found decreased activation of release of glycerol. IM modulate also genes involved in increased activation of cell death of connective tissue, among those genes we showed a decreased expression of VEGFA and HIF1A, two pro-angiogenic factors. The Ingenuity Pathway analysis highlighted that their decreased expression could lead to fibrosis of adipose tissue. In non-pathological conditions IM are the pro-angiogenic monocytes (17) exhibiting features of senescent cells and increased capacity for endothelial adhesion (44). Our findings suggest that in the context of obesity IM phenotype is modified by the storage of excess free fatty acid and therefore could be precursors of tissue macrophages that produce less angiogenic factors, promote cell death of connective tissues and are pro-fibrotic. This hypothesis is supported by a recent work that compared transcriptomes of foamy and nonfoamy macrophages that accumulate in the subcutaneous granulomas (induced by surgical sponge implantation) of fed-fat ApoE null mice and normal chow fed wild-type mice *in vivo*. Indeed, the results of this work show that foam cell formation *in vivo* leads to a pro-fibrotic macrophage phenotype (45).

NCM top up-regulated genes included NF1 and PXN. Both are involved in processes of immune response, metabolism and response to stress. PXN is a cytoskeletal protein that is phosphorylated in response to LPS in monocyte and macrophages. It is involved in the reorganization of actin cytoskeleton driving motility upon monocyte/macrophage LPS stimulation (46) (47). Miller et al. (48) showed that minimal Low Density Lipoprotein (LDL) induces via TLR4, signaling events and cytoskeletal rearrangements leading to enhanced uptake of both native and oxidized LDL; resulting in intracellular lipid accumulation. Therefore the up-regulation of PXN by obese-NCM suggests that this specific subset of circulating monocytes can accumulate lipoproteins. With regard to NF1, it is implicated in controlling myeloid cell proliferation (49). A mutation in this gene cause a disease named Neurofibromatosis type 1 and one of its manifestation involves disorders of the cardiovascular system with increased circulating inflammatory monocytes and arterial occlusion; inactivation of NF1 in myeloid cells enhanced neointima formation. It has been shown using murine in vivo model and in vitro migration assays that NF1 deficient macrophages demonstrate enhance migration and proliferation in response to growth factor stimulation compare to wild type ones. This response is dependent on the RAS-ERK pathway (50). The increased expression of NF1 by obese-NCM could be a response to control the obesity related inflammation.

The analysis of the top biological functions in which NCM obesity modulated genes are implicated revealed that NCM modulate gene involved in carbohydrate and lipid metabolism and in hematological development. The detailed analysis of those genes suggests that obese-NCM would store less glycogen than lean ones. It also suggests that the modulated genes would lead to increased quantity of megakaryocytes, the cells responsible for the production of platelets and increased migration of dendritic cells. Among the genes involved in dendritic cells migration we found FPR2, a receptor activated by SAA that is also upregulated by obese-CM. Showing that indeed both subsets are involved in sustaining obesity low grade inflammation. We also found up-regulation of the chemokine CXCL12. CXCL12 plays a critical role in monocyte extravasation and is expressed under homeostatic conditions at sites where resident macrophages are present, and is highly inducible in some pathologic conditions involving ischemia and/or hypoxia and in pro-angiogenic environments, such as tumors (51). It is secreted by monocytes that also express its receptors CXCR4 and CXCR7 which leads to an autocrine/paracrine loop that contributes to modulate differentiation of monocytes toward a distinct program with pro-angiogenic function and reduced functional ability to stimulate antigen-specific T-lymphocyte responses (52). Furthermore, it has been demonstrated that during obesity, adipocytes within human and mouse breast tissues recruit and activate macrophage, through a CCL2/IL-1β/CXCL12 signaling pathway (53). Finally, CXCL12 was identified as potential therapeutic target for atherosclerosis and thrombosis by genome-wide association studies (GWAS) (54). Therefore, targeting CXCL12 could be a possibility to reduce obesity related inflammation.

All together this study at the whole genome level confirms that indeed obesity modulate the transcriptome of monocytes and furthermore specific obesity related modulations occur within each monocyte subset. The obesity imprint on CM shows that they sustain obesity low-grade inflammation and that they could be involved in obesity-related cardiovascular diseases. The analysis of the IM obesity modulated genes suggests that circulating obese-IM could be able to store and neutralize excess free fatty acid and could give rise to pro-fibrotic macrophages within tissues. Obese-NCM modulate compare to lean ones genes involved in carbohydrate and lipid metabolism; their profile suggest that they could store less glycogen and the over-expression of PXN indicates that as well they could be able to accumulate lipoproteins. Obese-NCM could be responsible for an increased amount of megakaryocytes and an increase migration of dendritic cells. Finally, probably to control inflammation, obese-IM and NCM up-regulate molecules, CISD1 and NF1, with protective functions against obesity comorbidities.

Supplemental materials

flow cytometry, percentage of each subset was measured before (A) and after the cell sorting (B) to check the purity.

APC-conjugated anti-CD14 (clone MfP9 from Becton Dickinson)
FITC-conjugated anti-CD16 (clone 3G8 from Becton Dickinson)
PE-conjugated anti-CCR2 (clone 48607 from Becton Dickinson)
PE-anti-CD19 (clone HIB19 from Becton Dickinson)
PE-conjugated anti-CD56 (clone B159 from Becton Dickinson)

Dead cell marker: 4',6-diamidino-2-phenylindole dilactate (DAPI) (Life technologies)

Supplemental table 1. list of antibodies used for of monocyte subset FACS sorting

Symbol	Gene Name	Location	Type(s)	Fold Change	Ratio OB vs C (fluorescent Signal Intensity)	<i>p</i> -value
BUB1	BUB1 mitotic checkpoint serine/ threonine kinase	Nucleus	kinase	-3,721	64,035	4,66E-02

Symbol	Entrez Gene Name	Location	Type(s)	Fold Change	Other	p-value	Notes
C10orf113	chromosome 10 open reading frame 113	Other	other	-40,351	173,302	1,16E-02	
CCDC85C	coiled-coil domain containing 85C	Plasma Membrane	other	-23,888	267,723	3,44E-04	
PGBD4	piggyBac transposable element derived 4	Other	other	-17,889	58,343	5,66E-05	
BCKDHB	branched chain keto acid dehydrogenase E1, beta polypeptide	Cytoplasm	enzyme	-17,335	327,976	1,92E-02	
LINC00954	long intergenic non-protein coding RNA 954	Other	other	-16,335	222,333	2,65E-02	
ZP3	zona pellucida glycoprotein 3 (sperm receptor)	Extracellular Space	transporter	-15,297	225,786	7,55E-04	
TRIM65	tripartite motif containing 65	Other	other	-13,929	117,26	1,31E-03	
SPON2	spondin 2, extracellular matrix protein	Extracellular Space	other	-13,412	129,006	2,48E-02	
ARMCX5	armadillo repeat containing, X-linked 5	Other	other	-12,88	57,631	3,25E-02	
LOC100128079	uncharacterized LOC100128079	Other	other	-11,378	195,154	1,99E-02	
LOC642423/LOC727751	golgin A2 pseudogene	Other	other	-11,245	662,916	2,54E-02	
CYHR1	cysteine/histidine-rich 1	Nucleus	other	-10,408	66,038	3,41E-02	
C5orf63	chromosome 5 open reading frame 63	Cytoplasm	other	-9,237	46,715	3,62E-03	
RAPGEFL1	Rap guanine nucleotide exchange factor (GEF)-like 1	Other	other	-8,71	81,516	2,51E-02	
PSMG4	proteasome (prosome, macropain) assembly chaperone 4	Other	transcription regulator	-8,605	114,922	7,25E-03	
RDH12	retinol dehydrogenase 12 (all-trans/9-cis/11-cis)	Cytoplasm	enzyme	-8,427	111,168	3,64E-02	
LINC01530	long intergenic non-protein coding RNA 1530	Other	other	-8,265	298,288	2,12E-02	
C9orf41	chromosome 9 open reading frame 41	Other	other	-8,023	185,635	4,53E-03	
ALKBH8	alkB, alkylation repair homolog 8 (E. coli)	Cytoplasm	enzyme	-7,473	443,379	3,06E-02	
PEMT	phosphatidylethanolamine N-methyltransferase	Cytoplasm	enzyme	-7,001	560,638	4,73E-02	
LINC00869	long intergenic non-protein coding RNA 869	Other	other	-6,894	154,656	2,79E-02	
GATA1	GATA binding protein 1 (globin transcription factor 1)	Nucleus	transcription regulator	-6,889	66,576	4,31E-02	
SMIM13	small integral membrane protein 13	Other	other	-6,821	30,279	4,58E-02	
FAM189B	family with sequence similarity 189, member B	Other	other	-6,712	520,456	1,01E-02	
UVRAG	UV radiation resistance associated	Nucleus	other	-6,663	27,342	2,21E-02	
FAM110C	family with sequence similarity 110, member C	Cytoplasm	other	-6,244	137,982	1,35E-02	
SNORA2A	small nucleolar RNA, H/ACA box 2A	Other	other	-6,239	107,173	1,26E-02	

EGOT	eosinophil granule ontogeny transcript (non-protein coding)	Other	other	-6,209	63,301	2,47E-02	
TMC8	transmembrane channel-like 8	Cytoplasm	other	-6,203	1276,212	5,27E-03	
RPS14	ribosomal protein S14	Cytoplasm	translation regulator	-6,2	781,361	3,28E-02	
LPO	lactoperoxidase	Extracellular Space	enzyme	-6.198	107.035	1.59E-02	
CAPRIN1	cell cvcle associated protein 1	Plasma Membrane	other	-6.172	70.436	3.52E-02	
ZKSCAN5	zinc finger with KRAB and SCAN domains 5	Nucleus	transcription regulator	-6.035	67.877	1.70E-02	
PHF14	PHD finger protein 14	Nucleus	other	-6,002	74,699	8,85E-03	
ZNF618	zinc finger protein 618	Other	other	-5,969	57,514	7,83E-03	
C16orf58	chromosome 16 open reading frame 58	Other	other	-5,967	136,416	2,98E-02	
LRRC18	leucine rich repeat containing 18	Cytoplasm	other	-5,836	569,676	8,50E-03	
ALS2CL	ALS2 C-terminal like	Cytoplasm	other	-5,472	585,48	2,19E-02	
ITPK1	inositol-tetrakisphosphate 1-kinase	Cytoplasm	kinase	-5,315	130,474	2,18E-02	
TNK2-AS1	TNK2 antisense RNA 1	Other	other	-5,284	212,121	4,77E-02	
CDK11A	cyclin-dependent kinase 11A	Nucleus	kinase	-5,229	221,563	4,54E-02	
FEM1A	fem-1 homolog a (C. elegans)	Nucleus	transcription regulator	-5,217	212,234	3,23E-02	
AK4	adenylate kinase 4	Cytoplasm	kinase	-5,193	41,952	5,54E-03	
RPA1	replication protein A1, 70kDa	Nucleus	other	-5,157	100,101	2,34E-02	
ACADSB	acyl-CoA dehydrogenase, short/branched chain	Cytoplasm	enzyme	-4,997	119,773	4,72E-02	D
MORC2-AS1	MORC2 antisense RNA 1	Other	other	-4,975	150,802	1,80E-02	
CXCL2	chemokine (C-X-C motif) ligand 2	Extracellular Space	cytokine	-4.955	141.13	4.13E-02	
GAPVD1	GTPase activating protein and VPS9 domains 1	Cytoplasm	other	-4.884	145.154	1.31E-02	
EVL	Enah/Vasp-like	Plasma Membrane	other	-4.854	329.232	3.02E-03	
PCGF5	polycomb group ring finger 5	Cytoplasm	other	-4,824	41,431	7,76E-03	
CHGA	chromogranin A (parathyroid secretory protein 1)	Cytoplasm	other	-4,704	276.873	3,12E-02	
CRHR1-IT1	CRHR1 intronic transcript 1 (non-protein coding)	Other	other	-4,681	186,522	3,25E-02	
ROCK2	Rho-associated, coiled-coil containing protein kinase 2	Cytoplasm	kinase	-4,639	150,706	4,46E-02	
TAS2R39	taste receptor, type 2, member 39	Plasma Membrane	other	-4,599	234,412	1,81E-02	
RAB11FIP3	RAB11 family interacting protein 3 (class II)	Cytoplasm	other	-4,54	204,529	2,11E-02	
STARD9	StAR-related lipid transfer (START) domain containing 9	Cytoplasm	other	-4,488	217,342	4,86E-02	
BUB1	BUB1 mitotic checkpoint serine/threonine kinase	Nucleus	kinase	-4,461	41,672	1,82E-02	
SPDYA	speedy/RINGO cell cycle regulator family member A	Nucleus	other	-4,413	44,151	3,54E-02

TROK	TRC1 domain containing kinase	Other	kinase	4,440	124.61	4 77E-02	
7422	zine fingers and homenhoves 2	Nuclous	transcription regulator	4,407	001.0	3 005-02	
ZNF717	zine ingere and noncooked of	Nucleus	other	4,30	199.87	1.88E-02	
SEMBT1	Scm-like with four mht domains 1	Nucleus	transcription regulator	4,332	93 001	3 29E-02	
CA5B	carbonic anhydrase VB. mitochondrial	Cytoplasm	enzyme	4,348	304 818	3.94E-02	
CDPF1	cysteine-rich DPE motif domain containing 1	Extracellular	other	4,23	150 422	4.60E-02	D
	KH type splicing regulatory protein	Nuclous	007000	4,264	442 972	3 77E 00	5
	kaleh domain containing 2	Cytoplasm	other	4,20/	442,872	4.86E-02	
KIAA1270	KIAA1970	Cytoplasm	007//00	4,173	77 500	3.01E.02	
EPHB2	EPH recentor R2	Plasma Mombrana	kinase	4,027	277 /6/	2 41=-02	D
REGAIN	brain anriched guanylate kinace accepted	Nuclous	othor	4,025	121.072	2,705.02	5
DEGAIN	orani-ennoneu guattytate Kitase-associateu	Nucleus	oulei	4,015	131,972	3,19E-03	

