### Acknowledgment

Time flies so quickly, after an intensive period of thirty-nine months, my PhD career has quietly come to an end. Over the past three years, I gained tremendous knowledge in chemistry, my experimental skill and research ability were also significantly improved. Undoubtedly, it would not be possible to conduct my research and complete my dissertation without these people who have supported and helped so much during this period. Take this opportunity, I want here to thank all of you for your great help, and the good time we spent together.

Foremost, I would first like to express my sincerest gratitude to my supervisors Dr. Valérie MARAVAL and Prof. Remi CHAUVIN for your greatest support of my PhD study and research. The door of your office was always open for us whenever I ran into trouble or had any question not only in research, but sometimes also in life.

Without you, Valérie, this thesis would not have been completed or written. Your appearance always brought me energy and hope, especially in my most difficult time when working on *carbo-*mer chemistry in the beginning and writing this thesis. I really enjoyed the time working with you, your excited expression when we determined new final products or analyzed their structures of single crystals together, deeply impressed and greatly encouraged me. At that moment, I definitely realized that research brought us happiness, I am particularly grateful to you for everything that you have done for me.

Prof. Remi Chauvin, you are one of the greatest chemist in the world, your motivation for

## Acknowledgment

chemistry, enthusiasm for people, immense knowledge and meticulous working attitude have had a profound impact on me. I have learnt so much from and because of you, you always can enlighten me when I encountered difficulties. I sincerely thank you for your guidance and helping me grow as a research chemist. It has been my honor to be your PhD student.

Additionally, I would like to acknowledge my thesis committee members: Prof. Mogens Brøndsted NIELSEN (University of Copenhagen, Denmark), Dr. Irena STARA (Institute of Organic Chemistry and Biochemistry, Czech Republic), Dr. Philippe BLANCHARD (Université d'Angers, France), Dr. Suzanne FERY-FORGUES (Université Paul Sabatier, France), Prof. Xiuling CUI (invited people, Huaqiao University and Zhengzhou University, China), and Dr. Emmanuel GRAS (invited people, LCC-CNRS, France) for their time, their encouragement, and insightful comments, which broaden my horizons in the future research.

I would like to thank the other past and present group members: Dr. Y. CANAC, many thanks to you for your help in my first year; Dr. C. LEPETIT, thank you for your concern in my first year; Prof. V. BERNARDES-GENISSON, you are a very kind lady, I always feel warm when seeing you; C. BARTHES, you always answered very patiently my questions whatever any question I asked, thank you so much for what you have done for me; K. COCQ, you are the King in *carbo-*mer chemistry, at least in my opinion. Thank you very much for sharing your experience with me and your pertinent suggestion for me; C. POIDEVIN, thank you for taking me to visit city center of Toulouse when I arrived here, and your French lesson to me despite some bad words sometimes; D. LISTUNOV, although you look serious sometimes, you are a good chemistry and warm-hearted

## Acknowledgment

---

person, many thanks to you for discussion with me; C. D. MBOYI and A. MANKOU, You are really nice people, and helped me a lot in my first year, many thanks to both of you; M. CHAMMAM, thank you for what you have done for me, especially in my defense recently; E. M. CARVALHO, thanks for your help, man.

My appreciation also goes to our collaborators: Dr. E. GRAS, who works at LCC in Toulouse, supervised me as a co-supervisor in my first year and gave me a great support, I whole-heartedly appreciate you. Also, I want to thank Prof. H. F. HSU for the measurements of DSC, POM and PXRD experiments in Taiwan, Prof. Chun-hsien Chen for conducting STM measurement in Taiwan in *carbo*-mesogen project, Dr. A. POATER for performing the calculation for *carbo*-OPEs in Spain, Prof. J. L. MALDONADO for exploring of OPV application in Mexico.

I am also indebted to the following crystallographers: Dr. C. DUHAYON, it is so nice of you, you got involved in all the measurements and analyses of single crystals in my PhD career, I very much appreciate you. Dr. B. KAUFFMANN, who is from Bordeaux, my paper would not have been possible to be published without the high-quality data of single crystals. My appreciation also goes to Dr. N. SAFFON for attempts at picking single crystals.

I am hugely appreciative to Dr. A. SAQUET for electrochemical measurements of all the molecules in *carbo*-mer research.

