Remerciements

This thesis is a co-supervising PhD programme between China and France. Here I want to express my acknowledgements to all these people and institutes without which this work will not be completed successfully.

First, my deepest gratitude goes to Professor Michel Zinsmeister and Yuefei Wang, my supervisors of this thesis. During my thesis, they have gave a lot of instructive advices and useful suggestions on this work. Their insightful thoughts helped me broaden my horizon and their encouragements gave me more enthusiasm and passion on basic research. At the same time I want to thank Professor Weiyuan Qiu and Ilia Binder for the acceptance to be the referees of my thesis. Also many thanks would go to the the members in my jury.

Second, I want to thank my great motherland, it is the scholarship from Chinese Scholarship Council that supported all my expenses in France.

During my stay in Orleans, the members in the laboratory MAPMO have helped me a lot. In particular, I want to give my heartfelt thanks to Anne Liger, Marie-France Grespier, Marie-Laurence Poncet for their help in many things. At the same time, thanks to my friends in the lab, Remi, Manon, Hieu, Binh, Nhat, Tien, Gregoire for their discussion in research and accompanying in daily life. Also I am in deep debt to my Chinese friends, Xing Feng, Wang Yichang, Zhao Yue, Zhang Henshui, Wei Huaying, Zhang Yunzhi. With them I had enjoyed the traditional Chinese food here and also I didn't feel homesick.

In the last, my thanks would go to my beloved family for their loving considerations and continuous encouragement in me through these years.

Chapitre 1

Introduction

This thesis will focus on three topics related to the $SLE(\kappa)$ processes. The first part is about the dipolar $SLE(\kappa)$ process and the conformal restriction measure on the strip; the second part is about the connectivity property of the Brownian loop measure; and the third part is about the generalized integral means spectrum of the inner whole plane Loewner processes driven by a Lévy process.

The conformally invariant scaling limits of a series of planar lattice models can be described by the one-parameter family of random fractal curves $SLE(\kappa)$, which was introduced by Schramm. These models include site percolation on the triangular graph, loop erased random walk, Ising model, harmonic random walk, discrete Gaussian free field, FK-Ising model and uniform spanning tree. Using SLE, mathematicians can get many exponents related to these lattice models, which physicists predicted using non-rigorous methods. For example, Schramm, Werner and Lawler got the intersection exponents of the plane Brownian motion, and then proved Mandelbrot's conjecture about the Hausdorff dimension of Brownian frontier points. Also the arm exponent of these lattice can be obtained by studying some crossing events related to the $SLE(\kappa)$ process. During the past twenty years, the theory of $SLE(\kappa)$ process has developed very quickly. And more relations to physical models has been established such as the random surface theory created by Jason Miller and Scott Sheffield and the discrete holomorphic function theory concerning the lattice models. It is of no doubt that SLE process will continue to play the most important role in this area.

Let us now give the structure of this thesis. In chapter one, we will recall some basic facts about the $SLE(\kappa)$ process. And this include some background related to complex analysis and stochastic analysis. Also the definition of SLE process and some properties will be given.

Chapter two will be devoted to the introduction of the dipolar $SLE(\kappa)$ process and to the construction of the conformal restriction measure on the strip (which is called the dipolar conformal restriction measure). It is known that chordal $SLE(\kappa)$ process is generated by a random curve in a simply domain that connects two boundary points, radial $SLE(\kappa)$ process is a random curve in a simply connected domain

that connects an inner point and a boundary point, and the whole plane $\text{SLE}(\kappa)$ process is a random curve in the complex plane from a point to infinity. In this chapter we will see that dipolar $\text{SLE}(\kappa)$ process is a random curve that connects a boundary point to a boundary arc. And the dipolar $\text{SLE}(\kappa)$ also satisfies some nice properties as the chordal $\text{SLE}(\kappa)$ process. Then we will use dipolar SLE process and study the conformal restriction measure in the strip. This is a measure supported on the compact sets of the strip that satisfies conformal restriction properties. To be more precise, let us describe briefly the conformal restriction measure which we study in this thesis : let \mathcal{S} be the strip of width π in the plane, i.e,

$$\mathcal{S} = \{z = x + iy \in \mathbb{C} : x \in \mathbb{R}, 0 < y < \pi\}.$$

We are going to study closed random subsets K of \mathcal{S} that have the following form :

- (1) K is a connected compact set of $\bar{\mathcal{S}}$ such that $K \cap \mathbb{R} = \{0\}$ and $\mathcal{S} \setminus K$ has two connected components whose boundaries contain $+\infty$ and $-\infty$ respectively.
- (2) For any connected compact subset A of $\bar{\mathcal{S}}$ such that $A \cap \mathbb{R}_\pi = \emptyset$, $\mathcal{S} \setminus A$ is simply connected and $d(0, A) > 0$, the law of $\Phi_A(K)$ conditioned on the event $\{K \cap A = \emptyset\}$ is the same as the law of K , where Φ_A is the unique conformal map from $\mathcal{S} \setminus A$ to \mathcal{S} that fixes $+\infty$ and $-\infty$ and $\lim_{z \rightarrow +\infty} (\Phi_A(z) - z) = -\lim_{z \rightarrow -\infty} (\Phi_A(z) - z)$.

The law of such a set is called a dipolar restriction measure, which is the analogy of the chordal restriction measure defined in [9] and the radial restriction measure defined in [23].

In chapter three we will give an an introduction to the Brownian loop measure and prove a formula predicted by Cardy and Gasmann about the total mass that the Brownian loop in the upper half plane disconnects two given points from the boundary. Intuitively the Brownian loop measure is just a measure induced by a planar Brownian path starting from some point in the plane and conditions on returning at the same point. Given two points in the upper half plane, according to the property of the planar Brownian motion, these two points are not on the Brownian loop almost surely. So there are four position relations about the two points and the Brownian loop. We will see that only the case that two points are enclosed by the loop at the same time has the finite mass. In order to give the formula of this finite mass, the SLE bubble measure and its relation to Brownian bubble measure will be recalled. In fact SLE bubble measure is just the measure obtained by passing the two boundary points of chordal SLE to the same boundary point and then rescaling.

In chapter four, we study the generalized spectrum of the inner whole plane Loewner processes driven by Lévy process. Given an univalent function ϕ defined on the unit disk with $\phi'(0) = 1$, and $p, q \in \mathbb{R}$, the generalized integral spectrum of ϕ is defined as follows.

$$\beta_\phi(p, q) := \limsup_{r \rightarrow 1^+} \frac{\log \int_0^{2\pi} \left| \frac{z}{\phi(z)} \right|^q |\phi'(re^{i\theta})|^p d\theta}{|\log(r-1)|}.$$

Usually it is difficult to determine the generalized integral spectrum for a simply domain, since it is difficult to get the exact form of a conformal map from the unit disk to the domain. But for some random univalent functions, it is possible to use some methods to compute the **averaged generalized integral means spectrum** which is defined as the following :

$$\bar{\beta}_\phi(p, q) := \limsup_{r \rightarrow 1^+} \frac{\log \int_0^{2\pi} \mathbf{E}[|\frac{z}{\phi(z)}|^q |\phi'(re^{i\theta})|^p] d\theta}{|\log(r-1)|}.$$

For the inner whole plane SLE $(f_t)_{t \geq 0}$, f_0 is a conformal map on the unit disk with derivative equal to one at 0, we can compute its average generalized integral means spectrum. The situation happens the same when we replace the driving process by a Lévy process. In the fourth chapter we will first give the expressions of $G(z, \bar{z}) = \mathbf{E}[\frac{|z|^q |f'(z)|^p}{|f(z)|^q}]$ for some special values (p, q) and some special Lévy driven processes, and then get the generalized integral means spectrum.

Chapitre 2

SLE processes

In this chapter, we recall the basic knowledge about the Schramm Loewner Evolution (SLE). We will recall some basic facts in complex analysis.

We will use the following notations :

$$\mathbb{H} := \{z = x + iy \in \mathbb{C} : y > 0\},$$

$$\mathbb{D} := \{z \in \mathbb{C} : |z| < 1\}, \mathbb{D}_+ := \{z \in \mathbb{C} : |z| > 1\}.$$

2.1 Chordal Loewner Process

A **conformal map** on a planar domain is a one-to-one holomorphic function. Recall that a planar domain D is called **simply connected** if any closed curve in D is homotopic to a point. For such domains we have Riemann's conformal mapping theorem :

Theorem 1 (Riemann mapping theorem). *Given a simply connected domain $D \subset \mathbb{C}$ and a point $z_0 \in D$, then there exists a unique conformal map ϕ from \mathbb{D} onto D such that $\phi(0) = z_0$ and $\phi'(z_0) > 0$.*

Definition 2 (see Chapter 3 in [10]). *A connected compact set $A \subset \overline{\mathbb{H}}$ is called a \mathbb{H} -hull if $\mathbb{H} \setminus A$ is simply connected and $A = \overline{A} \cap \overline{\mathbb{H}}$. By Riemann's mapping theorem, given a \mathbb{H} -hull, there exists a unique conformal map $g_A(z)$ from $\mathbb{H} \setminus A$ onto \mathbb{H} such that $\lim_{z \rightarrow \infty} (g_A(z) - z) = 0$. And also we have $a(A) = \lim_{z \rightarrow \infty} z(g_A(z) - z) \geq 0$, which is called the **capacity** of A . We call g_A the normalised conformal map corresponding to A .*

Given a non-selfcrossing curve $\gamma[0, \infty) \rightarrow \overline{\mathbb{H}}$ such that $\gamma(0) = 0$ and $\gamma(\infty) = \infty$, then for any given $t \geq 0$, the compact set K_t enclosed by $\gamma[0, t]$ is a \mathbb{H} -hull. Denote by $a(t)$ the capacity of K_t and g_t the corresponding normalised conformal map of K_t . We have the following Loewner's theorem.

Lemma 3 (see Chapter 4 in [10]). *With above notations,*

- (1) $t \mapsto a(t)$ is strictly increasing and $a(t) \rightarrow \infty$ as $t \rightarrow \infty$;
- (2) The limit $W_t := \lim_{z \in \mathbb{H} \setminus K_t, z \rightarrow \gamma(t)} g_t(z)$ exists and $t \rightarrow W_t$ is a continuous function from \mathbb{R}^+ to \mathbb{R} ;
- (3) If γ is parameterized in such a way that $a(t) = 2t$, then g_t satisfies the differential equation

$$\partial_t g_t(z) = \frac{2}{g_t(z) - W_t}, \quad g_0(z) = z. \quad (2.1.1)$$

We call (2.1.1) the chordal **Loewner differential equation**. And this is what Oded Schramm found to define SLE. We have seen that, starting from a non-selfcrossing curve, we can get a continuous function W_t such that the corresponding family of conformal maps satisfies the chordal Loewner equation (2.1.1). Conversely, given a continuous function W_t , by solving the differential equation. For given z , define

$$\tau(z) := \sup\{t > 0, \min_{0 \leq s \leq t} |g_s(z) - W(s)| > 0\},$$

and

$$K_t := \{z \in \overline{\mathbb{H}} : \tau(z) \leq t\}, H_t := \mathbb{H} \setminus K_t.$$

Then we have

Lemma 4 (see Chapter 4 in [10]). *Suppose $W(t) : [0, T] \rightarrow \mathbb{R}$ is a continuous function. And $g_t(z)$ is the solution of the ODE (2.1.1). Define K_t and H_t as above, then*

- (1) For any $t \in [0, T]$, $g_t(z) : H_t \rightarrow \mathbb{H}$ is a conformal (holomorphic and injective) map;
- (2) For any $t \in [0, T]$, K_t is a \mathbb{H} -hull;
- (3) At $z = \infty$, $g_t(z)$ has the Laurent expansion $g_t(z) = z + \frac{2t}{z} + O(\frac{1}{|z|^2})$.

We call $(g_t : 0 \leq t \leq T)$ and $(K_t : 0 \leq t \leq T)$ the **chordal Loewner process (Loewner chain)** driven by W .

Remark 5. Usually, for a given continuous function W , the Loewner chain driven by W is not generated by a curve.

2.2 Radial Loewner Process

Definition 6. *If a compact set $K \subset \overline{\mathbb{D}}$ satisfies $0 \notin K$, $K = \overline{K} \cap \overline{\mathbb{D}}$ and $\mathbb{D} \setminus K$ is simply connected, we call K is a \mathbb{D} -hull.*

By Riemann mapping theorem, for a \mathbb{D} -hull, there exists a unique conformal map $g_K : \mathbb{D} \setminus K \rightarrow \mathbb{D}$ such that $g_K(0) = 0, g'_K(0) > 0$. We call g_K the **normalized conformal map** corresponding to K . By Schwarz lemma we have $g'_K(0) \geq 1$ and $g'_K(0) = 1$ if and only if $K \subset \partial\mathbb{D}$. Define the capacity of K as follows :

$$\text{cap}(K) := \log g'_K(0).$$

Suppose that $\gamma : [0, T] \rightarrow \overline{\mathbb{D}}$ is a non-selfcrossing curve with $\gamma(0) = 1$, $\gamma(0, T) \subset \mathbb{D}$ and $0 \notin \gamma$. Define K_t the hull enclosed by $\gamma[0, t]$, $g_t(z) : \mathbb{D} \setminus K_t \rightarrow \mathbb{D}$, $g_t(0) = 0$, $g_t'(0) > 0$ is the normalised conformal map.

Lemma 7 (see Chapter 4 in [10]). *With the above notations,*

- (1) $a(t)$ is a strictly increasing continuous non-negative function;
- (2) The limit $\lambda(t) := \lim_{z \in \mathbb{D} \setminus \gamma[0, t], z \rightarrow \gamma(t)} g_t(z) \in \partial\mathbb{D}$ exists, and we can choose a continuous real-valued function W_t such that $\lambda(t) = e^{iW(t)}$.
- (3) If γ is parameterized such that $a(t) = t$, we have the following Loewner differential equation :

$$\partial_t g_t(z) = g_t(z) \frac{\lambda(t) + g_t(z)}{\lambda(t) - g_t(z)}, \quad g_0(z) = z. \quad (2.2.1)$$

We call (2.2.1) the radial **Loewner differential equation**. Conversely, starting from a continuous real-valued function W_t , consider the differential equation (2.2.1). For given $z \in \overline{\mathbb{D}} \setminus \{1\}$, define

$$\tau(z) := \sup\{t > 0, \min_{0 \leq s \leq t} |g_s(z) - \exp\{iW(s)\}| > 0\},$$

and

$$K_t := \{z \in \overline{\mathbb{D}} : \tau(z) \leq t\}, \quad D_t := \mathbb{D} \setminus K_t.$$

Lemma 8 (see Chapter 4 in [10]). *Suppose $W(t) : [0, T] \rightarrow \mathbb{R}$ is a continuous real-valued function. And $g_t(z)$ is the solution of the ODE (2.2.1). Define K_t and D_t as above, then*

- (1) For any $t \in [0, T]$, $g_t(z) : D_t \rightarrow \mathbb{D}$ is a conformal map;
- (2) For any $t \in [0, T]$, K_t is a \mathbb{D} -hull;
- (3) At $z = 0$, $g_t(z)$ has the Taylor expansion $g_t(z) = e^t z + O(|z|^2)$.

We call $(g_t : 0 \leq t \leq T)$ and $(K_t : 0 \leq t \leq T)$ the **(inner)radial Loewner process (Loewner chain)** driven by W .

Remark 9. Denote by $f_t(z) := g_t^{-1}(z)$, then $f_t(z)$ satisfies the so-called reverse Loewner differential equation :

$$\begin{cases} \partial_t f_t(z) = z f_t'(z) \frac{z + \lambda_t}{z - \lambda_t} \\ f_0(z) = z, \text{ for } \forall z \in \mathbb{D}. \end{cases} \quad (2.2.2)$$

Remark 10. If we let $\tilde{g}_t(z) = \frac{1}{g_t(\frac{1}{z})}$, where $g_t(z)$ is defined as in Lemma 8, we can get

$$\begin{aligned} \partial_t \tilde{g}_t(z) &= \frac{-1}{g_t^2(\frac{1}{z})} \partial_t g_t\left(\frac{1}{z}\right) \\ &= \frac{-1}{g_t^2(\frac{1}{z})} g_t\left(\frac{1}{z}\right) \frac{\lambda_t + g_t(\frac{1}{z})}{\lambda_t - g_t(\frac{1}{z})} \\ &= -\tilde{g}_t(z) \frac{\tilde{g}_t(z) + \tilde{\lambda}_t}{\tilde{g}_t(z) - \tilde{\lambda}_t}, \end{aligned}$$

where $\tilde{\lambda}_t = \frac{1}{\lambda_t}$ and $\tilde{g}_0(z) = z$. Also we have $\tilde{f}_t(z) := \tilde{g}_t^{-1}(z) = \frac{1}{f_t(\frac{1}{z})}$, where $f_t(z) = g_t^{-1}(z)$. And we can check that

$$\begin{cases} \partial_t \tilde{f}_t(z) = z \tilde{f}'_t(z) \frac{z+\tilde{\lambda}_t}{z-\tilde{\lambda}_t} \\ \tilde{f}_0(z) = z \text{ for } \forall z \in \mathbb{D}_+. \end{cases}$$

So the **outer radial Loewner process** driven by W_t is defined as follows :

$$\begin{cases} \partial_t \tilde{g}_t(z) = -\tilde{g}_t(z) \frac{\tilde{g}_t(z)+\tilde{\lambda}_t}{\tilde{g}_t(z)-\tilde{\lambda}_t} & \left\{ \begin{array}{l} \partial_t \tilde{f}_t(z) = z \tilde{f}'_t(z) \frac{z+\tilde{\lambda}_t}{z-\tilde{\lambda}_t} \\ \tilde{f}_0(z) = z \text{ for } \forall z \in \mathbb{D}_+. \end{array} \right. \quad (2.2.3) \\ \tilde{g}_0(z) = z, \text{ for } \forall z \in \mathbb{D}_+. \end{cases}$$

Notice that for the outer radial Loewner process, g_t maps the complement of the hull in \mathbb{D}_+ onto \mathbb{D}_+ . Here we can easily define the hulls in \mathbb{D}_+ .

2.3 Whole Plane Loewner process

The proof of Bieberbach's conjecture in fact used the whole plane Loewner theory. In 1923 Loewner proved a part of the conjecture, De Branges proved the conjecture completely with the help of Loewner's method.

Definition 11. *If a compact set $K \subset \mathbb{C}$ satisfies $\hat{\mathbb{C}} \setminus K$ is simply connected, we call K is a **\mathbb{C} -hull**. Still by Riemann's mapping theorem, there exists a unique conformal map $F_K : \mathbb{C} \setminus \mathbb{D} \rightarrow \mathbb{C} \setminus K$ such that*

$$\lim_{z \rightarrow \infty} \frac{F_K(z)}{z} > 0.$$

In fact, if $0 \in K$, we have $F_K(z) = \frac{1}{f_K(\frac{1}{z})}$, where $f_K(z)$ is the conformal map from \mathbb{D} to $\{\frac{1}{z} : z \in \mathbb{C} \setminus K\}$ with $f_K(0) = 0, f'_K(0) > 0$. We call $g_K := F_K^{-1}$ the normalised conformal map corresponding to K . Denote by $\text{cap}(K) = -\log[f'_K(0)] = \log[\lim_{z \rightarrow \infty} \frac{F_K(z)}{z}]$, which is called the **capacity** of K .

Similarly, for a non-selfcrossing curve $\gamma : (-\infty, +\infty) \rightarrow \mathbb{C}$ with $\gamma(-\infty) = 0, \gamma(+\infty) = \infty$. For any $t \in \mathbb{R}$, denote by K_t the hull enclosed by $\gamma[-\infty, t]$ and denote by g_t the normalised conformal map and $a(t) = \text{cap}(K_t)$. In fact if we define $\tilde{D}_t := \{1/z : z \in D_t\}$, then there exists a unique function \tilde{g}_t from \tilde{D}_t to the unit disk \mathbb{D} such that $\tilde{g}_t(0) > 0$ and $\tilde{g}'_t(0) > 0$. And let $g_t(z) := \frac{1}{\tilde{g}_t(1/z)}$, we can get that

$$g_t(\infty) = \infty, \lim_{z \rightarrow \infty} \frac{g_t(z)}{z} = \frac{1}{\tilde{g}_t(0)} > 0.$$

And this is unique. Suppose that $t < s$, we have $D_s \subset D_t$ and then $\tilde{D}_s \subset \tilde{D}_t$. We have $\tilde{g}_t \circ \tilde{g}_s^{-1}(\mathbb{D}) \subset \mathbb{D}$ and then by Schwarz Lemma we have

$$\tilde{g}'_t(0) \leq \tilde{g}'_s(0).$$

Lemma 12 (see Chapter 4 in [10]). *Take the above notation, then*

- (1) $a(t)$ is a strictly increasing function and $a(-\infty) = 0, a(+\infty) = +\infty$;
- (2) The limit $\lambda(t) := \lim_{z \rightarrow \gamma(t), z \in \mathbb{C} \setminus K_t} g_t(z)$ exists and there exists a continuous real-valued function W such that $\lambda(t) = e^{iW_t}$;
- (3) If $a(t) = t$, then $g_t(z)$ satisfies the Loewner differential equation

$$\begin{cases} \partial_t g_t(z) = g_t(z) \frac{\lambda_t + g_t(z)}{\lambda_t - g_t(z)} \\ \lim_{t \rightarrow -\infty} e^t g_t(z) = z, \forall z \in \mathbb{C} \setminus \{0\}. \end{cases} \quad (2.3.1)$$

We call (2.3.1) the (outer) whole plane **Loewner differential equation**.

- (4) $\forall z \in \mathbb{C} \setminus \{0\}$, we have

$$\lim_{t \rightarrow -\infty} e^t g_t(z) = z.$$

Since (4) can not be found in any references, here we give the proof of (4).

Proof. Notice that (4) is equivalent to say that $\lim_{t \rightarrow -\infty} e^t \frac{1}{\tilde{g}_t(1/z)} = z$ holds for any $z \in \mathbb{C} \setminus \{0\}$, i.e

$$\lim_{t \rightarrow -\infty} e^{-t} \tilde{g}_t(z) = z, \quad \forall z \in \mathbb{C}.$$

Here \tilde{g}_t is defined just before the lemma. We define $\tilde{f}_t(z) := \tilde{g}_t^{-1}(z) : \mathbb{D} \rightarrow \mathbb{C}$, and let $h_t(z) := e^t \tilde{f}_t(z)$, then $h_t(0) = 0, h_t'(0) = 1$. By Koebe distortion theorem we have

$$\frac{|z|}{(1+|z|)^2} \leq |h_t(z)| \leq \frac{|z|}{(1-|z|)^2}.$$

And then we have

$$e^{-t} \frac{|\tilde{g}_t(z)|}{(1+\tilde{g}_t(z))^2} \leq |z| \leq e^{-t} \frac{|\tilde{g}_t(z)|}{(1-|\tilde{g}_t(z)|)^2}. \quad (2.3.2)$$

And then

$$(1-|\tilde{g}_t(z)|)^2 \leq e^{-t} \frac{|\tilde{g}_t(z)|}{|z|} \leq (1+|\tilde{g}_t(z)|)^2.$$

Since $|\tilde{g}_t(z)| \leq 1$ for any t and z . Then we have $\{e^{-t} \frac{\tilde{g}_t(z)}{z} : t \in \mathbb{R}\}$ is a normal family. And we know that if $t_k \rightarrow -\infty$ and $e^{-t_k} \frac{\tilde{g}_{t_k}(z)}{z} \rightarrow h(z)$, then by (2.3.2) we have that $|h(z)| = 1$ and then $h = 1$ since $h(0) = 1$. \square

Remark 13. Denote by $f_t(z) := g_t^{-1}(z)$, then $f_t(z)$ satisfies the so-called reverse Loewner differential equation :

$$\begin{cases} \partial_t f_t(z) = z f_t'(z) \frac{z + \lambda_t}{z - \lambda_t} \\ \lim_{t \rightarrow -\infty} f_t(e^{-t} z) = z, \quad \forall z \in \mathbb{D}_+. \end{cases} \quad (2.3.3)$$

Conversely, starting from a continuous real-valued function W_t , consider the differential equation (2.3.1). For given $z \in \mathbb{C} \setminus \{0\}$, define

$$\tau(z) := \sup\{t : \min_{0 \leq s \leq t} |g_s(z) - \exp\{iW(s)\}| > 0\},$$

and

$$K_t := \{z \in \mathbb{C} : \tau(z) \leq t\}, C_t := \hat{\mathbb{C}} \setminus K_t.$$

Lemma 14 (see Chapter 4 in [10]). *Suppose $W : \mathbb{R} \rightarrow \mathbb{R}$ is a continuous real-valued function. And $g_t(z)$ is the solution of the ODE (2.3.1). Define K_t and C_t as above, then*

- (1) For any $t \in \mathbb{R}$, $g_t(z) : C_t \rightarrow \mathbb{D}_+$ is a conformal map;
- (2) For any $t \in \mathbb{R}$, K_t is a \mathbb{C} -hull;
- (3) At $z = \infty$, $g_t(z)$ has the Laurent expansion $g_t(z) = e^{-t}z + O(\frac{1}{|z|})$.

We call (g_t) (or $f_t(z) := g_t^{-1}(z)$) and (K_t) the **outer whole plane Loewner process (Loewner chain)** driven by W .

In fact, we have an **inner version of the whole plane Loewner process**. To express the motivation, we still start from a non-selfcrossing curve γ from ∞ to 0 such that $\gamma(-\infty) = \infty$ and $\gamma(+\infty) = 0$. $D_t := \hat{\mathbb{C}} \setminus \gamma[-\infty, t]$, then there exists a unique function $g_t : D_t \rightarrow \mathbb{D}$ such that $g_t(0) = 0$ and $g_t'(0) > 0$. By Koebe's one quarter theorem, we have

$$\frac{1}{4} \frac{1}{d(0, \partial D_t)} \leq g_t'(0) \leq \frac{1}{d(0, \partial D_t)}.$$

So we have $\lim_{t \rightarrow +\infty} g_t'(0) = +\infty$ and $\lim_{t \rightarrow -\infty} g_t'(0) = 0$, and we assume $g_t'(0) = e^t$ and $g_t(\gamma(t)) = \lambda_t$. Define $\tilde{\gamma}(t) = \frac{1}{\gamma(t)}$, we get the same case as in Lemma 12. And this time $g_t(z) = \frac{1}{\tilde{g}_t(1/z)}$, where $\tilde{g}_t(z)$ here is like Lemma 12 and satisfies

$$\begin{cases} \partial_t \tilde{g}_t(z) = \tilde{g}_t(z) \frac{\tilde{\lambda}_t + \tilde{g}_t(z)}{\tilde{\lambda}_t - \tilde{g}_t(z)} \\ \lim_{t \rightarrow -\infty} e^t \tilde{g}_t(z) = z, \quad \forall z \in \mathbb{C} \setminus \{0\}. \end{cases}$$

Where $\tilde{\lambda}_t = \tilde{g}_t(\tilde{\gamma}(t)) = 1/\lambda_t$. Changing to $g_t(z)$, we have

$$\begin{cases} \partial_t g_t(z) = g_t(z) \frac{\lambda_t + g_t(z)}{\lambda_t - g_t(z)} \\ \lim_{t \rightarrow -\infty} e^{-t} g_t(z) = z, \quad \forall z \in \mathbb{C}. \end{cases}$$

And $f_t(z) := g_t^{-1}(z)$ satisfies

$$\begin{cases} \partial_t f_t(z) = z f_t'(z) \frac{z + \lambda_t}{z - \lambda_t} \\ \lim_{t \rightarrow -\infty} f_t(e^t z) = z, \quad \forall z \in \mathbb{D}. \end{cases}$$

And so we summarize as follows :

Lemma 15. *Take above notation,*

$$\begin{cases} \partial_t g_t(z) = g_t(z) \frac{g_t(z) + \lambda_t}{\lambda_t - g_t(z)} \\ \lim_{t \rightarrow -\infty} e^{-t} g_t(z) = z, \quad \forall z \in \mathbb{C}. \end{cases} \quad \begin{cases} \partial_t f_t(z) = z f_t'(z) \frac{z + \lambda_t}{z - \lambda_t} \\ \lim_{t \rightarrow -\infty} f_t(e^t z) = z, \quad \forall z \in \mathbb{D}. \end{cases}$$

To continue the procedure, we assume that γ is a simple curve from 0 to ∞ such that $\gamma(-\infty) = 0$ and $\gamma(+\infty) = \infty$. $D_t := \hat{\mathbb{C}} \setminus \gamma[t, \infty]$, then there exists a unique function $g_t : D_t \rightarrow \mathbb{D}$ such that $g_t(0) = 0$ and $g_t'(0) = e^{-t} > 0$. This time if we let $\tilde{\gamma}(t) = \gamma(-t)$, then $\tilde{\gamma}$ is like Lemma 15. And we can get,

$$\begin{cases} \partial_t g_t(z) = g_t(z) \frac{g_t(z) + \lambda_t}{g_t(z) - \lambda_t} \\ \lim_{t \rightarrow +\infty} e^t g_t(z) = z, \quad \forall z \in \mathbb{C}. \end{cases} \quad \begin{cases} \partial_t f_t(z) = z f_t'(z) \frac{\lambda_t + z}{\lambda_t - z} \\ \lim_{t \rightarrow +\infty} f_t(e^{-t} z) = z, \quad \forall z \in \mathbb{D}. \end{cases} \quad (2.3.4)$$

where $\lambda_t = g_t(\gamma(t))$. Similarly, starting from a real-valued continuous function W_t , let $\lambda_t = \exp\{iW_t\}$. We call the solution of above differential equation (2.3.4) the **inner whole plane Loewner process(chain)** driven by W_t .