CDKN2C	cyclin-dependent kinase inhibitor 2C (p18, inhibits CDK4)	Nucleus	transcription regulator	3,978	36,512	3,12E-02	
CTSC	cathepsin C	Cytoplasm	peptidase	3,961	28,365	3,04E-02	
OSBPL3	oxysterol binding protein-like 3	Cytoplasm	other	3,928	77,25	1,60E-02	
TSSC1	tumor suppressing subtransferable candidate 1	Other	other	3,922	2039,58	4,49E-02	
LOC100506374	uncharacterized LOC100506374	Other	other	3,89	386,274	2,44E-02	D
SARM1	sterile alpha and TIR motif containing 1	Plasma Membrane	receptor	3,874	1180,16	4,60E-02	D
NOP56	NOP56 ribonucleoprotein	Nucleus	other	3,862	725,13	2,08E-02	
CLIC4	chloride intracellular channel 4	Plasma Membrane	ion channel	3,849	210,165	3,20E-02	D
RYR3	ryanodine receptor 3	Plasma Membrane	ion channel	3,823	17,36	1,39E-03	
TMEM185B	transmembrane protein 185B	Other	other	3,795	105,034	9,06E-03	
PUF60	poly-U binding splicing factor 60KDa	Nucleus	other	3,79	1374,192	2,61E-02	
WDYHV1	WDYHV motif containing 1	Cytoplasm	other	3,79	432,914	2,69E-02	
GAB1	GRB2-associated binding protein 1	Cytoplasm	other	3,771	36,143	2,47E-02	
ZC3H13	zinc finger CCCH-type containing 13	Space	other	3,77	89,954	4,17E-02	
ZER1	zyg-11 related, cell cycle regulator	Other	enzyme	3,77	98,724	4,00E-02	
F8A1 (includes others)	coagulation factor VIII-associated 1	Nucleus	other	3,733	894,326	4,88E-02	
COQ4	coenzyme Q4	Cytoplasm	other	3,65	156,242	2,95E-02	
LINC00662	long intergenic non-protein coding RNA 662	Other	other	3,625	274,664	3,03E-02	
LRIF1	ligand dependent nuclear receptor interacting factor 1	Nucleus	other	3,604	30,019	1,89E-02	
PSMD4	proteasome (prosome, macropain) 26S subunit, non-ATPase, 4	Cytoplasm	other	3,578	1556,5	1,04E-02	
FAM220BP	Putative SIPAR-like protein C9orf51	Other	other	3,557	37,174	3,09E-02	
MAP7	microtubule-associated protein 7	Cytoplasm	other	3,53	37,264	1,97E-02	
SLC2A11	solute carrier family 2 (facilitated glucose transporter), member 11	Plasma Membrane Extracellular	other	3,471	168,662	3,06E-02	
CDPF1	cysteine-rich, DPF motif domain containing 1	Space	other	3,402	403,524	4,00E-02	D
MUC5B	mucin 5B, oligomeric mucus/gel-forming	Extracellular Space	peptidase	3.39	232.562	3,67E-02	
PGBD3	piggyBac transposable element derived 3	Other	other	3,367	52,556	1,13E-02	
THOP1	thimet oligopeptidase 1	Cytoplasm	peptidase	3,357	488,18	3,73E-02	
	nlovin A4	Plasma Marchara	transmembrane	2 2 2 2 2	45.004	1.625.00	
PLANA4	plexin A4	Plasma Memorane	receptor	3,333	45,064	1,62E-02	
	Tato DNace domain containing 2	Nucleus	other	3,293	791.2	4,93E-04	
	Tab Divase domain containing 2	Nucleus	transcription regulator	3,200	400.19	3,09E-02	
PDE3B	phosphodiesterase 3B cGMP.inhibited	Cytoplasm	enzyme	3 267	28.003	4,03E-02	
CIAPIN1	cytokine induced apoptosis inhibitor 1	Cytoplasm	other	3,149	359,236	3.42E-02	
ZNF232	zinc finger protein 232	Nucleus	other	3.09	200.378	1.92E-02	
TOR1A	torsin family 1, member A (torsin A)	Cytoplasm	enzyme	3,07	246,772	1,73E-02	
CRYBA1	crystallin, beta A1	Other	other	3,04	236,65	3,94E-02	
MIF4GD	MIF4G domain containing	Other	other	3,018	715.932	4.13E-02	
PAM16	presequence translocase-associated motor 16 homolog (S. cerevisiae)	Cytoplasm	other	3,017	109,252	3,20E-02

SGSH	N-sulfoglucosamine sulfohydrolase	Cytoplasm	enzyme	2,3	2538,8	3,05E-02
RNF187	ring finger protein 187	Nucleus	enzyme	2,28	496,72	4,63E-02
RBM48	RNA binding motif protein 48	Nucleus	other	2,277	177,9	4,07E-02
SCARNA17	small Cajal body-specific RNA 17	Other	other	2,261	49,443	4,72E-02
ZNF197	zinc finger protein 197	Nucleus	transcription regulator	2,23	164,078	2,83E-02
LGALS9C	lectin, galactoside-binding, soluble, 9C	Other	other	2,228	538,64	2,91E-02
SLC25A20	solute carrier family 25 (carnitine/acylcarnitine translocase), member 20	Cytoplasm	transporter	2,227	2961,36	4,52E-02
ZNF137P	zinc finger protein 137, pseudogene	Nucleus	transcription regulator	2,2	27,585	4,36E-02
PELI3	pellino E3 ubiquitin protein ligase family member 3	Cytoplasm	enzyme	2,161	769,52	3,53E-02
C11orf31	chromosome 11 open reading frame 31	Nucleus	other	2,157	1482,3	3,75E-02
DHX32	DEAH (Asp-Glu-Ala-His) box polypeptide 32	Other	enzyme	2,133	259,88	4,12E-02
CD2BP2	CD2 (cytoplasmic tail) binding protein 2	Cytoplasm	other	2,116	489,4	2,28E-02
HAGLROS	HAGLR opposite strand (non-protein coding)	Other	other	2,111	61,772	2,47E-02
EPHB2	EPH receptor B2	Plasma Membrane	kinase	2,106	665,02	1,90E-02 D
PTRH2	peptidyl-tRNA hydrolase 2	Cytoplasm	enzyme	2,106	351,22	4,74E-02
FITM1	fat storage-inducing transmembrane protein 1	Space	other	2,104	278,94	6,36E-03
ABCE1	ATP-binding cassette, sub-family E (OABP), member 1	Cytoplasm	transporter	2,097	39,11	2,76E-02 D
DCTN2	dynactin 2 (p50)	Cytoplasm	other	2,085	362,4	2,21E-02
MX2	MX dynamin-like GTPase 2	Nucleus	enzyme	2,061	1716,6	2,96E-02
KANSL2	KAT8 regulatory NSL complex subunit 2	Nucleus	other	2,059	373,28	2,16E-02
RALGAPB	Ral GTPase activating protein, beta subunit (non-catalytic)	Other	other	2,051	651,46	9,12E-03
INPPL1	inositol polyphosphate phosphatase-like 1	Cytoplasm	phosphatase	2,041	2637,4	3,27E-02
OAS3	2'-5'-oligoadenylate synthetase 3, 100kDa	Cytoplasm	enzyme	2,028	3754,8	4,75E-02
SYNGR2	synaptogyrin 2	Cytoplasm	other	2,001	239,648	3,96E-02
PTAR1	protein prenyltransferase alpha subunit repeat containing 1	Other	other	1,989	275,06	4,88E-02
RREB1	ras responsive element binding protein 1	Nucleus	transcription regulator	1,968	1902,2	2,11E-02
C20orf27	chromosome 20 open reading frame 27	Other	other	1,965	1001,66	4,86E-02
IDS	iduronate 2-sulfatase	Cytoplasm	enzyme	1,957	70,686	8,13E-03
EIF4EBP3	ankyrin repeat and KH domain containing 1	Other	other	1,93	179,98	4,41E-02
LOC729083	uncharacterized LOC729083	Other	other	1,928	466,84	4,88E-02
VKORC1	vitamin K epoxide reductase complex, subunit 1	Cytoplasm	enzyme	1,919	624,547	4,74E-02
C20orf196	chromosome 20 open reading frame 196	Other	other	1,918	456,08	3,87E-02
ST3GAL1	ST3 beta-galactoside alpha-2,3-sialyltransferase 1	Cytoplasm	enzyme	1,912	425,46	3,74E-02
SRGAP2	SLIT-ROBO Rho GTPase activating protein 2	Cytoplasm	other	1,909	676	2,16E-02
DCPS	decapping enzyme, scavenger	Nucleus	enzyme	1,904	567,82	3,57E-02
TMEM106A	transmembrane protein 106A	Cytoplasm	other	1,903	216,824	1,62E-02
DIS3L	DIS3 like exosome 3'-5' exoribonuclease	Cytoplasm	enzyme	1,898	430,96	3,35E-02
EPSTI1	epithelial stromal interaction 1 (breast)	Other	other	1,874	1206,96	3,28E-02
ZNHIT1	zinc finger, HIT-type containing 1	Nucleus	other	1,861	387,2	4,02E-02
BAG5	BCL2-associated athanogene 5	Cytoplasm	other	1,859	392,26	4,26E-02
LOC440292	uncharacterized LOC440292	Other	other	1,847	251,06	4,67E-02
ITIH3	inter-alpha-trypsin inhibitor heavy chain 3	Space	other	1,839	99,304	3,39E-02
LOC392364	nuclear pore associated protein 1 pseudogene	Other	other	1,832	228,92	4,57E-02
AMBRA1	autophagy/beclin-1 regulator 1	Cytoplasm	other	1,815	325,36	3,86E-02
CALHM2	calcium homeostasis modulator 2	Other	other	1,792	239	4,62E-02
CIAO1	cytosolic iron-sulfur assembly component 1	Nucleus	transcription regulator	1,791	281,04	1,06E-02
LAIR1	leukocyte-associated immunoglobulin-like receptor 1	Plasma Membrane	transmembrane receptor	1,775	1570,2	6,70E-05
NCF2	neutrophil cytosolic factor 2	Cytoplasm	enzyme	1,769	297,88	4,78E-02
CXorf21	chromosome X open reading frame 21	Other	enzyme	1,762	1256,42	4,58E-02
LINC00963	long intergenic non-protein coding RNA 963	Other	other	1,747	1011,24	4,87E-02
ATG13	autophagy related 13	Cytoplasm	other	1,73	231,8	4,48E-02
ZBTB8OS	zinc finger and BTB domain containing 8 opposite strand	Cytoplasm	other	1,724	4099	6,80E-03
TIRAP	toll-interleukin 1 receptor (TIR) domain containing adaptor protein	Cytoplasm	other	1,722	855,22	3,26E-02
GOLM1	golgi membrane protein 1	Cytoplasm	other	1,717	565,06	3,83E-02
IFITM3	interferon induced transmembrane protein 3	Plasma Membrane	other	1,709	19922,4	4,71E-02
PPL	periplakin	Cytoplasm	other	1,704	27,5	1,97E-02
GTPBP6	GTP binding protein 6 (putative)	Other	other	1,693	622,34	4,80E-02
LOC102725383	uncharacterized LOC102725383	Other	other	1,683	301,54	2,94E-02
BAALC	brain and acute leukemia, cytoplasmic	Cytoplasm	other	1,665	201,86	1,56E-02
EHD2	EH-domain containing 2	Nucleus	other	1,609	32,718	3,64E-02
CD300A	CD300a molecule	Plasma Membrane	receptor	1,6	3791,8	4,28E-02
SLC2A14	solute carrier family 2 (facilitated glucose transporter), member 14	Nucleus	transporter	1,6	40,032	1,25E-02
PRH2	proline-rich protein HaellI subfamily 2	Extracellular Space	other	1.541	AF 80	2.95E-02
TARP	TCR namma alternate reading frame protein	Cytoplasm	other	1.54	51.20	5 14E-03