I would like to thank Dr. Y. COPPEL for launching solid NMR experiment and helping resolve NMR spectra, and Dr. C. BIJANI for NMR measurements by using 500 MHz and 600

---

MHz spectrometer, and F. LACASSIN for carrying out  $^{103}\text{Rh}$  NMR experiments for the  $\text{Rh}^{\text{I}}$  complexes in the first chapter of this manuscript.

Special mention goes to my M.sc supervisor Prof. X. L. CUI for coming to my defense from the distant China.

I am grateful for conversations with the following people: O. SADEK, S. AYALA-MARISCAL, A. POCINHO, W. KHODJA, A. FERNANDEZ-ALVAREZ, C. ZHANG, X. D. LIN, L. CHEN, J. R. QIU, Y. P. WANG, who all work at LCC. Many thanks also go to my friends in Toulouse: L. Q. LANG, Q. LIAO, J. H. WANG, Z. H. ZHAO, you made my free time enjoyable by playing cards and eating together at weekends.

I also want to thank LCC (CNRS) for providing a safe and comfortable workplace, and UPS for offering us various interesting and useful courses and training.

My sincere thanks go to CSC (China Scholarship Council) for my PhD scholarship. The IDEX emergence program 2014 of Toulouse is acknowledged for financial support (*carbo*-device project).

Last but not the least, I would like to thank my family for their unconditional support and encouragement in these years, I haven't been able to find more time to accompany you, in particular for my grandfather, I couldn't go back to see you last time until you left us forever. But I want to say I really love all of you, thank you.

# **General Introduction**

## General Introduction

The thesis is divided into two parts corresponding to respective topics currently recognized to rely on distinct experimental specialties, namely phosphorus/organometallic coordination chemistry on one hand (for homogeneous catalysis), and carbon-rich/acetylenic organic chemistry on the other hand (for material physics).

The two topics being long studied in parallel in the group, a research priority change in 2016 (basically for budgetary reasons) gave the opportunity to address both of them sequentially, after completion of a first study: one year on organometallics (2015), then two years on acetylenics (2016-2017). Hence the thesis content plan, made of six chapters separated into two parts of unequal lengths: one chapter *vs* five chapters, respectively.

The research versatility, formally justified by the universal "soft variations across the Periodic Table", is practically based on general common points, namely molecular synthesis with similar bench techniques (from the use of a vacuum line and Schlenk tubes to liquid-liquid extraction and column chromatography) and identical analysis methods (NMR spectroscopy in solution, IR and UV-vis absorption spectroscopy, mass spectrometry, single crystal X-ray diffractometer...).

Each chapter of the thesis is hinged around one or two published articles or (to be) submitted manuscripts reproduced as such and preceded by an introduction of the context and a summary of results.

The first part relying on general phosphorus-organometallic chemistry (Chapter 1) is deemed within the context of ligand design with the general ambition of proposing "new types" of ligands for specific applications in homogeneous catalysis. The challenge is particularly addressed in the family of weakly electron-donating ligands of redox-flexible late transition metals most frequently encountered in homogeneous pre-catalysts (Ru, Rh, Pd...), with a focus on electron-poor phosphines towards Rh(I) Lewis acidic centers. While in the family of highly electron-rich ligands, enhancement of  $\sigma$ -donation has long been claimed to vary in the order trialkylphosphines < aminocarbenes < phosphonium ylides in the neutral series (L or X<sup>+</sup>),<sup>1</sup> followed by alkynyls < aryls < alkyls or yldiides in the anionic series (X),<sup>2</sup> the trend in the family of electron-poor ligands has attracted less attention and is today both more restricted and less delineated.<sup>3</sup> Nevertheless, the opposite order can be outlined in the P-aryl series: triarylphosphines > phosphinous esters (phosphinites) > phosphonous diesters

(phosphinites) > phosphorous triesters (posphites)  $\approx$  fluoroarylphosphines  $\approx$  amidinophosphines (e.g. imidazolophosphines)  $\gg$  imidazoliophosphines.<sup>4</sup> The latter gap is made worth to be filled because of the thermal lability of the P-imidazolium bond in the presence of weak nucleophiles (e.g. Cl<sup>-</sup>), preventing the use of imidazoliophosphines in catalysis.<sup>5</sup> As further P-impoverishment of imidazolophosphines was considered, e.g. by fluorination, one became aware that nitroaryl-phosphines were barely exemplified and their coordination chemistry unexplored. Exploration was thus initiated on the basis of a general research program in partnership with Prof. Xiuling Cui in Xiamen, China, then carried out in cooperation with Dr. Emmanuel Gras at LCC in Toulouse.