2.4 Approximate Whole Plane Loewner Process by Radial Loewner Process

In this section, we will give a relation between radial Loewner process and whole plane Loewner process, which will be very important in our computation of the spectrum of the random whole plane Loewner chains.

Given a real-valued continuous function $W_t : \mathbb{R} \rightarrow \mathbb{R}$, and let $\lambda_t := \exp\{iW_t\}$. For any given $s \in \mathbb{R}$, define conformal maps $(g_t^{(s)})$ as follows : $g_t^{(s)}(z) = e^{-t}z$ if $t \leq -s$; if $t \geq -s$, $g_t^{(s)}(z)$ is defined as the solution to the outer radial Loewner differential equation(2.2.3) with initial condition $g_{-s}^{(s)}(z) = e^s z$.

Lemma 16 (see Chapter 6 in [10]). *Take the above notations, then as s tends to $+\infty$, $(g_t^{(s)})$ converges locally uniformly to a limit which we will denote by (g_t) . Moreover (g_t) is the outer whole plane Loewner process driven by W_t (see Lemma 14).*

We can use above lemma to prove that the inner whole plane Loewner process can also be approximated by the modified inner radial Loewner process. For given $s \in \mathbb{R}$, define conformal maps $(g_t^{(s)})$ as follows : for $t > s$, $g_t^{(s)}(z) = e^{-t}z$; for $t \leq s$, $g_t^{(s)}$ is the solution to the **modified inner radial Loewner differential equation** which is defined as follows :

$$\partial_t g_t(z) = g_t(z) \frac{g_t(z) + \lambda(t)}{g_t(z) - \lambda(t)} \quad (2.4.1)$$

with the initial condition $g_s^{(s)}(z) = e^{-s}z$.

Lemma 17. *With $g_t^{(s)}$ defined as above, we have*

$$\lim_{s \rightarrow +\infty} g_t^{(s)}(z) = g_t(z)$$

locally uniformly, where (g_t) is the inner whole plane Loewner process (see (2.3.4)) driven by W_t .

Proof. Define $\tilde{g}_t^{(s)}(z) = \frac{1}{g_{-t}^{(s)}(\frac{1}{z})}$ and $\tilde{\lambda}(t) = \frac{1}{\lambda(-t)}$. Then $\tilde{g}_t^{(s)}$ satisfies Lemma 16. We have that as $s \rightarrow +\infty$, $\tilde{g}_t^{(s)}$ converges to a limit \tilde{g}_t , where \tilde{g}_t is the outer whole plane Loewner process driven by W_t (see Lemma 14). So $g_t^{(s)}$ converges locally uniformly to a limit $g_t(z) := \frac{1}{\tilde{g}_{-t}(\frac{1}{z})}$. We only need to check that $g_t(z)$ satisfies (2.3.4). \square

2.5 Driven by jump functions

Suppose that W_t is a function that is right continuous and has left limit at very point, then the corresponding Loewner equation (2.1.1), (2.2.1) and (2.3.1) driven by W_t still have the solution g_t which is conformal. This is because that we only need to consider the equation on the intervals on which W is continuous and then use the conclusions in the previous sections. And also the corresponding conclusions in the previous section still holds with slight modifications.

2.6 Stochastic Analysis

In this section we recall some facts from stochastic analysis.

Definition 18. *A standard Brownian motion is a stochastic process $(B_t)_{t \geq 0}$ such that*

- (1) $B_0 = 0$;
- (2) For any $0 \leq t_1 < t_2 < t_3 < \dots < t_n$, $B_{t_2} - B_{t_1}, B_{t_3} - B_{t_2}, \dots, B_{t_n} - B_{t_{n-1}}$ are independent;
- (3) For any $0 \leq s \leq t$, $B_t - B_s \sim N(0, t - s)$, where $N(0, t - s)$ denotes the normal distribution with mean 0 and variance $t - s$;
- (4) Almost surely, the sample path $t \rightarrow B_t$ is continuous.

Definition 19. *A Lévy process is a stochastic process $(L_t)_{t \geq 0}$ such that*

- (1) $L_0 = 0$ (a.s.);
- (2) For any $0 \leq t_1 < t_2 < t_3 < \dots < t_n$, $L_{t_2} - L_{t_1}, L_{t_3} - L_{t_2}, \dots, L_{t_n} - L_{t_{n-1}}$ are independent;
- (3) For any $0 \leq s \leq t$, $L_t - L_s$ has the same law as L_{t-s} ;

Notice that Brownian motion is a special Lévy process. The essential difference with Brownian motion is that jumps are allowed. The characteristic function of a Lévy process L_t has the form

$$\mathbf{E}[e^{i\xi L_t}] = e^{-t\eta(\xi)}, \quad (2.6.1)$$

where η is called the **Lévy symbol** and is a continuous complex function of $\xi \in \mathbb{R}$, satisfying $\eta(0) = 0$ and $\eta(-\xi) = \overline{\eta(\xi)}$. If $\eta(-\xi) = \eta(\xi)$, we call L_t a **symmetric Lévy process**. For Brownian motion, the Lévy symbol is $\eta(\xi) = \frac{\xi^2}{2}$. More generally, the function

$$\eta(\xi) = \frac{|\xi|^\alpha}{2}, \alpha \in (0, 2]$$

is the Lévy symbol of the so-called α -stable process.

Definition 20. A stochastic process $(M_t)_{t \geq 0}$ on a filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})$ is called a **martingale** if

- (1) For any $t \geq 0$, M_t is \mathcal{F}_t -measurable and integrable;
- (2) For any $s \leq t$, $\mathbf{E}[M_t | \mathcal{F}_s] = M_s$ a.s.

Given a filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})$, a non-negative random variable T is called a **stopping time** if for any $t \geq 0$, the event $\{T \leq t\}$ is measurable with respect to \mathcal{F}_t .

A stochastic process $(M_t)_{t \geq 0}$ is called a **local martingale** if there exists a sequence of increasing stopping times $T_n \rightarrow \infty$ such that for any $n \in \mathbb{N}$, $(M_{t \wedge T_n})_{t \geq 0}$ is a martingale.

Itô calculus is very important in stochastic analysis. Here we will not give the definition of stochastic integral with respect to Brownian motion, even for Lévy process. But we will give Itô's formula which will be used many times in this thesis.

Theorem 21 (see Proposition 1.6 of Chapter VII in [18]). Suppose that $f(t, x)$ is a function defined on $[0, \infty) \times \mathbb{R}$, and f is C^1 with respect to t , and C^2 with respect to x . If a stochastic process Y_t can be written as $dY_t = X_t dB_t + Z_t dt$, then

$$df(t, Y_t) = \left(\frac{\partial f}{\partial t}(t, Y_t) + \frac{\partial f}{\partial x}(t, Y_t) Z_t + \frac{1}{2} \frac{\partial^2 f}{\partial x^2}(t, Y_t) \right) dt + \frac{\partial f}{\partial x}(t, Y_t) X_t dB_t.$$

In particular, if $f(t, Y_t)$ is a local martingale, the drift term in above formula is equal to zero.

We also have an integral version of Itô's formula. It can be stated as the following :

Theorem 22. Suppose that L_t is a Lévy process, then for any C^2 function f ,

$$M_t^f := f(L_t) - f(L_0) - \int_0^t \Lambda f(L_s) ds$$

is a local martingale. In particular, if $f(L_t)$ is a local martingale, then $\Lambda f \equiv 0$. Here Λ is the **generator** corresponding to the Lévy process L_t which is defined as

$$\Lambda f(x) = \lim_{t \downarrow 0} \frac{\mathbf{E}^x[f(L_t)] - f(x)}{t}.$$

Remark 23. In fact, if $f(t, L_t)$ is a local martingale, then $\partial_t f = -\Lambda f$, here when Λ acts on f , it is considered as an function of the second variable x .

For martingales, the following stopping theorem is very useful to determine the expectation of some random variables.

Theorem 24 (see section 3 of Chapter II in [18]). *If $(M_t)_{0 \leq t \leq T}$ is a martingale and $\sup_{0 \leq t \leq T} \mathbf{E}[M_t] < \infty$, then $\mathbf{E}[M_0] = \mathbf{E}[M_t]$.*

2.7 Chordal Schramm Loewner Evolution

In 1999([20]), Oded Schramm founded that by assigning the driven process to be the one-dimensional standard Brownian motion, the Loewner chains can be used to be the candidate for describing the scaling limits of some lattice models in statistic physics. What he defined is called the **Schramm Loewner evolution (SLE)** process. Now we give the detailed definition of SLE.

Definition 25 (see [20]). *Given $\kappa > 0$, let $W_t = \sqrt{\kappa}B_t$, we call the random Lowner chain driven by W_t the **chordal SLE(κ) process** from 0 to ∞ in \mathbb{H} .*

Proposition 26 (see [19]). *Suppose $\{g_t(z) : t \geq 0\}$ and $\{K_t : t \geq 0\}$ are the chordal SLE process from 0 to ∞ in \mathbb{H} . Then*

- (1) *(scaling invariance) For any $r > 0$, the process $\hat{g}_t(z) := r^{-\frac{1}{2}}g_{rt}(\sqrt{r}z)$ has the same distribution as $g_t(z)$ considered as stochastic processes indexed by (t, z) . In particular, $t \rightarrow K_t$ has the same distribution as $t \rightarrow r^{-\frac{1}{2}}K_{rt}$ as \mathbb{H} -hulls.*
- (2) *(Markov property) Suppose that τ is a stopping time about the filtration generated by W_t . Then $\tilde{g}_t(z) := g_{t+\tau} \circ g_\tau^{-1}(z + W_\tau) - W_\tau$ is independent with $\{g_t : 0 \leq t \leq \tau\}$, and has the same distribution as $g_t(z)$.*

Remark 27. By (1), we can define the SLE for any triple (D, z, w) where D is a simply connected domain with $z, w \in \partial D$ by choosing any conformal map f from \mathbb{H} to D that sends 0 to z and sends ∞ to w and then defining the SLE process in D from z to w as the the image of the SLE process in \mathbb{H} from 0 to ∞ .

In fact, chordal SLE(κ) process is almost surely generated by a curve. And the property of the curve depends on the parameter κ .

Theorem 28 (see [19] and [12]). *Suppose that $(K_t : t \geq 0)$ is the chordal SLE(κ) process from 0 to ∞ in \mathbb{H} . Almost surely, there exists a continuous non self-crossing curve γ in $\overline{\mathbb{H}}$ such that $\gamma(0) = 0$, $\gamma(\infty) = \infty$ and for any $t \geq 0$, K_t is equal to the complement of the unbounded component of $\mathbb{H} \setminus \gamma[0, t]$ in $\overline{\mathbb{H}}$, i.e. the chordal SLE(κ) process is almost surely generated by a curve. We call γ the SLE(κ) **trace**.*

Theorem 29 (see [19]). *Suppose γ is the SLE(κ) trace from 0 to ∞ in \mathbb{H} , then*

- (a) *If $\kappa \in (0, 4]$, almost surely γ is a simple curve;*
- (b) *If $\kappa \in (4, 8)$, almost surely γ is a self-touching curve and encloses $\overline{\mathbb{H}}$, but for any given point $z \in \overline{\mathbb{H}} \setminus \{0\}$, almost surely $z \notin \gamma$;*
- (c) *If $\kappa \in [8, \infty)$, almost surely $\gamma[0, \infty] = \overline{\mathbb{H}}$, i.e. γ is a space-filling curve.*

For some special values κ , the $\text{SLE}(\kappa)$ trace satisfies some special properties. The most interesting case is $\kappa = 6$ and $\kappa = \frac{8}{3}$.

Proposition 30 (see [14][11]). *Suppose that γ is the $\text{SLE}(\kappa)$ trace from 0 to ∞ in \mathbb{H} .*

(a) *If $\kappa = 6$, for any \mathbb{H} -hull K with $0 \notin K$, define*

$$\tau_K := \inf\{t \geq 0 : \gamma(t) \in K\},$$

*then $\gamma[0, \tau_K)$ has the same distribution as the $\text{SLE}(6)$ in $\mathbb{H} \setminus K$ from 0 to ∞ upon hitting K . This is called the **local property** of $\text{SLE}(6)$.*

(b) *If $\kappa = \frac{8}{3}$, for any \mathbb{H} -hull K with $0 \notin K$. Define $\Phi_K(z) = g_K(z) - g_K(0)$, where $g_K(z)$ is the normalised conformal map corresponding to K . Then*

$$\mathbf{P}[\gamma \cap K = \emptyset] = \Phi'_K(0)^{\frac{5}{8}}. \quad (2.7.1)$$

Notice that for two \mathbb{H} -hulls K_1, K_2 that don't contain 0,

$$\Phi_{K_1 \cup \Phi_{K_1}^{-1}(K_2)} = \Phi_{K_2} \circ \Phi_{K_1}, \quad \Phi'_{K_1 \cup \Phi_{K_1}^{-1}(K_2)}(0) = \Phi'_{K_2}(0) \Phi'_{K_1}(0).$$

*Then conditioned on $\gamma \cap K = \emptyset$, γ has the same distribution as the $\text{SLE}(\frac{8}{3})$ from 0 to ∞ in $\mathbb{H} \setminus K$. This is called the **restriction property** of $\text{SLE}(\frac{8}{3})$.*

Given $z \in \mathbb{H}$, for $\kappa \in (0, 8)$, we have known that $z \notin \gamma$ a.s. So it makes senses to ask the question about the probability that z lies to the left(right) side of γ . In fact Oded Schramm has got a formula for this.

Proposition 31 (see [21]). *Given $z = x + iy \in \mathbb{H}$, $\kappa \in (0, 8)$. Suppose that γ is the $\text{SLE}(\kappa)$ trace from 0 to ∞ in \mathbb{H} . Then the probability that γ passes the left of z is*

$$p(z) = C \int_{-\infty}^{\frac{x}{y}} (1 + t^2)^{-\frac{4}{\kappa}} dt, \quad (2.7.2)$$

where $C = C(\kappa)$ is the constant that make the total integral above equal to 1.

Notice that for $\kappa = 4$, $p(z) = 1 - \frac{\arg(z)}{\pi}$; for $\kappa = \frac{8}{3}$, $p(z) = \frac{1}{2}(1 + \frac{x}{|z|})$. There are some other properties which we will not list here, they can be found in[19].

Remark 32. The properties we have given here are those that will be used in the proof of the main results of this thesis. There are also many other nice properties of $\text{SLE}(\kappa)$ such as the reversibility, duality and Hausdorff dimension etc. We will not give them here.

2.8 Radial and Whole Plane SLE

In this section, we will introduce the radial SLE and whole plane SLE process.

Definition 33. Suppose that $(B_t : t \in \mathbb{R})$ is a two-sided Brownian motion, we call the inner(outer) Loewner process (chain) driven by $W_t = \sqrt{\kappa}B_t$ the **inner (outer) radial SLE(κ)** process from 1 to $0(\infty)$ in $\mathbb{D}(\mathbb{D}_+)$ (see section 2.2). And the inner (outer) whole plane Loewner process (chain) driven by $W_t = \sqrt{\kappa}B_t$ the **inner (outer) whole plane SLE(κ)** process from $0(\infty)$ to $\infty(0)$ in \mathbb{C} (see section 2.3).

Remark 34. For any triple (D, z, w) , where D is a proper simple connected domain of \mathbb{C} with $z \in D$ and $w \in \partial D$, there exists a unique conformal map ϕ from \mathbb{D} onto D with $\phi(0) = z$ and $\phi(1) = w$. We can define the radial SLE(κ) in D from w to z as the image of the radial SLE(κ) in \mathbb{D} from 1 to 0 under the map ϕ .

In fact, radial SLE(κ) and whole plane SLE(κ) have many of the same properties as the chordal SLE(κ). By the Markov property of Brownian motion, for radial SLE(κ), the Markov property also holds.

Proposition 35 (see [10][11]). Suppose τ is a stopping time with respect to the filtration generated by $W_t = \sqrt{\kappa}B_t$ and (g_t) is the radial SLE(κ) process from 1 to 0 in \mathbb{D} . Then $\tilde{g}_t(z) := g_{t+\tau} \circ g_\tau^{-1}(z\lambda_\tau)/\lambda_\tau$ has the same distribution as $g_t(z)$ and is independent with $\{g_t : 0 \leq t \leq \tau\}$. Here $\lambda_t = \exp\{iW_t\}$.

But for the whole plane SLE(κ) the scaling property holds.

Proposition 36 (see [10] [11]). Suppose that $(g_t, K_t : t \in \mathbb{R})$ is the (outer) whole plane SLE(κ), and $r \in \mathbb{R}$. then $(g_{t+r}(e^r z), e^{-r} K_{t+r} : t \in \mathbb{R})$ has the same distribution as $(g_t, K_t : t \in \mathbb{R})$.

Remark 37. So given two different points $z, w \in \mathbb{C}$, we can define the whole plane SLE(κ) in \mathbb{C} from z to w as the image under any conformal map from \mathbb{C} to \mathbb{C} that send ∞ to z and 0 to w .

Theorem 38 (see [10]). Almost surely, the (inner)radial SLE(κ) is generated by a curve γ from 1 to 0, which we call the **(inner) radial SLE(κ) trace**. And

- (1) If $\kappa \in (0, 4]$, γ is a simple curve a.s;
- (2) If $\kappa \in (4, 8)$, γ is a selftouching but non-selfcrossing curve a.s. Also $\overline{\mathbb{D}} = \bigcup_{t \geq 0} K_t$, where K_t is the radial SLE(κ) hulls. But for a given $z \in \overline{\mathbb{D}} \setminus \{1\}$, $z \notin \gamma$ a.s.
- (3) If $\kappa \in [8, \infty)$, then $\overline{\mathbb{D}} = \gamma[0, \infty]$ a.s, i.e γ is a space-filling curve almost surely.

Remark 39. For the whole plane SLE(κ), it is also generated by a curve almost surely and the phase of the curve has the same behavior as the radial SLE(κ).

For special values $\kappa = 6$ and $\kappa = \frac{8}{3}$, the locality and restriction property also hold for radial SLE process.

Proposition 40 (see Chapter 6 in [10]). *Suppose that γ is the radial SLE(κ) trace from 1 to 0 in \mathbb{D} .*

(a) *If $\kappa = 6$, for any \mathbb{D} -hull K with $1 \notin K$, define*

$$\tau_K := \inf\{t \geq 0 : \gamma(t) \in K\},$$

*then $\gamma[0, \tau_K)$ has the same distribution as the radial SLE(6) in $\mathbb{D} \setminus K$ from 1 to 0 upon hitting K . This is called the **local property** of radial SLE(6).*

(b) *If $\kappa = \frac{8}{3}$, for any \mathbb{D} -hull K with $1 \notin K$. Define $\Phi_K(z) = g_K(z)/g_K(1)$, where $g_K(z)$ is the normalised conformal map corresponding to K . Then*

$$\mathbf{P}[\gamma \cap K = \emptyset] = |\Phi'_K(0)|^{\frac{5}{48}} |\Phi'_K(1)|^{\frac{5}{8}}. \quad (2.8.1)$$

Notice that for two \mathbb{D} -hulls K_1, K_2 that don't contain 1,

$$\Phi_{K_1 \cup \Phi_{K_1}^{-1}(K_2)} = \Phi_{K_2} \circ \Phi_{K_1},$$

$$\Phi'_{K_1 \cup \Phi_{K_1}^{-1}(K_2)}(0) = \Phi'_{K_2}(0) \Phi'_{K_1}(0), \Phi'_{K_1 \cup \Phi_{K_1}^{-1}(K_2)}(1) = \Phi'_{K_2}(1) \Phi'_{K_1}(1).$$

*Then conditioned on $\gamma \cap K = \emptyset$, γ has the same distribution as the SLE($\frac{8}{3}$) from 1 to 0 in $\mathbb{D} \setminus K$. This is called the **restriction property** of radial SLE($\frac{8}{3}$).*

For whole plane SLE(6), the locality also holds.

Proposition 41 (see Chapter 6 in [10]). *Suppose γ is a (outer)whole plane SLE(6) curve from 0 and ∞ and suppose $w \in \mathbb{C} \setminus \{0\}$. Let t^* be the first time t that $\gamma[0, t]$ disconnects w from ∞ . Then $(\gamma(t) : 0 \leq t \leq t^*)$ has the same distribution of a whole plane SLE(6) path from 0 to w stopped at the first time that it disconnects w from ∞ .*

Moreover the frontier points of the whole plane SLE(6) have the same distribution as the frontier points of planar Brownian motion. This is a very deep result that connects SLE and Brownian motion.

Theorem 42 (see Chapter 6 in [10]). *Let γ be a (outer) whole plane SLE(6) path from 0 to ∞ . Let D be a simply connected domain other than \mathbb{C} containing the origin. Define*

$$\tau_D = \inf\{t : \gamma(t) \in \partial D\}.$$

Let B_t denote a complex Brownian motion starting at the origin and define

$$\sigma_D = \inf\{t : B_t \in \partial D\}.$$

Then $\gamma(\tau_D)$ and $B(\sigma_D)$ have the same distribution, i.e., the measure on ∂D induced by $\gamma(\tau_D)$ is the harmonic measure in D started at 0.

It is easy to see from the definition that when stopping (outer)whole plane SLE(κ) at some time, the remaining of the trace is the radial SLE(κ) in the complement of the trace.

Proposition 43. *Let $(g_t, K_t : t \in \mathbb{R})$ be the whole plane SLE(κ) from 0 to ∞ . Suppose that $t_0 \in \mathbb{R}$ is a stopping time with respect to the filtration generated by B_t (Here $W_t = \sqrt{\kappa}B_t$ is the driven process and B_t is a standard two-sided Brownian motion). Then conditioned on $(K_t, t \leq t_0)$, $(K_t : t \geq t_0)$ has the distribution of a radial SLE(κ) in $\mathbb{C} \setminus K_{t_0}$ from $\gamma(t_0)$ to ∞ .*

Proof. For any $t \geq 0$, define

$$f_t(z) := \frac{e^{iW_t}}{g_{t+t_0}(z)},$$

Then $f_t(\infty) = 0$ and

$$\partial_t f_t(z) = f_t(z) \frac{e^{iW'_t} + f_t(z)}{e^{iW'_t} - f_t(z)},$$

where $W'_t = W(t_0) - W(t_0 + t) = \sqrt{\kappa}B_t$, which has the distribution of a standard one dimensional Brownian motion. \square

In fact chordal SLE(κ) and radial SLE(κ) are equivalent in some sense.

Theorem 44 (see Chapter 6 in [10][13]). *Suppose that $(K_t)_{t \geq 0}$ is a chordal SLE(κ) process from -1 to 1 in \mathbb{D} . and $(\tilde{K}_t)_{t \geq 0}$ is a radial SLE(κ) process from -1 to 0 in \mathbb{D} . Define*

$$\tau := \sup\{t > 0 : 0 \notin K_t\}, \tilde{\tau} := \sup\{t > 0 : 1 \notin \tilde{K}_t\}.$$

Then if $\kappa = 6$, $\{K_t : 0 \leq t < \tau\}$ has the same distribution as $\{\tilde{K}_t : 0 \leq t < \tilde{\tau}\}$; If $\kappa \neq 6$, there exist two sequences of stopping times $(T_n, n \geq 1) \uparrow T$ and $(\tilde{T}_n, n \geq 1) \uparrow \tilde{T}$ such that $\{K_t : 0 \leq t < T_n\}$ and $\{\tilde{K}_t : 0 \leq t < \tilde{T}_n\}$ are absolutely continuous with each other.

We have seen in section 2.4 that whole plane Loewner process can be approximated by radial Loewner process. So the whole plane SLE(κ) can also be approximated by radial SLE(κ). We will use this to give a result which will be very important in computing the spectrum of whole plane SLE(κ) process.

The definition of the (outer) radial SLE(κ) can be extended to $t \in \mathbb{R}$ by considering stochastic ODE :

$$\partial_t g_t(z) = g_t(z) \frac{\lambda(t) + g_t(z)}{\lambda(t) - g_t(z)}, \quad g_0(z) = z, \forall z \in \mathbb{D}_+,$$

where $\lambda(t) = \exp\{i\sqrt{\kappa}B_t\}$ and B_t is a two-sided Brownian motion. Then

Lemma 45. *Let $(g_t : t \in \mathbb{R})$ be the (outer) radial SLE(κ) defined above, then the map $z \rightarrow g_{-t}(z)$ has the same distribution as $z \rightarrow g_t^{-1}(z\lambda(t))/\lambda(t)$. And so the solution of the equation*

$$\partial_t f_t(z) = f_t(z) \frac{f_t(z) + \lambda(t)}{f_t(z) - \lambda(t)}, \quad f_0(z) = z, \forall z \in \mathbb{D}_+, \quad (2.8.2)$$

has the same distribution as $g_t^{-1}(z\lambda(t))/\lambda(t)$.

Lemma 46. *Suppose that $(f_t : t \in \mathbb{R})$ is defined as (2.8.2), then*

$$\lim_{t \rightarrow +\infty} e^{-t} f_t(z) \stackrel{(\text{law})}{=} F_0(z),$$

where $F_0(z) = h_0^{-1}(z)$ and $(h_t : t \in \mathbb{R})$ is the outer whole plane SLE(κ) process.

Proof. Given $s > 0$, recall the definition of $g_t^{(s)}$ in Lemma 16. For $t \geq -s$, it is the solution of the following differential equation :

$$\partial_t g_t^{(s)} = g_t^{(s)} \frac{\lambda(t) + g_t^{(s)}}{\lambda(t) - g_t^{(s)}}, \quad g_{-s}^{(s)} = e^s z.$$

Then $(g_{-t}^{(s)} : t \leq s)$ satisfies

$$\partial_t g_{-t}^{(s)} = g_{-t}^{(s)} \frac{g_{-t}^{(s)} + \tilde{\lambda}(t)}{g_{-t}^{(s)} - \tilde{\lambda}(t)}, \quad g_{-s}^{(s)} = e^s z.$$

where $\tilde{\lambda}(t) = \lambda(-t) \stackrel{(\text{law})}{=} \lambda(t)$. So by the uniqueness of solution the ODE, we have $g_{-t}^{(s)} \stackrel{(\text{law})}{=} f_t(g_0^{(s)})$. Let $t = s$ and combing $g_{-s}^{(s)} = e^s z$, we have

$$e^{-t} f_t(z) \stackrel{(\text{law})}{=} (g_0^{(t)})^{-1}(z),$$

where $(g_0^{(t)})^{-1}(z)$ is the inverse of $g_0^{(t)}$. By Lemma 16, as $t \rightarrow +\infty$, the conformal map $g_0^{(t)}$ converges locally uniformly to $h_0(z)$, where $(h_t : t \in \mathbb{R})$ is the outer whole plane SLE(κ). Therefore the inverse of $g_0^{(t)}$ converges to $h_0^{-1}(z)$. \square

Also the (inner) radial SLE(κ) can be extended to $t \in \mathbb{R}$ by considering stochastic ODE :

$$\partial_t g_t(z) = g_t(z) \frac{\lambda(t) + g_t(z)}{\lambda(t) - g_t(z)}, \quad g_0(z) = z, \forall z \in \mathbb{D},$$

where $\lambda(t) = \exp\{i\sqrt{\kappa}B_t\}$ and B_t is a two-sided Brownian motion. Then

Lemma 47. *Let $(g_t : t \in \mathbb{R})$ be the (inner) radial SLE(κ) defined above, then the map $z \rightarrow g_{-t}(z)$ has the same distribution as $z \rightarrow g_t^{-1}(z\lambda(t))/\lambda(t)$. And so the solution of the equation*

$$\partial_t f_t(z) = f_t(z) \frac{f_t(z) + \lambda(t)}{f_t(z) - \lambda(t)}, \quad f_0(z) = z, \forall z \in \mathbb{D}, \quad (2.8.3)$$

has the same distribution as $g_t^{-1}(z\lambda(t))/\lambda(t)$.

