Web Services

- Model
- Composition
- Orchestration
- Implementation
- Distributed orchestration
- Non-disclosure policy

Conclusions

Real encryption, e.g. AES

- Message: 'messagetoencrypt' — 0x7468 6576 6572 7973 6563 7265 746b 6579
- Key: 'theverysecretkey' — 0x6d65 7373 6167 6574 6f65 6e63 7279 7074
- Encrypted message: 0xcd54 381e 3b8f 5981 f108 76e9 4e64 b4b6 (no good ASCII representation)

Abstraction

- Message: m
- Key: k
- Encrypted message: $\{m\}_k^s$

Messages may be complex, e.g. $\{\{m.n\}_k^s\}_{a.n}^s$

Abstract away algorithms.

Conclusions

Symbolic analysis

Symbolic representation

$\{t_1\}_{t_2}^a$	t_1 encrypted with public key t_2
$\{t_1\}_{t_2}^s$	t_1 encrypted with symmetric key t_2
$t_1.t_2$	t_1 concatenated with t_2
$\text{priv}(t_2)$	private key for public key t_2
$[t_1]_{\text{priv}(t_2)}$	signature of message t_1 with $\text{priv}(t_2)$
$t_1(t_2)$	apply hash function t_1 on message t_2

Public-key encryption: Two types of keys

- **Public key** (to encrypt),

- **Private key** (to decrypt),

Symmetric encryption: **one** shared key

- Encryption:

- Decryption:

Conclusions

Messaging and Protocol participants

Terms

- a, b, c, \dots — atomic data. They are terms.
- X, Y, \dots — variables. They are terms.
- p, q — terms $\implies \{p\}_q^s, p.q, \dots$ are terms.
- Ground terms (messages) are terms without variables.

E.g. $\{\{a.b\}_k^s\}_c^s$ $X.[X]_{\text{priv}(pk)}$ $\{a\}_{pk}^a$

Protocol participants (agents, protocol roles instances)

Agent's behavior is defined as $?_I t_1; ?_I t_2; \dots; ?_I t_{k-1}; ?_I t_k$
? is “receive”, ! is “send”

Example of an agent with four actions

$? \{X\}_k^s; ! \text{md5}(X); ? X.Y; ! \{token\}_Y^s$

Conclusions

Analysis of protocol's sessions

Sample protocol (“password restore”)

$$A \rightarrow B : \{A.K\}_{K_B}^a$$

$$B \rightarrow A : \{pwd(A)\}_K^s$$

K — fresh symmetric key generated by A

K_B — public key of B

$pwd(A)$ — forgotten password

Protocol should guarantee

- $pwd(A)$ is known only by A and B .

Protocol insecurity problem

Given a finite set of protocol instances (or their number),
find out whether the security properties guaranteed by the protocol are not preserved in the presence of a DY intruder.

Conclusions

Some formal definitions

Deducibility constraint system

$\{E_i \triangleright t_i\}_{i=1,\dots,n}$, where

E_i — finite set of terms, t_i — term for all i .

Derivability

Term t is derivable from set of terms E , if $t \in \text{Der}(E)$, where $\text{Der}(E)$ is a closure of E w.r.t. deduction rules.

Model/solution of $E \triangleright t$

Ground substitution σ — model of $\{E_i \triangleright t_i\}_{i=1,\dots,n}$ iff $t_i\sigma \in \text{Der}(E_i\sigma)$ for all i .

Well-formed constraints

ACI symbol

Multiple intruders
(protocol analysis)

General constraints

Web Services

Model

Composition

Orchestration

Implementation

Distributed orchestration

Non-disclosure policy

Conclusions

Well-formed constraint systems

$\{E_i \triangleright t_i\}_{i=1,\dots,n}$ is well-formed, iff it satisfies

- **Knowledge monotonicity:** $i < j \implies E_i \subseteq E_j$
- **Variable origination:**
 $x \in \text{Vars}(E_i) \implies x$ occurs in some $t_j, j < i$.