DOK4	docking protein 4	Plasma Membrane	other	-10,529	02,43	3,40E-02	
DUK4	docking protein 4	Plasma Membrane	other	-16,529	92,43	3,40E-02	
SPEN	spen family transcriptional repressor	Nucleus	transcription regulator	-15,046	48,835	4,74E-05	
GPR137	G protein-coupled receptor 137	Other	other	-14,225	625,875	3,80E-03	
FANCA	Fanconi anemia, complementation group A	Nucleus	other	-10,417	73,766	2,49E-02	
ZNF254	zinc finger protein 254	Nucleus	other	-10,259	216,849	5,30E-03	
TRIM35	tripartite motif containing 35	Cytoplasm	other	-8,278	99,205	1,24E-02	
USP38	ubiquitin specific peptidase 38	Other	peptidase	-8,241	93,307	7,05E-04	
UBE2Q2	ubiquitin-conjugating enzyme E2Q family member 2	Other	enzyme	-7,602	55,323	7,75E-03	
MYBL1	v-myb avian myeloblastosis viral oncogene homolog-like 1	Nucleus	transcription regulator	-6,89	79,8	4,71E-02	
GLB1L	galactosidase, beta 1-like	Other	other	-6,855	202,24	1,20E-02	
MYO7A	myosin VIIA	Cytoplasm	enzyme	-6,611	67,116	2,75E-02	
TAF1	TAF1 RNA polymerase II, TATA box binding protein (TBP)-associated factor, 250kDa	Nucleus	transcription regulator	-6,425	33,401	4,05E-02	
PVT1	Pvt1 oncogene (non-protein coding)	Other	other	-6,416	76,891	1,21E-02	D
EXT2	exostosin glycosyltransferase 2	Cytoplasm	enzyme	-6,12	216,883	2,43E-02	
RIMKLB	ribosomal modification protein rimK-like family member B	Cytoplasm	other	-6,054	45,043	3,28E-03	
NP2C1	nuclear recenter subfamily 2, group C, member 1 (gluce astissid recenter)	Nueleus	ligand-dependent	E 904	20.44	1 515 02	D
THE AA	riacieal receptor sublamity 3, group C, member 1 (gracoconicola receptor)	Nucleus	nuclear receptor	-5,694	30,44	1,51E-02	0
ZNF544	zind linger protein 544	Nucleus	other	-5,765	/68,74	3,30E-02	
	uansmemorane protein 386	inucieus	ion channel	-5,544	101,793	1,35E-02	
KBFUX3	KINA binding protein, tox-1 nomolog (C. elegans) 3	inucleus	other	-5,522	/4,415	1,08E-03	
KIAA1328	KIAA1328	Other	other	-5,487	68,65	2,21E-02	
CATIP	ciliogenesis associated TTC17 interacting protein	Cytoplasm	other	-5,319	371,66	6,10E-03	
TSPYL6	TSPY-like 6	Other	other	-5,27	85,033	3,49E-02	
GALM	galactose mutarotase (aldose 1-epimerase)	Cytoplasm	enzyme	-5,254	206,858	4,22E-02	
LOC101929149	uncharacterized LOC101929149	Other	other	-5,198	68,912	4,27E-02	
LOC101928356	uncharacterized LOC101928356	Other	other	-5,033	161,66	3,29E-02	
OR4K14	olfactory receptor, family 4, subfamily K, member 14	Plasma Membrane	other	-4,967	32,132	3,14E-02	
FBRS	fibrosin	Extracellular Space	cvtokine	-4.898	134.68	3.81E-02	
CATSPER2	cation channel sperm associated 2	Plasma Membrane	ion channel	-4 875	381 941	2 91E-02	
or the late		r idonia monibilano	transmembrane	1,010	001,011	2,012.02	
CD6	CD6 molecule	Plasma Membrane	receptor	-4,786	65,625	3,09E-02	
WDR7	WD repeat domain 7	Cytoplasm	other	-4,783	32,552	1,20E-02	
ST7L	suppression of tumorigenicity 7 like	Other	other	-4,716	192,439	1,29E-02	
SDC3	syndecan 3	Plasma Membrane	other	-4,666	657,34	2,04E-02	
TMEM229B	transmembrane protein 229B	Other	other	-4,666	171,556	4,86E-02	
YY2	YY2 transcription factor	Other	other	-4,488	352,808	3,43E-02	
SLAIN2	SLAIN motif family, member 2	Cytoplasm	other	-4,412	26,552	5,05E-03	
SADM1	starile alpha and TIP motif containing 1	Plasma Mombrano	transmembrane	4 272	570 665	2 955 02	D
SARM1	setute corrier family 0, out family 4 (NHE1, online proton entirector 1), member 1	Plasma Membrane	ion channel	-4,372	290.659	1.925.02	
SLC9A1	uncherenterized LOC100121822	Other	other	-4,304	209,000	1,03E-02	
LUC100131822	Ditter (Control 1822	Other	other	-4,22	57,407	1,73E-02	
PVI1	Pvt1 oncogene (non-protein coding)	Extracellular	other	-4,173	178,737	4,03E-02	D
CBLN3	cerebellin 3 precursor	Space	other	-4,172	86,74	3,25E-02	
LOC642236	FSHD region gene 1 pseudogene	Other	other	-4,144	51,91	1,78E-02	
PNPLA2	patatin-like phospholipase domain containing 2	Cytoplasm	enzyme	-4,1	200,414	1,35E-02	
GUPP1L2	GLI pathogonosis related 1 like 2	Extracellular	othor	4 097	102 572	2 725 02	
BRM42	Bli parlogenesis-related 1 like 2	Other	other	-4,087	2081.6	0.265.02	
CARC CARC	and tRNA synthetics	Cutenleam	onturno	-3,967	112 017	3,200-03	
SARS	servi-trina synthetase	Cytoplasm	enzyme	-3,958	113,817	3,70E-02	
L3MBTL1	I(3)mbt-like 1 (Drosophila)	Nucleus	other	-3,912	78,098	1,22E-02	D
MAN1C1	mannosidase, alpha, class 1C, member 1	Cytoplasm	enzyme	-3,894	96,69	1,37E-02	
RRP9	ribosomal RNA processing 9, small subunit (SSU) processome component, homolog (yeast)	Nucleus	other	-3,849	434,76	3,93E-02	
MUN1	NUNI, midasin homolog (yeast)	NUCIEUS	other transmembrane	-3,771	87,021	4,46E-02	
IL1RAP	interleukin 1 receptor accessory protein	Plasma Membrane	receptor	-3,758	13,108	4,61E-02	
IFIT1B	interferon-induced protein with tetratricopeptide repeats 1B	Cytoplasm	other	-3,722	29,302	2,27E-02	
BUB1	BUB1 mitotic checkpoint serine/threonine kinase	Nucleus	kinase	-3,721	64,035	4,66E-02	
SYN1	synapsin I	Plasma Membrane	transporter	-3,655	221,622	4,37E-03	
CEAR44	cilia and floralla associated protein 44	Extracellular	othor	0.007	101 000	1.075.00	
ODE2R	cina ano nagena associated protein 44	Other	oner	-3,637	101,098	1,97E-03	
LONA	outer dense liber of sperm tails 35	Other	enzyme	-3,625	2075,46	2,05E-02	
LOM4	Lower nomolog, Up small nuclear KINA associated (S. cerevisiae)	Nucleus	other	-3,624	1056,44	4,01E-03	
LUC283710	Uncharacterized LUC283/10	Other	other	-3,607	209,798	4,32E-02	
DIS3L2	UIS3 like 3-5' exoridonuclease 2	Cytopiasm	G-protein coupled	-3,549	642,166	1,38E-02	
OR6P1	olfactory receptor, family 6, subfamily P, member 1	Plasma Membrane	receptor	-3,533	34,828	3,15E-02	
SREK1IP1	SREK1-interacting protein 1	Other	other	-3,519	63,742	3,06E-02	
NPPB	natriuretic peptide B	Extracellular Space	other	-3.507	80.314	4,91E-02	
SVIL-AS1	SVIL antisense RNA 1	Other	other	-3 507	86 723	2.91F-02	
		50.00	G-protein coupled	3,307	30,723	2,012-02	
OR1L4	olfactory receptor, family 1, subfamily L, member 4	Plasma Membrane	receptor	-3,494	88,788	4,23E-02	
H1FX	H1 histone family, member X	Nucleus	other	-3,474	236,892	1,21E-02	
AMMECR1	Apon syndrome, mental retardation, midface hypoplasia and elliptocytosis chromosomal region gene 1	Other	other	-3,459	80,62	1,81E-02	
DPP9	dipeptidyl-peptidase 9	Cytoplasm	peptidase	-3.453	463,202	4,06E-02	
PAAF1	proteasomal ATPase-associated factor 1	Other	other	-3.358	149.408	2.33E-02	
ZNF154	zinc finger protein 154	Nucleus	transcription regulator	-3.346	96 24	4,24E-02	
SI C3A1	solute carrier family 3 (amino acid transporter heavy chain), momber 1	Plasma Mombrono	transporter	2,040	42.06	4.455-02	
KRTAP20-4	keratin associated protein 20-4	Other	other	-3,203	21 244	2 76E-02	
		24101		3,210	-1,044	-,. 01-02	

ANKRD22	ankyrin repeat domain 22	Nucleus	transcription regulator	-3,271	28,189	2,06E-02
MRPL37	mitochondrial ribosomal protein L37	Cytoplasm	enzyme	-3,269	351,466	7,21E-03
NEIL1	nei endonuclease VIII-like 1 (E. coli)	Nucleus	enzyme	-3,265	340,326	4,41E-02
MPV17	MpV17 mitochondrial inner membrane protein	Cytoplasm	other	-3,227	196,873	4,87E-02
RTN4IP1	reticulon 4 interacting protein 1	Cytoplasm	enzyme	-3,173	191,579	3,98E-02
GSG2	germ cell associated 2 (haspin)	Nucleus	kinase	-3,141	47,158	3,50E-02
DNAJB2	DnaJ (Hsp40) homolog, subfamily B, member 2	Nucleus	other	-3,11	746,506	3,99E-02
ITGAV	integrin, alpha V	Plasma Membrane	ion channel	-3,105	20,642	4,83E-02
BCL2L13	BCL2-like 13 (apoptosis facilitator)	Cytoplasm	other	-3,084	316,636	7,11E-03
ATP7A	ATPase, Cu++ transporting, alpha polypeptide	Plasma Membrane	transporter	-3,075	77,37	4,68E-02 D
MED8	mediator complex subunit 8	Nucleus	other	-3,072	258,949	3,22E-02
TMEM198B	transmembrane protein 198B, pseudogene	Other	other	-3,038	1046,82	4,86E-02
TCFL5	transcription factor-like 5 (basic helix-loop-helix)	Nucleus	transcription regulator	-3,005	166,504	3,37E-02
00010		Extracellular		0.005		4 9 9 5 9 9
SPON2	spondin 2, extracellular matrix protein	Space	other	-2,995	169,911	4,06E-02
RNF121	ring finger protein 121	Other	other	-2,994	341,06	3,98E-03
MED19	mediator complex subunit 19	Nucleus	other	-2,983	580,842	2,64E-02
UBTF	upstream binding transcription factor, RNA polymerase I	Nucleus	transcription regulator	-2,975	118,946	4,09E-02
ASXL1	additional sex combs like transcriptional regulator 1	Nucleus	transcription regulator	-2,974	1494,58	1,92E-02
L3MBTL1	I(3)mbt-like 1 (Drosophila)	Nucleus	other	-2,97	65,024	4,91E-02 D
MATN2	matrilin 2	Space	other	-2,953	50,612	2,71E-02
1 70 400		5	G-protein coupled			0.045.00
LIB4R2	leukotriene B4 receptor 2	Plasma Membrane	receptor	-2,941	665,16	9,21E-03
FOXRED2	FAD-dependent oxidoreductase domain containing 2	Cytoplasm	other	-2,94	216,444	4,36E-02
ASF1A	anti-silencing function 1A histone chaperone	Nucleus	other	-2,906	46,154	4,87E-02
CD274	CD274 molecule	Plasma Membrane	enzyme	-2,894	73,122	4,45E-02
ZNF589	zinc finger protein 589	Nucleus	other	-2,855	234,536	4,12E-02
TSPAN16	tetraspanin 16	Other	other	-2,845	507,237	3,12E-02
CHRNAZ	cholineraic recentor, nicotinic, alpha 7 (neuronal)	Plasma Membrana	transmembrane	-2.827	31 542	4.62E-02
	TATA box binding protein (TPD) accorded factor, BNA solumerosa LA 49/Da	Nuclous		-2,03/	112 226	9.02E-02
IEITS	interferen induced protein uith tetratricescentide repeate 5	Plasma Marchara	other	-2,030	226.200	5.695.02
IFITO	Interioron-induced protein with tetrathcopeptide repeats 5	Plasma Membrane	other	-2,831	226,328	5,68E-03
KLRAP1	killer cell lectin-like receptor subfamily A pseudogene 1	Other	other	-2,793	26,516	4,59E-02
KRTAP4-2	keratin associated protein 4-2	Other	other	-2,764	17,166	6,96E-04
SLC25A23	solute carrier family 25 (mitochondrial carrier; phosphate carrier), member 23	Cytoplasm	transporter	-2,753	130,834	1,98E-02
NR3C1	nuclear receptor subfamily 3, group C, member 1 (glucocorticoid receptor)	Nucleus	nuclear receptor	-2,703	41,825	3,40E-02 D
SYTL3	synaptotagmin-like 3	Cytoplasm	other	-2,703	582,28	4,27E-02
PAOX	polyamine oxidase (exo-N4-amino)	Cytoplasm	enzyme	-2.696	327,634	3.36E-02
ANAPC1	anaphase promoting complex subunit 1	Nucleus	other	-2 688	81 235	1.88E-02
HIE1A	hunavia inducible factor 1 alpha subunit (basis balix loop balix transcription factor)	Nucleus	transcription regulator	2,000	720.02	1,05E-02
		Cutoploam		-2,000	123,02	1,95E-02

SLC26A5 | ATPase, Na+/K+ transporting, alpha 4 polypeptide
small Cajal body-specific RNA 22
Scm-like with four mbt domains 2
family with sequence similarity 35, member A
protein phosphatase 1, regulatory subunit 13B
chondroitin sulfate proteoglycan 4
chromatin target of PRMT1
POU class 4 homeobox 1
forkhead box 11
trichohyalin
folliculin interacting protein 1
StAR-related lipid transfer (START) domain containing 13
solute carrier family 9, subfamily A (NHE7, cation proton antiporter 7), member 7
RAP2A, member of RAS oncogene family
matrix extracellular phosphoglycoprotein
cadherin 3, type 1, P-cadherin (placental)
adenylate kinase 2
zinc finger protein 787
thymosin beta 4, Y-linked
olfactory receptor, family 2, subfamily AG, member 2
THO complex 1
olfactory receptor, family 4, subfamily S, member 1
arsenite methyltransferase
uncharacterized LOC158402
fatty acid binding protein 852
solute carrier family 15 (oligopeptide transporter), member 1
V-set and transmembrane domain containing 5
uridine-cytidine kinase 1-like 1
solute carrier family 26 (anion exchanger), member 5 | Plasma Membrane

small Cajal body-specific RNA 22
Scm-like with four mbt domains 2
family with sequence similarity 35, member A
protein phosphatase 1, regulatory subunit 13B
chondrottin sulfate proteoglycan 4
chromatin target of PRMT1
POU class 4 homeobox 1
forkhead box 11
trichohyalin
folliculin interacting protein 1
StAR-related lipid transfer (START) domain containing 13
solute carrier family 9, subfamily A (NHE7, cation proton antiporter 7), member 7
RAP2A, member of RAS oncogene family
matrix extracellular phosphoglycoprotein
cadherin 3, type 1, P-cadherin (placental)
adenylate kinase 2
zinc finger protein 787
thymosin beta 4, Y-linked
olfactory receptor, family 4, subfamily S, member 2
THO complex 1
olfactory receptor, family 4, subfamily S, member 1
arsenite methyltransferase
uncharacterized LOC158402
fatty acid binding protein 5 (psoriasis-associated)
zinc finger protein 822
solute carrier family 15 (oligopeptide transporter), member 1
V-set and transmembrane domain containing 5
uridine-cytidine kinase 1-like 1
solute carrier family 26 (anion exchanger), member 5
sorbin and SH3 domain containing 2
UL16 binding protein 3

small Cajal body-specific RNA 22
Scm-like with four mbt domains 2
family with sequence similarity 35, member A
protein phosphatase 1, regulatory subunit 13B
chondroitin sulfate proteoglycan 4
chromatin target of PRMT1
POU class 4 homeobox 1
forkhead box 11
trichohyalin
folliculin interacting protein 1
StAR-related lipid transfer (START) domain containing 13
solute carrier family 9, subfamily A (NHE7, cation proton antiporter 7), member 7
RAP2A, member of RAS oncogene family
matrix extracellular phosphoglycoprotein
cadhenin 3, type 1, P-cadhenin (placental)
adenylate kinase 2
zinc finger protein 787
thymosin beta 4, Y-linked
olfactory receptor, family 2, subfamily AG, member 2
THO complex 1
olfactory receptor, family 4, subfamily AG, member 2
THO complex 1
olfactory receptor, family 4, subfamily S, member 1
arsenite methyltransferase
uncharacterized LOC158402
fatty acid binding protein 852
solute carrier family 15 (oligopeptide transporter), member 1
V-set and transmembrane domain containing 5
uridine-cytidine kinase 1-like 1
solute carrier family 26 (anion exchanger), member 1
V-set and transmembrane domain containing 5
uridine-cytidine kinase 1-like 1
solute carrier family 26 (anion exchanger), member 5
sorbin and SH3 domain containing 2
UL16 binding protein 3
CD8a molecule
uncharacterized LOC441204 | Plasma Membrane Other Nucleus Extracellular Space Cytoplasm Nucleus Nucleus Nucleus Nucleus Nucleus Qytoplasm Cytoplasm Other Cytoplasm Other Plasma Membrane Cytoplasm Cytoplasm Other Plasma Membrane Cytoplasm Other Other Plasma Membrane Other Plasma Membrane Other <tr td=""> <td>transporter other transcription regulator other other other other enzyme other kinase transcription regulator other kinase transcription regulator other itransporter other itransporter other transporter other other transporter t</td><td>-2,037

DENR | ATPase, Na+/K+ transporting, alpha 4 polypeptide
small Cajal body-specific RNA 22
Scm-like with four mbt domains 2
family with sequence similarity 35, member A
protein phosphatase 1, regulatory subunit 13B
chondroitin sulfate proteoglycan 4
chromatin target of PRMT1
POU class 4 homeobox 1
forkhead box 11
trichohyalin
folliculin interacting protein 1
StAR-related lipid transfer (START) domain containing 13
solute carrier family 9, subfamily A (NHE7, cation proton antiporter 7), member 7
RAP2A, member of RAS oncogene family
matrix extracellular phosphoglycoprotein
cadherin 3, type 1, P-cadherin (placental)
adenylate kinase 2
zinc finger protein 787
thymosin beta 4, Y-linked
olfactory receptor, family 2, subfamily AG, member 2
THO complex 1
olfactory receptor, family 3, subfamily AG, member 2
THO complex 1
olfactory receptor, family 4, subfamily S, member 1
arsenite methyltransferase
uncharacetrized LOC18402
fatty acid binding protein 52
solute carrier family 15 (oligopeptide transporter), member 1
V-set and transmembrane domain containing 5
uridine-cytidine kinase 1-like 1
solute carrier family 15 (oligopeptide transporter), member 1
V-set and transmembrane domain containing 5
uridine-cytidine kinase 1-like 1
solute carrier family 15 (oligopeptide transporter), member 1
V-set and transmembrane domain containing 5
uridine-cytidine kinase 1-like 1
solute carrier family 26 (anion exchanger), member 5
sorbin and SH3 domain containing 2
UL16 binding protein 3
CD8a molecule
uncharacetrized LOC2441204