Lemma 48. *Suppose that $(f_t : t \in \mathbb{R})$ is defined as (2.8.3), then*

$$\lim_{t \rightarrow +\infty} e^t f_t(z) \stackrel{(\text{law})}{=} H_0(z),$$

where $H_0(z) = h_0^{-1}(z)$ and $(h_t : t \in \mathbb{R})$ is the inner whole plane SLE(κ) process.

Proof. Given $s > 0$, recall the definition of $g_t^{(s)}$ in Lemma 17. For $t \geq s$, it is the solution of the following differential equation :

$$\partial_t g_t^{(s)} = g_t^{(s)} \frac{g_t^{(s)} + \lambda(t)}{g_t^{(s)} - \lambda(t)}, \quad g_s^{(s)} = e^{-s} z.$$

So by the uniqueness of solution of the ODE, we have $g_t^{(s)}(z) \stackrel{(\text{law})}{=} f_t(g_0^{(s)}(z))$. Therefore $e^t f_t(z) \stackrel{(\text{law})}{=} e^t g_t^{(s)}((g_0^{(s)})^{-1})$. Let $t = s$, we get

$$e^t f_t(z) \stackrel{(\text{law})}{=} (g_0^{(t)})^{-1}(z)$$

Then combining Lemma 17 and let $t \rightarrow +\infty$, we finish the proof. \square

2.9 Driven by a Lévy process

Since a Lévy process has a modification which is left continuous and has right limit, by section 2.5 we can consider the Loewner process driven by a Lévy process. And by the Markov property of Lévy process, the random Loewner chain we get also satisfies the Markov property(notice that it may not be generated by a continuous curve now since Lévy process may have jumps). In fact, most of the conclusions of SLE process in the previous section still holds for the Loewner chain driven by a general Lévy process. Especially we emphasize that Lemma 48 still holds for Lévy driven processes. This will be used in the computation of the average spectrum of the inner whole plane Loewner processes driven by a Lévy process.

Chapitre 3

Dipolar Conformal Restriction Measure

In this chapter, we will use dipolar SLE(κ) process to construct a conformal restriction measure on the strip \mathcal{S} , which is defined as follows :

$$\mathcal{S} = \{z = x + iy \in \mathbb{C} : x \in \mathbb{R}, 0 < y < \pi\}. \quad (3.0.1)$$

This dipolar conformal restriction is a "dipolar version" of the results derived in the paper [9] by Lawler, Schramm, and Werner ("chordal version") and the paper [23] by Hao Wu ("radial version"). The goal is to describe the law of a random set on the strip that satisfies a certain restriction property.

We are going to study closed random subsets K of \mathcal{S} that have the following form :

- (1) K is a connected compact set of $\bar{\mathcal{S}}$ such that $K \cap \mathbb{R} = \{0\}$ and $\mathcal{S} \setminus K$ has two connected components that one of their boundaries contains $+\infty$ and the other contains $-\infty$;
- (2) For any connected compact subset A of $\bar{\mathcal{S}}$ such that $A \cap \mathbb{R}_\pi = \emptyset$, $\mathcal{S} \setminus A$ is simply connected and $d(0, A) > 0$, the law of $\Phi_A(K)$ conditioned on the event $\{K \cap A = \emptyset\}$ is the same as the law of K , where Φ_A is the unique conformal map from $\mathcal{S} \setminus A$ to \mathcal{S} that fixes $+\infty$ and $-\infty$ and $\lim_{z \rightarrow +\infty} (\Phi_A(z) - z) = -\lim_{z \rightarrow -\infty} (\Phi_A(z) - z)$.

The law of such a set is called a **dipolar restriction measure**, which is the analogy of the chordal restriction measure defined in [9] and the radial restriction measure defined in [23].

The main result of this chapter is the following characterization of all the dipolar restriction measures.

Theorem 49. (1) *A dipolar conformal restriction measure is fully characterized by two real parameters (α, β) such that*

$$\mathbf{P}[K \cap A = \emptyset] = |\Phi'_A(0)|^\beta \exp\{-\alpha S(A)\}$$

where A is any connected compact subset of $\bar{\mathcal{S}}$ such that $A \cap \mathbb{R}_\pi = \emptyset$, $\mathcal{S} \setminus A$ is simply connected and $d(0, A) > 0$, and Φ_A is the conformal map from $\mathcal{S} \setminus A$ to \mathcal{S} that fixes $\pm\infty$ and $S(A)$ is the capacity of A (see the definition in section 3.3). We denote this restriction measure by $\mathbf{P}(\alpha, \beta)$.

(2) For any $\beta \geq \frac{5}{8}$, the measure $\mathbf{P}(\frac{\beta(1-\beta)}{2\beta+1}, \beta)$ exists and if K is a sample of this measure, then $K \cap \mathbb{R}_\pi$ contains only one point $X + i\pi$ and the random variable has the density function (up to a constant)

$$\rho(x) = \left(\cosh \frac{x}{2}\right)^{-\frac{2}{3}(2\beta+1)}.$$

We will prove this theorem step by step in the following sections. It is necessary to give an introduction to the chordal conformal restriction measure and radial conformal restriction measure.

3.1 Chordal conformal restriction measure

Let $\mathbb{H} := \{x + iy \in \mathbb{C} : y > 0\}$ be the upper half plane and Ω is the collection of subset K of \mathbb{H} that satisfies the following conditions :

- (1) K a connected closed set, $K \cap \mathbb{R} = \{0\}$;
- (2) $\mathbb{H} \setminus K$ has two connected unbounded components.

Let \mathcal{A}_h be the collection of \mathbb{H} -hulls and $\mathcal{A}_h^* := \{A \in \mathcal{A}_h : 0 \notin A\}$. Suppose \mathcal{F}_h is the σ -algebra on Ω generated by the class below :

$$\{\{K : K \cap A = \emptyset\} : A \in \mathcal{A}_h^*\}.$$

If a probability measure \mathbf{P} on (Ω, \mathcal{F}_h) satisfies : for any $A \in \mathcal{A}_h^*$, conditioned on $K \cap A = \emptyset$, $\Phi_A(K)$ has the same law as K . Here K is a sample of \mathbf{P} . We call \mathbf{P} the **conformal restriction measure** on \mathbb{H} . Notice that if two probability measures \mathbf{P}, \mathbf{P}' on (Ω, \mathcal{F}_h) satisfies for any $A \in \mathcal{A}_h^*$, $\mathbf{P}[K \cap A = \emptyset] = \mathbf{P}'[K \cap A = \emptyset]$, then $\mathbf{P} = \mathbf{P}'$.

Theorem 50 (see [9]). *The conformal restriction measure on \mathbb{H} can be characterized as follows.*

- (1) If \mathbf{P} is a conformal restriction measure on \mathbb{H} , there exists a unique $\beta \in \mathbb{R}$ and $\beta \geq \frac{5}{8}$ such that for any $A \in \mathcal{A}_h^*$,

$$\mathbf{P}[K \cap A = \emptyset] = \Phi'_A(0)^\beta,$$

where $\Phi_A(z)$ is the conformal map from $\mathbb{H} \setminus A$ onto \mathbb{H} that fixes 0 and ∞ . So the conformal restriction can be characterized by one parameter β , which is denoted by $\mathbf{P}(\beta)$.

- (2) $\mathbf{P}(\beta)$ exists if and only if $\beta \geq \frac{5}{8}$.

Notice that by Proposition 30, chordal SLE($\frac{8}{3}$) has the law $\mathbf{P}(\frac{5}{8})$.

3.2 Radial conformal restriction measure

Similarly, we have the radial conformal restriction. Still we denote by $\mathbb{D} := \{z \in \mathbb{C} : |z| < 1\}$ the unit disk and Ω the collection of subsets of \mathbb{D} that satisfies the following conditions :

- (1) K is a connected closed set, $K \cap \partial\mathbb{D} = \{1\}$;
- (2) $0 \in K$ and $\mathbb{H} \setminus K$ is connected.

Denote by \mathcal{A}_d the collection of \mathbb{D} -hulls and $\mathcal{A}_d^* := \{A \in \mathcal{A}_d : 1 \notin A\}$. Suppose \mathcal{F}_d is the σ -algebra on Ω that is generated by the class below :

$$\{\{K : K \cap A = \emptyset\} : A \in \mathcal{A}_d^*\}.$$

If a probability measure \mathbf{P} on (Ω, \mathcal{F}_d) satisfies for any $A \in \mathcal{A}_d^*$, conditioned on $K \cap A = \emptyset$, $\Phi_A(K)$ has the same law as K . Here K is a sample of \mathbf{P} . We call \mathbf{P} a **conformal restriction measure** on D (or a radial conformal restriction measure). Notice that if two probability measures \mathbf{P}, \mathbf{P}' on (Ω, \mathcal{F}_d) satisfy that for any $A \in \mathcal{A}_d^*$, $\mathbf{P}[K \cap A = \emptyset] = \mathbf{P}'[K \cap A = \emptyset]$, then $\mathbf{P} = \mathbf{P}'$.

Theorem 51 (see[23]). *The radial conformal restriction measure can be characterized as follows.*

- (1) If \mathbf{P} is a radial conformal restriction measure on \mathbb{D} , there are two parameters (α, β) such that for $A \in \mathcal{A}_d^*$,

$$\mathbf{P}[K \cap A = \emptyset] = |\Phi'_A(0)|^\alpha |\Phi'_A(1)|^\beta,$$

where Φ_A is the conformal map from $\mathbb{D} \setminus A$ onto \mathbb{D} that fixes 0 and 1. Then a radial conformal restriction measure can be characterized by two parameters (α, β) , which is denoted by $\mathbf{P}(\alpha, \beta)$.

- (2) $\mathbf{P}(\alpha, \beta)$ exists if and only if $\beta \geq \frac{5}{8}$ and $\alpha \leq \frac{1}{48}((\sqrt{24\beta + 1} - 1)^2 - 4)$.

By Proposition 40, we know that radial SLE($\frac{8}{3}$) has the law $\mathbf{P}(\frac{5}{48}, \frac{5}{8})$.

3.3 Dipolar Loewner Process

In this section, the dipolar Loewner process will be given(the reader can also refer[24]). Just like the chordal Loewner process, this is a differential equation that describes the evolution of the conformal map corresponding a curve in \mathcal{S} .

The upper half plane is denoted by \mathbb{H} , the strip with width π is just defined as (3.0.1) and the upper boundary of \mathcal{S} is denoted by \mathbb{R}_π . We will frequently use the conformal map $\varphi_0(z) := e^z - 1$ from \mathcal{S} to \mathbb{H} that sends $-\infty, 0, +\infty$ to $-1, 0, \infty$ respectively.

Definition 52. *A compact connected subset $A \subset \overline{\mathcal{S}}$ is called a \mathcal{S} -hull (dipolar compact hull) if $A = \overline{A \cap \mathcal{S}}$, $A \cap \mathbb{R}_\pi = \emptyset$ and $\mathcal{S} \setminus A$ is simply connected. Denote by \mathcal{A}_s the collection of all \mathcal{S} -hulls.*

Lemma 53. *For any $A \in \mathcal{A}_s$, there exists a unique conformal map g_A from $\mathcal{S} \setminus A$ onto \mathcal{S} such that $g_A(\pm\infty) = \infty$ and*

$$\lim_{z \rightarrow +\infty} [g_A(z) - z] = - \lim_{z \rightarrow -\infty} [g_A(z) - z] < \infty.$$

Proof. (1)**Existence.** Define $f(z) = e^z$, then $f(A)$ is a \mathbb{H} -hull with $0 \notin f(A)$. Then by section 2.1, there exists a unique conformal map $\phi_{f(A)}$ from $\mathbb{H} \setminus f(A)$ onto \mathbb{H} such that

$$\phi_{f(A)}(0) = 0, \quad \lim_{z \rightarrow \infty} \frac{\phi_{f(A)}(z)}{z} = 1, \quad \phi'_{f(A)}(0) < 1.$$

Let $h(z) := \log [\phi_{f(A)}(e^z)]$, then

$$h : \mathcal{S} \setminus A \rightarrow \mathcal{S}, \quad h(-\infty) = -\infty, \quad h(+\infty) = +\infty,$$

$$h(\mathbb{R}) = \mathbb{R}, \quad h(\mathbb{R} + i\pi) = \mathbb{R} + i\pi,$$

$$\lim_{z \rightarrow +\infty} [h(z) - z] = \lim_{z \rightarrow +\infty} \log \frac{\phi_{f(A)}(e^z)}{z} = 0,$$

and

$$\lim_{z \rightarrow -\infty} [h(z) - z] = \lim_{z \rightarrow -\infty} \log \frac{\phi_{f(A)}(e^z)}{z} = \log \phi'_{f(A)}(0) < 0.$$

Therefore $g_A(z) := h(z) - \frac{1}{2} \log \phi'_{f(A)}(0)$ satisfies

$$\lim_{z \rightarrow +\infty} [g_A(z) - z] = -\frac{1}{2} \log \phi'_{f(A)}(0),$$

$$\lim_{z \rightarrow -\infty} [g_A(z) - z] = \frac{1}{2} \log \phi'_{f(A)}(0).$$

And $g_A(z)$ fixes \mathbb{R} and $\mathbb{R} + i\pi$.

(2)**Uniqueness.** If g_1 and g_2 both satisfy the conditions, let $h(z) = g_1 \circ g_2^{-1}(z) : \mathcal{S} \rightarrow \mathcal{S}$ and

$$h(\mathbb{R}) = \mathbb{R}, \quad h(\mathbb{R} + i\pi) = \mathbb{R} + i\pi \quad (*)$$

$$\lim_{z \rightarrow +\infty} [h(z) - z] = - \lim_{z \rightarrow -\infty} [h(z) - z] \quad (**)$$

By (*) we get that $h(z) = z + c$, where c a real number. By (**), we get $c = 0$. \square

We call $S(A) := \lim_{z \rightarrow +\infty} [g_A(z) - z]$ the **capacity** of A and g_A the **normalised conformal map** with respect to A . Notice that $S(A) \geq 0$ and the equality holds if and only if $A \subset \mathbb{R}$. Another useful conformal map about \mathcal{S} -hulls is : $\forall A \in \mathcal{A}_s$, there exists a unique conformal map $\Phi_A : \mathcal{S} \setminus A \rightarrow \mathcal{S}$ such that

$$\Phi_A(0) = 0, \quad \Phi_A(+\infty) = +\infty, \quad \Phi_A(-\infty) = -\infty$$

Indeed we just let $\Phi_A(z) := g_A(z) - g_A(0)$.

Just like the chordal case, start from a non-selfcrossing curve $\gamma[0, \infty) \subset \overline{\mathcal{S}}$ such that the \mathcal{S} -hulls created by γ is strictly increasing. In the purpose of simplifying the procedure, we assume that γ is a simple curve and $\gamma(0, \infty) \subset \mathcal{S}$. Then for any $t \geq 0$, $K_t := \gamma[0, t]$ is a \mathcal{S} -hull. Let $S_t := \mathcal{S} \setminus K_t$. Denote by $S(t)$ the capacity of $\gamma[0, t]$ and $g_t(z)$ the corresponding normalised conformal map. Then we have

Lemma 54. *With above notations,*

- (a) $S(t)$ is a strictly increasing continuous function ;
- (b) The limit $W_t := \lim_{z \in S_t; z \rightarrow \gamma(t)} g_t(z)$ exists and is a continuous function ;
- (c) If the curve is parameterized such that $S(t) = t$, then the conformal maps $g_t(z)$ satisfies the following differential equation :

$$\partial_t g_t(z) = \coth \frac{g_t(z) - W_t}{2}, \quad g_0(z) = z, \quad (3.3.1)$$

where $\coth(z) = (e^z + e^{-z})/(e^z - e^{-z})$.

We call (3.3.1) the **dipolar Loewner equation**.

Proof. Recall the proof of Lemma 53, let $f(z) := e^z$ and $\tilde{\gamma}(t) = f(\gamma(t))$. Then $\tilde{\gamma}[0, t]$ is a \mathbb{H} -hull and let \tilde{g}_t be the normalised conformal map of $\tilde{\gamma}[0, t]$. Then by Lemma 3 we have

$$g_t(z) = \log [\tilde{g}_t(e^z) - \tilde{g}_t(0)] - \frac{1}{2} \log g'_t(0), \quad S(t) = -\frac{1}{2} \log \tilde{g}'_t(0),$$

and the limit $\tilde{W}_t := \lim_{z \in \mathbb{H} \setminus \tilde{\gamma}[0, t], z \rightarrow \tilde{\gamma}(t)} \tilde{g}_t(z)$ exists and is continuous. Also by Lemma 3, $\tilde{g}'_t(0)$ is continuous with respect to t . Therefore $S(t)$ is continuous. Since K_t is strictly increasing, $S(t)$ is strictly increasing. And the limit

$$\begin{aligned} W_t &= \lim_{z \in S_t; z \rightarrow \gamma(t)} g_t(z) = \lim_{z \in S_t; z \rightarrow \gamma(t)} \log [\tilde{g}_t(e^z) - \tilde{g}_t(0)] - \frac{1}{2} \log g'_t(0) \\ &= \lim_{z \in \mathbb{H} \setminus \tilde{\gamma}[0, t], z \rightarrow \tilde{\gamma}(t)} \log [\tilde{g}_t(z) - \tilde{g}_t(0)] - \frac{1}{2} \log g'_t(0) \\ &= \log [\tilde{W}_t - \tilde{g}_t(0)] - \frac{1}{2} \log g'_t(0). \end{aligned}$$

exists and is continuous with respect to t . We are left to prove (c). Notice that for fixed $t \geq 0$, $\text{Im}(g_t^{-1}(z) - z)$ is a bounded harmonic function and therefore we have

$$\text{Im}(g_t^{-1}(z) - z) = -\frac{1}{\pi} \int_{I_t} \frac{e^x}{e^z - e^x} \text{Im}(g_t^{-1}(x)) dx,$$

where I_t is the interval of the image of $\gamma[0, t]$ under g_t . Since a holomorphic function is determined by its imaginary part up to a constant. We have

$$g_t^{-1}(z) - z = -\frac{1}{\pi} \int_{I_t} \frac{e^x}{e^z - e^x} \text{Im}(g_t^{-1}(x)) dx + C.$$

Since

$$g_t^{-1}(z) - z \rightarrow \begin{cases} -t & \text{as } z \rightarrow +\infty \\ t & \text{as } z \rightarrow -\infty, \end{cases}$$

we have

$$C = -t, \quad 2t = \frac{1}{\pi} \int_{I_t} \operatorname{Im}(g_t^{-1}(x)) dx.$$

Then

$$g_t^{-1}(z) - z = -\frac{1}{2\pi} \int_{I_t} \frac{e^z + e^x}{e^z - e^x} \operatorname{Im}(g_t^{-1}(x)) dx. \quad (3.3.2)$$

For fixed $h > 0$, apply above equation to $g_{t,t+h}(z) = g_{t+h} \circ g_t^{-1}(z)$, we have

$$g_t \circ g_{t+h}^{-1}(z) - z = -\frac{1}{2\pi} \int_{I_{t,h}} \frac{e^z + e^x}{e^z - e^x} \operatorname{Im}[g_t \circ g_{t+h}^{-1}(x)] dx. \quad (3.3.3)$$

Here $I_{t,h}$ is the interval of the image of $\gamma[t, t+h]$ which contains W_{t+h} . Notice that

$$h = \frac{1}{2\pi} \int_{I_{t,h}} \operatorname{Im}[g_t \circ g_{t+h}^{-1}(x)] dx.$$

Replace z by $g_{t+h}(z)$ in (3.3.3),

$$g_t(z) - g_{t+h}(z) = -\frac{1}{2\pi} \int_{I_{t,h}} \coth \frac{g_{t+h}(z) - x}{2} \operatorname{Im}[g_t \circ g_{t+h}^{-1}(x)] dx.$$

By using the integral middle theorem to both the real parts and imaginary parts of above equation and then divided by h and passing h to 0, we have

$$\partial_t^+ g_t(z) = \coth \frac{g_t(z) - W_t}{2}.$$

Similarly, we can also get the differential equation for the left derivative by letting $h < 0$. \square

Conversely, starting from a real-valued continuous function $W(t)$ on \mathbb{R}^+ , consider the dipolar Loewner equation (3.3.1). For a given $z \in \mathcal{S}$, define

$$\tau(z) := \sup\{t > 0, \min_{0 \leq s \leq t} |g_s(z) - W(s)| > 0\},$$

and

$$K_t := \{z \in \overline{\mathcal{S}} : \tau(z) \leq t\}, \quad S_t := \mathcal{S} \setminus K_t.$$

Then we have

Lemma 55. *Suppose $W(t) : [0, \infty) \rightarrow \mathbb{R}$ is a continuous function. And $g_t(z)$ is the solution of the ODE (3.3.1). Define K_t and S_t as above, then*

- (1) *For any $t \geq 0$, $g_t(z) : S_t \rightarrow \mathcal{S}$ is a conformal map;*
- (2) *For any $t \geq 0$, K_t is a \mathcal{S} -hull;*
- (3) *At $z = \pm\infty$, $g_t(z)$ has the Laurent expansion $g_t(z) = z \pm t + O(\frac{1}{|z|})$.*

*We call $(g_t : t \geq 0)$ and $(K_t : t \geq 0)$ the **dipolar Loewner process (Loewner chain)** driven by W .*

Proof. Notice that the blow up time of (3.3.1) is the first time that $g_t(z) - W(t) = 0, 2\pi i$ and

$$\coth \frac{z}{2} = \frac{e^{z/2} + e^{-z/2}}{e^{z/2} - e^{-z/2}}.$$

So $e^{z/2} = e^{-z/2} \Leftrightarrow e^z = 1 \Leftrightarrow z = 2k\pi i$. If $z \in \mathbb{R} + i\pi$, we have $\text{Im}(g_t(z)) = \pi$, so the maximal interval that the ODE (3.3.1) lives is $[0, \tau(z))$. Since the vector field $\coth(z/2)$ is holomorphic, we can get $g_t(z)$ is holomorphic.

Fix $T > 0$ and $w \in S$, consider the following initial value problem :

$$\partial_t f_t(w) = -\coth \frac{f_t(w) - W(T-t)}{2}, \quad f_0(w) = w$$

Since

$$-\text{Im} \coth \frac{x+iy}{2} = \frac{2 \sin y}{|e^{z/2} - e^{-z/2}|^2} > 0,$$

this ODE will not blow up in $[0, T]$.

Let $h_t(w) = f_{T-t}(w)$, then $h_t(w)$ satisfies

$$\partial_t h_t(w) = \coth \frac{h_t(w) - W_t}{2}, \quad h_T(w) = w$$

Therefore $g_t(h_0(w)) = h_t(w), 0 \leq t \leq T$. In particular $g_T(h_0(w)) = w$, this shows that $g_T(z)$ is surjective. By the unique dependence on the initial value of ODE, we can see that g_T is injective. So $g_T(z)$ is a conformal map from S_T onto S . By expanding at $\pm\infty$, we can see that for fixed T , if $|z|$ is large enough, $g_T(z)$ will not blow up. Therefore K_T is compact and a \mathcal{S} -hull. Also by expanding at $\pm\infty$, we have the Laurent expansion. \square

Remark 56. Usually, given a continuous function, the corresponding dipolar Loewner process(chain) is not generated by a non-selfcrossing curve.

3.4 Dipolar Schramm Loewner Evolution

In this section, we will introduce the dipolar Schramm Loewner Evolution and give its properties.

Definition 57. Let $\kappa > 0$ and $(B_t : t \geq 0)$ be a standard one dimensional Brownian motion, we call the dipolar Loewner process (chain) driven by $W_t := \sqrt{\kappa}B_t$ the **dipolar SLE(κ) process** from 0 to \mathbb{R}_π .

Remark 58. Choose a conformal map f from \mathcal{S} onto \mathbb{H} that sends $+\infty$ and $-\infty$ to x_1 and x_2 respectively and keeps 0. Then the image of dipolar SLE(κ) under this conformal map is a SLE($\kappa; \rho, \rho$) process with force points x_1 and x_2 , where $\rho = \frac{1}{2}\kappa - 3$ (see [22]). But it is more convenient to deal with dipolar SLE(κ) since there are no force points.

Remark 59. For any triple (D, z, I) , where D is a proper simple connected domain of \mathbb{C} with $z \in \partial D$ and $I \subset \partial D$ is an arc not containing z , there exists a unique conformal map ϕ from \mathcal{S} onto D with $\phi(0) = z$ and $\phi(\mathbb{R}_\pi) = I$. We can define the dipolar SLE(κ) in D from z to I as the image of the dipolar SLE(κ) in \mathcal{S} from 0 to \mathbb{R}_π under the map ϕ .

Dipolar SLE(κ) also has the Markov property.

Proposition 60 ((Markov property)). *Suppose $\{g_t(z) : t \geq 0\}$ and $\{K_t : t \geq 0\}$ are the dipolar SLE(κ) process from 0 to \mathbb{R}_π in \mathcal{S} . Suppose that τ is a stopping time about the filtration generated by W_t . Then $\tilde{g}_t(z) := g_{t+\tau} \circ g_\tau^{-1}(z + W_\tau) - W_\tau$ is independent with $\{g_t : 0 \leq t \leq \tau\}$, and has the same distribution as $g_t(z)$.*

In fact dipolar SLE(κ) is equivalent to chordal SLE(κ) in some sense.

Theorem 61 (see [24]). *Let $(K_t)_{t \geq 0}$ be the dipolar SLE(κ) process from 0 to \mathbb{R}_π in \mathcal{S} and $(\tilde{K}_t)_{t \geq 0}$ be the chordal SLE(κ) from 0 to $+\infty$ in \mathcal{S} . Define*

$$\tau := \inf\{t > 0 : K_t \cap \mathbb{R}_\pi \neq \emptyset\}, \tilde{\tau} := \inf\{t > 0 : \tilde{K}_t \cap \mathbb{R}_\pi \neq \emptyset\}.$$

Then if $\kappa = 6$, $\{K_t : 0 \leq t < \tau\}$ has the same distribution as $\{\tilde{K}_t : 0 \leq t < \tilde{\tau}\}$; if $\kappa \neq 6$, there exists two sequences of stopping times $(T_n, n \geq 1) \uparrow \tau$ and $(\tilde{T}_n, n \geq 1) \uparrow \tilde{\tau}$ such that $\{K_t : 0 \leq t < T_n\}$ and $\{\tilde{K}_t : 0 \leq t < \tilde{T}_n\}$ are mutually absolutely continuous.