In Chapter 1,<sup>6</sup> challenging also the forgotten coordination of nitroaromatic phosphine ligands, N-aryl benzimidazolodiphenylphosphines nitrated at various position of the aryl and/or benzimidazolyl substituents were targeted both in the free state and as Rh(I) P-ligands (Figure 1). The global  $\pi$ -back donating ability of the target ligands in RhCl(CO) complexes **1a** was envisaged to be quantifiable by complementary analytical probes, i.e. the <sup>103</sup>Rh NMR shielding and the CO stretching frequency (as by the Tolman's electronic parameter from Ni(CO)<sub>3</sub> complexes).<sup>7</sup> The unveiled trends will be presented, along with unexpected observations and serendipity results in solvate crystallo-chemistry of dinuclear complexes **1b**.

**Figure 1.** Devised or turned out targets of Part 1 (Chapter 1).

The second part relying on general acetylenic chemistry (Chapters 2-6) is deemed within the more general context of the chemistry of cumulene-containing macro-aromatics,<sup>8</sup> in particular of *carbo*-meric nature such as *carbo*-benzenes,<sup>9</sup> with the view to providing new fundamental knowledges and prospects of applications of *carbo*-benzene derivatives as "materials". More precisely, efforts have been dedicated to bring out the role of *supra-molecular* interactions in either local host-guest complexes or long-range *self-assemblies* of *carbo*-benzene derivatives in the broad sense. Long-range *covalent cohesion* in oligomeric

chains of *carbo*-benzene wires has also been considered. Selected targets were thus devised by combination of mental processes such as "lipidic functionalization", "homo-dearomatizing pericondensation", and catenation (Figure 2).

**Figure 2.** Targets of Part 2 (Chapters 2-6).

The first chapter (Chapter 2)<sup>10</sup> resumes, refines and completes characterizations of hexaaryl-*carbo*-benzenes **2**, in particular the hexaphenyl-*carbo*-benzene benchmark, regarding the efficiency of their synthesis, here carried out from the key bis-terminal triyne

**A<sub>Ph</sub>** and [6]pericyclynedione **B**,<sup>11</sup> intrinsic solubility, structural, spectroscopical and electrochemical properties, or thin-film deposition propensity with the view to designing new donor or acceptor components of futurist photovoltaic junctions in collaboration with Profs José-Luis Maldonado and Gabriel Ramos Ortiz in Leon Guanajuato, Mexico.

In Chapter 3,<sup>12</sup> the limited solubility enhancement effect of alkylaryl substituents at the C<sub>18</sub> *carbo*-benzene ring is suggested to be overcome by direct anchoring of two *n*-alkyl chains C<sub>n</sub>H<sub>2n+1</sub> with length varying from *n* = 2 to *n* = 20 in tetraphenyl derivatives **3**, to be from the [6]pericyclynedione **B**. In the lipidic series (*n* ≥ 8), dispersive interactions between chains centro-symmetrically positioned at *para* positions could also be anticipated to drive another type of non-covalent interaction, namely the long sought direct π-π stacking between C<sub>18</sub> rings, the theoretically evidenced cohesion force of the "graphityne" 3D carbon allotrope (the *carbo*-mer of graphite), having hitherto escaped the observation, even in the crystal state.

In Chapter 4,<sup>13</sup> "hyper-lipidic" *carbo*-benzenes of type **4**, bearing six dodecyl or octadecyl aliphatic chains and *a priori* accessible from the [6]pericyclynedione **B**, are considered for their possible mesogenic properties in discotic liquid crystals (LCs). Columnar arrangements of the hollow and rigid C<sub>18</sub> mesogenic core would allow hosting molecules, salts or metal atoms, that would keep longitudinal mobility within the channels, opening prospects for axial charge transport upon doping with metallic species. Regarding the LC cohesion, the lateral dispersive interactions between the putative columns could be studied by STM imaging after freezing the flexible chains on an ordered surface of HOPG (Highly Oriented Pyrolytic Graphite). The work has been undertaken in collaboration with Taiwanese partners in Taipei, Prof. Hsiu-Fu Hsu, leading specialist in the field of liquid crystals, and Prof. Chun-hsien Chen renowned expert in STM imaging.