LOC441204
DENR | ATPase, Na+/K+ transporting, alpha 4 polypeptide
small Cajal body-specific RNA 22
Scm-like with four mbt domains 2
family with sequence similarity 35, member A
protein phosphatase 1, regulatory subunit 13B
chondroitin sulfate proteoglycan 4
chromatin target of PRMT1
POU class 4 homeobox 1
forkhead box 11
trichohyalin
folliculin interacting protein 1
StAR-related lipid transfer (START) domain containing 13
solute carrier family 9, subfamily A (NHE7, cation proton antiporter 7), member 7
RAP2A, member of RAS oncogene family
matrix extracellular phosphoglycoprotein
cadherin 3, type 1, P-cadherin (placental)
adenylate kinase 2
zinc finger protein 787
thymosin beta 4, Y-linked
olfactory receptor, family 2, subfamily AG, member 2
THO complex 1
olfactory receptor, family 3, subfamily AG, member 2
THO complex 1
olfactory receptor, family 4, subfamily S, member 1
arsenite methyltransferase
uncharacetrized LOC18402
fatty acid binding protein 52
solute carrier family 15 (oligopeptide transporter), member 1
V-set and transmembrane domain containing 5
uridine-cytidine kinase 1-like 1
solute carrier family 15 (oligopeptide transporter), member 1
V-set and transmembrane domain containing 5
uridine-cytidine kinase 1-like 1
solute carrier family 15 (oligopeptide transporter), member 1
V-set and transmembrane domain containing 5
uridine-cytidine kinase 1-like 1
solute carrier family 26 (anion exchanger), member 5
sorbin and SH3 domain containing 2
UL16 binding protein 3
CD8a molecule
uncharacetrized LOC2441204

PHOX2B	paired-like homeobox 2b	Nucleus	transcription regulator	-1,804	12,74	2,08E-02
QKI	QKI, KH domain containing, RNA binding	Nucleus	other	-1,802	1004,58	2,36E-02
DCUN1D1	DCN1, defective in cullin neddylation 1, domain containing 1	Nucleus	other	-1.797	448.94	4.31E-02
01 5000		5. M .	transmembrane	4 700		4.005.00
CLEC2D	C-type lectin domain family 2, member D	Plasma Membrane	receptor	-1,792	234,06	4,88E-02
POLR1A	polymerase (RNA) I polypeptide A, 194kDa	Nucleus	enzyme	-1,787	101,63	4,15E-02
MAF1	MAF1 nomolog (S. cerevisiae)	Nucleus	other	-1,786	569,24	3,78E-02
CABP7	calcium binding protein 7	Cytoplasm	other	-1,778	18,202	3,09E-02
MRS2P2	MRS2 pseudogene 2	Other	other	-1,759	294,24	3,50E-02
LINC00955	long intergenic non-protein coding RNA 955	Other	other transmembrane	-1,758	9,503	3,95E-02
TNFRSF9	tumor necrosis factor receptor superfamily, member 9	Plasma Membrane	receptor	-1,754	24,66	1,66E-02
LOC101927043	uncharacterized LOC101927043	Other	other	-1,749	9,891	5,30E-03
HCFC1	host cell factor C1	Nucleus	transcription regulator	-1,747	358,06	3,77E-02
CCDC108	coiled-coil domain containing 108	Other	other	-1,738	110,674	4,22E-02
LOC102724220	uncharacterized LOC102724220	Other	other	-1,738	12,12	1,06E-02
CTAGE9 (includes others)	CTAGE family, member 4	Other	other	-1,729	171,3	1,47E-02
LRRC58	leucine rich repeat containing 58	Other	other	-1,729	73,688	4,72E-03
LOC102724861	uncharacterized LOC102724861	Other	other	-1,727	31,406	3,47E-02
ABCE1	ATP-binding cassette, sub-family E (OABP), member 1	Cytoplasm	transporter	-1,723	309,9	1,91E-02 D
NLK	nemo-like kinase	Nucleus	kinase	-1,71	578,88	1,53E-02
YAP1	Yes-associated protein 1	Nucleus	transcription regulator	-1,71	7,662	1,34E-02
KIAA1598	KIAA1598	Plasma Membrane	other	-1,703	568,86	1,55E-02
SLC15A4	solute carrier family 15 (oligopeptide transporter), member 4	Cytoplasm	transporter	-1,698	713,84	3,46E-02
570.40			G-protein coupled	4.007		4.005.00
	Inizzieg class receptor 10	Plasma Membrane	receptor	-1,697	14,994	4,86E-02
NUP50-AS1	NUP50 antisense RNA 1 (head to head)	Other	other	-1,694	2335,8	2,13E-04
SLC12A2	solute carrier family 12 (sodium/potassium/chloride transporter), member 2	Plasma Membrane	transporter	-1,694	134,16	1,19E-02
FRG2/FRG2B	FSHD region gene 2	Other	other	-1,692	51,71	1,95E-02
EIF3C	eukaryotic translation initiation factor 3, subunit C	Other	translation regulator	-1,686	2576,2	3,69E-03
USP53	ubiquitin specific peptidase 53	Space	enzyme	-1,685	18,69	2,04E-02
MEI4	meiosis-specific 4 homolog (S. cerevisiae)	Nucleus	other	-1,672	12,304	2,03E-02
PHF20	PHD finger protein 20	Nucleus	other	-1,666	467,14	2,09E-02

PIP5K1P1	phosphatidylinositol-4-phosphate 5-kinase type L pseudogene 1	Other	other	4 005	57 685	4.53E-02	
HOMER3	homer homolog 3 (Drosophila)	Plasma Membrane	other	3.99	123,936	2.68E-02	
NAA38	N/alnha)-acetyltransferase 38. NatC auvilian/ subunit	Nucleus	other	3 974	264.1	3 24E-02	
NAA50		Nucleus	transmembrane	0,014	204,1	0,242 02	
TNFRSF10C	tumor necrosis factor receptor superfamily, member 10c, decoy without an intracellular domain	Plasma Membrane	receptor	3,923	278,602	2,48E-02	
PVR	poliovirus receptor	Plasma Membrane	other	3,917	719,582	4,68E-02	
SLC25A13	solute carrier family 25 (aspartate/glutamate carrier), member 13	Cytoplasm	transporter	3,857	398,092	3,21E-02	
SLC10A3	solute carrier family 10, member 3	Plasma Membrane	transporter	3,848	119,756	1,89E-02	
LOC101928667	uncharacterized LOC101928667	Other	other	3,841	82,741	4,91E-02	
TMEM255B	transmembrane protein 255B	Other	other	3,77	34,996	4,33E-02	
RPS6KB1	ribosomal protein S6 kinase, 70kDa, polypeptide 1	Cytoplasm	kinase	3,712	98,845	1,00E-02	
SLC31A1	solute carrier family 31 (copper transporter), member 1	Plasma Membrane	transporter	3,698	121,522	1,89E-02	
APBA1	amyloid beta (A4) precursor protein-binding, family A, member 1	Cytoplasm	transporter	3,669	51,348	2,94E-02	
ZNF618	zinc finger protein 618	Other	other	3,633	137,372	3,55E-02	
NBPF25P	neuroblastoma breakpoint family, member 25, pseudogene	Other	other	3,602	40,824	2,47E-02	
NPM3	nucleophosmin/nucleoplasmin 3	Nucleus	other	3,6	665,48	4,07E-02	
PAAF1	proteasomal ATPase-associated factor 1	Other	other	3,57	140,852	2,55E-02	D
TRPV1	transient receptor potential cation channel, subfamily V, member 1	Plasma Membrane	ion channel	3,435	337,418	2,69E-02	
FBXL19	F-box and leucine-rich repeat protein 19	Other	other	3,371	1374,04	4,17E-02	
BMP1	bone morphogenetic protein 1	Space	peptidase	3,335	146,374	2,17E-02	
FANCM	Fanconi anemia, complementation group M	Nucleus	enzyme	3,334	68,604	1,70E-02	
LOC389831 (includes others)	uncharacterized LOC389831	Other	other	3 3 2 6	53 /21	3 78E-02	
CTSI 3P	cathanain L family member 3 nseudonene	Other	other	3,320	70.12	7 805-02	
TASD1		Nuclous	poptidaso	3,295	240.50	6.055.00	
ATG16L1	autophagy related 16 like 1 (S. corovicios)	Cutoplasm	othor	3,1/1	1150 4	3 775 00	
ATG2B	autophagy related 2B	Other	other	3,17	05.074	2 27E 02	
C6orf25	chromosome 6 open reading frame 25	Plasma Mombrar -	other	3,138	177 206	2,27 E-02	
787824	zine finger and PTP domain containing 24	Nuclous	other	3,134	222.000	2,90E-02	
EN2KPD	zine miger and DTD UUIIIdilli UUIIIdilli 24	Othor	kinaso	3,117	1005.00	0,95E-03	
	incuited adurates and the second seco	Cutenlear	niildSt	3,104	40,000	4,40E-02	
		Other	priospiratase	3,103	40,492	3,77E-02	
ATAN/L1	ataxiii /-iike 1	Other	other	3,085	1064,02	2,76E-02	

CDRT15	CMT1A duplicated region transcript 15	Other	other	3,082	129,294	4,18E-02
INPP5F	inositol polyphosphate-5-phosphatase F	Other	phosphatase	3,031	380,126	2,25E-02
C16orf93	chromosome 16 open reading frame 93	Other	other	3,026	277,592	1,08E-02
PLAC9	placenta-specific 9	Other	other	3,019	516,2	2,41E-03
PLAC9	placenta-specific 9	Other	other	3,019	516,2	2,41E-03
PPP1R10	protein phosphatase 1, regulatory subunit 10	Nucleus	other	3,016	515,7	2,21E-02
KIAA1671	KIAA1671	Other	other	3,005	40,838	3,27E-02
ZNF366	zinc finger protein 366	Nucleus	transcription regulator	2,992	38,634	4,45E-02
DIS3L	DIS3 like exosome 3'-5' exoribonuclease	Cytoplasm	enzyme	2,982	23,572	3,39E-02
APOBEC3A	apolipoprotein B mRNA editing enzyme, catalytic polypeptide-like 3A	Cytoplasm	enzyme	2,977	449,54	1,76E-02
SIX5	syntaxin 5	Cytoplasm	transporter	2,971	746,88	8,77E-03
DNMT	BNA (supplies 7) methyltraneference	Plasma Membrane		2,93	333,33	1,53E-02
ERGS	Riva (guanine-7-) metriyitiansierase	Othor	othor	2,920	312,490	9,04E-03
PTER	nhoshotriesterase related	Cytoplasm	enzyme	2 908	21 202	4 48E-02
EXOC3L1	exocyst complex component 3-like 1	Cytoplasm	other	2,905	80.928	1,50E-02
NUDT18	nudix (nucleoside diphosphate linked moiety X)-type motif 18	Cytoplasm	other	2,887	224,844	2,74E-02
CCSAP	centriole, cilia and spindle-associated protein	Cytoplasm	other	2,883	123,286	2,48E-02
TAF12	TAF12 RNA polymerase II, TATA box binding protein (TBP)-associated factor, 20kDa	Nucleus	transcription regulator	2,831	301,872	2,82E-02
DENND6B	DENN/MADD domain containing 6B	Other	other	2,821	198,608	1,25E-02
FAM173A	family with sequence similarity 173, member A	Other	other	2,816	487,34	5,02E-04
CENPC	centromere protein C	Nucleus	other	2,809	612,12	3,92E-02
AAMDC	adipogenesis associated, Mth938 domain containing	Cytoplasm	other	2,806	836,2	3,33E-02
RBM15	RNA binding motif protein 15	Nucleus	other	2,796	425,48	8,60E-03
GYPB	glycophorin B (MNS blood group)	Plasma Membrane	other	2,791	24,389	1,11E-02
ZNF490	zinc finger protein 490	Nucleus	other	2,741	1084,14	4,14E-02
ILR8-AS1	ILR8 antisense RNA 1	Other Extracellular	other	2,737	19,624	3,76E-02
LTBP1	latent transforming growth factor beta binding protein 1	Space	other	2,722	23,201	3,74E-02
COIL	coilin	Nucleus	enzyme	2,716	88,908	1,10E-02
ARFRP1	ADP-ribosylation factor related protein 1	Cytoplasm	enzyme	2,67	123,109	4,51E-02
ZBTB20	zinc finger and BTB domain containing 20	Nucleus	other	2,664	251,002	1,53E-02
APBB3	amyloid beta (A4) precursor protein-binding, family B, member 3	Cytoplasm	other	2,615	1410,36	3,95E-02
LRRC40	leucine rich repeat containing 40	Nucleus	other	2,614	29,126	3,74E-02
7NE575	Tipe finger protein 675	Nucleus	other	2,300	241.5	4,12E-02
VMAC	vimentin-type intermediate filament associated coiled-coil protein	Cytoplasm	other	2,573	560.1	5,55E-03
TRABD2B	TraB domain containing 2B	Plasma Membrane	peptidase	2,567	42.41	3.02E-03
GPSM2	G-protein signaling modulator 2	Nucleus	other	2,562	281,99	1,28E-02
HTRA4	HtrA serine peptidase 4	Other	peptidase	2,561	59,886	3,82E-02
RAB28	RAB28, member RAS oncogene family	Plasma Membrane	enzyme	2,555	425,88	4,93E-02
SRP14-AS1	SRP14 antisense RNA1 (head to head)	Other	other	2,532	49,139	4,93E-02
ANKLE1	ankyrin repeat and LEM domain containing 1	Other	other	2,527	334,24	8,16E-03
RGL4	ral guanine nucleotide dissociation stimulator-like 4	Other	other	2,521	291,558	2,57E-02
LIG1	ligase I, DNA, ATP-dependent	Nucleus	enzyme	2,509	454,22	3,21E-02
HCG26	HLA complex group 26 (non-protein coding)	Other	other	2,491	148,926	1,24E-02
EVPLL	envoplakin-like	Other	other	2,471	10,176	4,58E-02
DNM1P46	DNM1 pseudogene 46	Other	other	2,47	1541,34	1,10E-02 D
LOC101928424	uncharacterized LOC101928424	Other	other	2,457	118,038	3,56E-02
HINEP	histone H4 transcription factor	Nucleus	transcription regulator transmembrane	2,45	352,2	3,71E-02
CLEC1B	C-type lectin domain family 1, member B	Plasma Membrane	receptor	2,44	337,96	4,68E-02
MTG1	mitochondrial ribosome-associated GTPase 1	Cytoplasm	enzyme	2,431	1227,68	2,86E-02
OAS2	2'-5'-oligoadenylate synthetase 2, 69/71kDa	Cytoplasm	enzyme	2,414	48,488	3,81E-02
CTDSP1	CTD (carboxy-terminal domain, RNA polymerase II, polypeptide A) small phosphatase 1	Nucleus	phosphatase	2,398	858,9	3,77E-02
CINS	cystinosin, lysosomai cystine transporter	Cytopiasm	transporter	2,384	452,28	1,09E-02
RIF1	replication timing regulatory factor 1	Nucleus	other	2,305	77 40	3 78E-02
DNM1P46	DNM1 pseudogene 46	Other	other	2,355	1015.66	4.41E-02 D
MSH5	mutS homolog 5	Nucleus	enzyme	2,342	1053,78	2,41E-02
LOC389834	ankyrin repeat domain 57 pseudogene	Other	other	2,339	1408,16	3,57E-02 D
SPATA13	spermatogenesis associated 13	Plasma Membrane	other	2,338	626,2	1,08E-02
RAD54L2	RAD54-like 2 (S. cerevisiae)	Nucleus	transcription regulator	2,334	1222,94	3,89E-02
DDX39A	DEAD (Asp-Glu-Ala-Asp) box polypeptide 39A	Nucleus	enzyme	2,328	1974,8	4,11E-02
TMEM194B	transmembrane protein 194B	Other	other	2,323	56,234	3,83E-02
AK4	adenylate kinase 4	Cytoplasm	kinase	2,314	38,462	6,65E-03
WDFY4	WDFY family member 4	Other	other	2,305	564,66	1,31E-02
SNRPN	small nuclear ribonucleoprotein polypeptide N	Nucleus	other	2,299	13,827	4,34E-02 D
STK40	serine/threonine kinase 40	Cytoplasm	kinase	2,294	1126,46	4,66E-02
RIN3	reticulon 3	Cytoplasm	other	2,285	674,74	2,72E-02
ALDH3B1	ardenyde denydrogenase 3 ranniy, member B1	Extracellular	enzyme	2,275	1314,8	1,08E-03
C1QA	complement component 1, q subcomponent, A chain	Space	other	2,272	321,836	1,90E-02
MMP17	matrix metallopeptidase 17 (membrane-inserted)	Space	peptidase	2,25	243,7	1,52E-02
FAM73A	family with sequence similarity 73, member A	Other	other	2,242	50,108	2,55E-02
NISCH	nischarin	Plasma Membrane	receptor	2,235	408,88	4,40E-02
NKAIN3	Na+/K+ transporting ATPase interacting 3	Other	other	2,224	18,389	4,90E-02
HCLS1	hematopoietic cell-specific Lyn substrate 1	Nucleus	other	2,206	469,94	6,20E-03
TACR1	tachykinin receptor 1	Plasma Membrane	G-protein coupled	2,206	117,406	2,97E-02