Proof. Denote by $\phi(z) = e^z - 1 : S_\pi \rightarrow \mathbb{H}$, then $\phi(0) = 0$, $\phi(+\infty) = \infty$ and $\phi(-\infty) = -1$. Suppose $g_t(z)$ is the chordal SLE(κ) maps from 0 to ∞ in \mathbb{H} . For $t < \tilde{\tau}$, $h_t(z) := g_t(e^z - 1) : S_\pi \setminus \tilde{K}_t \rightarrow \mathbb{H}$ satisfies $h_t(+\infty) = \infty$. Define

$$\phi_t(z) := \log[g_t(e^z - 1) - g_t(-1)].$$

So $\phi_t(z) : S_\pi \setminus \tilde{K}_t \rightarrow S_\pi$ satisfies $\phi_t(+\infty) = +\infty$, $\phi_t(-\infty) = -\infty$ and

$$\lim_{z \rightarrow +\infty} [\phi_t(z) - z] = 0, \lim_{z \rightarrow -\infty} [\phi_t(z) - z] = \log g'_t(-1).$$

Define

$$\Phi_t(z) := \phi_t(z) - \frac{1}{2} \log g'_t(-1).$$

Then $\Phi_t(z) : S_\pi \setminus \tilde{K}_t \rightarrow S_\pi$ satisfies $\Phi_t(+\infty) = +\infty$, $\Phi_t(-\infty) = -\infty$ and

$$\lim_{z \rightarrow +\infty} [\Phi_t(z) - z] = -\frac{1}{2} \log g'_t(-1) > 0, \lim_{z \rightarrow -\infty} [\Phi_t(z) - z] = \frac{1}{2} \log g'_t(-1).$$

Since $\partial_t g_t(z) = \frac{-2}{g_t(z) - \sqrt{\kappa} B_t}$, we have

$$\partial_t g'_t(-1) = \frac{-2g'_t(-1)}{(g_t(-1) - \sqrt{\kappa} B_t)^2}.$$

Therefore

$$\begin{aligned}\partial_t \log g'_t(-1) &= \frac{-2}{(g_t(-1) - \sqrt{\kappa}B_t)^2} \\ \log g'_t(-1) &= \int_0^t \frac{-2}{(g_s(-1) - \sqrt{\kappa}B_s)^2} ds. \\ -\frac{1}{2} \log g'_t(-1) &= \int_0^t \frac{1}{(g_s(-1) - \sqrt{\kappa}B_s)^2} ds.\end{aligned}$$

Since as S -hulls, $S(\tilde{K}_t) = \int_0^t \frac{1}{(g_s(-1) - \sqrt{\kappa}B_s)^2} ds$. Let $u(t) := S(\tilde{K}_t)$, use u as the parameter. Define $\beta(t) := \log[\sqrt{\kappa}B_t - g_t(-1)] - \frac{1}{2} \log g'_t(-1)$, then

$$\begin{aligned}\partial_t \Phi_t(z) &= \partial_t \phi_t(z) - \frac{1}{2} \partial_t \log g'_t(-1) \\ &= \frac{1}{g_t(e^z - 1) - g_t(-1)} \left[\frac{2}{g_t(e^z - 1) - \sqrt{\kappa}B_t} - \frac{2}{g_t(-1) - \sqrt{\kappa}B_t} \right] \\ &\quad + \frac{1}{(g_t(-1) - \sqrt{\kappa}B_t)^2} \\ &= \frac{g_t(e^z - 1) + \sqrt{\kappa}B_t - 2g_t(-1)}{(g_t(e^z - 1) - \sqrt{\kappa}B_t)(g_t(-1) - \sqrt{\kappa}B_t)^2}.\end{aligned}$$

So

$$\begin{aligned}\partial_u \Phi_t(z) &= \partial_t \Phi_t(z) \partial_u t = \partial_t \Phi_t(z) (g_t(z) - \sqrt{\kappa}B_t)^2 \\ &= \frac{g_t(e^z - 1) + \sqrt{\kappa}B_t - 2g_t(-1)}{(g_t(e^z - 1) - \sqrt{\kappa}B_t)}.\end{aligned}$$

Since

$$g_t(e^z - 1) - g_t(-1) = e^{\phi_t(z)} = e^{\Phi_t(z) + \frac{1}{2} \log g'_t(-1)} = e^{\Phi_t(z)} \sqrt{g'_t(-1)}.$$

$$\sqrt{\kappa}B_t - g_t(-1) = e^{\beta(t)} \sqrt{g'_t(-1)}.$$

We can get

$$\partial_u \Phi_t(z) = \frac{e^{\Phi_t(z)} + e^{\beta(t)}}{e^{\Phi_t(z)} - e^{\beta(t)}} = \coth \frac{\Phi_t(u) - \beta(t(u))}{2}.$$

Let $W_t := \sqrt{\kappa}B_t$, then

$$\begin{aligned}
 d\beta(t) &= \frac{1}{W_t - g_t(-1)}(dW_t - dg_t(z)) \\
 &+ \frac{1}{(W_t - g_t(-1))^2}d\langle W_t - g_t(-1), W_t - g_t(-1) \rangle - \frac{1}{2}\partial_t \log g'_t(-1)dt \\
 &= \frac{1}{W_t - g_t(-1)}\sqrt{\kappa}dB_t + \frac{2}{(W_t - g_t(-1))^2}dt \\
 &\quad - \frac{\kappa}{2}\frac{1}{(W_t - g_t(-1))^2}dt - \frac{1}{2}\frac{-2}{(W_t - g_t(-1))^2}dt \\
 &= \frac{1}{W_t - g_t(-1)}\sqrt{\kappa}dB_t + \left(3 - \frac{\kappa}{2}\right)\frac{1}{(W_t - g_t(-1))^2}dt.
 \end{aligned}$$

Therefore $d\beta(t(u)) = \sqrt{\kappa}d\tilde{B}_u + (3 - \frac{\kappa}{2})du$, where \tilde{B}_u is a standard one dimensional Brownian motion. So if $\kappa = 6$, $\{K_t : 0 \leq t < \tau\}$ and $\{\tilde{K}_t : 0 \leq t < \tilde{\tau}\}$ have the same distribution up to a time-change. If $\kappa \neq 6$, by Girsanov's theorem(see [18]) we can get the result. \square

Remark 62. By the absolutely continuous property in above lemma, we know that dipolar SLE(κ) is also generated by a continuous curve(we call the SLE(κ) **trace**) almost surely and has the same phase transition depending on κ .

In fact for dipolar SLE(κ) process, we have the following property.

Proposition 63 (see [24]). *Let γ be the dipolar SLE(κ) trace from 0 to \mathbb{R}_π in \mathcal{S} . Then*

- (1) *If $0 \leq \kappa \leq 4$, γ is a simple curve and $\gamma[0, \infty) \subset S_\pi \cup \{0\}$ a.s;*
- (2) *If $4 < \kappa < 8$, almost surely γ is a non-selfcrossing curve and for any given $z \in S_\pi \setminus \{0\}$ but $z \notin \gamma[0, \infty)$;*
- (3) *If $\kappa \geq 8$, almost surely $\gamma[0, \infty)$ has Hausdorff dimension 2, i.e. γ fills the area it encloses;*
- (4) *Almost surely the limit $m := \lim_{t \rightarrow \infty} \gamma(t)$ exists;*
- (5) *Almost surely, $m \in \mathbb{R}_\pi$. If denote by $m = X + i\pi$, then the random variable X has the density function $\rho(x) = (\cosh(\frac{x}{2}))^{-\frac{4}{\kappa}}/c_\kappa$, where $c_\kappa = \int_{-\infty}^{+\infty} (\cosh(\frac{x}{2}))^{-\frac{4}{\kappa}} dx$.*

Remark 64. By above proposition if $(K_t)_{t \geq 0}$ is the \mathbb{H} -hulls corresponding to dipolar SLE(κ), denote by

$$K_\infty = \bigcup_{t \geq 0} K_t,$$

Then K_∞ is bounded. In fact the author in [24] used the boundness of K_∞ to prove above proposition.

Just like the chordal SLE, dipolar SLE(6) satisfies local property and dipolar SLE($\frac{8}{3}$) satisfies restriction property. In [8], the author gave a proof using the conformal field theory to find a martingale to prove the restriction property. Here we use the method in [9] to construct the martingale directly.

It is necessary to give the detailed proof of local property and restriction property here since we can not find any reference about this although it is direct. The main point is to determine how the capacity of a hull changes under a conformal map.

Let $A \in \mathcal{A}_s$ be a \mathcal{S} -hull such that $0 \notin A$, and Φ_A is the unique conformal map $\mathcal{S} \setminus A \rightarrow \mathcal{S}$ that fixes $0, +\infty$ and $-\infty$. Suppose that $(K_t : t \geq 0)$ is the dipolar Loewner chain driven by a continuous function $(W_t : t \geq 0)$. Write $\tau_A := \inf\{t \geq 0 : K_t \cap A \neq \emptyset\}$. Then for any $t < \tau_A$, $\Phi_A(K_t)$ is a \mathcal{S} -hull. Denote by \tilde{g}_t the normalised conformal map corresponding to $\Phi_A(K_t)$ and $S(t)$ the capacity of $\Phi_A(K_t)$, then \tilde{g}_t satisfies the rescaled dipolar Loewner equation :

$$\partial_t \tilde{g}_t(z) = \partial_t S(t) \coth \frac{\tilde{g}_t(z) - \tilde{W}_t}{2} \quad \tilde{g}_0(z) = z.$$

where $\tilde{W}_t = h_t(W_t)$ is a continuous function. Denote by $h_t(z) := \tilde{g}_t \circ \Phi_A \circ g_t^{-1}(z)$, and $A_t := g_t(A)$, by Schwarz reflection theorem $h_t(z)$ can be analytically extended to a neighbourhood of W_t . We have the following :

Lemma 65. *Take the notations above, for $0 \leq t < T_A$,*

$$\begin{aligned} S(A_t) &= S(t) + S(A) - t, \\ \partial_t S(t) &= h'_t(W_t)^2, \\ \partial_t h_t(W_t) &= -3h''_t(W_t), \\ \partial_t h'_t(W_t) &= \frac{1}{2} \frac{(h''_t(W_t))^2}{h'_t(W_t)} - \frac{4}{3} h'''_t(W_t) + \frac{(h'_t(W_t))^3 - h'_t(W_t)}{6}. \end{aligned}$$

Proof. By the definition of h_t ,

$$\begin{aligned} \lim_{z \rightarrow \pm\infty} (h_t(z) - z) &= \lim_{z \rightarrow \pm\infty} (h_t(z) - \Phi_A \circ g_t^{-1}(z)) \\ &+ \lim_{z \rightarrow \pm\infty} (\Phi_A \circ g_t^{-1}(z) - g_t^{-1}(z)) + \lim_{z \rightarrow \pm\infty} (g_t^{-1}(z) - z) \\ &= \pm S(t) \pm S(A) - g_A(0) \mp t. \end{aligned}$$

So $h_t(z) + g_A(0)$ is the normalised conformal map corresponding to A_t and therefore $S(A_t) = S(t) + S(A) - t$.

For the second equation take the derivative of $h_t(z)$ with respect to t , we get

$$\partial_t h_t(z) = [\partial_t S(t)] \coth \frac{h_t(z) - h_t(W_t)}{2} - h'_t(z) \coth \frac{z - W_t}{2}. \quad (3.4.1)$$

By multiplying $\frac{z-W_t}{2}$ on both side of above equation and let $z \rightarrow W_t$, we can get

$$0 = \partial_t S(t) \frac{1}{h'_t(W_t)} - h'_t(W_t).$$

So $\partial_t S(t) = h'_t(W_t)^2$.

The third equation is obtained by passing $z \rightarrow W_t$ in the equation (3.4.1).

Take the derivative of z on both sides of (3.4.1) we have

$$\partial_t h'_t(z) = -\frac{1}{2} \frac{h'_t(z)(h'_t(W_t))^2}{\sinh \frac{(h_t(z)-h_t(W_t))^2}{2}} - h''_t(z) \coth \frac{z-W_t}{2} + \frac{1}{2} h'_t(z) \frac{1}{(\sinh \frac{z-W_t}{2})^2}.$$

Then the fourth equation is obtained by passing $z \rightarrow W_t$ on the both side of above equation. \square

By above lemma, we can get the local property of dipolar SLE(6) and restriction property of dipolar SLE($\frac{8}{3}$).

Proposition 66. *Suppose that γ is the dipolar SLE(κ) trace from 0 to \mathbb{R}_π in \mathcal{S} .*

(a) *If $\kappa = 6$, for any \mathcal{S} -hull A with $0 \notin A$, define*

$$\tau_A := \inf\{t \geq 0 : \gamma(t) \in A\},$$

*then $\gamma[0, \tau_A)$ has the same distribution as the dipolar SLE(6) in $\mathcal{S} \setminus A$ from 0 to \mathbb{R}_π upon hitting K . This is called the **local property** of dipolar SLE(6).*

(b) *If $\kappa = \frac{8}{3}$, for any \mathcal{S} -hull A with $0 \notin A$. Define $\Phi_A(z) = g_A(z) - g_A(0)$, where $g_A(z)$ is the normalised conformal map corresponding to A . Then*

$$\mathbf{P}[K \cap A = \emptyset] = |\Phi'_A(0)|^{\frac{5}{8}} \exp\{-\frac{5}{48} S(A)\}.$$

where $A_t = g_t(A)$ and $S(A)$ and $S(A_t)$ are the capacities of these two hulls. Notice that for two \mathcal{S} -hulls K_1, K_2 that don't contain 0,

$$\Phi_{K_1 \cup \Phi_{K_1}^{-1}(K_2)} = \Phi_{K_2} \circ \Phi_{K_1}, S(K_1 \cup \Phi_{K_1}^{-1}(K_2)) = S(K_1) + S(K_2),$$

$$\Phi'_{K_1 \cup \Phi_{K_1}^{-1}(K_2)}(0) = \Phi'_{K_2}(0) \Phi'_{K_1}(0).$$

*Then conditioned on $\gamma \cap A = \emptyset$, γ has the same distribution as the dipolar SLE($\frac{8}{3}$) from 0 to \mathbb{R}_π in $\mathcal{S} \setminus K$. This is called the **restriction property** of dipolar SLE($\frac{8}{3}$).*

Proof. Suppose that $W_t = \sqrt{\kappa} B_t$ is the driven process of dipolar SLE(κ). Using the same notation as Lemma 65. For $t < \tau_A$, we see that the driven process of the curve $\Phi_A(\gamma)$ is $\tilde{W}_t = h_t(W_t)$. By Itô's formula and combing Lemma 65, we have

$$\begin{aligned} d\tilde{W}_t &= \partial_t h_t(W_t) dt + h'_t(W_t) dW_t + \frac{\kappa}{2} h''_t(W_t) dt \\ &= \left(\frac{\kappa}{2} - 3\right) h''_t(W_t) dt + h'_t(W_t) \sqrt{\kappa} dB_t. \end{aligned}$$

3.4. DIPOLAR SCHRAMM LOEWNER EVOLUTION

So if $\kappa = 6$, by a time change, \tilde{W}_t is scaled a Brownian motion and this proves the locality of dipolar SLE(6).

For $\kappa = \frac{8}{3}$, define

$$Y_t = 1_{\{t < \tau_A\}} h'_t(W_t)^{\frac{5}{8}} \exp\left\{-\frac{5}{48} S(A_t)\right\}.$$

Denote by $N_t = \log Y_t = \frac{5}{8} \log h'_t(W_t) - \frac{5}{48} S(A_t)$. By lemma 65, we have

$$\begin{aligned} dh'_t(W_t) &= \partial_t h'_t(W_t) dt + h''_t(W_t) dW_t + \frac{1}{2} h'''_t(W_t) d\langle W, W \rangle_t \\ &= \left[\frac{1}{2} \frac{(h''_t(W_t))^2}{h'_t(W_t)} + \frac{(h'_t(W_t))^3 - h'_t(W_t)}{6} \right] dt + h''_t(W_t) \sqrt{\frac{8}{3}} dB_t, \end{aligned}$$

and

$$dS(A_t) = (h'_t(W_t)^2 - 1) dt.$$

So

$$\begin{aligned} dN_t &= \frac{5}{8} d \log h'_t(W_t) - \frac{5}{48} dS(A_t) \\ &= \frac{5}{8} \left[-\frac{5}{6} \frac{(h''_t(W_t))^2}{(h'_t(W_t))^2} + \frac{(h'_t(W_t))^2 - 1}{6} \right] dt \\ &\quad - \frac{5}{48} (h'_t(W_t)^2 - 1) dt + \frac{5}{8} \frac{h''_t(W_t)}{h'_t(W_t)} \sqrt{\frac{8}{3}} dB_t \\ &= -\frac{25}{48} \frac{(h''_t(W_t))^2}{(h'_t(W_t))^2} + \frac{5}{8} \frac{h''_t(W_t)}{h'_t(W_t)} \sqrt{\frac{8}{3}} dB_t \end{aligned}$$

And then

$$dY_t = Y_t (dN_t + \frac{1}{2} d\langle N, N \rangle_t) = \sqrt{\frac{25}{24}} Y_t \frac{h''_t(W_t)}{h'_t(W_t)} dB_t.$$

Therefore Y_t is a local martingale. Since $S(A_t) \geq 0$ and $h'_t(W_t) \leq 1$, we get that Y_t is a martingale. Just using the same method as [9] (In fact if we regard $h'_t(W_t)$ as the probability that a Brownian motion starting from W_t in \mathcal{S} avoids A_t before exiting \mathcal{S} , then for $\tau_A < \infty$, $h'_t(W_t) \rightarrow 0$; for $\tau_A = \infty$, $h'_t(W_t) \rightarrow 1$ and $S(A_t) \rightarrow 0$.), we can get $\lim_{t \rightarrow \tau_A} Y_t = 1_{\{\tau_A = \infty\}}$. So by the optional stopping theorem

$$\mathbf{P}[K \cap A = \emptyset] = \mathbf{E}[M_{\tau_A}] = \mathbf{E}[M_0] = |\Phi'_A(0)|^{\frac{5}{8}} \exp\left\{-\frac{5}{48} S(A)\right\}.$$

□

Remark 67. By above lemma, we have constructed the conformal restriction measure $\mathbf{P}(\frac{5}{48}, \frac{5}{8})$ in Theorem 49.

3.5 Brownian Bridge on the strip

In this section the brownian bridge on the strip \mathcal{S} will be given, this is a probability measure defined on the space of the curves from 0 to \mathbb{R}_π . The exact definition is as follows :

Suppose that μ_ϵ is the law of a planar Brownian motion (B_t) starting from $i\epsilon$ and conditioned to first exit \mathcal{S} from \mathbb{R}_π . By the optional stopping time theorem, the probability that a one dimension Brownian motion started from ϵ hits π before 0 is ϵ/π , so the law $\frac{\pi}{\epsilon}\mu_\epsilon$ converges to a probability measure $\mu_{0,\mathbb{R}_\pi}^{exc}$ in the Prohorov sense, we call this measure the *Brownian bridge measure or Brownian excursion measure* from 0 to \mathbb{R}_π on the strip. In fact this measure is just the normalisation of the Brownian excursion measure defined in chapter 5 of the book [10]. The measure is supported on the curves from 0 to \mathbb{R}_π in the strip \mathcal{S} . We can show that $\mu_{0,\mathbb{R}_\pi}^{exc}$ satisfies the conformal restriction property.

Proposition 68. *Suppose that K has the law $\mu_{0,\mathbb{R}_\pi}^{exc}$, then for any $A \in \mathcal{A}_s$ with $0 \notin A$,*

$$\mathbf{P}[K \cap A = \emptyset] = \Phi'_A(0). \quad (3.5.1)$$

Moreover, by definition K almost surely intersects \mathbb{R}_π at some point $X + i\pi$, the law of X has the density function $\rho(x) = \frac{e^x}{(1+e^x)^2}$.

Proof. Let $P(\epsilon)$ be the probability that a Brownian motion started from $i\epsilon$ hits \mathbb{R}_π before $\mathbb{R} \cup A$. By the conformal invariance of planar Brownian motion,

$$P(\epsilon) = \mathbf{P}(B_t \text{ started from } \Phi_A(i\epsilon) \text{ hits } \mathbb{R}_\pi \text{ before } \mathbb{R}) = \frac{\text{Im } \Phi_A(i\epsilon)}{\pi}$$

Then we have

$$\mathbf{P}[K \cap A = \emptyset] = \lim_{\epsilon \rightarrow 0} \frac{\pi}{\epsilon} P(\epsilon) = \lim_{\epsilon \rightarrow 0} \frac{\pi}{\epsilon} \frac{\text{Im } \Phi_A(i\epsilon)}{\pi} = \Phi'_A(0).$$

Notice the Poisson kernel of \mathcal{S} is $H(z, x + i\pi) = -\frac{1}{\pi} \text{Im} \frac{e^x}{e^x + e^z}$, we have

$$\begin{aligned} & \mathbf{P}[B_t \text{ from } i\epsilon \text{ hits } \mathbb{R}_\pi \text{ at } (-\infty, x + i\pi] | B_t \text{ from } i\epsilon \text{ hits } \mathbb{R}_\pi \text{ before } \mathbb{R}] \\ &= \frac{\pi}{\epsilon} \int_{-\infty}^x \frac{-1}{\pi} \text{Im} \frac{e^t}{e^{i\epsilon} + e^t} dt = \frac{1}{\epsilon} \int_{-\infty}^x \frac{e^t \sin \epsilon}{e^{2t} + 2e^t \cos \epsilon + 1} dt. \end{aligned}$$

So the hitting point of the Bridge have the distribution function

$$\mathbf{P}[X \leq x] = \lim_{\epsilon \rightarrow 0} \frac{1}{\epsilon} \int_{-\infty}^x \frac{e^t \sin \epsilon}{e^{2t} + 2e^t \cos \epsilon + 1} dt = \int_{-\infty}^x \frac{e^t}{e^{2t} + 2e^t + 1} dt.$$

□

3.6 Characterization of the conformal restriction measure

In this section we will show that a dipolar conformal restriction can be characterized by two parameters.

Let Ω be the collection of compact connected subsets K of $\bar{\mathcal{S}}$ such that $K \cap \mathbb{R} = \{0\}$ and $\mathcal{S} \setminus K$ has two connected components that each of them contains $+\infty$ and $-\infty$ on the boundary respectively. Endow Ω with the σ -field generated by the family of sets of the type $\{K \in \Omega : K \cap A = \emptyset\}$ where $A \in \mathcal{A}_s^*$. Just like the chordal and radial case this σ -algebra is the same as the σ -algebra induced by the Hausdorff metric on Ω . Notice that $\{\{K \in \Omega : K \cap A = \emptyset\} : A \in \mathcal{A}_s^*\}$ forms an algebra. As the chordal case [9] and radial case [23], by the unique extension theorem of probability measures on algebras, we have :

Lemma 69. *If \mathbf{P} and \mathbf{P}' are two probability measures on Ω such that $\mathbf{P}[K \cap A = \emptyset] = \mathbf{P}'[K \cap A = \emptyset]$ for all $A \in \mathcal{A}_s^*$, then $\mathbf{P} = \mathbf{P}'$.*

Just like the chordal case [9], by endowing \mathcal{A}_s^* with the Hausdorff metric, the function $A \rightarrow \mathbf{P}[K \cap A = \emptyset]$ is continuous and this fact will be used in this section.

To prove the existence of the two values α and β , it is necessary to introduce the *perfect hull* (this notation was first used in [23]) :

Fix $x \in \mathbb{R} \setminus \{0\}$, suppose $(K_t(x))_{t \geq 0}$ is the hulls generated by the driven function $W_t = x - \coth \frac{x}{2}t$ and g_t is the corresponding conformal maps. These hulls $(K_t(x))_{t \geq 0}$ are called the **perfect hulls from x** . We can check that $g_t(0) = -\coth \frac{x}{2}t$.

Lemma 70. *With the notations above.*

(1) *Define $h_t(z) = g_t(z) - g_t(0) = g_t(z) + \coth \frac{x}{2}t$, then $h_{t+s} = h_t \circ h_s$.*

(2) *Let K be a dipolar restriction sample, then there exists a constant $\nu(x)$ such that*

$$\mathbf{P}[K \cap K_t = \emptyset] = \exp\{-\nu(x)t\} \quad \forall t \geq 0.$$

Proof. For fixed $s \geq 0$, by the uniqueness of the solution of the following ODE :

$$\partial_t f_t(z) = \coth \frac{f_t(z) - x}{2} + \coth \frac{x}{2}, \quad f_0(z) = h_s(z),$$

we can see that both h_{t+s} and $h_t \circ h_s$ satisfies this ODE, and so we have (1). From (1), we have $h_t(K_{s+t}(x) \setminus K_t(x)) = (K_s(x))$ for any $t, s \geq 0$. Then for any $t, s \geq 0$, by the conformal restriction property, we have that

$$\begin{aligned} & \mathbf{P}[K \cap K_{t+s}(x) = \emptyset | K \cap K_t(x) = \emptyset] \\ &= \mathbf{P}[K \cap h_t(K_{s+t}(x) \setminus K_t(x)) = \emptyset] = \mathbf{P}[K \cap K_s(x) = \emptyset]. \end{aligned}$$

Thus for any $t, s \geq 0$, we have

$$\mathbf{P}[K \cap K_{t+s}(x) = \emptyset | K \cap K_t(x) = \emptyset] = \mathbf{P}[K \cap K_t(x) = \emptyset] \times \mathbf{P}[K \cap K_s(x) = \emptyset].$$

3.6. CHARACTERIZATION OF THE CONFORMAL RESTRICTION MEASURE

Combining the fact that $t \rightarrow K_t(x)$ is continuous, there exists a constant $\nu(x) \geq 0$ such that

$$\mathbf{P}[K \cap K_t(x) = \emptyset] = \exp\{-t\nu(x)\}.$$

□

In the chordal case, the analogous quantity $\nu(x)$ should be a constant because of the scaling-invariance, but here, just like the radial case, we have a different situation (with one more freedom because of the lack of a restriction condition). In fact, we will show that $\nu(x)$ is a smooth function.

Now we are ready to prove the first part of Theorem 49 that we state as following :

Proposition 71. *For any dipolar restriction sample K , there exists two constants $\alpha, \beta \in \mathbb{R}$ such that for any $A \in \mathcal{A}_s^*$,*

$$\mathbf{P}[K \cap A = \emptyset] = \Phi'_A(0)^\beta \exp\{-\alpha S(A)\} \quad (3.6.1)$$

where $S(A)$ is the capacity of A .

By lemma 69, for any $\alpha, \beta \in \mathbb{R}$, there exists at most one law that satisfies (3.6.1). The strategy of the proof of above proposition is the same as the strategy used in [23] : first show that (3.6.1) holds for any perfect hulls $K_t(x)$ and then show that the hulls generated by the family of perfect hulls are dense in \mathcal{A}_s^* in the sense of the Hausdorff metric (here the hull generated by two hulls A_1, A_2 is defined as $A_1 \cup g_{A_1}^{-1}(A_2)$). And then use the continuity of the map $A \rightarrow \mathbf{P}[K \cap A = \emptyset]$.

We will begin by showing that the function $x \rightarrow \nu(x)$ is a smooth function on $\mathbb{R} \setminus \{0\}$. And then use the commutation relations derived in Lemma 9 of [23] . It seems that it is easier to work on the upper half plane because we can write down the exact form of the conformal maps from subdomains of \mathbb{H} onto itself.

Let $\varphi_0(z) = e^z - 1$ be the conformal map from \mathcal{S} to \mathbb{H} that sends $+\infty, 0, -\infty$ to $-1, 0, \infty$ respectively. Suppose that K is a sample of the dipolar conformal restriction measure on the strip, then $\tilde{K} := \varphi_0(K)$ is a sample of what we call the dipolar restriction measure on the upper half plane. For $x \in \mathbb{C}$, let $B(x, r)$ denote the ball centered at x with radius r .

For $\epsilon > 0$ small enough and $x \in (-1, 0) \cup (0, \infty)$, the map

$$g_{x,\epsilon}(z) := z + \frac{\epsilon^2}{z-x}$$

is a conformal map from $\mathbb{H} \setminus B(x, \epsilon)$ onto H that fix ∞ . Define

$$f_{x,\epsilon}(z) = \frac{1}{1 - \frac{\epsilon^2}{x(1+x)}} \left(g_{x,\epsilon}(z) + \frac{\epsilon^2}{x} \right) = \frac{1}{1 - \frac{\epsilon^2}{x(1+x)}} \left(z + \frac{\epsilon^2}{z-x} + \frac{\epsilon^2}{x} \right).$$

This is the unique conformal map from $\mathbb{H} \setminus B(x, \epsilon)$ onto H that fixes $-1, 0, \infty$. Denote

$$p_\epsilon(x) = \mathbf{P}[\tilde{K} \cap B(x, \epsilon) \neq \emptyset].$$

Just as Lemma 5 in [23], we have

Lemma 72. *Let \tilde{K} be a dipolar restriction sample in \mathbb{H} . For any $x \in (-1, 0) \cup (0, \infty)$, the following limits exists*

$$\lambda(x) := \lim_{\epsilon \rightarrow 0} \frac{1}{\epsilon^2} p_\epsilon(x).$$

And further $\lambda(x) \in (0, \infty)$.

Proof. For fixed $x \in (-1, 0) \cup (0, \infty)$, let $(\tilde{K}_t(x) : t \geq 0)$ be the perfect hulls from x , here we mean $\tilde{K}_t(x) = \varphi_0(K_t(\varphi_0^{-1}(x)))$, where $K_t(\varphi_0^{-1}(x))$ is the perfect hulls in \mathcal{S} from $\varphi_0^{-1}(x) = \log(x+1)$ as defined at the beginning Lemma 70. For small enough $\epsilon > 0$, define $N(\epsilon) = \lceil \epsilon^{-2} \rceil$ which is the integer part of ϵ^{-2} . And $\phi_1 = \phi_2 = \dots = \phi_N = f_{x,\epsilon}$. Let $\Phi_\epsilon = \phi_{N(\epsilon)} \circ \phi_{N(\epsilon)-1} \circ \dots \circ \phi_1$ be the conformal map from $H := \phi_1^{-1} \circ \dots \circ \phi_{N(\epsilon)}^{-1}(\mathbb{H})$ onto \mathbb{H} that fixes $-1, 0, \infty$. Define $A_\epsilon(x) = \overline{\mathbb{H}} \setminus H$. Then the same as, we have $A_\epsilon(x) \rightarrow \tilde{K}_{t_x}(x)$ in the Hausdorff sense as $\epsilon \rightarrow 0$. Moreover we have that $K_{t_x}(x) \subset A_\epsilon(x)$. Here by compute the capacity we can see that $t_x = \frac{1}{2(1+x)^2}$. In fact

$$S(\varphi^{-1}(B(x, \epsilon) \cap \mathbb{H})) = \frac{1}{2} \log f'_{x,\epsilon}(\infty) - \frac{1}{2} \log f'_{x,\epsilon}(-1) = -\frac{1}{2} \log \left[1 - \frac{\epsilon^2}{(1+x^2)} \right],$$

and so

$$t_x = \lim_{\epsilon \rightarrow 0} S(A_\epsilon(x)) = \lim_{\epsilon \rightarrow 0} -\frac{N(\epsilon)}{2} \log \left[1 - \frac{\epsilon^2}{(1+x^2)} \right] = \frac{1}{2(1+x)^2}.$$

Now by the conformal restriction property we have

$$\mathbf{P}[K \cap A_\epsilon(x) = \emptyset] = (1 - p_\epsilon(x))^{N(\epsilon)}.$$

On the other hand, by Lemma 70, we have

$$\begin{aligned} & \mathbf{P}[K \cap A_\epsilon(x) = \emptyset] \rightarrow \mathbf{P}[\tilde{K} \cap \tilde{K}_{t_x}(x) = \emptyset] \\ &= \mathbf{P}[K \cap K_{t_x}(\varphi_0^{-1}(x)) = \emptyset] = \exp\{-\nu(\log(x+1))t_x\}, \text{ as } \epsilon \rightarrow 0. \end{aligned}$$

Therefore

$$\lim_{\epsilon \rightarrow 0} N(\epsilon) \log(1 - p_\epsilon(x)) = -\frac{1}{2(1+x)^2} \nu(\log(x+1)).$$

This completes the proof. We further get that

$$\lambda(x) = \frac{1}{2(1+x)^2} \nu(\log(x+1)). \quad (3.6.2)$$

□

In fact the function $\lambda(x)$ in the above lemma has a very nice form. In order to determine the exact form of $\lambda(x)$, we need to find some functional relations satisfied by $\lambda(x)$. We will give two functional relations in the following two lemmas : one is the symmetric relation, and the other is the commutation relation.