In Chapter 5<sup>14</sup> are envisaged *carbo*-meric versions of the oligophenylethynylene wires, ubiquitous in functional organic materials for their unique combination of electronic and conformational steric features. From the nomenclature standpoint, the so-called "*carbo*-OPEs" involving ethynylene tethers between aromatic C<sub>18</sub> rings are skeletal *carbo*-mers of oligo-*p*-phenylenes (OPPs), starting with *carbo*-biphenyls and *carbo*-terphenyls. With the view to ensuring sufficient solubility for full characterization of the targets, *n*-octyl substituents are placed at the wire ends. Inspired by the widely exemplified efficiency of routes to tetraphenyl-mono-*carbo*-benzenes, retrosynthesis of the two types of objects **5a** and **5b** is based on a sequential catenation of tetraphenyl-hexaoxy[6]pericyclyne units, followed by a one-step total reductive aromatization. On the basis of the anticipated poor solubility of

the dodecaphenylated *carbo*-terphenyl core, an optimized target was devised by changing the four central phenyl parents into four *p*-pentylphenyl groups. After the recently disclosed synthesis and characterization of the first oligo-*carbo*-benzenic molecule, exemplified in the fused mode of a *carbo*-naphthalene,<sup>15</sup> the *carbo*-OPE targets are counterparts in the catenated mode, and *carbo*-terphenyls would be the first examples of molecules containing three *carbo*-benzene rings. The influence of catenation on the aromatic character of the C<sub>18</sub> rings, according to the magnetic, structural and energetic criteria, was to be studied by DFT-based computational method, which was performed by Dr. Albert Poater, collaborator in Girona, Spain.

In Chapter 6,<sup>16</sup> other bis-*carbo*-benzenic derivatives are considered, and first of all upon derivation to a "homo-de-aromatized" pericondensed version, occurring in the skeletal *carbo*-mers of barrelene **6** (with two bridgehead *sp*<sup>3</sup> carbon vertices through which triple homo-conjugation of three adjacent triple bonds can occur). In spite of the large aperture of the three faces defining the inner volume of the elongated triangular bipyramid (of global nonaedral shape), the molecule is expected to act as a potential "porous cage" for H-bond donor hosts (e.g. NH<sub>4</sub><sup>+</sup>) susceptible of interacting with surrounding triple bonds as H-bond acceptors. The devised synthesis and the original idea are based on a cyclizing intramolecular double addition of the key synthon **A<sub>Ph</sub>** or **A<sub>Bu</sub>** to the key [6]pericyclynedione **B**. A naturally competing process is the intermolecular double addition of **A<sub>R</sub>** to two molecules of **B**: as a spinoff, complete SnCl<sub>2</sub>-mediated reduction of the latter acyclic adducts would afford skeletal *carbo*-mers of stilbene of type **7**. These butatriene (or [3]cumulene)-catenated congeners of *carbo*-biphenyl **5a** described in Chapter 5 were therefore also targeted, opening electronic and stereo-chemical natural issues, such as the chromophoric comparison with parent stilbenes, and the barrier of the *cis/trans* (*E/Z*) interconversion of the diphenyl-dialkynyl-central butatriene moiety.

In the following, the adopted "paper-stapling" presentation is completed by the corresponding Supporting Information files as experimental sections.

# **Part I**

The coordination chemistry of nitro-aromatic phosphines

# Chapter 1

The forgotten nitroaromatic phosphines as weakly  
donating P-ligands: an N-aryl-benzimidazolyl  
series in RhCl(CO) complexes

## Introduction & Summary

Phosphorus is an abundant element in the earth's crust, and a key element of living organisms. From the societal-industrial standpoint, organophosphorus derivatives are widely encountered amongst materials, agrochemicals, pharmaceuticals, and chemical auxiliaries or reagents for various transformations.<sup>1</sup> As ligands of transition metals, phosphanes thus play a crucial role in homogeneous catalysis of diverse processes such as C-H bond activation,<sup>2</sup> C-C cross-coupling,<sup>3</sup> olefin metathesis,<sup>4</sup> isomerization, hydrogenation or hydroformylation,<sup>5</sup> the electronic and steric features of phosphanes can indeed be readily adjusted for the corresponding purposes.<sup>6</sup>

Regarding the electronic features, ligands are commonly classified into two families: electron-rich and electron-poor. Over the past few decades, electron-rich phosphines (phosphanes with three P-C bonds) have been extensively studied and used as ligands in catalysts for C-C, C-H or C-heteroatom bond formation.<sup>7</sup> The P(III) atom of electron-rich phosphines and related P-ligands (such as aminophosphines) is indeed surrounded by a high electron density, providing them with a strong  $\sigma$ -donating character towards metal centers, allowing stabilization of the catalytic species and facilitation of oxidative addition processes in catalytic cycles.<sup>8</sup> Representative electron-rich P-ligands are listed below (Figure 1).