Decidable, NP-complete (2001)

Later: algebraic properties

- XOR (2003) i.e. $((a \oplus b) \oplus c) = (a \oplus (b \oplus c)), a \oplus b = b \oplus a$ and $a \oplus a = 0$
- Modular exponentiation (2003/4) $a^1 = a, (a^b)^c = a^{b \times c}, \times$ is AC...
- Prefix rules (2005) $\{X.Y\}_K^s \rightarrow \{X\}_K^s$.
- Commutativity of public-key encryption (2003/4)
 $\left\{ \{m\}_{k_1}^a \right\}_{k_2}^a = \left\{ \{m\}_{k_2}^a \right\}_{k_1}^a$ (RSA)
- Combination of theories (2005)
disjoint signatures OR bounded message depth, etc.

Protocols analysis

Reduction to constraints

Deducibility constraints

Well-formed constraints
ACI symbol
Multiple intruders
(protocol analysis)
General constraints

Web Services

Model
Composition
Orchestration
Implementation
Distributed orchestration
Non-disclosure policy

Conclusions

Contribution 1: Decidability modulo ACI

ACI: set behaviour

- Associative: $(a \bullet b) \bullet c = a \bullet (b \bullet c) = a \bullet b \bullet c$
- Commutative: $a \bullet b = b \bullet a$
- Idempotent: $(a \bullet a) = a$

Intruder's additional rules

$m_1, m_2, \dots, m_n \rightarrow m_1 \bullet m_2 \bullet \dots \bullet m_n$

$m_1 \bullet m_2 \bullet \dots \bullet m_n \rightarrow m_i$ for all i

Modeling set of nodes in XML messaging

```
<data>
  <i><id>a</id><n>2</n></i>
  <i><id>b</id><n>1</n></i>
  <i><id>c</id><n>1</n></i>
  <i><id>d</id><n>3</n></i>
</data>
```

As a term:

$a.2 \bullet b.1 \bullet$
 $c.1 \bullet d.3$

In protocol we can write:

$?c.N \bullet X$

Conclusions

Contribution 2: Multiple intruders model

- Multiple “local” intruders, different control domains
- Cannot communicate during attack, only after
- Secrecy is decidable, for protocol sessions analysis

Multiple intruders require general constraints

Moreover, variables produced by I_1 can appear in knowledge of I_2 ...

Protocols analysis

Deducibility constraints

- Well-formed constraints
- ACI symbol
- Multiple intruders (protocol analysis)**
- General constraints

Web Services

- Model
- Composition
- Orchestration
- Implementation
- Distributed orchestration
- Non-disclosure policy

Conclusions

Contribution 3: Deciding general constraint systems

Satisfiability of “general” deducibility constraint systems

- Decidable for both DY and DY+ACI
- *NP*-complete.

Closest work

L.Mazaré (PhD thesis, 2006):
atomic keys, decidable for DY

Here:

- Complex symmetric keys
- ACI symbol

General constraints

Web Services

Model
Composition
Orchestration
Implementation
Distributed orchestration
Non-disclosure policy

Conclusions

Decidability of general constraint systems

Key property

If \mathcal{S} is satisfiable **then** there exists a solution σ that maps each variable to a set of non-variable subterms of \mathcal{S} (and private keys...) instantiated with σ .

For the case of DY constraints (w/o ACI), instead of “ACI sets” we may use “pair of pairs”.

Using this property we may find a bound on the size of such solution. Thus, bound a space for searching a solution.

Protocols analysis

- Intro

Deducibility constraints

- Well-formed constraints
- ACI symbol
- Multiple intruders (protocol analysis)
- General constraints

Web Services

- Model
- Composition
- Orchestration
- Implementation
- Distributed orchestration
- Non-disclosure policy

Conclusions

General constraints are more complex to solve

Subterm deduction system

- composition rules: $x_1, \dots, x_k \rightarrow f(x_1, \dots, x_k)$
- decomposition rules pattern: $f(t_1, \dots, t_m) \rightarrow s$, where s is a subterm of t_i for some i .