Lemma 73 (*symmetric relation*). *For any $x > 0$, the function λ satisfies*

$$\lambda(x) = \frac{1}{(1+x)^4} \lambda\left(-\frac{x}{1+x}\right). \quad (3.6.3)$$

Proof. Write $E(x, \epsilon) := \varphi_0^{-1}(B(x, \epsilon))$. Denote by $I(z) = -\bar{z}$ the reflection of the imaginary axis. Since the law of the conformal restriction measure is invariant under the reflection of the imaginary axis, we have that

$$\mathbf{P}[K \cap E(x, \epsilon) \neq \emptyset] = \mathbf{P}[K \cap I(E(x, \epsilon)) \neq \emptyset]$$

Notice that $\psi := \varphi_0 \circ I \circ \varphi^{-1}(z) = -\frac{\bar{z}}{1+\bar{z}}$, we have

$$\mathbf{P}[\tilde{K} \cap B(x, \epsilon) \neq \emptyset] = \mathbf{P}[\tilde{K} \cap \psi(B(x, \epsilon)) \neq \emptyset].$$

Therefore

$$\begin{aligned} \lambda(x) &= \lim_{\epsilon \rightarrow 0} \frac{1}{\epsilon^2} \mathbf{P}[\tilde{K} \cap B(x, \epsilon) \neq \emptyset] = \lim_{\epsilon \rightarrow 0} \mathbf{P}[\tilde{K} \cap \psi(B(x, \epsilon)) \neq \emptyset] \\ &= \lim_{\epsilon \rightarrow 0} |\psi'(x)|^2 \frac{1}{\epsilon^2 |\psi'(x)|^2} \mathbf{P}[\tilde{K} \cap B(\psi(x), |\psi'(x)|\epsilon) \neq \emptyset] \\ &= \frac{1}{(1+x)^4} \lambda\left(-\frac{x}{1+x}\right). \end{aligned}$$

□

Fix $x, y \in (-1, 0) \cup (0, \infty)$, define

$$F(x, y) = \lim_{\epsilon \rightarrow 0} \frac{1}{\epsilon^2} (f_{x, \epsilon}(y) - y), \quad G(x, y) = \lim_{\epsilon \rightarrow 0} \frac{1}{\epsilon^2} (f'_{x, \epsilon}(y) - 1).$$

By direct computation, we have that

$$F(x, y) = \frac{1}{y-x} + \frac{1}{x} + \frac{y}{x(1+x)}, \quad G(x, y) = \frac{1}{x(1+x)} - \frac{1}{(y-x)^2}.$$

By exactly the same argument as the Lemma 6, Lemma 7, Lemma 8 in [23], we can get the second functional relation satisfied by $\lambda(x)$ which is called the commutation relations. Since the argument is totally the same as, we omit the proof and just give the statement.

Lemma 74. *The function λ is differentiable in $x \in (-1, 0) \cup (0, \infty)$ and satisfies the following commutation relation : for any $x, y \in (-1, 0)$ or $x, y \in (0, \infty)$,*

$$\lambda'(y)F(x, y) + 2\lambda(y)G(x, y) = \lambda'(x)F(y, x) + 2\lambda(x)G(y, x). \quad (3.6.4)$$

Combining Lemma 73 and Lemma 74, we can get the exact form of $\lambda(x)$:

Lemma 75. *There exists two constants c_1 and c_2 such that*

$$\lambda(x) = \frac{c_1(1+x) + c_2x^2}{x^2(1+x)^2}. \quad (3.6.5)$$

Proof. Fix x , expand the two sides of (3.6.4) and then let $y \rightarrow x$, we can get

$$\begin{aligned} x^2(1+x)^2\lambda'''(x) + 6x(1+x)(2x+1)\lambda''(x) \\ + 6(1+6x+6x^2)\lambda'(x) + 12(1+2x)\lambda(x) = 0. \end{aligned}$$

The solution of above differential equation have the following form :

$$\lambda(x) = \frac{c_1 + c_3x + c_2x^2}{x^2(1+x)^2}$$

Since $\lambda(x)$ satisfies (3.6.3), we can get $c_1 = c_3$. □

Proof of proposition 71 Recall that for the perfect hulls $K_t(x)$ from x , the corresponding function $h_t(z)$ satisfies

$$\partial_t h_t(z) = \coth \frac{h_t(z) - x}{2}, \quad h_0(z) = z.$$

From $h_t(0) = 0$ and take the derivative of above differential equation at $z = 0$, we can get

$$h'_t(0) = \exp\left\{-\frac{1}{4} \frac{1}{(\sinh \frac{x}{2})^2} t\right\}.$$

Combining $\mathbf{P}[K \cap K_t(x) = \emptyset] = \exp\{-\nu(x)t\}$ and $S(K_t(x)) = t$. By (3.6.2), we have

$$\nu(x) = 2c_2 + 2c_1 \frac{1}{4(\sinh \frac{x}{2})^2}.$$

So if we set $\alpha = 2c_2$ and $\beta = 2c_1$, we can see that

$$\mathbf{P}[K \cap K_t(x) = \emptyset] = \exp\{-\nu(x)t\} = |h'_t(0)|^\beta \exp\{-\alpha S(K_t(x))\}.$$

Now we have proved that proposition 71 holds for all the hulls generated by perfect hulls. Then use the same method as Proposition 3.3 in [9], the hulls generated by perfect hulls are dense in \mathcal{A}_s^* , combing the continuity of $A \rightarrow \mathbf{P}[K \cap A = \emptyset]$, we proved proposition 71 for all the hulls in \mathcal{A}_s^* .

3.7 Construction by Poisson cloud

In this section we will use Brownian bubble measure and $\text{SLE}(\frac{8}{3})$ to construct $\mathbf{P}(\frac{\beta(1-\beta)}{2\beta+1}, \beta)$. For a conformal map f , define the modified Schwarzian derivative as follows :

$$\tilde{S}f(z) = \frac{f'''(z)}{f'(z)} - \frac{3}{2} \left(\frac{f''(z)}{f'(z)} \right)^2 + \frac{1 - f'(z)^2}{2}. \quad (3.7.1)$$

Define

$$\beta = \beta(\kappa) = \frac{6 - \kappa}{2\kappa}, \quad \alpha = \alpha(\kappa) = \frac{(\kappa - 2)(6 - \kappa)}{8\kappa},$$

$$\lambda = \lambda(\kappa) = \frac{(6 - \kappa)(8 - 3\kappa)}{2\kappa}.$$

Lemma 76. *Suppose that $W_t = \sqrt{\kappa}B_t$ is the driven process of the dipolar $\text{SLE}(\kappa)$, and K is the hull generated by the dipolar $\text{SLE}(\kappa)$. Take the same notations as lemma 65, and $\alpha(\kappa), \beta(\kappa), \lambda(\kappa)$ are as above. Then*

$$Y_t = 1_{\{t < \tau_A\}} h'_t(W_t)^\beta \exp\{-\alpha S(A_t)\} \exp\{\lambda \int_0^t \tilde{S}h_s(W_s) ds\},$$

is a local martingale. In particular, when $\kappa \leq \frac{8}{3}$, Y_t is a martingale and

$$\mathbf{E}[1_{\{\tau_A = \infty\}} \exp\{\lambda \int_0^\infty \tilde{S}h_s(W_s) ds\}] = \Phi'_A(0)^\beta \exp\{-\alpha S(A)\}$$

Proof. It is proved by the standard stochastic analysis. \square

Lemma 77. *Suppose that $\mu_S^{\text{bub}}(0)$ is the Brownian bubble measure on the strip at 0 and K is a sample of this law, then*

$$\mu_S^{\text{bub}}(0)[K \cap A \neq \emptyset] = -\frac{1}{6} \tilde{S}\Phi_A(0), \quad \forall A \in \mathcal{A}_s^*. \quad (3.7.2)$$

Proof. Denote $\tilde{A} = \varphi_0(A)$, and \tilde{A} is a compact hull in \mathbb{H} . By the definition of the Brownian bubble measure, we have

$$\mu_S^{\text{bub}}(0)[K \cap A \neq \emptyset] = \frac{1}{|\varphi'_0(0)|^2} \mu_{\mathbb{H}}^{\text{bub}}(0)[K \cap \tilde{A} \neq \emptyset] = -\frac{1}{6} Sg_{\tilde{A}}(0).$$

where Sg_A is the Schwarzian derivative. We can check that the normalised conformal map corresponding to \tilde{A} is

$$g_{\tilde{A}}(z) = e^{-S(A)} [e^{g_A(\log(z+1))} - 1].$$

By direct computation, we have $Sg_{\tilde{A}}(0) = \tilde{S}g(0)$. \square

Now we can use the above two lemmas to construct the dipolar conformal restriction measure. Just exactly the same argument as [9], we have the following analysis : Suppose that $\kappa \leq 8/3$ and take the notations at the beginning of this section. Consider a Poisson point process X on $\Omega \times [0, \infty)$ with mean (intensity) $\lambda \mu \times dt$, where dt is Lebesgue measure. As before, let γ denote the SLE $_{\kappa}$ path, g_t the corresponding conformal maps, and W_t the Loewner driving process. We take γ to be independent from X .

Let

$$\hat{X} := \{g_t^{-1}(K + W_t) : (K, t) \in X, t \in [0, \infty)\},$$

and let Ξ be the filling of the union of elements of \hat{X} and γ , i.e, Ξ is the closure of the domains between \hat{X} and γ .

Let $A \in \mathcal{A}_s^*$, and let h_t be the normalized conformal map from $\mathcal{S} \setminus g_t(A)$ onto \mathcal{S} . By Lemma 77, for any $t > 0$ on the event $\gamma[0, t] \cap A = \emptyset$,

$$\begin{aligned} & \mathbf{P}[\{K : g_t^{-1}(K + W_t) \cap A \neq \emptyset\} \mid g_t] \\ &= \mathbf{P}[\{K : (K + W_t) \cap g_t(A) \neq \emptyset\} \mid g_t] \\ &= -\tilde{S}h_t(W_t)/6, \end{aligned}$$

where K is independent from γ and has law $\mu_S^{\text{bub}}(0)$. Consequently, on the event $\gamma[0, \infty) \cap A = \emptyset$,

$$\mathbf{P}[\Xi \cap A = \emptyset \mid \gamma] = \exp\left(\lambda \int_0^\infty \frac{\tilde{S}h_t(W_t)}{6} dt\right).$$

By taking expectation and applying Theorem 76 , we get

$$\mathbf{P}[\Xi \cap A = \emptyset] = \Phi'_A(0)^\beta \exp\{-\alpha S(A)\}, \quad (3.7.3)$$

Using the same method as [9], we have

Proposition 78. *For any $\kappa \in [0, 8/3]$, the law of $\Xi(\kappa)$ is $\mathbf{P}(\alpha(\kappa), \beta(\kappa))$.*

Notice that $\beta(\kappa) \geq \frac{5}{8}$ and $\alpha(\kappa) = \alpha(\beta) = \frac{\beta(1-\beta)}{2\beta+1}$. So we have constructed $\mathbf{P}(\beta, \frac{\beta(1-\beta)}{2\beta+1})$ for $\beta \geq \frac{5}{8}$.

3.8 Construction from One-sided restriction measure

In proposition 71, we showed that a dipolar conformal restriction is uniquely characterized by two parameters (α, β) such that for any $A \in \mathcal{A}_s^*$, $\mathbf{P}[K \cap A = \emptyset] = \Phi'_A(0)^\beta \exp\{-\alpha S(A)\}$. We denote this measure by $\mathbf{P}(\alpha, \beta)$. By Proposition 66 and Proposition 3.5.1, we know that $\mathbf{P}(\frac{5}{48}, \frac{5}{8})$ and $\mathbf{P}(0, 1)$ exists. In this section, we will use dipolar SLE $(\kappa; \rho)$ process to construct $\mathbf{P}(\alpha, \beta)$ for other values of (α, β) .

Dipolar SLE($\kappa; \rho$) processes are variants of SLE(κ) processes. For what we will use in this chapter, we will here only describe the dipolar SLE($\kappa; \rho$) with one force point. It is defined as the solution of the dipolar Loewner equation (3.3.1) where the driven function is replaced by the solution to the following SDE systems :

$$\begin{cases} dW_t = \frac{\rho}{2} \coth \frac{W_t - V_t}{2} dt + \sqrt{\kappa} dB_t \\ dV_t = \coth \frac{V_t - W_t}{2} dt \\ W_0 = 0, V_0 = x \in \mathbb{R} \setminus \{0\}, \frac{W_t - V_t}{W_0 - U_0} > 0. \end{cases} \quad (3.8.1)$$

By the same method as the chordal SLE($\kappa; \rho$) processes, it can be proven that when $\kappa > 0$ and $\rho > -2$, there is a pathwise unique solution to the above SDE system. And the SLE($\kappa; \rho$) is almost surely generated by a continuous curve from 0 to \mathbb{R}_π .

If we take the limit $x \rightarrow 0^+$ (respectively 0^-), the process has a limit which is called the dipolar SLE(ρ) process with force point 0^+ (respectively 0^-).

Fix $\rho > 0$. Let $g_t(z)$ be the dipolar Loewner chain SLE($\frac{8}{3}; \rho$) with force point 0^+ generated by the driven function $(W_t : t \geq 0)$, where (W_t, V_t) is the unique solution of the system in (3.8.1). Recall that dipolar SLE($\frac{8}{3}; \rho$) is generated by a curve γ . For any $A \in \mathcal{A}_s^*$, let τ_A be the first time that γ hits A . For any $t < \tau_A$, let \tilde{g}_t be the normalised conformal map of the dipolar hull $\Phi_A(\gamma(t))$. Denote by $h_t(z) = \tilde{g}_t \circ \Phi_A \circ g_t^{-1}(z)$ the conformal map from $\mathcal{S} \setminus g_t(A)$ onto \mathcal{S} that fixes $\pm\infty$. Then we have the following lemma.

Lemma 79.

$$M_t = |h'_t(W_t)|^{\frac{5}{8}} |h'_t(V_t)|^\lambda \exp\{-\alpha S(A_t)\} Z_t^{\frac{3}{8}\rho}$$

is a local martingale where

$$\begin{aligned} Z_t &= \sinh \frac{Y_t}{2} / \sinh \frac{X_t}{2}, \\ Y_t &= h_t(V_t) - h_t(W_t), \quad X_t = V_t - W_t, \\ \alpha &= \frac{5}{48} + \frac{3}{64}\rho(\rho + 4), \quad \lambda = \frac{1}{32}\rho(3\rho + 4), \end{aligned}$$

and $A_t = g_t(A)$ and $S(A_t)$ is the capacity of A_t .

Proof. Using Itô formula, combined with lemma 65 we have

$$\begin{aligned} d \log \sinh \frac{Y_t}{2} &= \left[\frac{1}{6} (\coth \frac{Y_t}{2})^2 (h'_t(W_t))^2 + \frac{5}{6} \coth \frac{Y_t}{2} h''_t(W_t) \right. \\ &\quad \left. - \frac{\rho}{4} h'_t(W_t) \coth \frac{Y_t}{2} \coth \frac{X_t}{2} + \frac{1}{3} (h'_t(W_t))^2 \right] dt - \frac{1}{2} \coth \frac{Y_t}{2} h'_t(W_t) \sqrt{\frac{8}{3}} dB_t, \end{aligned}$$

$$d \log \sinh \frac{X_t}{2} = \frac{3\rho + 2}{12} (\coth \frac{X_t}{2})^2 dt + \frac{1}{3} dt - \frac{1}{2} \coth \frac{X_t}{2} \sqrt{\frac{8}{3}} dB_t,$$

$$d \log h'_t(W_t) = \left(-\frac{5(h''_t(W_t))^2}{6(h'_t(W_t))^2} + \frac{(h'_t(W_t))^2 - 1}{6} \right. \\ \left. + \frac{h''_t(W_t)}{h'_t(W_t)} \frac{\rho}{2} \coth \frac{W_t - V_t}{2} \right) dt + \sqrt{\frac{8}{3}} \frac{h''_t(W_t)}{h'_t(W_t)} dB_t,$$

$$d \log h'_t(V_t) = \frac{dh'_t(V_t)}{h'_t(V_t)} = \frac{1}{2} [(\coth \frac{X_t}{2})^2 - 1] dt - \frac{1}{2} [h'_t(W_t)]^2 [(\coth \frac{Y_t}{2})^2 - 1] dt,$$

$$d \log S(A_t) = ([h'_t(W_t)]^2 - 1) dt.$$

Let $N_t = \log M_t$, then we have $dM_t = M_t(dN_t + \frac{1}{2}d\langle N, N \rangle_t)$ and we can use the above results to get that the drift term of dM_t is equal to zero and so M_t is a local martingale. \square

Remark 80. In order to make the computation process more precise, we give the detailed procedure of using Itô's formula to prove that M_t is a local martingale.

$$dh_t(V_t) = \partial_t h_t(V_t) dt + h'_t(V_t) dV_t \\ = (h'_t(W_t))^2 \coth \frac{h_t(V_t) - h_t(W_t)}{2} dt - h'_t(V_t) \coth \frac{V_t - W_t}{2} dt \\ + h'_t(V_t) \coth \frac{V_t - W_t}{2} dt = (h'_t(W_t))^2 \coth \frac{h_t(V_t) - h_t(W_t)}{2} dt.$$

$$dh_t(W_t) = \partial_t h_t(W_t) dt + h'_t(W_t) \left[\frac{\rho}{2} \coth \frac{V_t - W_t}{2} + \sqrt{\frac{8}{3}} dB_t \right] + \frac{h''_t(W_t)}{2} \frac{8}{3} dt \\ = -3h''_t(W_t) dt + h'_t(W_t) \left[\frac{\rho}{2} \coth \frac{V_t - W_t}{2} + \sqrt{\frac{8}{3}} dB_t \right] + \frac{h''_t(W_t)}{2} \frac{8}{3} dt \\ = \left[-\frac{5}{3} h''_t(W_t) + \frac{\rho}{2} h'_t(W_t) \coth \frac{V_t - W_t}{2} \right] dt + \sqrt{\frac{8}{3}} h'_t(W_t) dB_t$$

Denote by $Y_t = h_t(V_t) - h_t(W_t)$ and $X_t = V_t - W_t$, we have

$$dY_t = \left[(h'_t(W_t))^2 \coth \frac{Y_t}{2} + \frac{5}{3} h''_t(W_t) - \frac{\rho}{2} h'_t(W_t) \coth \frac{X_t}{2} \right] dt - h'_t(W_t) \sqrt{\frac{8}{3}} dB_t.$$

$$\begin{aligned}
 d \sinh \frac{Y_t}{2} &= \frac{1}{2} \cosh \frac{Y_t}{2} dY_t + \frac{1}{8} \sinh \frac{Y_t}{2} d \langle Y, Y \rangle_t \\
 &= \left[\frac{1}{2} \frac{(\cosh \frac{Y_t}{2})^2}{\sinh \frac{Y_t}{2}} (h'_t(W_t))^2 + \frac{5}{6} h''_t(W_t) \cosh \frac{Y_t}{2} - \frac{\rho}{4} h'_t(W_t) \cosh \frac{Y_t}{2} \coth \frac{X_t}{2} \right. \\
 &\quad \left. + \frac{1}{3} \sinh \frac{Y_t}{2} (h'_t(W_t))^2 \right] dt - \frac{1}{2} \cosh \frac{Y_t}{2} h'_t(W_t) \sqrt{\frac{8}{3}} dB_t. \\
 d \log \sinh \frac{Y_t}{2} &= \left[\frac{1}{2} (\coth \frac{Y_t}{2})^2 (h'_t(W_t))^2 + \frac{5}{6} \coth \frac{Y_t}{2} h''_t(W_t) - \frac{\rho}{4} h'_t(W_t) \coth \frac{Y_t}{2} \coth \frac{X_t}{2} \right. \\
 &\quad \left. + \frac{1}{3} (h'_t(W_t))^2 - \frac{1}{2} \frac{1}{(\sinh \frac{Y_t}{2})^2} \frac{1}{4} \frac{8}{3} (\cosh \frac{Y_t}{2})^2 (h'_t(W_t))^2 \right] dt - \frac{1}{2} \coth \frac{Y_t}{2} h'_t(W_t) \sqrt{\frac{8}{3}} dB_t \\
 &= \left[\frac{1}{6} (\coth \frac{Y_t}{2})^2 (h'_t(W_t))^2 + \frac{5}{6} \coth \frac{Y_t}{2} h''_t(W_t) - \frac{\rho}{4} h'_t(W_t) \coth \frac{Y_t}{2} \coth \frac{X_t}{2} \right. \\
 &\quad \left. + \frac{1}{3} (h'_t(W_t))^2 \right] dt - \frac{1}{2} \coth \frac{Y_t}{2} h'_t(W_t) \sqrt{\frac{8}{3}} dB_t.
 \end{aligned}$$

Since

$$dV_t = \coth \frac{V_t - W_t}{2} dt, \quad dW_t = \frac{\rho}{2} \coth \frac{W_t - V_t}{2} dt + \sqrt{\frac{8}{3}} dB_t,$$

We have

$$\begin{aligned}
 dX_t &= dV_t - dW_t = (1 + \frac{\rho}{2}) \coth \frac{X_t}{2} dt - \sqrt{\frac{8}{3}} dB_t. \\
 d \sinh \frac{X_t}{2} &= \frac{1}{2} \cosh \frac{X_t}{2} dX_t + \frac{1}{8} \sinh \frac{X_t}{2} d \langle X, X \rangle_t \\
 &= \frac{1}{2} \cosh \frac{X_t}{2} \left((1 + \frac{\rho}{2}) \coth \frac{X_t}{2} dt - \sqrt{\frac{8}{3}} dB_t \right) + \frac{1}{8} \sinh \frac{X_t}{2} \frac{8}{3} dt \\
 &= \frac{1}{2} (1 + \frac{\rho}{2}) \frac{(\cosh \frac{X_t}{2})^2}{\sinh \frac{X_t}{2}} dt + \frac{1}{3} \sinh \frac{X_t}{2} dt - \frac{1}{2} \cosh \frac{X_t}{2} \sqrt{\frac{8}{3}} dB_t. \\
 d \log \sinh \frac{X_t}{2} &= \frac{1}{2} (1 + \frac{\rho}{2}) (\coth \frac{X_t}{2})^2 dt + \frac{1}{3} dt - \frac{\frac{1}{4} (\cosh \frac{X_t}{2})^2 \frac{8}{3}}{2 (\sinh \frac{X_t}{2})^2} dt - \frac{1}{2} \coth \frac{X_t}{2} \sqrt{\frac{8}{3}} dB_t \\
 &= \frac{3\rho + 2}{12} (\coth \frac{X_t}{2})^2 dt + \frac{1}{3} dt - \frac{1}{2} \coth \frac{X_t}{2} \sqrt{\frac{8}{3}} dB_t.
 \end{aligned}$$

$$\begin{aligned}
 dh'_t(W_t) &= \partial_t h'_t(W_t) dt + h''_t(W_t) dW_t + \frac{1}{2} h'''_t(W_t) d\langle W, W \rangle_t \\
 &= \left(\frac{1}{2} \frac{(h''_t(W_t))^2}{h'_t(W_t)} - \frac{4}{3} h'''_t(W_t) + \frac{(h'_t(W_t))^3 - h'_t(W_t)}{6} \right) dt \\
 &\quad + h''_t(W_t) \left[\frac{\rho}{2} \coth \frac{W_t - V_t}{2} dt + \sqrt{\frac{8}{3}} dB_t \right] + \frac{1}{2} h'''_t(W_t) \frac{8}{3} dt \\
 &= \left(\frac{1}{2} \frac{(h''_t(W_t))^2}{h'_t(W_t)} + \frac{(h'_t(W_t))^3 - h'_t(W_t)}{6} + h''_t(W_t) \frac{\rho}{2} \coth \frac{W_t - V_t}{2} \right) dt \\
 &\quad + \sqrt{\frac{8}{3}} h''_t(W_t) dB_t.
 \end{aligned}$$

$$\begin{aligned}
 d \log h'_t(W_t) &= \frac{1}{h'_t(W_t)} dh'_t(W_t) + \frac{-1}{2(h'_t(W_t))^2} [dh'_t(W_t)]^2 \\
 &= \left(\frac{1}{2} \frac{(h''_t(W_t))^2}{(h'_t(W_t))^2} + \frac{(h'_t(W_t))^2 - 1}{6} + \frac{h''_t(W_t)}{h'_t(W_t)} \frac{\rho}{2} \coth \frac{W_t - V_t}{2} \right) dt \\
 &\quad + \sqrt{\frac{8}{3}} \frac{h''_t(W_t)}{h'_t(W_t)} dB_t - \frac{1}{2(h'_t(W_t))^2} \frac{8}{3} [h''_t(W_t)]^2 dt \\
 &= \left(-\frac{5}{6} \frac{(h''_t(W_t))^2}{(h'_t(W_t))^2} + \frac{(h'_t(W_t))^2 - 1}{6} + \frac{h''_t(W_t)}{h'_t(W_t)} \frac{\rho}{2} \coth \frac{W_t - V_t}{2} \right) dt \\
 &\quad + \sqrt{\frac{8}{3}} \frac{h''_t(W_t)}{h'_t(W_t)} dB_t
 \end{aligned}$$

$$\begin{aligned}
 dh'_t(V_t) &= \partial_t h'_t(V_t) dt + h''_t(V_t) dV_t \\
 &= \frac{1}{2} \frac{h'_t(V_t)}{(\sinh \frac{X_t}{2})^2} dt - \frac{1}{2} \frac{h'_t(V_t) [h'_t(W_t)]^2}{[\sinh \frac{Y_t}{2}]^2} dt \\
 &= \frac{1}{2} h'_t(V_t) [(\coth \frac{X_t}{2})^2 - 1] dt - \frac{1}{2} h'_t(V_t) [h'_t(W_t)]^2 [(\coth \frac{Y_t}{2})^2 - 1] dt
 \end{aligned}$$

$$d \log h'_t(V_t) = \frac{dh'_t(V_t)}{h'_t(V_t)} = \frac{1}{2} [(\coth \frac{X_t}{2})^2 - 1] dt - \frac{1}{2} [h'_t(W_t)]^2 [(\coth \frac{Y_t}{2})^2 - 1] dt$$

$$d \log S(A_t) = d[a(t) + S(A) - t] = ([h'_t(W_t)]^2 - 1) dt.$$

Using above lemma we can construct a "one-sided" restriction measure, we state it as a lemma as follows :

Lemma 81. *Suppose that γ is the dipolar SLE($\frac{8}{3}; \rho$) curve with force point 0^+ (respectively 0^-). Then for any $A \in \mathcal{A}_s^*$ such that $A \cap (0, \infty) = \emptyset$ (respectively $A \cap (-\infty, 0) = \emptyset$),*

$$\mathbf{P}[\gamma \cap A = \emptyset] = \Phi'_A(0)^\beta \exp\{-\alpha S(A)\},$$

where $\alpha = \alpha(\rho)$ is the same as Lemma 79 and

$$\beta = \beta(\rho) = \frac{5}{8} + \lambda + \frac{3}{8}\rho = \frac{1}{32}(\rho + 2)(3\rho + 10).$$

Proof. Use the same notation as Lemma 79. By the same method as [9], we can see that $0 < h'_t(W_t) \leq 1$ and $h'_t(V_t), Z_t$ are uniformly bounded, hence M_t is a martingale. In fact we can regard $h'_t(W_t)$ as the probability that a Brownian bridge in the strip \mathcal{S} from W_t avoids $g_t(A)$.