(i) Arylphosphines 1A decorated with electron-donating groups, such as OR or NR<sub>2</sub>.<sup>9</sup>

(ii) Alkylphosphines 1B, whose design can be largely adapted to specific requirements of steric demand and/or chirality at the P-center. The strong P→metal  $\sigma$ -donation of alkylphosphines is also widely used to accelerate the activation of *a priori* poorly reactive aryl-Br or aryl-Cl bonds.<sup>10</sup>

(iii) Imidazol-2-ylidenaminophosphines 1C (IAPs), among aminophosphines (phosphanes with at least one P-N bond) exhibiting a strong Lewis base character, were recently reported by Dielmann *et al.* to be more strongly donating than NHCs such as R<sub>2</sub>Im's and CAACs (**1E**).<sup>11</sup> The P atom of these guanidinophosphines indeed undergoes the combined  $\pi$ -donation effects from the -N atom and -imidazol-2-yliden moiety.<sup>6b,12</sup> It is here noteworthy that more electronegative P-substituents with less donating lone pairs, such as alkoxy groups, exert an opposite electron-withdrawing effect on the P<sup>III</sup> atom (e.g. in phosphinites or phosph(on)ites).<sup>13</sup>

(iv) **Phosphinophosphinidenes 1D** containing a monocoordinated P(I) atom in the free state with two lone pairs and a low-lying vacant orbital, were first reported by Guy Bertrand *et al.* in 2016. As singlet aminocarbenes (**1E**), phosphinophosphinidenes have a zwitterionic character, the phosphide end making them potential electron-rich ligands. Their use in catalysis has however remained elusive.<sup>14</sup>

It is finally noteworthy that amongst potential C-ligands and beyond NHCs (**1E**), phosphonium ylides **1F**,<sup>15</sup> which can be regarded as phosphane-stabilized carbenes, are endowed with three valuable characteristics: basicity, nucleophilicity, and C-donating ability. These features make them more electro-donating ligands than NHCs.<sup>16</sup>

**Figure 1.** Examples of electron-rich P- and C-ligands.

Compared to electron-rich P-ligands, the investigation of electron-poor counterparts has remained less explored. Nonetheless, the specific efficiency of electron-deficient phosphane ligands in particular transition metal-catalyzed reactions, such as olefin metathesis or hydroformylation, has long attracted the chemists' attention.<sup>17</sup> On the very outset, electron-poor ligands can only be weakly coordinated to Lewis acidic centers, making the corresponding complexes prone to dissociation and exchange with possibly concomitant transformations, and thus not likely to act as efficient (pre-)catalysts.<sup>18</sup>

Electron-poor P-ligands are currently devised by one of the following ways (Figure 2).