			receptor			
C16orf59	chromosome 16 open reading frame 59	Other	other	2,201	69,278	1,15E-02
DHRS7C	dehydrogenase/reductase (SDR family) member 7C	Cytoplasm	enzyme	2,201	12,367	4,43E-02
FUT7	fucosyltransferase 7 (alpha (1,3) fucosyltransferase)	Cytoplasm	enzyme	2,198	133,752	1,81E-02
NDUFA3	NADH dehydrogenase (ubiquinone) 1 alpha subcomplex, 3, 9kDa	Cytoplasm	enzyme	2,195	1231,94	3,93E-02
PNMA6A/PNMA6B	paraneoplastic Ma antigen family member 6A	Cytoplasm	other	2,195	155,524	1,19E-02
POLR2H	polymerase (RNA) II (DNA directed) polypeptide H	Nucleus	enzyme	2,186	86,226	1,09E-02
TRAPPC12	trafficking protein particle complex 12	Other	other	2,178	3444,6	3,42E-02
LOC100129785	uncharacterized LOC100129785	Other	other	2,177	1245,54	4,35E-02
GNA15	guanine nucleotide binding protein (G protein), alpha 15 (Gq class)	Plasma Membrane	enzyme	2,173	1359,62	4,50E-02
EMC4	ER membrane protein complex subunit 4	Other	other	2,171	2033	4,21E-02
PTPRJ	protein tyrosine phosphatase, receptor type, J	Plasma Membrane	phosphatase	2,167	22,065	3,45E-02
PGC	progastricsin (pepsinogen C)	Space	peptidase	2,159	18,44	8,65E-03
DNAL1	dynein, axonemal, light chain 1	Other	other	2,132	88,26	1,54E-02
BCL6	B-cell CLL/lymphoma 6	Nucleus	transcription regulator	2,131	94,086	4,19E-02
HIST1H2AC	histone cluster 1, H2ac	Nucleus	other	2,11	264,44	4,63E-02
MTM1	myotubularin 1	Cytoplasm	phosphatase	2,11	65,258	1,39E-02
VILL	villin-like	Cytoplasm	other	2,108	429,2	4,53E-02
HCG18	HLA complex group 18 (non-protein coding)	Other	other	2,107	739,8	1,15E-02 D
SNTB2	syntrophin, beta 2 (dystrophin-associated protein A1, 59kDa, basic component 2)	Plasma Membrane	other	2,099	8,363	1,27E-02
PRSS57	protease, serine, 57	Other	peptidase	2,095	118,362	3,10E-02
DUX4L9	double homeobox 4 like 9	Nucleus	other	2,094	297,32	1,67E-02
YME1L1	YME1-like 1 ATPase	Cytoplasm	peptidase	2,091	11,668	3,06E-02
TAPBPL	TAP binding protein-like	Cytoplasm	other	2,089	1336,9	2,43E-02
ASUN	asunder spermatogenesis regulator	Cytoplasm	other	2,086	707,26	2,71E-02
ADAM15	ADAM metallopeptidase domain 15	Plasma Membrane	peptidase	2,085	255,4	1,49E-02
PPIG	peptidylprolyl isomerase G (cyclophilin G)	Nucleus	enzyme	2,072	332,08	2,08E-02
MLST8	MTOR associated protein, LST8 homolog (S. cerevisiae)	Cytoplasm	other	2,039	116,228	4,31E-02
NR4A2	nuclear receptor subfamily 4, group A, member 2	Nucleus	nuclear receptor	2,039	<u>590,</u> 48	3,53E-02
LIME1	Lek interacting transmembrane adapter 1	Extracellular	other	2.027	159 904	1 425 02
		Space	G-protein coupled	2,037	156,694	1,42E-02
HCRTR1	hypocretin (orexin) receptor 1	Plasma Membrane	receptor	2,035	234,474	3,36E-02
TMEM222	transmembrane protein 222	Other	other Corretain counled	2,035	371,96	3,76E-02
GPR132	G protein-coupled receptor 132	Plasma Membrane	receptor	2,031	204,4	3,87E-02
TMEM9	transmembrane protein 9	Cytoplasm	other	2,022	209,76	4,82E-02
RTF1	Rtf1, Paf1/RNA polymerase II complex component, homolog (S. cerevisiae)	Nucleus	other	2,009	210,26	2,94E-02
CROCCP2	ciliary rootlet coiled-coil, rootletin pseudogene 2	Other	other	2,008	437,58	2,08E-02
C10orf99	chromosome 10 open reading frame 99	Other	other	2,007	16,022	3,58E-02
TUBG2	tubulin, gamma 2	Cytoplasm	other	2,007	1282,54	4,34E-02
TTC34	tetratricopeptide repeat domain 34	Other	other	1,984	450,74	4,68E-02
LOC285191	uncharacterized LOC285191	Other	other	1,98	186,24	2,85E-02
NASP	nuclear autoantigenic sperm protein (histone-binding)	Nucleus	other	1,977	385,46	4,02E-02
TCEB3	transcription elongation factor B (SIII), polypeptide 3 (110kDa, elongin A)	Nucleus	transcription regulator	1,974	69,644	4,75E-02
HCG18	HLA complex group 18 (non-protein coding)	Other	other	1,969	635,38	2,15E-02 D
TTYH3	tweety family member 3	Plasma Membrane	ion channel	1,961	3105,8	3,53E-02
LPIN3	lipin 3	Nucleus	phosphatase	1,956	36,398	2,03E-02
IGLL1/IGLL5	immunoglobulin lambda-like polypeptide 1	Plasma Membrane	other	1,95	642,38	3,35E-02
NRSN1	neurensin 1	Plasma Membrane	other	1,95	37,124	4,00E-02
TMEM106A	transmembrane protein 106A	Cytoplasm	other	1,94	288,68	5,98E-04
DNM1P46	DNM1 pseudogene 46	Other	other	1,932	1787	6,26E-03 D
STAU1	staufen double-stranded RNA binding protein 1	Cytoplasm	transporter	1,928	266,78	4,78E-02
IFT122	intraflagellar transport 122	Nucleus	other	1,925	169,84	3,20E-02
MTMR8	myotubularin related protein 8	Nucleus	phosphatase	1,922	77,952	3,35E-02
LRRC37B	leucine rich repeat containing 37B	Cytoplasm	other	1,921	715,02	1,93E-02
INRC6C-AS1	TINKUbU antisense RNA 1	Other	other	1,92	2205,8	4,38E-02
	INKUGU ANTISENSE KNA 1	Other	omer	1,92	2205,8	4,38E-02
	oriactory receptor, ramily 10, subramily D, member 1 pseudogene	Other	other	1,909	13,576	1,33E-02
UBINZ		NUCIEUS	G-protein coupled	1,906	57,176	3,30E-02
FZD2	frizzled class receptor 2	Plasma Membrane	receptor	1,903	112,284	2,20E-02
LINC01567	long intergenic non-protein coding RNA 1567	Other	other	1,898	134,942	2,67E-02
EGFLAM	EGF-like, fibronectin type III and Iaminin G domains	Space	other	1,895	42,122	3,27E-02
HP	hantonlohin	Extracellular	pentidase	1 895	244.26	2 48E-02
RNE126	ring finger protein 126	Other	other	1,882	551.06	4 96E-02
10093463	uncharacterized I OC93463	Other	other	1,000	0.74	3 13E-02
DRAP1	DR1-associated protein 1 (negative cofactor 2 alpha)	Nucleus	transcription regulator	1,879	315.66	3.38E-02
DUOXA1	dual oxidase maturation factor 1	Plasma Membrane	other	1,876	77,804	4.01E-02
AGA	aspartylglucosaminidase	Cytoplasm	enzvme	1,871	449.22	4.42E-02
SRPK3	SRSF protein kinase 3	Cytoplasm	kinase	1.87	269.8	4.47E-02
TRAPPC2	trafficking protein particle complex 2	Cytoplasm	other	1,869	18,506	2.51E-02
ADCY4	adenylate cyclase 4	Plasma Membrane	enzyme	1,867	842.92	4,96E-02
UBXN11	UBX domain protein 11	Cytoplasm	other	1,867	3453.8	4,20E-02
PYCR2	pyrroline-5-carboxylate reductase family. member 2	Cytoplasm	enzyme	1,854	386.08	8,22E-03
ZFYVE19	zinc finger, FYVE domain containing 19	Cytoplasm	other	1,854	484,78	1,95E-02
C12orf42	chromosome 12 open reading frame 42	Other	other	1,852	156.4	3,87E-02
PRAM1	PML-RARA regulated adaptor molecule 1	Other	other	1,837	424,84	1,28E-02
ARSE	arylsulfatase E (chondrodysplasia punctata 1)	Cytoplasm	enzyme	1,802	13.561	4,14E-02
· · · · · · · · · · · · · · · · · · ·	· · · · · · · · · · · · · · · · · · ·			,	-,	

SCARNA22	small Cajal body-specific RNA 22	Other	other	1,799	23,872	8,24E-03
SEMA4A	sema domain, immunoglobulin domain (Ig), transmembrane domain (TM) and short cytoplasmic domain, (semaphorin) 4A	Plasma Membrane	other	1,794	835,96	5,29E-03
EMILIN1	elastin microfibril interfacer 1	Extracellular Space	other	1.789	221.84	3.92E-02
FNBP1	formin binding protein 1	Nucleus	enzvme	1.787	271.86	4.10E-02
FAM110C	family with sequence similarity 110, member C	Cvtoplasm	other	1.783	18.354	4.50E-02
CDRT15P1	CMT1A duplicated region transcript 15 pseudogene 1	Other	other	1,78	219,08	4,19E-02
SLC22A23	solute carrier family 22, member 23	Other	transporter	1,777	326,58	3,77E-02
GCC2	GRIP and coiled-coil domain containing 2	Cytoplasm	other	1,77	67,482	4,44E-02
CXCL12	chemokine (C-X-C motif) ligand 12	Extracellular Space	cytokine	1,766	114,52	4,36E-02
C2orf83	chromosome 2 open reading frame 83	Other	transporter	1,764	19,972	2,26E-02
OR2M5	olfactory receptor, family 2, subfamily M, member 5	Plasma Membrane	G-protein coupled receptor	1.751	30.518	2.53E-02
FOXP4	forkhead box P4	Nucleus	transcription regulator	1,75	338,68	4,21E-02
HCRT	hypocretin (orexin) neuropeptide precursor	Extracellular Space	other	1.745	120.48	4.81E-02
PRODH2	proline dehvdrogenase (oxidase) 2	Cytoplasm	enzvme	1,744	19,154	4.65E-02
ZNF81	zinc finger protein 81	Nucleus	transcription regulator	1.733	583.78	6.03E-03
LOC643711	platelet-activating factor acetylhydrolase 1b, catalytic subunit 2 (30kDa) pseudogene	Other	other	1,724	165,16	4,37E-02
KSR2	kinase suppressor of ras 2	Cytoplasm	kinase	1,72	18,348	4,71E-02
5000		Dia ana Marakara	G-protein coupled	4 700	070 5	4 005 00
PPR2	BNA hinding matif protein X linked 2	Other	receptor	1,706	276,5	1,06E-02
	LUCZ like 2 (C. serevision)	Nucleus	other	1,095	00.708	4,70E-02
MEDCE	mothylabesabate capping enzyme	Othor	onzumo	1,070	750.02	4,00E-02
TRPV6	transient recentor potential cation channel subfamily V member 6	Plasma Membrane	ion channel	1.672	16 704	4,95E-02
000450			G-protein coupled	1,012	00,100	4,005,00
GPR 156	G protein-coupled receptor 156	Plasma Membrane	receptor	1,003	20,132	1,89E-02
LBBC24	CDC42 Small elector 1	Plasma Membrane	other	1,049	16 429	3,30E-02
HOXDO	homoshey D0	Nucleus		1,040	101 704	4,51E-02