So if $\tau_A < \infty$, $h'_t(W_t) \rightarrow 0$ as $t \rightarrow \tau_A$, and therefore $M_t \rightarrow 0$, as $t \rightarrow \tau_A$.

If $\tau_A = \infty$, as $t \rightarrow \infty$, $h'_t(W_t) \rightarrow 1$. Since $V_t \geq W_t$, the brownian Bridge of course will avoid $g_t(A)$ if the Brownian bridge from W_t avoids $g_t(A)$ (here we use the fact that $A \cap (0, \infty) = \emptyset$), hence $h'_t(V_t) \rightarrow 1$ as $t \rightarrow \infty$. On the other hand, if $\gamma \cap A = \emptyset$, $h_t(z)$ tends to the identity map as $t \rightarrow \infty$, hence $S(A_t) \rightarrow 0$ as $t \rightarrow \infty$. By comparing with the Bessel process, we can see that $Z_t \rightarrow 1$ as $t \rightarrow \infty$. Thus, almost surely ,

$$\lim_{t \rightarrow \tau_A} M_t = 1_{\{\gamma \cap A = \emptyset\}}.$$

By the optional stopping theorem we have

$$\mathbf{P}[\gamma \cap A = \emptyset] = \mathbf{E}[M_{\tau_A}] = M_0 = \Phi'_A(0)^\beta \exp\{-\alpha S(A)\}.$$

The proof of the case with 0^- as a force point is the same. □

Remark 82. We call probability measures that satisfies the conditions in Lemma 81 the **one-sided dipolar conformal restriction measure**. In fact we can also get the one-sided restriction measure by adding poisson cloud to SLE($\kappa; \rho$) process for $\kappa \in [0, \frac{8}{3}]$. Using the same notation as lemma 79, we only replace the SLE($\frac{8}{3}, \rho$) in Proposition 78 by a SLE($\kappa; \rho$) process. Define

$$a(\kappa, \rho) = \frac{6 - \kappa}{2\kappa}, \quad b(\kappa, \rho) = \frac{\rho}{4\kappa}(\rho + 4 - \kappa), \quad c(\kappa, \rho) = \frac{\rho}{\kappa}.$$

$$\lambda(\kappa) = \frac{(8 - 3\kappa)(6 - \kappa)}{2\kappa}, \quad \alpha(\kappa, \rho) = \frac{(6 - \kappa)(\kappa - 2) + \rho(\rho + 4)}{8\kappa}.$$

Lemma 83. *Take notations above,*

$$M_t = 1_{\{t < \tau_A\}} (h'_t(W_t))^a (h'_t(V_t))^b \exp\{-\alpha S(A_t)\} Z_t^c \exp\left\{\lambda \int_0^t \tilde{S}h_s(W_s) ds\right\}$$

is a local martingale.

The proof of this lemma is just by Ito's calculus. Using the same method as Proposition 78, we can add Brownian bubbles to this $SLE(\kappa; \rho)$ with force point 0^+ (0^-) to get the one-sided restriction measure with parameters $(a(\kappa, \rho) + b(\kappa, \rho) + c(\kappa, \rho), \alpha(\kappa, \rho))$ for $\kappa \leq \frac{8}{3}$.

Now we are ready to construct the dipolar conformal restriction measure from one-sided measure.

Proposition 84. *For $\beta > \frac{5}{8}$, let $\rho = \frac{2}{3}(\sqrt{24\beta + 1} - 1) - 2 > 0$. Let γ^R be the dipolar $SLE(\frac{8}{3}, \rho)$ curve with force point 0^- . Denote by X the terminal point of γ^R on \mathbb{R}_π . Given γ^R , let γ^L be an independent chordal $SLE(\frac{8}{3}, \rho - 2)$ curve with force point 0^+ from 0 to X in the left connected component of $\mathcal{S} \setminus \gamma^R$. Define K as the closure of union of the domains between γ^R and γ^L . Then the law of K is the dipolar conformal restriction measure $\mathbf{P}(\alpha, \beta)$, where α is the same as Lemma 79, i.e.*

$$\alpha = \alpha(\beta) = \frac{5}{48} + \frac{3}{64}\rho(\rho + 4) = \frac{1}{48}((\sqrt{24\beta + 1} - 1)^2 - 4).$$

Proof. We only need to check that

$$\mathbf{P}[K \cap A = \emptyset] = \Phi'_A(0)^\beta \exp\{-\alpha S(A)\}.$$

Since γ^R is the dipolar $SLE(\frac{8}{3}, \rho)$ curve with force point 0^- , it satisfies the one-sided restriction property by Lemma 81, we know that this is true for A such that $A \cap (-\infty, 0) = \emptyset$. Notice that any hull in \mathcal{A}_s^* can be generated by two hulls one of which does not intersect with the positive axis and one of which does not intersect with the negative axis. So we only need to show that this proposition hold for any $A \in \mathcal{A}_s^*$ such that $A \cap (0, \infty) = \emptyset$.

With the same notations as Lemma 79. Since $\rho > 0$, M_t is a martingale by the same analysis as Lemma 81. From the proof of lemma 81, we notice that when $\tau_A < \infty$, $M_t \rightarrow 0$ as $t \rightarrow \tau_A$. When $\tau_A = \infty$, as $t \rightarrow \infty$, $h'_t(W_t) \rightarrow 1$, $S(A_t) \rightarrow 0$ and $Z_t \rightarrow 1$. But the situation is different with respect to $h'_t(V_t)$. By one-sided property of the chordal $SLE(\frac{8}{3}, \rho)$ process, we have

$$h'_t(V_t)^\lambda \rightarrow \mathbf{P}[\gamma^L \cap A = \emptyset | \gamma^R], \quad \text{as } t \rightarrow \infty.$$

Thus by optional stopping theorem,

$$\mathbf{P}[K \cap A = \emptyset] = \mathbf{E}[1_{\{\tau_A = \infty\}} \mathbf{E}[\gamma^L \cap A = \emptyset | \gamma^R]] = \mathbf{E}[M_{\tau_A}] = M_0.$$

□

Remark 85. In fact, our construction from $\text{SLE}(\frac{8}{3}, \rho)$ have an pre-request : we should make sure that dipolar $\text{SLE}(\frac{8}{3}, \rho)$ intersects with \mathbb{R}_π . According to [17] and the equivalent relations between dipolar SLE and chordal SLE(see [22]), we can see that only if $\rho \in (-2, 2)$, the dipolar $\text{SLE}(\frac{8}{3}, \rho)$ can intersect with \mathbb{R}_π . So we should add $\rho \in (0, 2)$ in Proposition 84. Now $\beta \in (\frac{5}{8}, 2)$. Therefore $\beta \in (\frac{5}{8}, 2)$ we have constructed $\mathbf{P}(\alpha(\beta), \beta)$ for $\beta \in (\frac{5}{8}, 2)$ and here $\alpha(\beta) = \frac{1}{48}((\sqrt{24\beta + 1} - 1)^2 - 4)$.

Remark 86. So far, we can not give the sufficient conditions that (α, β) should satisfy for making sure the conformal restriction measure exists like [9] and [23]. And this is one of the continuing work of the author.

Chapitre 4

On the Brownian Loop Measure

Using SLE as a tool, many problems relating to the properties of the lattice models have been solved, such as the arm exponents for these models. There are also some variants of SLE (conformal loop ensemble, Brownian loop measure, Brownian bubble measure) that describe the scaling limit of the random loops in these models. Therefore it is natural to use SLE to get properties of these loop measures. One of these applications is to use $\text{SLE}(\frac{8}{3})$ to study the properties of the Brownian bubble measure and Brownian loop measure. In fact, by rescaling and letting the two endpoints tend to one common point, one can get the Brownian bubble measure (differ by a constant).

Recently Beliaev and Viklund [4] got a formula for the probability that two given points lie to the left of the $\text{SLE}(\frac{8}{3})$ curve and used it to study some connectivity functions for $\text{SLE}(\frac{8}{3})$ bubbles and reconstructed the chordal restriction measure introduced by Lawler, Werner and Schramm [9]. In this chapter, we will follow their work to use the $\text{SLE}(\frac{8}{3})$ bubble to derive the formula for the total mass of the Brownian loop that disconnects two given points from the boundary. This formula was predicted by Cardy and Gamsa [7], here the formula we get just differ by a constant from theirs.

In the following sections, we will give a brief introduction to the topics that will be used in this paper, which include the Brownian bubble measure, Brownian loop measure, $\text{SLE}(\kappa)$ bubble measure and the relation between these measures. We first state our main theorem of this chapter as follows.

Theorem 87. *Denote by $\mu_{\mathbb{H}}^{\text{loop}}$ the Brownian loop measure on the upper half plane and γ is a sample of the Brownian loop. Given two points $z = x + iy, w = u + iv \in \mathbb{H}$, let $E(z, w)$ denote the event that γ disconnects both z and w from the boundary of \mathbb{H} . Then we have*

$$\mu_{\mathbb{H}}^{\text{loop}}[E(z, w)] = -\frac{\pi}{5\sqrt{3}} - \frac{1}{10}\eta {}_3F_2\left(1, \frac{4}{3}, 1; \frac{5}{3}, 2; \eta\right) - \frac{1}{10}\log(\eta(\eta - 1)) \quad (4.0.1)$$

$$+ \frac{\Gamma(\frac{2}{3})^2}{5\Gamma(\frac{4}{3})}(\eta(\eta - 1))^{\frac{1}{3}} {}_2F_1\left(1, \frac{2}{3}; \frac{4}{3}, \eta\right). \quad (4.0.2)$$

where

$$\eta = \eta(z, w) = -\frac{(x-u)^2 + (y-v)^2}{4yv}, \quad (4.0.3)$$

and ${}_3F_2, {}_2F_1$ are the hypergeometric functions.

(4.0.1) was first given by Cardy using conformal field theory which assumes that $O(n)$ model has the scaling limit. In fact (4.0.1) has a nicer form :

$$\mu^{\text{loop}}[E(z, w)] = -\frac{1}{10}[\log \sigma + (1 - \sigma) {}_3F_2(1, \frac{4}{3}, 1; \frac{5}{3}, 2; 1 - \sigma)], \quad (4.0.4)$$

where

$$\sigma = \sigma(z, w) = \frac{|z-w|^2}{|z-\bar{w}|^2} = \frac{(x-u)^2 + (y-v)^2}{(x-u)^2 + (y+v)^2}, \quad (4.0.5)$$

and ${}_3F_2$ is the hypergeometric function.

Remark 88. By the conformal invariance of Brownian loop measure (see [15]), for any simply connected domain $D \subset \mathbb{C}$ with $z, w \in D$, we can get the total mass of the Brownian loop in D that disconnect both z and w from ∂D by the conformal map from D to \mathbb{H} . In particular, if $D = \mathbb{D}$, we choose the conformal map $\phi(z) = i\frac{1+z}{1-z}$ from \mathbb{D} onto \mathbb{H} . Then the total mass of the Brownian loop measure in \mathbb{D} that disconnects $z, w \in \mathbb{D}$ from $\partial \mathbb{D}$ is

$$-\frac{1}{10}[\log \tilde{\sigma} + (1 - \tilde{\sigma}) {}_3F_2(1, \frac{4}{3}, 1; \frac{5}{3}, 2; 1 - \tilde{\sigma})],$$

where $\tilde{\sigma} = \tilde{\sigma}(z, w) = \frac{|z-w|^2}{|1-z\bar{w}|^2}$.

4.1 Brownian loop measure and bubble measure

In this section, we will introduce several measures on the space of continuous curves in the plane. To keep the present chapter short, we will not provide the detailed discussions but instead refer the reader to the fifth chapter of Lawler's book [10] and [15] or the appendix of the thesis.

Let $\mu(z, \cdot; t)$ be the law of a complex Brownian motion ($B_s : 0 \leq s \leq t$) starting from z . And $\mu(z, \cdot; t)$ can be written as

$$\mu(z, \cdot; t) = \int_{\mathbb{C}} \mu(z, w; t) dw$$

where the above integral can be regarded as the integral of functions which take values in the space of measures. Using the density function of the complex Brownian motion, we can see that the total mass of $\mu(z, w; t)$ is $\frac{1}{2\pi t} \exp\{-\frac{1}{2t}|z-w|^2\}$.

Let $\mu(z, w)$ be the measure defined by $\mu(z, w) = \int_0^\infty \mu(z, w; t)$. This is a σ -finite infinite measure. If $D \subset \mathbb{C}$ is a simply connected domain with nice boundary and $z, w \in D$, we can define $\mu_D(z, w)$ be the restriction of $\mu(z, w)$ on the space of curves

that lie inside D . If $z \neq w$, the total measure of $\mu_D(z, w)$ is $\pi G_D(z, w)$, where $G_D(z, w)$ is the Green function on D .

If D is a simply connected domain with nice boundary, let B be a complex Brownian motion starting from $z \in D$ and τ_D the exit time. Denote $\mu_D(z, \partial D)$ the law of $(B_t : 0 \leq t \leq \tau_D)$, we can write

$$\mu_D(z, \partial D) = \int_{\partial D} \mu_D(z, w) dw.$$

Here we can regard $\mu_D(z, w)$ as a measure on the space of curves in D from z to $w \in \partial D$, and the total mass of $\mu_D(z, w)$ is the the poisson kernel $H_D(z, w)$. For $z \in D, w \in \partial D$, $\mu_D(z, w)$ can also be equivalently defined by the limits

$$\mu_D(z, w) = \lim_{\epsilon \rightarrow 0} \frac{1}{2\epsilon} \mu_D(z, w + \epsilon \mathbf{n}_w),$$

where \mathbf{n}_w is the inner normal at w .

And similarly for $z, w \in \partial D$, we can also define

$$\mu_D(z, w) = \lim_{\epsilon \rightarrow 0} \frac{1}{2\epsilon^2} \mu_D(z + \epsilon \mathbf{n}_z, w + \epsilon \mathbf{n}_w)$$

It can be showed that above limits exists in sense of Prohorov convergence(see Chapter 5 of [10]).

Given $z \in \partial D$, the **Brownian bubble measure** $\mu_D^{\text{bub}}(z)$ is defined as the limit

$$\mu_D^{\text{bub}}(z) := \lim_{w \in \partial D, w \rightarrow z} \pi \mu_D(z, w).$$

The **Brownian loop measure** is defined as following :

$$\mu_{\mathbb{C}}^{\text{loop}} := \int_{\mathbb{C}} \frac{1}{t_\gamma} \mu(z, z) dz = \int_{\mathbb{C}} \int_0^\infty \frac{1}{t_\gamma} \mu(z, z; t) dt dz.$$

Since $\mu(z, z)$ is a measure defined on loops with z as a marked point(called a root), the Brownian loop measure should be understood as the above integral of measures by forgetting the root. For any domain D , let μ_D^{loop} be the restriction of the Brownian loop measure on the space of loops inside D .

For any $a \in \mathbb{R}$, define $\mathbb{H}_a := \{x + iy \in \mathbb{C} : y > a\}$, according to the lowest point of the Brownian loop, the Brownian loop can be decomposed into the following integral of Brownian bubbles(see [15]) :

$$\mu_{\mathbb{C}}^{\text{loop}} = \frac{1}{\pi} \int_{\mathbb{C}} \mu_{\mathbb{H}_y}^{\text{bub}}(x + iy) dx dy. \quad (4.1.1)$$

(4.1.1) will be very important in our computation.

4.2 SLE bubble measure

In this section we will define the SLE bubble measure and give the relation between $\text{SLE}(\frac{8}{3})$ bubble and Brownian bubble measure.

Suppose $\kappa \in (0, 4]$, $\epsilon > 0$ and γ^ϵ is the $\text{SLE}(\kappa)$ curve from 0 to ϵ in the upper half plane. Let μ^ϵ denote the law of γ^ϵ .

Lemma 89. *The limit of the following limit exists :*

$$\mu_{\text{SLE}(\kappa)}^{\text{bub}}(0) = \lim_{\epsilon \rightarrow 0} \epsilon^{1-\frac{8}{\kappa}} \mu^\epsilon. \quad (4.2.1)$$

We call $\mu_{\text{SLE}(\kappa)}^{\text{bub}}(0)$ the $\text{SLE}(\kappa)$ -*bubble measure*.

Proof. We only need to show that the limit restricted to some generated algebras that consist of finite mass exists. Here we choose the measurable sets $\{\gamma : \gamma \text{ disconnects } z \text{ from } \infty\}$ for fixed $z \in \mathbb{H}$. By the definition of the $\text{SLE}(\kappa)$ from 0 to ϵ , we choose the auto-conformal map $F_\epsilon(z) = \frac{\epsilon z}{z+1}$ that sends ∞ to ϵ and fixes 0. We have

$$\mathbf{P}[\gamma \text{ disconnects } z \text{ from } \infty] = p(F_\epsilon^{-1}(z)),$$

where $p(z)$ is the probability that a point z lies to the right side of a chordal $\text{SLE}(\kappa)$ from 0 to ∞ in \mathbb{H} , which is obtained in (2.7.2).

Therefore

$$\lim_{\epsilon \rightarrow 0} \epsilon^{1-\frac{8}{\kappa}} p(F_\epsilon^{-1}(z)) = \frac{\Gamma(\frac{4}{\kappa})}{\sqrt{\pi} \Gamma(\frac{8-\kappa}{2\kappa})(\frac{8}{\kappa}-1)} \left(\frac{x^2+y^2}{y}\right)^{1-\frac{8}{\kappa}} \quad (4.2.2)$$

So for fix $z \in \mathbb{H}$, if we denote $\mu^\epsilon(z)$ the restriction of μ^ϵ restricted to the curves that disconnect z from ∞ , then by the above equation, we know that the limit

$$\mu_{\text{SLE}(\kappa)}^{\text{bub}}(0, z) := \lim_{\epsilon \rightarrow 0} \epsilon^{1-\frac{8}{\kappa}} \mu^\epsilon(z)$$

exists and therefore we can define $\mu_{\text{SLE}(\kappa)}^{\text{bub}}(0)$ as the limit of $\mu_{\text{SLE}(\kappa)}^{\text{bub}}(0, z)$ as z tends to zero. \square

If $\kappa = \frac{8}{3}$, from (4.2.2), we get that the total mass of the $\text{SLE}(\frac{8}{3})$ -bubble that disconnects a given point $z = x+iy \in \mathbb{H}$ is $\frac{1}{4}(\frac{y}{x^2+y^2})^2 = \frac{1}{4}(\text{Im} \frac{1}{z})^2$ which corresponding to the part (a) of proposition 3.1 in [4]. In fact, [4] also gives the measure of the $\text{SLE}(\frac{8}{3})$ -bubble that disconnects two points $z, w \in \mathbb{H}$ from ∞ which we will state as the following lemma.

Lemma 90 (see [4]). *Let $E(z, w)$ be the event that two points $z, w \in \mathbb{H}$ are disconnected from ∞ by a $\text{SLE}(\frac{8}{3})$ curve from 0 to ϵ , then*

$$\mu^\epsilon[E(z, w)] = \frac{1}{4} \text{Im} \left(\frac{1}{z}\right) \text{Im} \left(\frac{1}{w}\right) G(\sigma(z, w)) \epsilon^2 + O(\epsilon^3). \quad (4.2.3)$$

where σ is defined as (4.0.5) and

$$G(t) = 1 - t {}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; 1 - t\right). \quad (4.2.4)$$

Here ${}_2F_1$ is the hypergeometric function.

Notice that when $\kappa = \frac{8}{3}$, it holds that $1 - \frac{8}{\kappa} = -2$. so we have

$$\mu_{\text{SLE}}^{\text{bub}}(0)[E(z, w)] = \frac{1}{4} \text{Im}\left(\frac{1}{z}\right) \text{Im}\left(\frac{1}{w}\right) = \frac{1}{4} \frac{yv}{(x^2 + y^2)(u^2 + v^2)} G(\sigma(z, w)). \quad (4.2.5)$$

SLE($\frac{8}{3}$)-bubble measure is very closely related to Brownian bubble, in fact they only differ by a constant.

Lemma 91.

$$\mu_{\mathbb{H}}^{\text{bub}}(0) = \frac{8}{5} \mu_{\text{SLE}(\kappa)}^{\text{bub}}(0).$$

Proof. By the construction of the Brownian bubble measure at 0 (see the Chapter 5 of Lawler's book [10]), it is the limit of the unique measure on loops in \mathbb{H} rooted at 0 such that the measure that the sample intersect $|z| = r$ is $\frac{1}{r^2}$ for any $r > 0$. So we only need to show that the total mass of the SLE($\frac{8}{3}$)-bubble sample intersecting $|z| = r$ is $\frac{5}{8r^2}$. Define $F_\epsilon(z) = \frac{z}{\epsilon - z}$, the image of the circle $|z| = r$ under F_ϵ is a circle with center $c_0 = -\frac{r^2}{r^2 - \epsilon^2}$ and radius $\rho = \frac{\epsilon r}{r^2 - \epsilon^2}$. Define the conformal map $\phi_\epsilon(z) = z - c_0 + \frac{\rho^2}{z - c_0}$ which maps $\mathbb{H} \setminus B(c_0, \rho)$ onto \mathbb{H} with the derivative at ∞ equaling to 1. By the conformal restriction property of SLE($\frac{8}{3}$), we have

$$\mu^\epsilon[\gamma \cap |z| = r = \emptyset] = \mu^\infty[\gamma \cap B(c_0, \rho) = \emptyset] = \phi'_\epsilon(0)^{\frac{5}{8}}.$$

Therefore we can check that

$$\mu_{\text{SLE}(\kappa)}^{\text{bub}}(0)[\gamma \cap |z| = r \neq \emptyset] = \lim_{\epsilon \rightarrow 0} \frac{1}{\epsilon^2} (1 - \phi'_\epsilon(0)^{\frac{5}{8}}) = \frac{5}{8r^2}.$$

□

4.3 Proof of the nicer form

Given two points $z_0 = x_0 + iy_0$ and $w_0 = u_0 + iv_0 \in \mathbb{H}$. By the symmetric property of the the Brownian loop measure, we can assume $y_0 \leq v_0$, $u_0 \geq x_0$ without loss of generality. By (4.1.1),

$$\begin{aligned} \mu_{\mathbb{H}}^{\text{loop}}[E(z_0, w_0)] &= \frac{1}{\pi} \int_{\mathbb{H}} \mu_{\mathbb{H}_y}^{\text{bub}}(x + iy)[E(z_0, w_0)] dx dy \\ &= \frac{1}{\pi} \int_0^{y_0} \int_{\mathbb{R}} \mu_{\mathbb{H}_y}^{\text{bub}}(x + iy)[E(z_0, w_0)] dx dy. \end{aligned}$$

4.3. PROOF OF THE NICER FORM

Here $E(z_0, w_0)$ denotes the event that the Brownian loop sample in \mathbb{H} disconnects both z_0 and w_0 from the boundary of \mathbb{H} .

By the translation invariance of the Brownian bubble measure, we have

$$\mu_{\mathbb{H}_y}^{\text{bub}}(x + iy)[E(z_0, w_0)] = \mu_{\mathbb{H}}^{\text{bub}}(0)[E(z_0 - z, w_0 - z)].$$

By Lemma 91 we have $\mu_{\mathbb{H}}^{\text{bub}}(0) = \frac{8}{5}\mu_{\text{SLE}(\kappa)}^{\text{bub}}(0)$. Therefore by (4.2.5),

$$\begin{aligned} \mu_{\mathbb{H}}^{\text{loop}}[E(z_0, w_0)] &= \frac{8}{5\pi} \int_0^{y_0} \int_{\mathbb{R}} \mu_{\text{SLE}(\kappa)}^{\text{bub}}(0)[E(z_0 - x - iy, w_0 - x - iy)] dx dy \\ &= \frac{8}{5\pi} \int_0^{y_0} \int_{\mathbb{R}} \frac{1}{4} \text{Im} \left(\frac{1}{z_0 - x - iy} \right) \text{Im} \left(\frac{1}{w_0 - x - iy} \right) \\ &\quad G(\sigma(z_0 - x - iy, w_0 - x - iy)) dx dy. \end{aligned} \quad (4.3.1)$$

So in order to prove the theorem, we only need to compute above integral. Define two functions as follows :

$$f(x, y) := \frac{(y_0 - y)(v_0 - y)}{[(x_0 - x)^2 + (y_0 - y)^2] \times [(u_0 - x)^2 + (v_0 - y)^2]}. \quad (4.3.2)$$

$$\begin{aligned} g(y) &:= \frac{(x_0 - u_0)^2 + (y_0 - v_0)^2}{(x_0 - u_0)^2 + (y_0 + v_0 - 2y)^2} \\ &\quad {}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; \frac{4(y_0 - y)(v_0 - y)}{(x_0 - u_0)^2 + (y_0 + v_0 - 2y)^2}\right). \end{aligned} \quad (4.3.3)$$

Lemma 92. *Take the notations as above, for fixed $y > 0$,*

$$\int_{\mathbb{R}} f(x, y) dx = \frac{2(y_0 - y) + v_0 - y_0}{(x_0 - u_0)^2 + (2(y_0 - y) + v_0 - y_0)^2} \pi. \quad (4.3.4)$$

Proof. For fixed $y > 0$, denote

$$a = y_0 - y, \quad b = v_0 - y, \quad c = u_0 - x_0, \quad d = v_0 - y_0.$$

Then we have

$$f(x, y) = \frac{ab}{[(x_0 - x)^2 + a^2][(u_0 - x)^2 + b^2]}.$$

Doing the standard calculus as follows.

$$\begin{aligned}
 \int_{\mathbb{R}} f(x, y) dx &= \int_{\mathbb{R}} \frac{ab}{[(x_0 - x)^2 + a^2][(u_0 - x)^2 + b^2]} dx \\
 &= ab \int_{\mathbb{R}} \frac{1}{[x^2 + a^2][(x + c)^2 + b^2]} dx \\
 &= \frac{ab\pi}{ab(a^4 - 2a^2(b^2 - c^2) + (b^2 + c^2)^2)} \left(b(b^2 + c^2 - a^2) \arctan\left[\frac{x}{a}\right] \right. \\
 &\quad \left. + a[(a^2 + c^2 - b^2) \arctan\left[\frac{c + x}{b}\right] + bc \log \frac{b^2 + (c + x)^2}{a^2 + x^2}] \right) \Big|_{-\infty}^{\infty} \\
 &= \pi \frac{b(b^2 + c^2 - a^2) + a(a^2 + c^2 - b^2)}{a^4 - 2a^2(b^2 - c^2) + (b^2 + c^2)^2}.
 \end{aligned}$$

Replace b by $a + d$, we can get

$$\int_{\mathbb{R}} f(x, y) dx = \frac{(2a + d)\pi}{c^2 + (2a + d)^2}.$$

And this is what we want. □

By (4.3.1), we have

$$\begin{aligned}
 \mu_{\mathbb{H}}^{\text{loop}}[E(z_0, w_0)] &= \frac{8}{5\pi} \int_0^{y_0} \int_{\mathbb{R}} \frac{1}{4} f(x, y) (1 - g(y)) dx dy \\
 &= \frac{8}{5\pi} \int_0^{y_0} \frac{\pi}{4} \frac{2a + d}{c^2 + (2a + d)^2} [1 - g(y)] dy = \frac{2}{5} (A - B),
 \end{aligned} \tag{4.3.5}$$

where

$$A = A(z_0, w_0) = \int_0^{y_0} \frac{2(y_0 - y) + v_0 - y_0}{(x_0 - u_0)^2 + (2(y_0 - y) + v_0 - y_0)^2} dy, \tag{4.3.6}$$

and

$$B = B(z_0, w_0) = \int_0^{y_0} \frac{2(y_0 - y) + v_0 - y_0}{(x_0 - u_0)^2 + (2(y_0 - y) + v_0 - y_0)^2} g(y) dy. \tag{4.3.7}$$

Lemma 93.

$$A = \frac{1}{4} \log \frac{1}{\sigma},$$

where σ is defined as (4.0.5).

Proof. By (4.3.6) we have

$$\begin{aligned} A &= \int_0^{y_0} \frac{2(y_0 - y) + d}{c^2 + (2(y_0 - y) + d)^2} dy = \int_0^{y_0} \frac{2y + d}{c^2 + (2y + d)^2} dy \\ &= \frac{1}{2} \int_{d/c}^{\frac{2y_0+d}{c}} \frac{y}{1 + y^2} dy = \frac{1}{4} \log \frac{c^2 + (2y_0 + d)^2}{c^2 + d^2}. \end{aligned}$$

In the second equation we used the variable change $y \rightarrow y_0 - y$ and in the last equation we used the variable change $y \rightarrow \frac{2y+d}{c}$. Notice that

$$\frac{c^2 + (2y_0 + d)^2}{c^2 + d^2} = \frac{(u_0 - x_0)^2 + (y_0 + v_0)^2}{(u_0 - x_0)^2 + (v_0 - y_0)^2} = \frac{1}{\sigma}.$$

□

Lemma 94.

$$B = \frac{1}{4}(1 - \sigma) {}_3F_2\left(1, \frac{4}{3}, 1; \frac{5}{3}, 2; 1 - \sigma\right),$$

where σ is defined as (4.0.5).