- (i) Substitution of triarylphosphine backbones by neutral electron-withdrawing groups, such as CF<sub>3</sub> or CN in **2A** and **2B**, respectively.<sup>19</sup>
- (ii) Introduction of P–O bonds, exerting an electron-withdrawing effect on the free or coordinated P center by  $\sigma$ (-I)-induction, and allowing  $\pi$ -back-donation from a coordinated metal center to the s\* orbitals of the P-O linkages. Nevertheless, phosphinous, phosphonous and phosphorous esters **2C** -i.e. phosphinites, phosphonites and phosphites, respectively- are sensitive to protic cleavage, thus restricting their catalytic use to particular cases under mild conditions.<sup>20</sup>
- (iii) Positive chemical ionization around the P center, making the lone pair less available on the basis of simple electrostatics.  $\alpha$ -Cationic phosphines, or carbeniophosphines, where the carbenium center in a position to the P atom is stabilized by +M donation of adjacent nitrogen lone pairs, can thus be prepared by N-alkylation of imino- or amidino-phosphines or P-substitution of a chlorophosphine by the corresponding (di)aminocarbene. Many imidazoliophosphines **2D**, where the positive charge is delocalized over a [RN<sup>+</sup>–C<sup>–</sup>–NR]<sup>+</sup> diaminocarbyl unit, have thus been long described in the monodentate<sup>21a-e</sup> or symmetric chelate versions.<sup>26f-g</sup> Few of them also contain a second "normal" diphenylphosphino group (without any aminoalkenyl substituent) or a NHC moiety ensuring dissymmetrical chelate ability.<sup>22</sup> In diaminocyclopropeniophosphines **2E** or N-alkyl-pyridinio-phosphines **2F**,<sup>23</sup> the positive charge is further stabilized by aromatic delocalization.
- More or less coordinating di- $\alpha$ -cationic monophosphines are also available, such as the diazaphosphepines **2G** (or "benzodiiimidaziophosphepines" = BODIMIOPs; R = Ph, N<sup>t</sup>Pr<sub>2</sub>)<sup>24</sup> and the phenyl- or *tert*-butyl-dicyclopropeniophosphine **2H** (R-DCPs, R = Ph, <sup>t</sup>Bu).<sup>25b-c</sup> Tri- $\alpha$ -cationic phosphines were also exemplified as the tricyclopropeniophosphines **2I**.<sup>29a</sup> While cyclopropeniophosphines such as **2E** have found applications in catalysis, they are definitely less P-electron-poor than their imidazoliophosphine counterparts **2D**, which turned out to undergo decomposition in catalytic conditions:<sup>26</sup> both free imidazoliophosphines and complexes thereof were indeed shown to undergo C-P bond cleavage in the presence of weak nucleophiles under mild condition, such as Cl<sup>-</sup> at 50 °C.<sup>27</sup> The  $\alpha$ -cationic character of imidazoliophosphines is thus *a priori* not compatible with general catalytic conditions involving some amount of basic reagent, and the search for neutral equivalents in terms of P-electron-poorness thus appears as a natural issue. This is addressed in the next section.

**Figure 2.** Representatives of electron-poor ligands: functional triarylphosphines (neutral) and carbeniophosphines ( $\alpha$ -cationic).

(iv) Replacements of aryl P-substituents of neutral phosphines by heteroaryl groups, possibly exerting a  $-M$  electron-withdrawing effect on the P atom by  $\pi$ -donation of the P lone pair into the antibonding  $\pi^*$  orbitals of the heterocycle, if lower in energy than in carboaryl groups (e.g.  $E(\pi^*) = E(\text{LUMO}) = -0.026$  Ha for pyridine ( $B_2$ ), vs 0.000 Ha for benzene ( $E_{2u}$ ), at the DFT level B3PW91/6-31G(d,p)). Simple hetero-aromatic phosphines were thus exemplified for more or less  $\pi$ -accepting five-membered heterocycles such furan in **3Aa**,<sup>28</sup> thiophene in **3Ab**,<sup>29</sup> or pyrrole in **3Ac**<sup>30a</sup> (Figure 3). The case of diazoles has attracted more attention, e. g. with N-methyl-imidazole in the tris(imidazolyl)phosphine **3B** (TIMP),<sup>30b</sup> and N-aryl/alkyl-imidazoles, N-aryl-benzimidazoles or oxadiazole in the mono-diazolyl-phosphines **3C**,<sup>30c</sup> **3D**<sup>22a</sup> or **3E**,<sup>30c</sup> respectively.<sup>30</sup>

**Figure 3.** Examples of neutral heteroaryl-monophosphines.

The electron density at P atom actually varies not only with the nature of the heterocycle, but also with its position on a given heterocycle. The steric demand towards the P atom can also be modulated by anchoring suitable substituents at suitable positions. From a more practical standpoint, the synthetic routes to heteroaryl phosphines are more versatile than in the carboaryl series. In particular, the CH vertex in  $\alpha$ -position to the endocyclic heteroatom is quite acidic, and can be regio-selectively substituted by the phosphinyl or selected decorating groups **3A** under mild conditions.<sup>31</sup>