		Cytopiasm	transporter	1,629	558,44	1,11E-02
SLC11A2	solute carrier family 11 (proton-coupled divalent metal ion transporter), member 2	Plasma Membrane	transporter	1,622	826,38	4,03E-02
LOC101929709	uncharacterized LOC101929709	Other	other	1,607	181,42	2,20E-02
	pyruvate denydrogenase prospnatase regulatory subunit	Cytopiasm	enzyme	1,607	809,46	3,26E-02
ZINF468	zind ninger protein 468	Other	other	1,59	131,98	3,11E-02
IGLU1	(minunoglobulin lambda constant 1 (Mcg marker)	Cytopiasm	other	1,585	23,232	9,66E-03
FAM219A	ramity with sequence similarity 219, member A	Other	G-protein coupled	1,574	697,78	2,48E-02
OR5J2	olfactory receptor, family 5, subfamily J, member 2	Plasma Membrane	receptor	1,563	21,24	3,51E-02
COL9A2	collagen, type IX, alpha 2	Space	other	1,559	12,694	4,35E-02
CDC40	cell division cycle 40	Nucleus	other	1,552	445,7	3,01E-02
TGFBRAP1	transforming growth factor, beta receptor associated protein 1	Other	other	1,549	388,48	4,73E-02 D
SOX13	SRY (sex determining region Y)-box 13	Nucleus	transcription regulator	1,547	7,434	2,13E-02
ASMTL-AS1	ASMTL antisense RNA 1	Other	other	1,543	2620,6	1,07E-02
LCAT	lecithin-cholesterol acyltransferase	Extracellular Space	enzyme	1,505	616,06	4,96E-02
SPDYE2 (includes others)	speedy/RINGO cell cycle regulator family member E6	Other	other	1,502	8504,4	4,34E-02

Symbol	Entrez Gene Name	Location	Type(s)	Fold Change	Other p	o-value	Notes
FAHD2A	fumarylacetoacetate hydrolase domain containing 2A	Other	enzyme	-41,465	5 127,604	1,93E-02	
ATP6AP1L	ATPase, H+ transporting, lysosomal accessory protein 1-like	Other	other	-36,83	430,14	4,22E-02	
OLFM1	olfactomedin 1	Cytoplasm	other	-24,833	416,689	2,37E-02	
PDXP	pyridoxal (pyridoxine, vitamin B6) phosphatase	Plasma Membrane	phosphatase	-23,527	153,05	8,47E-03	
ATF7IP2	activating transcription factor 7 interacting protein 2	Nucleus	other	-22,341	85,291	1,64E-02	
LILRB5	leukocyte immunoglobulin-like receptor, subfamily B (with TM and ITIM domains), member 5	Plasma Membrane	transmembrane recepto	r -14,716	6 99,251	1,22E-02	
AACS	acetoacetyl-CoA synthetase	Cytoplasm	enzyme	-13,754	54,841	2,67E-02	
SLC35G2	solute carrier family 35, member G2	Cytoplasm	other	-12,348	42,41	7,98E-03	
KLHL21	kelch-like family member 21	Cytoplasm	other	-11,437	7 108,323	2,54E-03	
SNORA58	small nucleolar RNA, H/ACA box 58	Other	other	-11,097	63,577	1,26E-03	
LMO7	LIM domain 7	Cytoplasm	enzyme	-10,122	2 105,019	1,98E-02	
GK	glycerol kinase	Cytoplasm	kinase	-9,763	111,417	5,56E-03	
PRKAR1B	protein kinase, cAMP-dependent, regulatory, type I, beta	Cytoplasm	kinase	-9,094	53,05	4,70E-02	
TYW3	tRNA-yW synthesizing protein 3 homolog (S. cerevisiae)	Other	other	-8,799	188,176	1,06E-03	
MTFR1	mitochondrial fission regulator 1	Cytoplasm	other	-7,716	90,847	3,44E-02	
TPK1	thiamin pyrophosphokinase 1	Cytoplasm	kinase	-7,585	54,237	9,71E-03	
PRKAB2	protein kinase, AMP-activated, beta 2 non-catalytic subunit	Cytoplasm	kinase	-7,402	2 106,96	3,84E-03	
MAGED1	melanoma antigen family D1	Plasma Membrane	transcription regulator	-6,94	133,872	7,58E-03	
SNHG7	small nucleolar RNA host gene 7 (non-protein coding)	Other	other	-6,629	72,335	4,41E-02	
SNORD8	small nucleolar RNA, C/D box 8	Other	other	-6,341	203,12	3,80E-02	
DKFZp667F0711	uncharacterized protein DKFZp667F0711	Other	other	-6,313	45,866	3,43E-03	
YTHDF3	YTH N(6)-methyladenosine RNA binding protein 3	Cytoplasm	other	-5,885	5 75,536	1,27E-02	
ABCC2	ATP-binding cassette, sub-family C (CFTR/MRP), member 2	Plasma Membrane	transporter	-5,533	50,919	1,50E-02	
ERC1	ELKS/RAB6-interacting/CAST family member 1	Cytoplasm	other	-5,437	26,952	4,67E-02	
EVA1B	eva-1 homolog B (C. elegans)	Other	other	-5,422	2 73,809	1,70E-02	
DUSP3	dual specificity phosphatase 3	Cytoplasm	phosphatase	-5,392	152,89	3,78E-02	

LINC00649	long intergenic non-protein coding RNA 649	Other	other	-5,329	123,585	5,95E-03
LMAN2L	lectin, mannose-binding 2-like	Cytoplasm	other	-5,156	120,855	7,47E-03
ZNF252P	zinc finger protein 252, pseudogene	Other	other	-5,151	72,975	1,57E-02
MED8	mediator complex subunit 8	Nucleus	other	-5,025	324,15	1,89E-02
CCDC85C	coiled-coil domain containing 85C	Plasma Membrane	other	-4,915	138,771	3,76E-02
FBXO42	F-box protein 42	Other	other	-4,76	160,527	2,49E-02
FLYWCH1	FLYWCH-type zinc finger 1	Other	other	-4,53	156,283	3,38E-02
BTF3L4	basic transcription factor 3-like 4	Other	other	-4,37	46,427	1,72E-02
TULP2	tubby like protein 2	Other	enzyme	-4,232	46,329	1,90E-02
DNAJC16	DnaJ (Hsp40) homolog, subfamily C, member 16	Other	other	-4,215	46,269	3,32E-02
ABCD4	ATP-binding cassette, sub-family D (ALD), member 4	Cytoplasm	transporter	-4,179	394,545	3,90E-02
TGFBRAP1	transforming growth factor, beta receptor associated protein 1	Other	other	-4,172	103,398	1,29E-02 D
TSPAN16	tetraspanin 16	Other	other	-4,171	946,82	2,44E-03
ORAI1	ORAI calcium release-activated calcium modulator 1	Plasma Membrane	ion channel	-4,147	104,167	3,25E-02
AZIN2	antizyme inhibitor 2	Cytoplasm	enzyme	-4,039	33,8	4,66E-02
LINC01355	long intergenic non-protein coding RNA 1355	Other	other	-4,008	52,494	2,83E-02
KRTAP5-3/KRTAP5-5	keratin associated protein 5-5	Other	other	-3,994	138,992	4,62E-02
ZNF275	zinc finger protein 275	Nucleus	other	-3,981	39,424	9,08E-03
PDE8B	phosphodiesterase 8B	Cytoplasm	enzyme	-3,929	32,81	3,55E-02
GSG2	germ cell associated 2 (haspin)	Nucleus	kinase	-3,867	162,633	4,80E-02
ANKRD52	ankyrin repeat domain 52	Nucleus	transcription regulator	-3,864	162,574	1,52E-02
ZNF326	zinc finger protein 326	Nucleus	transcription regulator	-3,833	49,07	1,96E-02
ZNF555	zinc finger protein 555	Other	other	-3,814	63,075	4,35E-02 D
F8	coagulation factor VIII, procoagulant component	Extracellular Space	peptidase	-3,765	91,261	1,30E-02
KIF9	kinesin family member 9	Cytoplasm	enzyme	-3,752	29,908	4,14E-02
CCDC71L	coiled-coil domain containing 71-like	Other	other	-3,745	22,667	1,45E-02
ZNF12	zinc finger protein 12	Nucleus	transcription regulator	-3,729	69,471	2,78E-02
WTAP	Wilms tumor 1 associated protein	Nucleus	other	-3,665	114,738	3,64E-02
ZNF555	zinc finger protein 555	Other	other	-3,648	33,061	3,94E-02 D
EYA3	EYA transcriptional coactivator and phosphatase 3	Nucleus	phosphatase	-3,615	506,3	1,07E-02
ARPIN/C15orf38-AP3S2	C15orf38-AP3S2 readthrough	Plasma Membrane	other	-3,609	48,261	2,26E-02
POLRMT	polymerase (RNA) mitochondrial (DNA directed)	Cytoplasm	enzyme	-3,537	264,596	4,69E-02
RACGAP1P	Rac GTPase activating protein 1 pseudogene	Other	other	-3,495	50,242	1,97E-02
NHSL2	NHS-like 2	Other	other	-3,456	90,001	1,45E-02
RPS6KA4	ribosomal protein S6 kinase, 90kDa, polypeptide 4	Cytoplasm	kinase	-3,443	202,862	3,43E-02

DISCUSSION

L'obésité provoque des modifications de l'homéostasie immunitaire associées à des complications affectant de nombreux organes. En effet, l'obésité active des réponses inflammatoires dans le tissu adipeux, le foie, les muscles, le pancréas et le cerveau. Des modifications fonctionnelles au niveau de l'épithélium intestinal, telle que la modification de sa perméabilité, pourraient être à l'origine de l'inflammation chronique de l'obésité. L'inflammation systémique est centrale dans le maintien de l'inflammation chronique. Elle est caractérisée par une augmentation chronique des marqueurs circulants de l'inflammation, une activation de l'endothélium, et une activation des cellules immunitaires mononuclées circulantes. Les monocytes capables de détecter des facteurs circulants modifiés dans l'obésité sont augmentés, et la proportion des trois sous populations de monocytes est modifiée. Afin de comprendre leur implication éventuelle dans le développement des complications associées à l'obésité nous avons cherché à caractériser le plus largement possible les monocytes en considérant chacune des trois sous populations individuellement.

A. Modulations phénotypiques et fonctionnelles des monocytes par l'obésité

Notre première étude a confirmé le phénotype pro-inflammatoire des monocytes dans l'obésité avec l'up-régulation par les trois sous populations de monocytes des récepteurs PPRs TLR4 et TLR8. Cette étude a également montré une up-régulation des récepteurs de chimiokine CCR2, CCR5 et CX3CR1 qui est variable en fonction des sous populations de monocytes. Les tests d'activation *in vitro* de TLR4 et de TLR8 ont montré également que la modulation de leur réponse par l'obésité était variable selon la sous-population considérée. Le premier point à discuter concerne la modulation spécifique de certains marqueurs ou de certaines fonctions par chacune des sous populations de monocytes. Si effectivement ces effets sont observés, il ne faut pas perdre de vue que chaque sous-population exprime différentiellement ces marqueurs en situation non pathologique. Si nous prenons par exemple le cas de CCR2, il est normalement très fortement exprimé par les CM, peu par les IM et pas du tout par les NCM. Chez les sujets obèses, il y a up-régulation tout en conservant la même hiérarchie dans l'expression par les sous populations. Nous retrouvons le même principe avec CX3CR1, qui est exprimé par chacune des sous populations de monocytes mais moins par les CM que par les IM qui eux l'expriment moins que les NCM. Concernant CCR5, la situation

est un peu différente puisque l'on observe l'acquisition de l'expression de ce récepteur par les CM. Ceci implique que chez les sujets obèses, le chimiotactisme des monocytes et de leur sous population majoritaire les CM, est non seulement très fortement gouverné par CCL2 (un des ligands de CCR2), mais également par CCL5 (un des ligands de CCR5) dont la production est augmentée par le tissu adipeux au cours de l'obésité (196). Au niveau fonctionnel cette remarque est également valable. Les IM des témoins stimulés par LPS ou ssRNA produisent le plus TNF-α et IL-1β comparés aux CM et aux NCM. De la même façon, les IM des sujets obèses produisent également plus de TNF-α et IL-1β comparés aux CM et aux NCM. Par contre, les CM de sujets obèses comparés à ceux des témoins produisent significativement plus d'IL-1 β après stimulation de TLR4 par LPS et de TNF- α après stimulation de TLR8 par l'ARN simple brin. Ils sont donc devenus plus réactifs et cette modulation de la fonctionalité n'est pas négligeable étant donné que les CM représentent 80 à 90% des monocytes. Concernant, la quantité de TNF-α sécrétée par les CM après stimulation de TLR8 par l'ARN simple brin chez les sujets obèses, elle rejoint celle des deux sous populations minoritaires. Par conséquent, chez les sujets obèses toutes les sous populations de monocytes produiraient TNF-a dans les mêmes proportions et en plus grande quantité que chez les témoins suite à une stimulation de TLR8. Ce qui signifie que l'ensemble des monocytes pourrait participer à l'augmentation du taux de TNF-α observé dans la circulation de patients obèses comparés à des témoins (Tableau 1) par le biais de la signalisation par TLR8 qui serait activée par des signaux qu'il reste à définir. Cela aurait des conséquences sur le métabolisme du glucose des cellules immunitaires circulantes dont les monocytes, par une action paracrine et autocrine. En effet, le TNF-a sécrété par les monocytes activés pourrait intéragir avec son récepteur à la surface des monocytes ce qui entrainerait une activation de la voie de signalisation NF-kB et la production de cytokines pro-inflammatoires dont IL-1β. L'IL-1ß sécrétée pourrait lui même intéragir avec son récepteur à la surface des monocytes et entrainer l'activation de MAPKs qui inhiberaient la voie de signalisation de l'insuline. Le métabolisme du glucose des monocytes serait modifié avec par exemple une diminution du transport du glucose dans les cellules et une augmentation du stockage du glycogène. L'inhibition de la voie de signalisation de l'insuline pourrait aussi avoir des conséquences sur la différentiation des monocytes. Mais ces hypothèses restent à démontrer. Le TNF-α sécrété pourrait également avoir le même effet sur d'autres cellules immunitaires circulantes (Figures 2).

B. L'up-régulation et l'augmentation de la fonctionnalité de TLR4 et de TLR8 par les monocytes chez les sujets obèses

L'up-regulation de TLR4 par les monocytes se manifeste au niveau fonctionnel par une augmentation de la sécrétion de TNF- α par les CM après une stimulation par LPS. Les CM chez les sujets obèses répondent plus fortement à la stimulation par LPS que les CM chez les témoins. Dans le contexte de l'obésité deux études parmi lesquelles une étude finlandaise portant sur une cohorte de 2452 individus suivis sur dix ans montrent que dans l'obésité humaine le LPS est augmenté dans la circulation sanguine (22) (227). Nos résultats montrent bien la position clef du LPS, qui proviendrait du microbiote intestinal modifié chez les sujets obèses (228) (115) (229). Le LPS serait l'initiateur de l'inflammation systémique, de par sa capacité à induire une réponse pro-inflammatoire notamment par le biais des monocytes et plus significativement par les CM. Il y aurait donc une synergie entre : l'augmentation du nombre de monocytes, l'augmentation de la fonctionalité de TLR4, et l'augmentation de LPS, chez les sujets obèses. De plus, si le LPS est le principal ligand de TLR4, il n'est pas le seul et il est maintenant bien établi que d'autres ligands endogènes peuvent entretenir un état proinflammatoire. Ces ligands endogènes ou « Damage Associated Molecular Pattern » (DAMPs) sont relargués par les cellules mortes ou mourantes comme signaux de danger pour initier une réponse inflammatoire (230). A ce jour, quinze DAMPs reconnus par TLR4 ont été identifiés : la High Mobility-Group Box protein 1 (HMGB-1), les protéines Heat Shock, les protéines S100, le fibrinogène, les fragments de sulphate d'héparan, la fibronectine, les fragments d'acide hyaluronique, la tenascin-C, la b-defensine-3, les protéines surfactantes A&D, l'elastase neutrophile, la lactoferrine, le SAA, les OxLDL, et les acides gras saturés. Parmi celles-ci, le fibrinogène (231), la SAA (232) et l'HMGB-1 (233) sont augmentés dans le sérum de patients obèses. Ils participeraient donc aussi à l'entretien de l'inflammation systémique dans l'obésité par l'intermédiaire de TLR4. Il pourrait être intéressant de doser les autres DAMPs ligands de TLR4 dans le sérum de patients obèses afin d'encore mieux comprendre ce qui provoque/entretien le phénotype pro-inflammatoire des monocytes dans l'obésité.