Proof. By (4.3.7) and the definition of $g(y)$, we have

$$\begin{aligned} B &= \int_0^{y_0} \frac{2(y_0 - y) + d}{c^2 + (2(y_0 - y) + d)^2} \cdot \frac{c^2 + d^2}{c^2 + (2(y_0 - y) + d)^2} \\ &\quad {}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; \frac{4(y_0 - y)((y_0 - y) + d)}{c^2 + (2(y_0 - y) + d)^2}\right) dy \\ &= \int_0^{y_0} \frac{2y + d}{c^2 + (2y + d)^2} \cdot \frac{c^2 + d^2}{c^2 + (2y + d)^2} \cdot {}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; \frac{4y(y + d)}{c^2 + (2y + d)^2}\right) dy \\ &= \int_{\frac{d}{c}}^{\frac{2y_0+d}{c}} \frac{cy}{c^2 + c^2y^2} \cdot \frac{c^2 + d^2}{c^2 + c^2y^2} \cdot {}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; \frac{c^2y^2 - d^2}{c^2 + c^2y^2}\right) \cdot \frac{c}{2} dy \\ &= \frac{1}{2} \frac{c^2 + d^2}{c^2} \int_{\frac{d}{c}}^{\frac{2y_0+d}{c}} \frac{y}{(1 + y^2)^2} \cdot {}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; \frac{c^2y^2 - d^2}{c^2 + c^2y^2}\right) dy \\ &= \frac{1}{4} \int_0^{\frac{4y_0(y_0+d)}{c^2 + (2y_0+d)^2}} {}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; y\right) dy \\ &= \frac{1}{4} \frac{4y_0(y_0 + d)}{c^2 + (2y_0 + d)^2} \cdot {}_3F_2\left(1, \frac{4}{3}, 1; \frac{5}{3}, 2; \frac{4y_0(y_0 + d)}{c^2 + (2y_0 + d)^2}\right) \\ &= \frac{1}{4}(1 - \sigma) {}_3F_2\left(1, \frac{4}{3}, 1; \frac{5}{3}, 2; 1 - \sigma\right). \end{aligned}$$

Here the second equation used the variable change $y \rightarrow y_0 - y$, the third equation used the variable change $y \rightarrow \frac{2y+d}{c}$, the fifth equation used the variable change $\frac{c^2y^2 - d^2}{c^2 + c^2y^2} \rightarrow y$ and the sixth equation used the equation about hypergeometric functions below :

$$\int_0^x {}_2F_1(a, b; c; y) dy = x {}_3F_2(a, b, 1; c, 2, x).$$

□

Now by (4.3.5) and Lemma 93 and Lemma 94 we get (4.0.4).

4.4 Proof of the Gamsа formula

In this section we will prove the the equivalence of formula (4.0.1) and (4.0.4). First we will recall some identities of the hypergeometric functions which will be used in our proof. We will assume that our hypergeometric functions are all well defined. And they satisfies the following identities (see Chapter 8 of [1]) :

$${}_2F_1(a, b; c; x) = (1-x)^{-b} {}_2F_1(c-a, b; c; \frac{x}{x-1}). \quad (4.4.1)$$

$$\begin{aligned} {}_2F_1(a, b; c; x) &= \frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)} {}_2F_1(a, b; a+b+1-c; 1-x) \\ &+ \frac{\Gamma(c)\Gamma(a+b-c)}{\Gamma(a)\Gamma(b)} (1-x)^{c-a-b} {}_2F_1(c-a, c-b; c+1-a-b; 1-x). \end{aligned} \quad (4.4.2)$$

$${}_2F_1(a, b; c; x) = (1-x)^{c-a-b} {}_2F_1(c-a, c-b; c; x). \quad (4.4.3)$$

Notice that $\eta = \frac{\sigma}{\sigma-1}$ and $\sigma \in (0, 1)$. We define a function ϕ on $[0, 1]$ as following.

$$\begin{aligned} \phi(t) &= \frac{2\pi}{\sqrt{3}} + \frac{t}{t-1} {}_3F_2(1, \frac{4}{3}, 1; \frac{5}{3}, 2; \frac{t}{t-1}) - (1-t) {}_3F_2(1, \frac{4}{3}, 1; \frac{5}{3}, 2; 1-t) \\ &- 2 \log(1-t) - 2 \frac{\Gamma(\frac{2}{3})^2}{\Gamma(\frac{4}{3})} \sqrt[3]{\frac{t}{(t-1)^2}} {}_2F_1(1, \frac{2}{3}; \frac{4}{3}; \frac{t}{t-1}). \end{aligned} \quad (4.4.4)$$

To prove that (4.0.1) and (4.0.4) are equivalent, it only needs to show that $\phi(t) \equiv 0$. Notice that $\phi(0) = \frac{2\pi}{\sqrt{3}} - {}_3F_2(1, \frac{4}{3}, 1; \frac{5}{3}, 2; 1) = 0$, it is left to show that $\phi'(t) \equiv 0$. Take the following notations.

$$I(t) := \frac{t}{t-1} {}_3F_2(1, \frac{4}{3}, 1; \frac{5}{3}, 2; \frac{t}{t-1}) - 2 \log(1-t),$$

$$J(t) := -(1-t) {}_3F_2(1, \frac{4}{3}, 1; \frac{5}{3}, 2; 1-t),$$

$$K(t) := -2 \frac{\Gamma(\frac{2}{3})^2}{\Gamma(\frac{4}{3})} \sqrt[3]{\frac{t}{(t-1)^2}} {}_2F_1(1, \frac{2}{3}; \frac{4}{3}; \frac{t}{t-1}).$$

4.4. PROOF OF THE GAMSА FORMULA

Define a function $f(x) = x {}_3F_2(1, \frac{4}{3}, 1; \frac{5}{3}, 2; x)$. It is easy to check that

$$f'(x) = {}_2F_1(1, \frac{4}{3}; \frac{5}{3}; x).$$

So

$$\begin{aligned} \frac{dI(t)}{dt} &= \frac{2}{1-t} + f'\left(\frac{t}{t-1}\right) \frac{-1}{(1-t)^2} = \frac{2}{1-t} - \frac{1}{(1-t)^2} {}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; \frac{t}{t-1}\right) \\ &= \frac{2}{1-t} - \frac{1}{1-t} {}_2F_1\left(1, \frac{1}{3}; \frac{5}{3}; t\right). \end{aligned} \quad (4.4.5)$$

The last equation is due to (4.4.1) by assigning $a = \frac{1}{3}, b = 1, c = \frac{5}{3}$. Similarly we can get that

$$\frac{dJ(t)}{dt} = f'(1-t) = {}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; 1-t\right).$$

Using (4.4.2), let $a = 1, b = \frac{4}{3}, c = \frac{5}{3}$, we have

$${}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; 1-t\right) = -{}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; t\right) + \frac{2}{3} \frac{\Gamma(\frac{2}{3})^2}{\Gamma(\frac{4}{3})} t^{-\frac{2}{3}} {}_2F_1\left(\frac{1}{3}, \frac{2}{3}; \frac{1}{3}; t\right)$$

By letting $a = \frac{1}{3}, b = \frac{2}{3}, c = \frac{1}{3}$ in (4.4.3), the following holds

$${}_2F_1\left(\frac{1}{3}, \frac{2}{3}; \frac{1}{3}; t\right) = (1-t)^{-\frac{2}{3}} {}_2F_1\left(0, -\frac{1}{3}; \frac{1}{3}; x\right) = (1-t)^{-\frac{2}{3}}.$$

Therefore

$$\frac{dJ(t)}{dt} = -{}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; t\right) + \frac{2}{3} \frac{\Gamma(\frac{2}{3})^2}{\Gamma(\frac{4}{3})} (t(1-t))^{-\frac{2}{3}}. \quad (4.4.6)$$

In the last we deal with the derivative of $K(t)$ with respect to t . By letting $a = \frac{1}{3}, b = \frac{2}{3}, c = \frac{4}{3}$ in (4.4.1), we can get

$${}_2F_1\left(1, \frac{2}{3}; \frac{4}{3}; \frac{t}{t-1}\right) = (1-t)^{\frac{2}{3}} {}_2F_1\left(1, \frac{2}{3}; \frac{4}{3}; t\right).$$

Consequently,

$$K(t) = -2 \frac{\Gamma(\frac{2}{3})^2}{\Gamma(\frac{4}{3})} t^{\frac{1}{3}} {}_2F_1\left(1, \frac{2}{3}; \frac{4}{3}; t\right).$$

And

$$\begin{aligned} \frac{dK(t)}{dt} &= -2 \frac{\Gamma(\frac{2}{3})^2}{\Gamma(\frac{4}{3})} \left[\frac{1}{3} t^{-\frac{2}{3}} {}_2F_1\left(1, \frac{2}{3}; \frac{4}{3}; t\right) + t^{\frac{1}{3}} \frac{(1-t)^{-\frac{2}{3}} - {}_2F_1\left(1, \frac{2}{3}; \frac{4}{3}; t\right)}{3t} \right] \\ &= -\frac{2}{3} \frac{\Gamma(\frac{2}{3})^2}{\Gamma(\frac{4}{3})} t^{-\frac{2}{3}} (1-t)^{-\frac{2}{3}}. \end{aligned} \quad (4.4.7)$$

Combining (4.4.5),(4.4.6) and (4.4.7), we have

$$\phi'(t) = \frac{dI(t)}{dt} + \frac{dJ(t)}{dt} + \frac{dK(t)}{t} = \frac{2}{1-t} - \frac{1}{1-t} {}_2F_1\left(1, \frac{1}{3}; \frac{5}{3}; t\right) - {}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; t\right).$$

Lemma 95.

$$2 - {}_2F_1\left(1, \frac{1}{3}; \frac{5}{3}; t\right) - (1-t) {}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; t\right) = 0.$$

Proof. By definition we have

$${}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; t\right) = 1 + \sum_{n=1}^{\infty} \frac{\Gamma(n + \frac{4}{3})\Gamma(\frac{5}{3})}{\Gamma(\frac{4}{3})\Gamma(n + \frac{5}{3})} t^n.$$

Therefore

$$t {}_2F_1\left(1, \frac{4}{3}; \frac{5}{3}; t\right) = \sum_{n=1}^{\infty} \frac{\Gamma(n + \frac{1}{3})\Gamma(\frac{5}{3})}{\Gamma(\frac{4}{3})\Gamma(n + \frac{2}{3})} t^n.$$

Similarly

$${}_2F_1\left(1, \frac{1}{3}; \frac{5}{3}; t\right) = 1 + \sum_{n=1}^{\infty} \frac{\Gamma(n + \frac{1}{3})\Gamma(\frac{5}{3})}{\Gamma(\frac{1}{3})\Gamma(n + \frac{5}{3})} t^n.$$

By using the relation $\Gamma(x+1) = x\Gamma(x)$, we can see that the coefficient of t^n in the sum is

$$\frac{\Gamma(n + \frac{1}{3})\Gamma(\frac{5}{3})}{\Gamma(\frac{4}{3})\Gamma(n + \frac{2}{3})} - \frac{\Gamma(n + \frac{4}{3})\Gamma(\frac{5}{3})}{\Gamma(\frac{4}{3})\Gamma(n + \frac{5}{3})} - \frac{\Gamma(n + \frac{1}{3})\Gamma(\frac{5}{3})}{\Gamma(\frac{1}{3})\Gamma(n + \frac{5}{3})} = 0.$$

□

From Lemma 95, we have $\phi'(t) \equiv 0$, and therefore $\phi \equiv \phi(0) = 0$. This completes the proof of the equivalence between (4.0.1) and (4.0.4).

4.5 The other cases

Given $z, w \in \mathbb{H}$, and γ the sample of the Brownian loop in the upper half plane. According to the property of Brownian path, almost surely, $z, w \notin \gamma$. So except the case that γ disconnects both z and w from the boundary, there are three other cases :

- (1) γ disconnects z from the boundary but does not disconnect w from the boundary ;
- (2) γ disconnects w from the boundary but does not disconnect z from the boundary ;
- (3) γ does neither disconnects z from the boundary nor disconnects w from the boundary.

We will show that the total measure of above three cases are infinite. In fact, using the same method as [4], we can show the following lemma.

Lemma 96. *Suppose that γ is the sample of the SLE($\frac{8}{3}$) from 0 to ϵ and denote above three cases by $E_1(z, w)$, $E_2(z, w)$ and $E_3(z, w)$ respectively. Then*

$$\mathbf{P}[E_1(z, w)] = \frac{1}{4}\epsilon^2\left(\left(\operatorname{Im}\frac{1}{z}\right)^2 - \operatorname{Im}\frac{1}{z}\operatorname{Im}\frac{1}{w}G(\sigma)\right) + O(\epsilon^3), \quad (4.5.1)$$

$$\mathbf{P}[E_2(z, w)] = \frac{1}{4}\epsilon^2\left[\left(\operatorname{Im}\frac{1}{w}\right)^2 - \operatorname{Im}\frac{1}{z}\operatorname{Im}\frac{1}{w}G(\sigma)\right] + O(\epsilon^3), \quad (4.5.2)$$

$$\mathbf{P}[E_3(z, w)] = 1 - \frac{1}{4}\epsilon^2\left[\left(\operatorname{Im}\frac{1}{w}\right)^2 + \left(\operatorname{Im}\frac{1}{z}\right)^2 - \operatorname{Im}\frac{1}{z}\operatorname{Im}\frac{1}{w}G(\sigma)\right] + O(\epsilon^3). \quad (4.5.3)$$

The proof of this lemma is the same as in [4]. We only need to prove that for SLE($\frac{8}{3}$) γ from 0 to ∞ , the following holds.

$\mathbf{P}[\gamma \text{ passes the left of } z \text{ and the right of } w]$

$$= \frac{1}{4}\left(1 - \frac{x}{|z|}\right)\left(1 + \frac{u}{|w|}\right)\left(1 - \frac{y}{|z| - x}\frac{v}{|w| + u}G(\sigma)\right).$$

$\mathbf{P}[\gamma \text{ passes the left of } w \text{ and the right of } z]$

$$= \frac{1}{4}\left(1 + \frac{x}{|z|}\right)\left(1 - \frac{u}{|w|}\right)\left(1 - \frac{y}{|z| + x}\frac{v}{|w| - u}G(\sigma)\right).$$

$\mathbf{P}[\gamma \text{ passes the right of both } z \text{ and } w]$

$$= \frac{1}{4}\left(1 - \frac{x}{|z|}\right)\left(1 - \frac{u}{|w|}\right)\left(1 + \frac{y}{|z| - x}\frac{v}{|w| - u}G(\sigma)\right).$$

where $G(\sigma)$ is the same as (4.2.4). Then using the conformal map $F_\epsilon(z) = \frac{\epsilon z}{1+z}$ to convert the SLE($\frac{8}{3}$) from 0 to ∞ into the SLE($\frac{8}{3}$) from 0 to ϵ . Combing above lemma and the definition of the Brownian bubble measure and lemma 91, we can get

$$\mu_{\mathbb{H}}^{\text{bub}}(0)(E_1(z, w)) = \frac{1}{10}\left[\left(\frac{y}{x^2 + y^2}\right)^2 - \frac{y}{x^2 + y^2}\frac{v}{u^2 + v^2}G(\sigma(z, w))\right].$$

$$\mu_{\mathbb{H}}^{\text{bub}}(0)(E_2(z, w)) = \frac{1}{10}\left[\left(\frac{v}{u^2 + v^2}\right)^2 - \frac{y}{x^2 + y^2}\frac{v}{u^2 + v^2}G(\sigma(z, w))\right].$$

$$\mu_{\mathbb{H}}^{\text{bub}}(0)(E_3(z, w)) = \infty.$$

By relation (4.1.1) and calculating the integral on the upper half plane, we can see that the total mass of the Brownian loop measure on these three sets are infinite. In fact, we can see intuitively that these three cases all contain the loops with arbitrary small diameter, while the event $E(z, w)$ in the main theorem exclude these small loops.

Chapitre 5

Integral Means Spectrum of the modified inner Whole plane SLE

In the theory of univalent function, the extremal problems has always been a very important issue. In this chapter we will recall one of the issues in extremal problems—spectrum problem. We will first give some basic definitions of the integral spectrum and the integral means spectrum. And then we will recall some results about the integral means spectrum of the outer whole plane $SLE(\kappa)$ process. In the last we will recall the so-called generalized integral means spectrum and give the integral means spectrum of the inner whole plane Loewner chain driven by some special Lévy process.

5.1 Spectrum problem

Denote by

$$\mathbb{D} := \{z \in \mathbb{C} : |z| < 1\}, \mathbb{D}_+ := \{z \in \bar{\mathcal{C}} : |z| > 1\}.$$

There are two classes \mathcal{S} and Σ of univalent functions which are very important. They are defined as follows :

$$\mathcal{S} := \{\phi(z) = z + a_2z^2 + a_3z^3 + \dots \text{ is univalent on } \mathbb{D}\}, \quad (5.1.1)$$

$$\Sigma := \{\psi(z) = z + \frac{b_1}{z} + \frac{b_2}{z^2} + \dots \text{ is univalent on } \mathbb{D}_+\}, \quad (5.1.2)$$

where "univalent" function we means one-to-one holomorphic function and a_n and b_n are the coefficients of the corresponding Taylor expansion and Laurent expansion.

A natural question is which extremal values a_n and b_n can have among these two classes. First for \mathcal{S} , define the Koebe function as follows :

$$k(z) := \sum_{n=1}^{\infty} nz^n = \frac{z}{(1-z)^2}, \quad (5.1.3)$$

It can be verified that $\phi \in \mathcal{S}$ and $a_n = n$. In fact Bieberbach conjectured in 1916 that among \mathcal{S} , Koebe is the function that makes $|a_n|$ attain the maximal value, i.e. for any $\phi(z) = z + a_2z^2 + a_3z^3 + \dots \in \mathcal{S}$, $|a_n| \leq n$ holds for any n . This conjecture was completely proved by De Branges in 1985 (see [5]). For Σ , no corresponding conclusion has been established so far, even the asymptotic behavior of b_n is open. Another extremal problem about univalent function is the spectrum problem. The spectrum has a close relation with the behavior of harmonic measure. Given $p \in \mathbb{R}$, $\phi \in \Sigma$, define $\beta_\phi(p)$ as follows :

$$\beta_\phi(p) := \limsup_{r \rightarrow 1^+} \frac{\log \int_0^{2\pi} |\phi'(re^{i\theta})|^p d\theta}{|\log |r - 1||}.$$

we call $\beta_\phi(p)$ the **integral means spectrum** of ϕ or the corresponding simply connected domain $\phi(\mathbb{D}_+)$. Define $B(p) := \sup_{\phi \in \Sigma} \beta_\phi(p)$. Call $B(p)$ the **universal integral means spectrum**. About $B(p)$, there is the following conjecture :

$$B(p) = \begin{cases} \frac{p^2}{4} & \text{if } p^2 < 4 \\ |p| - 1 & \text{if } |p| \geq 2. \end{cases}$$

Notice that if $p = 1$, $\int_0^{2\pi} |\phi'(re^{i\theta})| d\theta$ tends to the length of the boundary $|\partial\phi(\Sigma)|$ as $r \rightarrow 1$. Therefore in some sense $\beta_\phi(p)$ reflects the regularity of the boundary of $\phi(\Sigma)$.

For $\phi \in \mathcal{S}$, we can also define the spectrum. Here we use the definition in [6]. Given $p, q \in \mathbb{R}$, $\phi \in \mathcal{S}$. Define $\beta_\phi(p, q)$ as follows :

$$\beta_\phi(p, q) := \limsup_{r \rightarrow 1^+} \frac{\log \int_0^{2\pi} \left| \frac{z}{\phi(z)} \right|^q |\phi'(re^{i\theta})|^p d\theta}{|\log |r - 1||}.$$

Call $\beta_\phi(p, q)$ is the **generalized means integral spectrum** of ϕ or the corresponding $\phi(\mathbb{D})$. Notice that for $\phi \in \Sigma$,

$$\beta_\phi(p) = \beta_\psi(p, 2p), \text{ here } \psi(z) = \frac{1}{\phi(1/z)}.$$

Usually, for a given simply connected domain D , it is very difficult to compute the integral means spectrum since it is difficult to get the exact form of the conformal map from \mathbb{D} onto D . But for some random simply connected domains (the complement of the whole plane SLE(κ) hulls), some tools can be used to compute the **average integral means spectrum** which is defined as follows :

$$\begin{aligned} \beta_\phi(p) &:= \limsup_{r \rightarrow 1^+} \frac{\log \int_0^{2\pi} \mathbf{E}[|\phi'(re^{i\theta})|^p] d\theta}{|\log |r - 1||}. & (5.1.4) \\ \beta_\phi(p, q) &:= \limsup_{r \rightarrow 1^+} \frac{\log \int_0^{2\pi} \mathbf{E}\left[\left|\frac{z}{\phi(z)}\right|^q |\phi'(re^{i\theta})|^p\right] d\theta}{|\log |r - 1||}. \end{aligned}$$

In the following section, for convenience we will use "spectrum" to denote the average integral means spectrum.

For the outer whole plane SLE(κ) ($g_t : t \in \mathbb{R}$) (see the definition 33), $f_t(z) := g_t^{-1}(z)$ is the conformal map from \mathbb{D}_+ onto $\overline{\mathbb{C}} \setminus K_t$ and $f_t(\infty) = \infty, f_t'(\infty) = e^t$. Therefore $e^{-t}f_t(z) \in \Sigma$. So it is natural to consider the spectrum of $e^{-t}f_t(z)$. By the scaling property of whole plane SLE(κ) (see Proposition 36), we only need to consider the spectrum of f_0 . In the seminal paper [3] and the following paper [2], the authors used the method of finding special solution of some partial differential equation to compute the spectrum of outer whole plane SLE(κ). We stated the result as follows :

Theorem 97 (see[2] and [3]). *The spectrum of the whole plane SLE(κ) at $t = 0$ is*

$$\begin{aligned} \beta_{\text{tip}}(t) &= -t - 1 + \frac{1}{4}(4 + \kappa - \sqrt{(4 + \kappa)^2 - 8\kappa t}), & t \leq t_2, \\ \beta_0(t) &= -t + \frac{4 + \kappa}{4\kappa}(4 + \kappa - \sqrt{(4 + \kappa)^2 - 8\kappa t}), & t_2 \leq t \leq t_3, \\ \beta_{\text{lin}}(t) &= t - \frac{(4 + \kappa)^2}{16\kappa} & t_3 \leq t. \end{aligned}$$

where

$$\begin{aligned} t_1 &= -\frac{1}{128}(4 + \kappa)^2(8 + \kappa), \\ t_2 &= -1 - \frac{3\kappa}{8}, \\ t_3 &= \frac{3(4 + \kappa)^2}{32\kappa}. \end{aligned}$$

In [6], the authors analyzed the generalized integral means spectrum of inner whole plane process and give the exact form of the spectrum for some special values (p, q) that are on some parabolas.

5.2 Spectrum of the Loewner process driven by Lévy process

In this section, we will analyze the spectrum of the inner Loewner process driven by Lévy process. Recall (2.3.4), the inner whole Loewner process driven by the real-valued function W_t is defined as the solution of the following ODE :

$$\begin{cases} \partial_t g_t(z) = g_t(z) \frac{g_t(z) + \lambda_t}{g_t(z) - \lambda_t} & \partial_t f_t(z) = z f_t'(z) \frac{\lambda_t + z}{\lambda_t - z} \\ \lim_{t \rightarrow +\infty} e^t g_t(z) = z, \quad \forall z \in \mathbb{C}. & \lim_{t \rightarrow +\infty} f_t(e^{-t}z) = z, \quad \forall z \in \mathbb{D}. \end{cases} \quad (5.2.1)$$

Here $\lambda_t = \exp\{iW_t\}$.

In this section, we will assume that $W_t = L_t$ where L_t is a Lévy process. We want to compute the average integral means spectrum of f_0 , where f_t is defined as

(2.3.4). Recall for Lévy driven Loewner process, we still have Lemma 48 since the proof of Lemma 48 only uses the Markov property of the driven process. Therefore we have

$$\lim_{t \rightarrow +\infty} e^t \tilde{f}_t(z) \stackrel{(\text{law})}{=} f_0(z), \quad (5.2.2)$$

where \tilde{f}_t is defined as follows :

$$\partial_t \tilde{f}_t(z) = \tilde{f}_t(z) \frac{\tilde{f}'_t(z) + \lambda(t)}{\tilde{f}_t(z) - \lambda(t)}, \quad \tilde{f}_0(z) = z, \quad \forall z \in \mathbb{D}, \quad (5.2.3)$$

By the Markov property of Lévy process, we know that for any $s \leq t$:

$$\tilde{f}_t(z) \stackrel{(\text{law})}{=} \lambda(s) \tilde{f}_{t-s}(\tilde{f}_s(z)/\lambda(s)). \quad (5.2.4)$$

Denote by $f := f_0(z)$, according to the definition, we want to compute

$$\mathbb{E}[|f'(z)|^p] = \mathbb{E}[|f'(z)|^{\frac{p}{2}} \overline{f'(z)}^{\frac{p}{2}}],$$

for $p \in \mathbb{R}$. In fact we can study the two-point function for $z_1, z_2 \in \mathbb{D}$,

$$G(z_1, \bar{z}_2) := \mathbb{E}\left[|z_1|^{\frac{q}{2}} \frac{f'(z_1)^{\frac{p}{2}}}{f(z_1)^{\frac{q}{2}}} \overline{|z_2|^{\frac{q}{2}} \frac{f'(z_2)^{\frac{p}{2}}}{f(z_2)^{\frac{q}{2}}}}\right].$$

where $p, q \in \mathbb{C}$.

We define a time-dependent, auxiliary two-point function,

$$\tilde{G}(z_1, \bar{z}_2, t) := \mathbb{E}\left[|z_1|^{\frac{q}{2}} \frac{\tilde{f}'_t(z_1)^{\frac{p}{2}}}{\tilde{f}_t(z_1)^{\frac{q}{2}}} \overline{|z_2|^{\frac{q}{2}} \frac{\tilde{f}'_t(z_2)^{\frac{p}{2}}}{\tilde{f}_t(z_2)^{\frac{q}{2}}}}\right],$$

where \tilde{f}_t is defined as (5.2.3).