Subterm (convergent) deduction system

Input: Subterm (convergent) deduction system D and a constraint system C .

Question: is C satisfiable?

Undecidable

if either knowledge monotonicity or variable origination is not satisfied.

Decidable for well-formed constraints

- Subterm-convergent equational theories [Baudet '05]
- Later, Subterm-convergent deduction systems

Conclusions

Web service

is a software system with machine-processable interface.

Web Service is a black box with...

- **Interface** (WSDL): set of operations, operation is a pair “receive-send”.
- **Usage scenario** (e.g. WS-BPEL): sequence to follow, Moreover, one may need to invoke second operation with a specific value used in the first one.
- **Security policies** (WS-SecurityPolicy). E.g. a given part of the input of a given operation must be encrypted/signed with given key...

... Exactly as an instance of cryptographic protocol role ...

Web Services use XML as basis for the interface and communications.

General constraints

Web Services

Model

Composition

Orchestration

Implementation

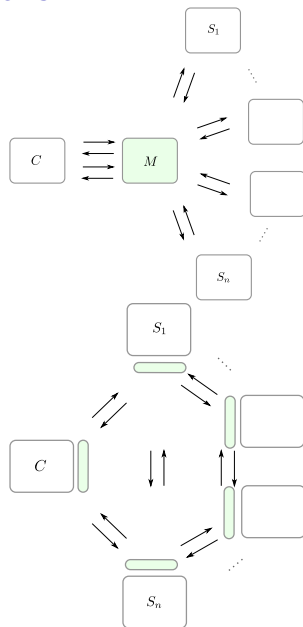

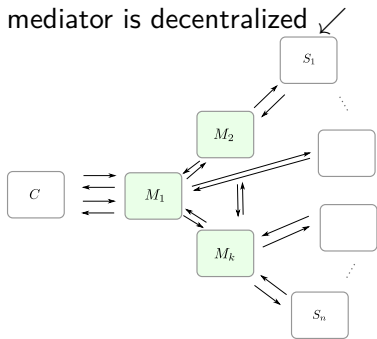

Distributed orchestration

Non-disclosure policy

Conclusions

Web Services composition options

- Orchestration: a central entity, mediator (orchestrator) →
- Choreography: services communicate directly with each other following a global strategy ↘
- Distributed orchestration: mediator is decentralized ↙

Web Services orchestration problem

Given a finite set of available services

Each in a form of a sequence of operations on which the security policies are already applied.

Client

- Sequence of requests with expected responses.

To build a *mediator*

- Is a new “executable” Web Service, white box
- Satisfying the client’s requests
- Reusing existing Web Services
- Adapting messages
- Have initial knowledge
(e.g. account information, public keys)

General constraints

Web Services

Model

Composition

Orchestration

Implementation

Distributed orchestration

Non-disclosure policy

Conclusions

Automata-based approaches (e.g. Roman model)

Available services

- State machines
- Transitions are labeled with service's operations

Orchestration problem

Simulate the behaviour of a given target service by delegating operation invocations to the community of available services

- Usually message structure is not considered (working on the level of operations)
- Security policies are not taken into account

Web Services Example

Web Services Example

The number of invocations is bounded \implies automated solution exists!

Web Services Example

The number of invocations is bounded \implies automated solution exists!

Contribution 4: Tool for automatic orchestration

If the number of interactions is bounded:

- Build deducibility constraints for the Mediator M
- Can solve the constraint system \implies can implement M

WS Orchestration vs Protocol Analysis

Services	Protocols
Available service/Client	Protocol role
Mediator	Intruder
Final state of Client	Attack state (secret emitted)

Implemented as AVANTSSAR Orchestrator

- reused a tool (CL-AtSe) for protocol analysis
- <http://avantssar.eu>; <http://cassis.loria.fr/>,
→ AVANTSSAR Orchestrator

Conclusions

About the approach

Advantages

- Allows fully automatic procedure
- Rich message adaptation abilities
- Take into account security primitives.