L'up-régulation de TLR8 par tous les monocytes qui se manifeste fonctionnellement par une plus forte sécrétion de TNF- α , d'IL-1 β et d'IL-10 par les CM, indique que les CM dans l'obésité répondent plus fortement à la stimulation par ssRNA qu'en condition non pathologique. A notre connaissance c'est la première fois que l'up-régulation et l'augmentation de la fonctionnalité de TLR8 sont observées au niveau des monocytes chez des sujets obèses. TLR8 est un détecteur intracellulaire d'acides nucléiques d'origine le plus souvent virale. L'étude détaillée de lignées transgéniques de souris exprimant le TLR8 humain avec différents niveaux d'expression a révélé que le pancréas, le foie et les reins de ces animaux étaient inflammés. De plus la concentration du sérum de ces souris en TNF-a, IL-6, IL-17, IL-12p40, CCL2 et IP-10 est significativement augmentée par rapport aux souris sauvages, ainsi que le taux d'auto-anticorps anti-ADN double brin et anti-ribonucléoproteines (234). Ces derniers auto-anticorps peuvent activer TLR8 en vertu de leur très haute affinité pour les ssRNA. Finalement, l'ensemble de ce travail montre que la reconnaissance par TLR8 des ARNs peut conduire à une inflammation de type auto-immune (234). Une autre étude, chez l'homme, laisse entrevoir que des auto-anticorps contre les petites ribonucleoproteines nucléaires (snRNP) qui s'organisent en grappe à la surface des cellules en apoptose initieraient le Lupus Systémique Erythémateux en stimulant TLR8 (231). Mécanistiquement, deux études impliquent des auto-anticorps anti-phospholipides dans l'up-régulation de TLR8 notamment par leur implication dans la translocation de TLR8 du réticulum endoplasmique vers l'endosome qui résulte en une plus grande sensibilité envers ses ligands (236) (237). D'où la question suivante : est-ce que l'inflammation systémique de bas grade associée à l'obésité présente des caractéristiques de type auto-immunes? Pour répondre à cette question nous avons déjà recherché dans les listes de gènes dont l'expression par les monocytes est modulée chez les sujets obèses ceux qui pourraient être impliqués dans l'auto-immunité et nous avons trouvé que les CM et les IM up-régulent respectivement TXLNA (taxilin alpha) et FLT3LG (fms-related tyrosine kinase 3 ligand) (238) (239) (240) (données non présentées), deux cytokines favorisant la production d'(auto)anticorps par les lymphocytes B. Ce qui présente un premier élément de réponse, nous devons bien sur confirmer ces données sur un plus grand nombre de patients. Nous pourrions aussi entreprendre de rechercher dans le sérum de patients obèses la présence d'auto-anticorps en orientant nos recherches vers les autoanticorps anti-ADN double brin et les auto-anticorps anti-snRNP qui sont augmentés dans les souris transgéniques exprimant le TLR8 humains. Les anti-snRNPs devraient être tout particulièrement augmentés chez les sujets obèses, en raison notamment du nombre très important de cellules en apoptose dans leur tissu adipeux, présentant potentiellement à leur surface des snRNP en grappe. La recherche d'auto-anticorps anti-phospholipides serait également intéressante, puisqu'il a été montré qu'ils intervenaient dans l'up-régulation de TLR8. Si ces éléments de réponse consolidaient notre hypothèse nous pourrions aller encore plus loin en comparant le phénotype et la fonctionalité des lymphocytes B dans la circulation de patients obèses et de témoins sains.

L'up-régulation et la fonctionnalité accrue de TLR4 et de TLR8 par les monocytes de sujets obèses comparés à ceux de témoins, peuvent avoir des conséquences sur la fibrose du tissu adipeux chez les usjets obèses, surtout si l'on considère l'augmentation de la capacité migratoire des CM et des IM, qui up-régulent CCR2 et CCR5, faisant de ces cellules les précurseurs de macrophages du tissu adipeux. En effet, TLR4 et TLR8 participent à la régulation de la matrice extracellulaire (241). Nous pouvons donc imaginer que des ARNs relargués par des cellules nécrotiques complexés à des auto-anticorps stimulent TLR8 et/ou que des DAMPs stimulent TLR4. Dans les deux cas une voie de signalisation activant IRAK4 et NFkB conduit à la sécrétion de TIMP-1 (inhibiteur tissulaire de la metalloproteinases-1) et TIMP-1 inhibe l'activité de la MMP-1 (metalloproteinases matricielle-1) ce qui débouche sur un excès de matrice extra cellulaire (242) (243).

TLR4 est un récepteur qui est exprimé aussi bien au niveau des cellules immunitaires circulantes et tissulaires, qu'au niveau des adipocytes, des hépatocytes et des myocytes (119) (108) (109). Il s'agit donc d'un récepteur fondamental qui par l'augmentation de sa fonctionnalité au niveau des monocytes circulants dans l'obésité exerce un rôle central dans l'initiation et le maintien de l'inflammation de bas grade. Il est donc concevable d'envisager de limiter son action par des traitements à base d'antagonistes. Deux antagonistes : E5564 (Eritoran, Eisai Inc) et AK-242 (Takeda Biological), ont été évalués lors d'essais cliniques afin de limiter l'inflammation en contrôlant particulièrement le taux d'Il-6 dans la sepsis sévère. Ces essais ont été suspendus par manque d'efficacité (244) (245). Néanmoins dans une étude publiée dans la revue « Atherosclerosis » en 2015 (246), l'effet d'une nouvelle petite molécule antagoniste de TLR4 (IAXO-102, [Innaxon, Tewkesbury]) a été testé. Ces tests ont été réalisés in vitro par des expériences de culture cellulaire de cellules HUVEC (Human umbilical vein endothelial) et in vivo à l'aide d'un modèle murin d'anévrisme de l'aorte abdominale induit par l'angiotensine II. Les résultats de ces expériences ont montré qu'IAXO-102 inhibe MAPK et la phosphorylation p65 de NF-kB associée à une downrégulation de TLR4 et de protéines pro-inflammatoires dépendantes de TLR4, au niveau des cellules endothéliales. De plus IAXO-102 réduit les risques liés à l'anévrisme de l'aorte abdominale induit par l'angiotensine II. Pour les auteurs de cette étude, IAXO-102 inhiberait la signalisation par TLR4 induite par des ligands de l'inflammation stérile comme les oxLDL. Les résultats de cette étude sont encourageants mais des expériences similaires doivent être effectuées sur d'autres types cellulaires et d'autres pathologies inflammatoires afin de vérifier l'action de cette molécule sur les monocytes circulants mais aussi sur les macrophages, les hépatocytes et les adipocytes. Une autre étude (247), cette fois-ci sur un modèle murin (lipoprotein receptor-deficient, LDLR-/-) de diabète de type II induit par un régime riche en antagoniste connu de TLR4, Rhodobacter graisse montre qu'un sphaeroides lipopolysaccharide (Rs-LPS), atténue le développement de l'athérosclérose sans pour autant améliorer le statut métabolique des animaux. Le traitement par l'antagoniste de TLR4 diminue l'infiltration des monocytes/macrophages, l'expression de l'IL-6 et la metalloproteinase matricielle 9 (MMP9) dans les lésions athérosclérotiques des souris diabétiques. Il n'existe pas à ce jour d'essais cliniques avancés qui présagent d'une utilisation dans un avenir proche d'antagoniste de TLR4 pour lutter contre les conséquences de l'inflammation chronique qui caractérise l'obésité.

Etant donné les conséquences probables et multiples de l'augmentation de la fonctionalité de TLR8 notamment sur l'inflammation des tissus comme ceux du foie, du pancréas et des reins, sur la production de cytokines pro-inflammatoires, sur la production d'auto-anticorps et sur le développement de la fibrose du tissu adipeux, il est aussi possible d'envisager chez les sujets obèses, un traitement à base d'antagoniste de TLR8. Deux études portant sur des modèles murins de psoriasis (une pathologie de la peau à caractère inflammatoire) utilisant des antagonistes de TLR8 ont montré des résultats concluants (248) (300). IMO-8044 est un oligonucléotide antagoniste de TLR7, 8 et 9 utilisé dans l'une de ces deux études et qui a été testé lors d'essais cliniques de phase I puis de phase II par la société Idera Pharmaceuticals, Inc. Les essais se sont terminés en mars 2014 et ont démontré que cet antagoniste était bien toléré par les sujets sains et par des patients atteints de psoriasis avec en plus une activité clinique avérée. Nous pourrions donc envisager l'emploi d'un tel antagoniste afin de limiter les effets de l'up-régulation de TLR8 par les monocytes de patients obèses sur l'inflammation systémique et chronique associée à l'obésité en espérant notamment une amélioration du métabolisme du glucose par une diminution de la sécrétion de TNF- α par les monocytes circulants.

C. Les IM comme précurseurs de macrophages anti-inflammatoires au profil profibrotique

Nous avons montré au niveau transcriptomique qu'il existe pour les CM une signature de l'obésité. Ils modulent des gènes impliqués dans la migration cellulaire, l'adhésion, dans la réponse immunitaire et dans la régulation de leur métabolisme. Concernant la migration cellulaire cela est en accord avec l'up-régulation au niveau protéique des récepteurs : CCR5, CX3CR1, CCR2. Ce qui ferait des CM les précurseurs d'un grand nombre de macrophages dans les tissus inflammés. L'étude de leur transcriptome sous entend qu'ils sont impliqués dans le maintien de l'inflammation systémique de bas grade, ce que nous avons observé par la fonctionnalité accrue de TLR4 et TLR8 chez les CM obèses. De plus, ils up-régulent FPR2 un récepteur du SAA, un facteur pro-inflammatoire augmenté dans l'obésité. Il serait ainsi les précurseurs de macrophages inflammatoires de polarisation de type M1. Au niveau du transcriptome, nous n'avons pas trouvé pour les IM une signature de l'obésité aussi évidente que celle des CM ni au niveau fonctionnel où nous n'avons pas montré d'augmentation significative de la fonctionalité de TLR4 et de TLR8 par les IM de sujets obèses. Les IM uprégulent très fortement CISD1 ou MitoNEET, une protéine de la membrane externe de la mitochondrie dont l'expression est diminuée dans les tissus adipeux et hépatiques de souris DIO. Les mitochondries d'adipocytes sur-exprimant MitoNEET de souris transgéniques ont une activité respiratoire réduite associée à une diminution des dommages causés par les dérivés réactifs de l'oxygène et une augmentation de la production d'adiponectine. Des effets semblables ont été mesurés sur des hépatocytes sur-exprimant mitoNEET. De plus, ces cellules ont une capacité augmentée à stocker les lipides. Des souris transgéniques surexprimant MitoNEET et rendues obèses par une alimentation riche en graisse restent sensible à l'insuline (250). La concordance entre les modifications fonctionnelles des adipocytes et des hépatocytes sur-exprimant MitoNEET suggère des effets similaires sur la physiologie cellulaire dans d'autres tissus. Ainsi MitoNEET est une molécule dont l'action a des propriétés protectrices contre les acides gras en excès et elle est aujourd'hui considérée comme une cible thérapeutique pour le traitement du diabète de type II (251) (252). Une extrapolation aux monocytes indiquerait que les IM dans l'obésité par l'up-régulation de MitoNEET seraient capables de stocker les acides gras libres en excès et produiraient moins de ROS. Par l'accumulation de lipides, ils pourraient s'orienter vers un phénotype profibrotique, comme cela a été montré par la comparaison du transcriptome de macrophages spumeux et non spumeux chez des souris recevant une alimentation riche en graisses (253). Ce que corrobore l'analyse intégrative du transcriptome par IPA indiquant que les IM dans l'obésité favoriseraient la fibrose et la mort du tissu conjonctif. Ils pourraient donc être les précurseurs de macrophages profibrotiques infiltrant les tissus inflammés chez les sujets

obèses. Cette hypothèse est étayée par le fait qu'ils up-régulent aussi des récepteurs membranaires aux propriétés anti-inflammatoires (CCRL2 [chemokine (C-C motif) receptor-like 2] et MC1R [melanocortin 1 receptor]) (254) (255) (256) (données non présentées) mais reste à démontrer.

D. Le phénotype des NCM est un indicateur des altérations métaboliques

Il existe une corrélation positive entre le pourcentage de NCM et la glycémie, indépendante de la masse grasse (193). De plus, le degré d'expression par les NCM de CCR2 et CX3CR1 est négativement corrélé avec le taux d'HDL-c ; le degré d'expression de CSF-1R est positivement corrélé avec l'HOMA-IR et le degré d'expression de CCR5 est positivement corrélé avec le taux de triglycerides circulants et l'HOMA-IR (257). Ces corrélations existent pour les IM et les CM mais sont significativement moins fortes. Le phénotype des NCM serait donc un indicateur des altérations métaboliques associées à l'obésité. En vertu d'une plus faible up-régulation de l'expression de CCR5 et CCR2 par l'obésité associée au profil de base des NCM où ces deux récepteurs sont très faiblement exprimés, voir pas exprimés en ce qui concerne CCR2, les NCM auraient un plus faible potentiel migratoire que les IM et les CM. De plus, ils répondent plus fortement à la stimulation de TLR8 chez les sujets obèses. Ce qui est en accord avec les travaux de Cros et al. (237) qui ont montré que les NCM patrouillaient les endothéliums et répondaient de façon sélective aux virus et à des complexes immunologiques comprenant des acides nucléiques par une voie pro-inflammatoire TLR7-TLR8-MyD88-MEK. Ils seraient donc impliqués dans la surveillance des endothéliums et de la circulation grâce à l'up-régulation de récepteurs membranaires comme par exemple GPR132 (G protein-coupled receptor 132) capables de détecter des nutriments (258) (données non présentées). Ils participeraient de plus à l'inflammation systémique notamment par la production accrue d'IL-1β suite à une stimulation de TLR8 mais aussi par l'up-régulation de molécules pro-inflammatoires comme CXCL12 ou TCAR1 (tachykinin receptor 1) aussi appelé NK1-R (259) (260) (261) (Neurokinin-1 receptor) (données non présentées) dont le ligand SP, un neuropeptide pro-inflammatoire, est augmenté dans la sérum de souris DIO (262) et dans celui d'enfants obèses comparés à celui d'enfants témoins (23). L'up-régulation de CXCL12 confère aux NCM un rôle important dans le contrôle des populations de cellules immunitaires circulantes puisqu'elle intervient notamment dans la migration des cellules dentritiques et serait responsable de l'augmentation des mégacaryocytes, mais aussi de la migration de nombreux autres types cellulaires tels que les lymphocytes T et B et les monococytes.