This time by (5.2.2), the two point function $G(z_1, \bar{z}_2)$ is the limit

$$\lim_{t \rightarrow +\infty} e^{\text{Re}(p-q)t} \tilde{G}(z_1, \bar{z}_2, t) = G(z_1, \bar{z}_2). \quad (5.2.5)$$

Let us introduce the shorthand notation,

$$X_t(z_1) = \frac{\tilde{f}'_t(z_1)^{\frac{p}{2}}}{\tilde{f}_t(z_1)^{\frac{q}{2}}}, \quad Y_t(z_2) = \frac{\overline{\tilde{f}'_t(z_2)^{\frac{p}{2}}}}{\overline{\tilde{f}_t(z_2)^{\frac{q}{2}}}}.$$

Then $\mathcal{M}_s := \mathbb{E}[X_t(z_1)Y_t(z_2)]$ is a local martingale. In fact by the Markov property of Lévy process, we know that for any $s \leq t$:

$$\tilde{f}_t(z) \stackrel{(\text{law})}{=} \lambda(s) \tilde{f}_{t-s}(\tilde{f}_s(z)/\lambda(s)). \quad (5.2.6)$$

Therefore $\mathcal{M}_s = X_s(z_1)Y_s(z_2)G(z_{1,s}, \overline{z_{2,s}}, t - s)$, $\forall s < t$, where

$$z_{1,s} = \frac{\tilde{f}_s(z_1)}{\lambda_s}, \quad z_{2,s} = \frac{\tilde{f}_s(z_2)}{\lambda_s}.$$

Notice that

$$\begin{aligned} dX_s(z_1) &= X_s(z_1) \left[\frac{p}{2} - \frac{q}{2} - \frac{p}{(1 - z_{1,s})^2} + \frac{q}{1 - z_{1,s}} \right] ds, \\ dY_s(z_2) &= Y_s(z_2) \left[\frac{\bar{p}}{2} - \frac{\bar{q}}{2} - \frac{\bar{p}}{(1 - \overline{z_{2,s}})^2} + \frac{\bar{q}}{1 - \overline{z_{2,s}}} \right] ds, \\ \frac{dz_{1,s}}{ds} &= z_{1,s} \frac{z_{1,s} + 1}{z_{1,s} - 1}, \quad \frac{d\overline{z_{2,s}}}{ds} = \overline{z_{2,s}} \frac{\overline{z_{2,s}} + 1}{\overline{z_{2,s}} - 1}. \end{aligned}$$

Since $H(s, L_s) := X_s(z_1)Y_s(z_2)\tilde{G}(z_{1,s}, \overline{z_{2,s}}, t - s)$ is a local martingale for all $s \leq t$, by Remark 23, we have

$$-\Lambda H(s, L_s) = \partial_s H(s, L_s),$$

where Λ is the generator of the Lévy process L_t .

$$\begin{aligned} \partial_s H &= H \left[\frac{p}{2} - \frac{q}{2} - \frac{p}{(1 - z_{1,s})^2} + \frac{q}{1 - z_{1,s}} \right] \\ &+ H \left[\frac{\bar{p}}{2} - \frac{\bar{q}}{2} - \frac{\bar{p}}{(1 - \overline{z_{2,s}})^2} + \frac{\bar{q}}{1 - \overline{z_{2,s}}} \right] \\ &- X_s(z_1)Y_s(z_2)\partial_\tau \tilde{G}(z_{1,s}, \overline{z_{2,s}}, t - s) \\ &+ X_s(z_1)Y_s(z_2)\partial_{z_1} \tilde{G}(z_{1,s}, \overline{z_{2,s}}, t - s) z_{1,s} \frac{z_{1,s} + 1}{z_{1,s} - 1} \\ &+ X_s(z_1)Y_s(z_2)\partial_{\overline{z_2}} \tilde{G}(z_{1,s}, \overline{z_{2,s}}, t - s) \overline{z_{2,s}} \frac{\overline{z_{2,s}} + 1}{\overline{z_{2,s}} - 1}, \end{aligned}$$

where $\tau = t - s$. So we have

$$\begin{aligned} -\Lambda \tilde{G}(z_{1,s}, \overline{z_{2,s}}, t - s) &= \tilde{G}(z_{1,s}, \overline{z_{2,s}}, t - s) \left[\frac{p}{2} - \frac{q}{2} - \frac{p}{(1 - z_{1,s})^2} + \frac{q}{1 - z_{1,s}} \right] \\ &+ \tilde{G}(z_{1,s}, \overline{z_{2,s}}, t - s) \left[\frac{\bar{p}}{2} - \frac{\bar{q}}{2} - \frac{\bar{p}}{(1 - \overline{z_{2,s}})^2} + \frac{\bar{q}}{1 - \overline{z_{2,s}}} \right] \\ &- \partial_\tau \tilde{G}(z_{1,s}, \overline{z_{2,s}}, t - s) + \partial_{z_1} \tilde{G}(z_{1,s}, \overline{z_{2,s}}, t - s) z_{1,s} \frac{z_{1,s} + 1}{z_{1,s} - 1} \\ &+ \partial_{\overline{z_2}} \tilde{G}(z_{1,s}, \overline{z_{2,s}}, t - s) \overline{z_{2,s}} \frac{\overline{z_{2,s}} + 1}{\overline{z_{2,s}} - 1}. \end{aligned} \tag{5.2.7}$$

Note that by (5.2.5), it holds that

$$\begin{aligned} \exp\left\{\left(\frac{p-q}{2} + \frac{\bar{p}-\bar{q}}{2}\right)t\right\} \tilde{G}(z_1, \bar{z}_2, t) \left(\frac{p-q}{2} + \frac{\bar{p}-\bar{q}}{2}\right) \\ + \exp\left\{\left(\frac{p-q}{2} + \frac{\bar{p}-\bar{q}}{2}\right)t\right\} \partial_t \tilde{G}(z_1, \bar{z}_2, t) \rightarrow 0 \text{ as } t \rightarrow +\infty. \end{aligned}$$

So as $t \rightarrow +\infty$,

$$\exp\left\{\left(\frac{p-q}{2} + \frac{\bar{p}-\bar{q}}{2}\right)t\right\} \partial_t \tilde{G}(z_1, \bar{z}_2, t) \rightarrow -\left(\frac{p-q}{2} + \frac{\bar{p}-\bar{q}}{2}\right)G(z_1, z_2).$$

Multiplying $\exp\left\{\left(\frac{p-q}{2} + \frac{\bar{p}-\bar{q}}{2}\right)(t-s)\right\}$ on the two sides of (5.2.7) and passing t to ∞ we can get

$$\begin{aligned} -\Lambda G(z_1, \bar{z}_2) &= G(z_1, \bar{z}_2) \left[\frac{p}{2} - \frac{q}{2} - \frac{p}{(1-z_1)^2} + \frac{q}{1-z_1} \right] \\ &+ G(z_1, \bar{z}_2) \left[\frac{\bar{p}}{2} - \frac{\bar{q}}{2} - \frac{\bar{p}}{(1-\bar{z}_2)^2} + \frac{\bar{q}}{1-\bar{z}_2} \right] \\ &+ \left(\frac{p-q}{2} + \frac{\bar{p}-\bar{q}}{2}\right)G(z_1, \bar{z}_2) + \partial_{z_1} G(z_1, \bar{z}_2) z_1 \frac{z_1+1}{z_1-1} \\ &+ \partial_{\bar{z}_2} G(z_1, \bar{z}_2) \bar{z}_2 \frac{\bar{z}_2+1}{\bar{z}_2-1}. \end{aligned} \tag{5.2.8}$$

Then $G(z_1, \bar{z}_2)$ satisfies $\mathcal{P}(D)G(z_1, \bar{z}_2) = 0$, where

$$\begin{aligned} \mathcal{P}(D) &= \Lambda + z_1 \frac{z_1+1}{z_1-1} \partial_{z_1} + \bar{z}_2 \frac{\bar{z}_2+1}{\bar{z}_2-1} \partial_{\bar{z}_2} + p - q + \bar{p} - \bar{q} \\ &- \frac{p}{(1-z_1)^2} + \frac{q}{1-z_1} - \frac{\bar{p}}{(1-\bar{z}_2)^2} + \frac{\bar{q}}{1-\bar{z}_2}. \end{aligned} \tag{5.2.9}$$

Recall the definition of Λ in Theorem 22 :

$$\Lambda f(x) = \lim_{t \downarrow 0} \frac{\mathbf{E}^x[f(L_t)] - f(x)}{t}.$$

For $k, l \in \mathbb{Z}$, we have

$$\begin{aligned} \Lambda(z^k \bar{z}^l) &= r^{k+l} \Lambda(e^{i\theta(k-l)}) \\ &= r^{k+l} \lim_{t \downarrow 0} \frac{\mathbf{E}^\theta[e^{i(k-l)L_t}] - e^{i(k-l)\theta}}{t} \\ &= r^{k+l} \lim_{t \downarrow 0} \frac{e^{i(k-l)\theta}(e^{-t\eta(k-l)} - 1)}{t} \\ &= -\eta(k-l)z^k \bar{z}^l, \end{aligned} \tag{5.2.10}$$

where η is the Lévy symbol of L_t (see (2.6.1)).

5.2.1 Drifted Brownian motion

In this section, we consider the special Lévy process $L_t = at + \sqrt{\kappa}B_t$, where $a \in \mathbb{R}$, $\kappa \geq 0$ and B_t is a standard one-dimensional Brownian motion. By the definition of the Lévy symbol

$$\mathbf{E}[e^{i\xi L_t}] = \mathbf{E}[e^{i\xi(at + \sqrt{\kappa}B_t)}] = e^{ia\xi t - t\frac{\kappa}{2}|\xi|^2} = e^{-t\eta(\xi)}.$$

So

$$\eta(\xi) = \frac{\kappa}{2}|\xi|^2 - ia\xi.$$

By (5.2.10), we have

$$\Lambda(z^k \bar{z}^l) = -\eta(k-l)z^k \bar{z}^l = -\frac{\kappa}{2}(k-l)^2(z^k \bar{z}^l) + ia(k-l)(z^k \bar{z}^l),$$

So

$$\Lambda = -\frac{\kappa}{2}(z\partial_z - \bar{z}\partial_{\bar{z}})^2 + ia(z\partial_z - \bar{z}\partial_{\bar{z}}).$$

The operator in (5.2.9) becomes

$$\begin{aligned} \mathcal{P}(D) &= -\frac{\kappa}{2}(z_1\partial_{z_1} - \bar{z}_2\partial_{\bar{z}_2})^2 + z_1\left(\frac{z_1+1}{z_1-1} + ia\right)\partial_{z_1} \\ &\quad + \bar{z}_2\left(\frac{\bar{z}_2+1}{\bar{z}_2-1} - ia\right)\partial_{\bar{z}_2} + p - q + \bar{p} - \bar{q} \\ &\quad - \frac{p}{(1-z_1)^2} + \frac{q}{1-z_1} - \frac{\bar{p}}{(1-\bar{z}_2)^2} + \frac{\bar{q}}{1-\bar{z}_2}. \end{aligned} \quad (5.2.11)$$

We want to find a solution of the PDE

$$\mathcal{P}(D)G(z_1, \bar{z}_2) = 0, \quad G(0, 0) = 1.$$

Suppose that the solution has the form

$$G(z_1, \bar{z}_2) = (1-z_1)^\alpha (1-\bar{z}_2)^{\bar{\alpha}} P(z_1 \bar{z}_2).$$

Then we can see that

$$\mathcal{P}(D)[(1-z_1)^\alpha (1-\bar{z}_2)^{\bar{\alpha}} P(z_1 \bar{z}_2)] = (I) + (II) + (III),$$

where

$$(I) = z_1 \bar{z}_2 (1-z_1)^{\alpha-1} (1-\bar{z}_2)^{\bar{\alpha}-1} (\kappa|\alpha|^2 P(z_1 \bar{z}_2) + 2(z_1 \bar{z}_2 - 1)P'(z_1 \bar{z}_2)),$$

$$(II) = [\mathcal{P}(\partial)(1-z_1)^\alpha](1-\bar{z}_2)^{\bar{\alpha}} P(z_1 \bar{z}_2),$$

$$(III) = [\mathcal{P}(\bar{\partial})(1-\bar{z}_2)^{\bar{\alpha}}](1-z_1)^\alpha P(z_1 \bar{z}_2);$$

and

$$\begin{aligned}\mathcal{P}(\partial) &:= -\frac{\kappa}{2}(z_1\partial_1)^2 + \left(\frac{z_1+1}{z_1-1} + ia\right)z_1\partial_1 + p - q + \frac{q}{1-z_1} - \frac{p}{(1-z_1)^2}, \\ \mathcal{P}(\bar{\partial}) &:= -\frac{\kappa}{2}(\bar{z}_2\bar{\partial}_2)^2 + \left(\frac{\bar{z}_2+1}{\bar{z}_2-1} - ia\right)\bar{z}_2\bar{\partial}_2 + \bar{p} - \bar{q} + \frac{\bar{q}}{1-\bar{z}_2} - \frac{\bar{p}}{(1-\bar{z}_2)^2}.\end{aligned}$$

Notice that $\mathcal{P}(\partial)(1-z_1)^\alpha = 0 \Leftrightarrow \mathcal{P}(\bar{\partial})(1-\bar{z}_2)^{\bar{\alpha}} = 0$. So if $\mathcal{P}(\partial)(1-z_1)^\alpha = 0$, we have

$$\begin{aligned}\mathcal{P}(D)[(1-z_1)^\alpha(1-\bar{z}_2)^{\bar{\alpha}}P(z_1\bar{z}_2)] &= 0 \\ \Leftrightarrow \kappa|\alpha|^2P(z_1\bar{z}_2) + 2(z_1\bar{z}_2-1)P'(z_1\bar{z}_2) &= 0 \\ \Leftrightarrow P(z_1\bar{z}_2) &= (1-z_1\bar{z}_2)^{-\frac{\kappa|\alpha|^2}{2}}.\end{aligned}$$

So we need to find α such that $(1-z)^\alpha$ is a solution of $\mathcal{P}(\partial)(1-z)^\alpha = 0$.

By computation, we can see that

$$\mathcal{P}(\partial)(1-z)^\alpha = A(1-z)^\alpha + B(1-z)^{\alpha-1} + C(1-z)^{\alpha-2},$$

where

$$\begin{aligned}A &= -\frac{\kappa}{2}\alpha^2 + (1+ia)\alpha + p - q, \\ B &= \kappa\alpha^2 - \left(\frac{1}{2}\kappa + 3\right)\alpha - ia\alpha + q, \\ C &= -\frac{\kappa\alpha^2}{2} + \left(2 + \frac{\kappa}{2}\right)\alpha - p.\end{aligned}$$

Notice that $A + B + C = 0$. By choosing p, q, α such that $A = B = C = 0$, we get

$$\mathbf{E} \left[z_1^{\frac{q}{2}} \frac{f'(z_1)^{\frac{p}{2}}}{f(z_1)^{\frac{q}{2}}} \bar{z}_2^{\frac{\bar{q}}{2}} \frac{\overline{f'(z_2)^{\frac{\bar{p}}{2}}}}{\overline{f(z_2)^{\frac{\bar{q}}{2}}}} \right] = (1-z_1)^\alpha(1-\bar{z}_2)^{\bar{\alpha}}(1-z_1\bar{z}_2)^{-\frac{\kappa|\alpha|^2}{2}}.$$

Since we want to calculate the average spectrum, we need $p, q \in \mathbb{R}$, so we need to get α from $A = B = C = 0$.

Assume $\alpha = \alpha_1 + i\alpha_2$. By $C = 0$, we get $p = -\frac{\kappa}{2}\alpha^2 + (2 + \frac{\kappa}{2})\alpha$. Then by $\text{Im } p = 0$, we get

$$\alpha_2 \left(-\kappa\alpha_1 + 2 + \frac{\kappa}{2} \right) = 0.$$

So $\alpha_2 = 0$ or $\alpha_1 = \frac{4+\kappa}{2\kappa}$.

By $B = 0$, we get $q = -\kappa\alpha^2 + (3 + \frac{\kappa}{2})\alpha - ia\alpha$. Then by $\text{Im } q = 0$, we get that

$$2\kappa\alpha_1\alpha_2 - \left(\frac{\kappa}{2} + 3\right)\alpha_2 + a\alpha_1 = 0.$$

So if $\alpha_2 = 0$, we have $a = 0$, this is the usual case which has been discussed in [6]. So we assume $a \neq 0$, then

$$\alpha_1 = \frac{\kappa + 4}{2\kappa}, \quad \alpha_2 = -\frac{a(\kappa + 4)}{\kappa(\kappa + 2)},$$

and

$$\alpha = \frac{4 + \kappa}{2\kappa} \left(1 - i \frac{2a}{\kappa + 2} \right).$$

Then

$$p = p(\kappa, a) = \frac{(\kappa + 4)^2}{8\kappa} \left(1 + \frac{4a^2}{(\kappa + 2)^2} \right),$$

$$q = q(\kappa, a) = \frac{\kappa + 4}{2\kappa} \left(1 + \frac{4a^2}{(\kappa + 2)^2} \right).$$

Notice that $\frac{\kappa}{2}|\alpha|^2 = p$. So with these special values we have

$$\mathbf{E}[|z|^q \frac{|f'(z)|^p}{|f(z)|^q}] = \frac{|(1-z)^\alpha|^2}{(1-|z|^2)^{\frac{\kappa|\alpha|^2}{2}}}.$$

Notice that $\operatorname{Re} \alpha > 0$, then we can get that

$$\lim_{r \rightarrow 1} \int_{|z|=r} \frac{|(1-z)^\alpha|^2}{(1-|z|^2)^{\frac{\kappa|\alpha|^2}{2}}} |dz| \asymp (1-r^2)^{-\frac{\kappa|\alpha|^2}{2}}.$$

So in our special case the average (p, q) -spectrum is $\beta(p, q) = p$. We summary our results as the following theorem :

Theorem 98. *Let $f(z) = f_0(z)$ where (f_t) is the whole-plane Loewner process driven by $\lambda(t) = e^{i(at + \sqrt{\kappa}B_t)}$. If p, q take the following values :*

$$\begin{cases} p = p(\kappa, a) = \frac{(\kappa+4)^2}{8\kappa} \left(1 + \frac{4a^2}{(\kappa+2)^2} \right), \\ q = q(\kappa, a) = \frac{\kappa+4}{2\kappa} \left(1 + \frac{4a^2}{(\kappa+2)^2} \right); \end{cases}$$

then the generalized integral means spectrum $\beta(p, q)$ of f is equal to p .

Remark 99. In fact we can regard the Loewner process driven by $L_t = at + \sqrt{\kappa}B_t$ as a stochastic perturbation of the *logarithmic spiral*, which corresponds to the case $\kappa = 0$. Also note that when $\kappa = 0$, f_0 is the just the Koebe function, therefore SLE_κ might be looked upon as a stochastic perturbation of the Koebe map as κ tends to 0.

 FIGURE 5.2.1 – The logarithmic spiral with $a = 5$.

5.2.2 Generalized integral means spectrum of the logarithmic spiral

The logarithmic spiral with parameter $a \in \mathbb{R}$ is the curve parametrized by

$$\gamma(t) = e^{(1+ia)t}, t \geq 0.$$

Let $\Omega_t = \mathbb{C} \setminus \gamma[t, +\infty)$ and $f_t(z) : \mathbb{D} \rightarrow \Omega_t$ be the Riemann map, i.e. the conformal map with

$$f_t(0) = 0, f_t'(0) > 0. \quad (5.2.12)$$

By the Koebe-1/4 theorem, $\lim_{t \rightarrow -\infty} f_t'(0) = 0$ and $\lim_{t \rightarrow \infty} f_t'(0) = \infty$. Then, there exists t_0 such that $f_{t_0}'(0) = 1$. Suppose that $f_{t_0}(e^{i\theta_0}) = \gamma(t_0) = e^{(1+ia)t_0}$ for some $\theta_0 \in [0, 2\pi]$.

Consider now the function \tilde{f}_t defined by

$$\tilde{f}_t(z) = e^{(1+ia)t} f_{t_0}(e^{-iat} z).$$

We have $\tilde{f}_t(0) = 0$, $\tilde{f}_t'(0) = e^t$, and

$$\tilde{f}_t(e^{i(\theta_0+at)}) = e^{(1+ia)(t+t_0)} = \gamma(t+t_0).$$

Hence $\tilde{f}_t : \mathbb{D} \rightarrow \Omega_{t+t_0}$ is the Loewner map corresponding to the curve

$$\tilde{\gamma}(t) = e^{(1+ia)(t+t_0)}, t \in \mathbb{R}.$$

Since $\tilde{f}_t(e^{i(\theta_0+at)}) = \tilde{\gamma}(t)$, the associated process is driven by $\tilde{\lambda}(t) = e^{i(\theta_0+at)}$.

Define then the curve

$$\eta(t) = e^{-i\theta_0} \tilde{\gamma}(t), t \in \mathbb{R},$$

and the function

$$h_t(z) = e^{-i\theta_0} \tilde{f}_t(e^{i\theta_0} z).$$

It is clear that h_t is the Loewner map corresponding to η and since $h_t(e^{iat}) = \eta(t)$, the associated driven function is $\lambda(t) = e^{iat}$.

Notice that the curve η can be obtained by a rotation and a time-translation of the logarithmic spiral γ . Thus the generalized integral means spectrum should be the same for the maps h_0 and f_0 .

Let us compute the generalized integral means spectrum of f_0 . We define the function Φ as follows :

$$\Phi(z) := e^{(1+ia)\frac{2}{1+a^2}\log(i\frac{1-z}{1+z})} = \left(i\frac{1-z}{1+z}\right)^{\frac{2(1+ia)}{1+a^2}}, z \in \mathbb{D}.$$

We know that $z \mapsto \log(z)$ maps conformally the upper half plane onto the strip \mathbb{S}_π , and $z \mapsto e^{(1+ia)z}$ the strip domain $\mathbb{S}_{2\pi/(1+a^2)} := \{x + iy : 0 < y < 2\pi/(1+a^2)\}$ onto \mathbb{C} with a cut along the whole logarithmic spiral $\gamma(t), t \in \mathbb{R}$. Consequently, Φ is a conformal map from the unit disk to the complement of the whole logarithmic spiral with $\Phi(1) = 0, \Phi(-1) = \infty$.

Suppose $f_0(z)$ is conformal map corresponding to the whole plane Loewner process driven by e^{iat} at $t = 0$. We call this the half spiral. Near ∞ , the half spiral and whole spiral have the same spectrum. So we can use Φ to calculate the spectrum near ∞ .

Since $|\Phi(z)| = e^{\frac{2}{1+a^2}(\operatorname{Re} \log \frac{i(1-z)}{1+z} - a \operatorname{Im} \log \frac{i(1-z)}{1+z})}$ and $\operatorname{Im} \log \frac{i(1-z)}{1+z} \in [0, 2\pi]$ is bounded.

We only need to see $e^{\frac{2}{1+a^2}(\operatorname{Re} \log \frac{i(1-z)}{1+z})}$.

Then

$$|\Phi(z)| \sim \left|\frac{1-z}{1+z}\right|^{\frac{2}{1+a^2}}, |\Phi'(z)| \sim |1+z|^{-\frac{3+a^2}{1+a^2}} |1-z|^{\frac{1-a^2}{1+a^2}}.$$

Thus

$$\frac{|\Phi'(z)|^p}{|\Phi(z)|^q} \sim |1+z|^{-p\frac{3+a^2}{1+a^2} + \frac{2q}{1+a^2}} |1-z|^{p\frac{1-a^2}{1+a^2} - \frac{2}{1+a^2}q}.$$

Around $z = -1$, $|1+z|^2 = (r^2 + 2r \cos \theta + 1)$ behaves like $(\pi - \theta)^2$, so its integral around π behaves like $\theta^{-p + \frac{2(q-p)}{1+a^2} + 1} \sim (1-r)^{-p + \frac{2(q-p)}{1+a^2} + 1}$. Then we have $\beta_1(p, q) = -p + \frac{2(q-p)}{1+a^2} + 1$.

Suppose

$$\phi(z) = \frac{z}{(1-z)^2} : \mathbb{D} \rightarrow \mathbb{C} \setminus (0, -\frac{1}{4}]$$

is the Koebe function with $\phi(0) = 0, \phi(1) = \infty, \phi(-1) = -\frac{1}{4}$.

Let g be the conformal map from $\mathbb{C} \setminus (0, -\frac{1}{4}]$ to $\Omega_0 := \mathbb{C} \setminus \gamma[0, \infty]$ with $g(0) = 0, g(-\frac{1}{4}) = 1$. Then $f_0 = g \circ \phi$. Notice that g and g' is bounded near $-\frac{1}{4}$. So near -1 ,

$$\int \frac{|f'_0(z)|^p}{|f(z)|^q} \sim \int |\phi'(z)|^p.$$

Since the spectrum of a half line near the tip is $-p - 1$. Then we get that near the tip 1, the spectrum of the half spiral should be $\beta_{tip} = -p - 1$.

FIGURE 5.2.2 – Phases for the generalized integral means spectrum of the logarithmic spiral.

Since away from ∞ and the tip 1, the half spiral is rectifiable, then the spectrum should be $\beta_0 := 0$. We get the following theorem.

Theorem 100. *The generalized integral means spectrum of f_0 where f_t is the whole-plane Loewner process driven by $\lambda(t) = e^{iat}$ is given by*

$$\beta(p, q) = \max\{\beta_{tip}, \beta_0, \beta_1\}.$$

5.2.3 General Lévy process with special symbols

In this section, we will consider general Lévy process but with special symbols. We will use the same method as [16] to compute the generalized integral means spectrum for some special values.

In the following we assume that $p \equiv 2$ and L_t is symmetric (see section 2.6). Suppose $G(z, \bar{z})$ has the form

$$G(z, \bar{z}) = (1 - z)(1 - \bar{z})h(z, \bar{z}).$$

Substituting into (22),

$$\begin{aligned} -\hat{\eta}[(1 - z)(1 - \bar{z})h(z, \bar{z})] + (z + 1)(\bar{z} - 1)z\partial_z h + \\ (\bar{z} + 1)(z - 1)\bar{z}\partial_{\bar{z}} h + (3 - q)(2z\bar{z} - z - \bar{z})h = 0. \end{aligned} \quad (5.2.13)$$

Assume

$$h(z, \bar{z}) = \sum_{n=0}^{\infty} \theta_n(\chi)(z^n + \bar{z}^n), \quad \chi := z\bar{z}.$$

By comparing the coefficients before z^n , we can get a recursion relation among $\theta_n(\chi)$: (The symmetric assumption of L_t assures that we only need to compare the coefficient of z^n for $n \in \mathbb{N}$)

$$2\chi(\chi - 1)\theta'_n(\chi) - \left(\eta_n + n + (\eta_n + 2q - n - 6)\chi\right)\theta_n \quad (5.2.14)$$

$$+ \chi\left(\eta_n + n - 2 + q\right)\theta_{n+1}(\chi) + (\eta_n - n - 2 + q)\theta_{n-1}(\chi) = 0. \quad (5.2.15)$$

Therefore, we have

(a) If $\eta_1 = 3 - q$, only θ_0 is not equal to 0, and we have

$$\theta_0(\chi) = \frac{1}{2(1 - \chi)^{3-q}}, \quad G(z, \bar{z}) = \frac{|1 - z|^2}{(1 - |z|^2)^{3-q}}.$$

So

$$\lim_{r \rightarrow 1} \int_{|z|=r} \frac{|1 - z|^2}{(1 - |z|^2)^{3-q}} |dz| \asymp (1 - r^2)^{q-3}.$$

Then the corresponding generalized integral means spectrum is

$$\beta(2, q) = 3 - q.$$

(b) If $\eta_1 = 1 - q$, only θ_0 and θ_1 don't vanish. And they satisfy the ODE system :

$$\begin{cases} (\chi - 1)\theta'_0(\chi) + (3 - q)\theta_0(\chi) + (q - 2)\theta_1(\chi) = 0 \\ 2\chi(\chi - 1)\theta'_1(\chi) + \left(q - 2 + (6 - q)\chi\right)\theta_1(\chi) - 2\theta_0(\chi) = 0. \end{cases}$$

Solving this ODE system (combing the initial values $G(0) \equiv 1$), we have

$$\begin{cases} \theta_0(\chi) = \frac{1+\chi}{(1-\chi)^{4-q}} \\ \theta_1(\chi) = -\frac{2}{(2-q)(1-\chi)^{4-q}}. \end{cases}$$

Then

$$\begin{aligned} G(z, \bar{z}) &= |1 - z|^2 \left(\frac{1 + |z|^2}{(1 - |z|^2)^{4-q}} + \frac{2(z + \bar{z})}{(q - 2)(1 - |z|^2)^{4-q}} \right) \\ &= \frac{|1 - z|^2}{(1 - |z|^2)^{4-q}} \left(1 + |z|^2 + \frac{2(z + \bar{z})}{q - 2} \right). \end{aligned}$$

Since $\eta_1 = 1 - q > 0$, we have $q < 1$ and $1 + |z|^2 + \frac{2(z + \bar{z})}{q - 2}$ is uniformly bounded. Therefore

$$\lim_{r \rightarrow 1} \int_{|z|=r} \frac{|1 - z|^2}{(1 - |z|^2)^{4-q}} \left(1 + |z|^2 + \frac{2(z + \bar{z})}{q - 2} \right) |dz| \asymp (1 - r^2)^{q-4}.$$

We get the corresponding generalized integral means spectrum is

$$\beta(2, q) = 4 - q.$$

We summarize above results as the theorem below :

Theorem 101. *Suppose $f = f_0$, here (f_t) is the inner Loewner process driven by $\lambda_t = \exp\{iL_t\}$, where L_t is a symmetric Lévy process. Then*

- (1) *If $p = 2$, $\eta_1 = 3 - q$, the average generalized integral means spectrum f is $\beta(2, q) = 3 - q$;*
- (2) *If $p = 2$, $\eta_1 = 4 - q$, the average generalized integral means spectrum f is $\beta(2, q) = 4 - q$.*

Remark 102. Here $p = 2$ is essential, otherwise we will not have the nice form . So far all the spectrum we have got used the special solution of the PDE. And we can not get the special for general (p, q) .

Certains problèmes concernant le SLE

Résumé :

Cette thèse se concentre sur trois sujets liés aux $SLE(\kappa)$ processus. La première partie concerne le processus dipolar $SLE(\kappa)$ et la mesure de restriction conforme à la bande ; La deuxième partie porte sur la propriété de connectivité de la mesure de la boucle brownienne ; Et la troisième partie porte sur le spectre des moyens intégrés généralisés du processus entier intérieur des processus Loewner piloté par un processus Lévy.

Mots clés : dipolar SLE ; dipolar restriction mesure ; la mesure de la boucle brownienne ; le spectre des moyens intégrés généralisés.

Some problems about SLE

Abstract :

This thesis focuses on three topics related to the $SLE(\kappa)$ processes. The first part is about the dipolar $SLE(\kappa)$ process and the conformal restriction measure on the strip ; the second part is about the connectivity property of the Brownian loop measure ; and the third part is about the generalized integral means spectrum of the inner whole plane Loewner processes driven by a Lévy process.

Keywords : dipolar SLE ; dipolar restriction measure ; Brownian loop measure ; average integral means spectrum.