Assessment of the tool

- Digital Contract Signing (OpenTrust)
- Public Bidding (OpenTrust)
- Car Registration Process (Siemens AG)

Disadvantages

- Limit on number of invocations (with all consequences)

AVANTSSAR platform, ASLan

A transition in
ASLan
language

step step_0 (A, I, J) :=
state_Adder(A, 1, dummy_msg, dummy_msg) .
iknows(pair(I, J))
=> state_Adder(A, 2, I, J) .
iknows(apply(plus, pair(I, J)))

Orchestration problem

Contribution 5: Distributed orchestration model

- Available services S_i with list of actions
- Partners P_j with knowledge K_j , confidential data N_j
- Communication channels with message patterns p_i
- Accessibility of services (e.g. private services for organizations)

Non-disclosure policy

Problem

- Partner P_i represents some organization.
- P_i possesses some data (initial) K_i .
- K_i contains confidential information N_i .
- P_i does not want to send such messages to P_j that would allow P_j to obtain any element of N_i .
- Still, N_i can be used for WS invocations.

Direct approach

Use negative constraints, i.e. $E \not\vdash n$ (E — knowledge of P_j ,
 n — confidential data of P_i)

Sufficient condition we use

Confidential data n should not appear as a subterm in messages sent to partners.

Deciding existence of partner-mediators

- **Reducing** distributed orchestration to general constraint systems:
 - E.g., *Partner P_i invokes service's operation:*
Current knowledge $K_i \triangleright$ operation input
 $K_i := K_i \cup$ operation output
- **Non-disclosure conditions:** For every step $P_i \rightarrow P_j : t$ we must ensure $\text{Sub}(t) \cap N_i = \emptyset$

Extending the general constraints satisfiability procedure

If exists solution for deducibility constraint system that satisfies non-disclosure condition, **then** there exists one with bounded size which satisfies both constraint system and non-disclosure condition.

Summary

Contributions

Deducibility constraints

- ACI symbol in deducibility constraints
- Relaxing “well-formedness”
- Complexity class NP -complete

Protocol analysis

- Multiple non-communicating intruders model
- Decidability for secrecy problem
- Modeling sets of XML nodes

Web services composition

- AVANTSSAR Orchestrator tool
- Model for a distributed orchestration with non-disclosure policy
- Automatic decision procedure for mediators synthesis

Conclusions

Summary

Research directions

Theoretical

- Allowing negation in general constraint systems
- More algebraic properties for general constraints (e.g. XOR)
- Remove atomicity for public keys
- Web Services composition with unbounded number of invocations

Practical

- Explicit link (with a tool) from standards to model
- Effective implementation of general constraints satisfiability

- Well-formed constraints
- ACI symbol
- Multiple intruders (protocol analysis)
- General constraints

Web Services

- Model
- Composition
- Orchestration
- Implementation
- Distributed orchestration
- Non-disclosure policy

Conclusions

Special case: choreography

Protocols analysis

- Intro
- Symbolic model
- Dolev-Yao intruder
- Reduction to constraints

Deducibility constraints

- Well-formed constraints
- ACI symbol
- Multiple intruders (protocol analysis)
- General constraints

Web Services

- Model
- Composition
- Orchestration
- Implementation
- Distributed orchestration
- Non-disclosure policy

Conclusions

Benefits of considering multiple intruders

- Communications resistant to DY intruder require more exigent protocols.
Need a **compromise** between resources (including responsiveness) and security.
- An organization that knows the weak links (easy for physical access) **can verify** whether such multiple intruders may damage the confidentiality of their data.