E. Existe-t-il une relation entre l'état inflammatoire des monocytes et des modifications de leur métabolisme dans l'obésité ?

L'analyse transcriptomique a révélé que l'expression de gènes impliqués dans le métabolisme était modulée dans l'obésité au niveau des trois sous populations. Concernant les vingt gènes les plus modulés nous trouvons cinq gènes impliqués dans le métabolisme pour les CM, six pour les IM et cinq pour les NCM. Parmi ces gènes huit sont également impliqués dans la réponse immunitaire (CLU, CISD1 ou MitoNEET, PXN, ATP2A1, CD22, DOK4, NF1, KLHL21 et PDXP). Concernant les fonctions les plus probablement modulées, nous avons également trouvé des fonctions métaboliques avec notamment le métabolisme des sucres et des lipides pour les CM et les NCM. Ces données mettent en avant une possible relation de cause à effet entre le métabolisme des monocytes et leur fonctionnalité dans l'obésité. Il est possible d'envisager cette relation de deux façons : 1/ le métabolisme des monocytes serait modifié par leur environnement (hyperglycémie et hyperlipidémie) entrainant des modifications phénotypique et fonctionnelle en particulier de type proinflammatoire. 2/ à l'inverse nous pouvons envisager que l'activation des monocytes par des facteurs circulants augmentés dans l'obésité entraine des modifications de leur métabolisme. Notre étude exploratoire ne permet pas de démontrer le sens de cette relation mais permet d'envisager des pistes de recherche.

V. CONCLUSION

Par ce travail de thèse nous avons caractérisé phénotypiquement et fonctionnellement les monocytes circulants dans l'obésité. Nous nous sommes appuyés sur des travaux antérieurs de notre équipe qui ont montré qu'en plus d'être augmentés en nombre, les monocytes étaient modulés en qualité. C'est à dire que les proportions des IM et des NCM sont augmentées par l'obésité alors que le nombre absolu de monocytes appartenant à chacune des sous populations est augmenté. Ces travaux avaient montré en plus un lien entre le pourcentage de NCM et la glycémie (193).

Ici nous avons montré que les CM qui représentent la majeure partie des monocytes, entre 80% et 90%, étaient ceux qui portaient la signature transcriptomique de l'obésité la plus évidente. Ils soutiendraient donc par leur phénotype et leur nombre l'inflammation systémique de bas grade qui caractérise l'obésité, mais aussi l'inflammation tissulaire puisque nous avons montré qu'ils up-régulent dans l'obésité des gènes impliqués dans la migration cellulaire. Parmi ceux-là nous pouvons citer CCR2, CCR5 et CX3CR1 dont nous avons aussi montré l'up-régulation au niveau protéique. Il est donc très probable qu'ils soient les précurseurs de l'essentiel des macrophages surnuméraires que l'on trouve dans les tissus métaboliques inflammés chez les sujets obèses : le tissu adipeux, le foie, les muscles et le pancréas. Notre analyse au niveau du génome complet a montré que les CM modulent chez les sujets obèses des gènes impliqués dans les maladies cardivasculaires, ils migreraient donc aussi vers les plaques d'athérome. L'analyse transcriptomique a révélé l'up-régulation de gènes dont le rôle au niveau de l'inflammation est important de part l'amplitude de leur modulation par l'obésité et/ou leur possible intéraction avec des facteurs circulant présents dans le sérum de malades obèses ou des récepteurs up-régulés par l'obésité à la surface des autres cellules immunitaires circulantes et de l'endothélium. Il s'agit d'abord du gène CLU, le plus up-régulé par les CM et dont le taux dans le sérum est positivement corrélé avec les marqueurs de l'obésité et de l'inflammation systémique (263). Nous devons donc dans un premier temps confirmer sur une plus large cohorte cette up-régulation avant de poursuivre par d'autres analyses afin de comprendre quelles pourraient être les conséquences au niveau du développement des maladies cardiovasculaires de l'up-régulation de CLU par les CM. Nous devons également confirmer l'up-régulation au niveau des mRNA et au niveau protéique de FPR2, le récepteur du SAA, un des marqueurs cliniques de l'inflammation de bas grade de l'obésité (207) (20) qui serait impliqué dans l'initiation de l'athérosclérose (264) (265). Par leurs caractéristiques pro-inflammatoires ils pourraient être les précurseurs de macrophages dont la polarisation est de type M1.

La signature de l'obésité au niveau des IM est moins homogène. Cependant dans l'obésité ils modulent l'expression de gènes intéressants qui interviennent dans la mise en place de mécanismes de protection contre un excès d'acides gras. En effet, les IM pourraient avoir une capacité réduite à libérer le glycérol. De plus, les IM up-régulent très fortement CISD1 ou MitoNEET, une molécule qui les rendraient capable de stocker les acides gras. L'analyse transcriptomique laisse supposer que dans l'obésité les IM présentent un caractère anti-inflammatoire et qu'ils interviendraient dans la fibrose et la mort du tissu conjonctif. Ils pourraient donc être les précurseurs de macrophages anti-inflammatoires et profibrotiques dont la polarisation serait de type M2. Nous devons confirmer sur une plus large cohorte l'up-régulation à la fois au niveau des messagers mais aussi au niveau protéique de MitoNEET, des gènes controlant la libération du glycerol et des gènes anti-inflammatoires CCRL2 et MC1R. Si ces modulations étaient confirmées cela indiquerait que dans le contexte de l'obésité le métabolisme des IM est modifié, ces modifications pourraient avoir des conséquences sur leur fonctionnalité (253).

Nos deux premières études visant à charactériser les monocytes dans l'obésité montrent une relation entre soit la fréquence des NCM (193), soit leur phénotype (257) et les anomalies métaboliques de l'obésité. Il s'agit respectivement de la glycémie pour la première étude (193), du taux de HDL-c, de triglycéride et de l'estimation de la résistance à l'insuline pour la seconde (257). Le phénotype des NCM peut être donc considéré comme un indicateur de risque cardiovasculaire. Nos travaux vont également dans le sens d'une fonction de patrouilleurs (183) accrue dans l'obésité. En up-régulant le moins les récepteurs de chimiokines CCR2 et CCR5, ils migreraient le moins vers les tissus inflammés.

Les trois sous populations de monocytes sont donc différentiellement impliquées dans l'inflammation chronique de bas grade qui caractérise l'obésité et les pathologies qui y sont associées mais elles partagent également des traits communs. Nous avons montré qu'elles présentaient toutes un phénotype pro-inflammatoire par l'up-régulation de TLR4 et de TLR8 bien qu'au niveau fonctionnel les CM augmentent plus dans l'obésité leur réponse à la stimulation de TLR4 que les deux autres sous populations. Les CM et les NCM augmentent plus dans l'obésité leur réponse à la stimulation de TLR4 que les deux autres sous populations. Les CM et les NCM augmentent plus dans l'obésité leur réponse à la stimulation de TLR8 que les IM. L'up-régulation de TLR4 par les monocytes dans l'obésité parle en faveur d'un rôle clef du LPS du microbiote

intestinal parmi les possibles facteurs initiateurs de l'inflammation chronique de bas grade. Cela n'exclue pas l'intervention dans le maintien de l'inflammation de DAMPs présents dans la circulation dont certains sont des ligands de TLR4 et ont déjà été identifiés comme étant augmenté dans l'obésité. C'est le cas du Fibrinogène (231), du SAA (232) et de HMGB-1 (233). L'up-régulation de TLR8 et l'augmentation de sa fonctionalité dans les CM et les NCM sont des éléments nouveaux dans la compréhension du rôle des monocytes dans l'obésité. Si TLR8 intervient dans la production de cytokines pro-inflammatoires comme TNF- α et IL-1 β , il participe donc à l'inflammation chronique mais cela ne serait pas les seules conséquences de son activation. L'augmentation de la fonctionnalité de TLR8 dans l'obésité pourrait être responsable d'une orientation à caractère auto-immune de l'inflammation par la production accrue d'(auto)anticorps (234). Ces auto-anticorps par leur très grande affinité pour les ARNs simples brins participeraient à l'entretien de l'activation de TLR8 qui serait ainsi sans cesse activé avec des conséquences multiples au niveau des tissus métaboliques (foie, muscles, pancréas et rein) observées chez des souris transgéniques exprimant avec une plus une moins forte intensité TLR8 (234). De plus, l'activation de TLR8 par les monocytes obèses participerait aussi à la fibrose du tissu adipeux obèse (242) (243). Cibler thérapeutiquement TLR8 avec un antagoniste pourrait donc présenter de nombreux avantages et limiter les conséquences de l'obésité sur le métabolisme. Une molécule IMO-8044 a déjà été testée lors d'essais cliniques de phase I puis de phase II dont les résultats sont positifs sur des sujets sains et des patients souffrant de maladies inflammatoires (psoriasis, lupus) par la société Idera Pharmaceuticals, Inc.

L'augmentation probable du taux d'auto-anticorps dans la circulation des patients obèses en relation avec l'activation de TLR8 ainsi que la découverte de l'up-régulation par l'obésité au niveau des IM et des CM de gènes (TXLNA [taxilin alpha] et FLT3LG [fms-related tyrosine kinase 3 ligand]) impliqués dans développement de réponses auto-immunes (données non présentées ici) ouvrent la porte vers une composante auto-immune de l'inflammation chronique de bas grade qui caractérise l'obésité. Il serait donc nécéssaire de vérifier l'up-régulation de TXLNA par les CM obèses et de FLT3LG par les IM, de doser les auto-anticorps qui devraient être augmentés suite à l'activation de TLR8. C'est à dire les auto-anticorps anti-ADN double brin et les auto-anticorps anti-snRNP dans le sérum de patients obèses et dans celui de donneurs sains. Enfin une analyse phénotypique et fonctionnelle des lymphocytes B dans la circulation de patients obèses et de sujets sains complèterait la description de cette composante.

Afin de mettre en évidence les liens existant entre des modifications du métabolisme des monocytes et leur phénotype pro-inflammatoire dans l'obésité nous envisageons dans un premier temps de confirmer pour chaque sous population la modulation des gènes impliqués dans le métabolisme et tout particulièrement des gènes ayant à la fois un rôle dans le métabolisme et la réponse immunitaire. Dans un second temps nous pourrions envisager des tests fonctionnels où nous mettrions en culture des monocytes de sujets minces en présence de concentrations pathologiques de glucose, de certains lipides (céramide, palmitate, cholesterol) et de LPS afin d'étudier l'expression des gènes mis en évidence par microarrays et ainsi voir qui de l'inflammation ou du métabolisme induit la modification de ces gènes dans les monocytes des obèses. Nous pourrions aussi étudier par microscopie des modifications morphologiques dues par exemple à l'accumulation de goutelettes lipidiques.

L'ensemble de ce travail confirme le profil pro-inflammatoire de tous les monocytes dans l'obésité par l'up-régulation de TLR4 et de TLR8. Avec une très forte implication des CM qui interviendraient dans les complications cardiovasculaires. Nous ouvrons deux nouvelles voies d'investigation. La première serait la composante auto-immune de l'inflammation de bas grade qui caractérise l'obésité. La seconde serait la mise en évidence de relations entre des modifications du métabolisme des monocytes dans l'obésité et leur fonctionnalité. Envisager de limiter les effets de l'up-régulation de TLR8 par les monocytes de patients obèses sur l'inflammation systémique et chronique associée à l'obésité à l'aide d'un antagoniste ne peut néanmoins pas être considérées comme une solution en soi. Ce serait plutôt un complément d'autres thérapies associées à une perte de poids telles que la chirurgie bariatrique et/ou des modifications du mode de vie avec un changement du régime alimentaire et une augmentation de l'activité physique qui ont déjà montré des effets bénéfiques sur le statut inflammatoire des patients (266) (267) (268).

RESUME

Les monocytes détectent des signaux métaboliques circulants qu'ils traduisent en signaux immunologiques. ils infiltrent les tissus inflamés et sont également les précurseurs des macrophages. Dans l'obésité, la fréquence, le nombre, le phénotype et la fonctionnalité des sous populations de monocytes (CD14⁺⁺CD16⁻ [CM], CD14⁺⁺CD16⁺ [IM] et CD14⁺CD16⁺⁺ [NCM]) sont spécifiquement modulés. Le phénotype des monocytes est pro-inflammatoire avec une plus forte réponse à la stimulation de TLR4 et de TLR8. Nos travaux suggèrent une capacité migratoire accrue des CM et des IM. La comparaison du transcriptome des sous populations chez des sujets obèses et des témoins, révèle une signature spécifique de chaque sous population montrant un plus fort impact de l'obésité sur les CM. Ils soutiendraient l'inflammation en modulant des gènes impliqués dans la signalisation cellulaire. Ils migreraient avec les IM vers les tissus inflamés. Les NCM resteraient plus longtemps dans la circulation où leur fonction de « patrouilleurs » serait accrue. Les gènes les plus modulés par les CM et les IM, respectivement Clusterine et CDGSH iron sulfur domain 1 sont des ponts entre la réponse immunitaire, le métabolisme et la réponse au stress. L'étude des « tops » gènes dont l'expression est la plus fortement modulée et des fonctions les plus probablement modulées révèle que le métabolisme des monocytes serait modifié dans l'obésité. Ce travail ouvre des perspectives concernant : 1) une éventuelle composante auto-immune de l'inflammation de bas grade et 2) des relations entre des modifications du métabolisme des monocytes et leur fonctionnalité.

Mots clés : sous populations de monocytes, obésité, inflammation, métabolisme

ABSTACT

Systemic inflammation is pivotal in establishing and sustaining the obesity low-grade inflammatory status. Studying monocytes is important because they can detect metabolic cues in the circulation that are then translated into immunological factors. Monocytes infiltrating inflamed tissues are also macrophage precursors. In obesity, frequency, number, phenotype and functionality of the three monocyte-subsets (CD14⁺⁺CD16⁻ [CM], CD14⁺⁺CD16⁺ [IM] et CD14⁺CD16⁺⁺ [NCM]) are specifically altered. We observed a pro-inflammatory phenotype of monocytes in obesity with an increased response to TLR4 and TLR8 stimulation. Our work suggests an increased migratory capacity of CM and IM. Comparison of the transcriptome of the three subsets in obese and control subjects shows an increased imprint of obesity on CM. CM could sustain inflammation by modulating genes involved in cell signaling. They most probably migrate with the IM toward inflamed tissues. Whereas, NCM should stay longer in the circulation where their patrolling function could be increased. The most modulated genes by CM and IM, respectively Clusterin and CDGSH iron sulfur domain 1 (CISD1) are bridges between immune response, metabolism and stress response. The analysis of the top modulated genes and of the most probably modulated functions indicates that monocyte metabolism is altered by obesity. We open new paths of research: 1) a possible auto-immune trait of the low grade inflammation and 2) a possible link between altered monocyte metabolism and their functionality.

Key words : monocyte subsets, obesity, inflammation, metabolism