**Figure 4.** Representative  $C_2$ -symmetric diheteroaryl-diphosphine ligands.

Quite early, in 1995, inspired by the in-time challenging development of  $C_2$ -symmetric diphosphines,<sup>32,33</sup> initiated by the discovery of BINAP **4A** in 1980,<sup>34</sup> Sannicolò *et al.* reported the first example of  $C_2$ -symmetric diheteroaryl-diphosphine, BITIANP **4B**,<sup>35</sup> followed the

next year, by BISCAP **4C** where the P(III) atoms are directly bound to endocyclic nitrogen atoms (Figure 4).<sup>36</sup> Simultaneously, the first atropo-chiral diheteroaryl-diphosphine BIMIP **4D**, based on the *N,N'*-bisbenzimidazolyl scaffold, was prepared in enantiomeric pure form: on this occasion, the authors highlighted the paradox between the electron-poor character of BIMIP and its coordinating ability towards metal centers.<sup>37</sup> In 2000 was reported the four-step synthesis of tetramethyl-bithiophene diphosphine, tetraMe-BITIOP **4E**.<sup>38</sup> On the basis of these results, a large number of atropochiral diheteroaryl-diphosphine ligands were then devised, as illustrated by BINAPFu **4F**,<sup>39</sup> N-Me-BINP **4G**,<sup>40</sup> or P-Phos **4H**.<sup>41</sup> C<sub>1</sub>-symmetric aryl-heteroaryl-diphosphines were also considered, such as BINATIP **5A** (Figure 5).<sup>42</sup> Congeners **5B-5H** were subsequently developed for their efficiency in the catalysis of Diels-Alder, hydrogenation and allylation reactions, including in the asymmetric version using enantio-enriched ligands such as (+)- or (-)-BIMINAP **5H**.<sup>26,43</sup>

Figure 5. Selected examples of aryl-heteroaryl-diphosphines (**5A-H**), and aryl-heteroaryl-monophosphines (**5I-J**).

The mono-phosphine versions "MONATIP" **5I** and IMNAP **5J** (actually **3D**, Figure 3), of **5A** and **5H** respectively, deserve emphasis as particularly rigid aryl-heteroaryl monophosphines.

With the view to enhancing further the P-electron-poor character of heteroaryl-phosphines while keeping their electric neutrality, substitution by electron-withdrawing substituents was considered. Beside the widely used groups in the carboaryl-phosphine series (F, CF<sub>3</sub>, CN, COR, SO<sub>2</sub>CF<sub>3</sub> (triflone)... See Figure 2), one became aware that the NO<sub>2</sub> group has remained unexplored, likely because of a possible redox incompatibility with the P<sup>III</sup> center. However, the electron-withdrawing effect of NO<sub>2</sub> through an aromatic system is *a priori* much stronger than that of CF<sub>3</sub> or CN, and deserves some attention. The challenge was thus addressed by designing a set of nitro-substituted (*N*-phenyl-benzimidazol-1-yl)diphenylphosphines, and targeting their complexes at a Rh(CO)Cl center, where the C=O IR stretching frequency and <sup>103</sup>Rh NMR chemical shift could serve as probes of the (weak) electron-donating character of the P-ligand.

In conclusion, a series of (*N*-phenyl-benzimidazol-1-yl)diphenylphosphines bearing a variable number of nitro groups at *N*-phenyl ring or/and benzimidazol core were prepared in the presence of optimized base LDA, and their corresponding *trans*-L<sub>2</sub>Rh<sup>I</sup>Cl(CO) complexes were also obtained through two strategies. (See Scheme 1.) The systematic variations of IR  $\nu_{CO}$  and <sup>103</sup>Rh NMR revealed the weakly  $\sigma$ -donating electronic properties of these nitro-substituted phosphines compared to the non-nitrated parent and cationic *N*-methylbenzimidazolium counterpart. Additionally, Dinuclear ( $\mu$ -CO)(LRhCl)<sub>2</sub> clathrate with a high content (6.7:1) of dichoromenthane in crystal state was observed in nitro-substituted series.

**Scheme 1.** The employed route for preparation of nitro-substituted (*N*-phenyl-benzimidazol-1-yl)diphenylphosphines and corresponding Rh<sup>I</sup> complexes.

## Rhodium Carbonyl Complexes

# The Forgotten Nitroaromatic Phosphines as Weakly Donating P-ligands: An *N*-Aryl-benzimidazolyl Series in RhCl(CO) Complexes

Chongwei Zhu,<sup>[a, b]</sup> Emmanuel Gras,<sup>\*[a, b]</sup> Carine Duhayon,<sup>[a, b]</sup> Francis Lacassin,<sup>[a, b]</sup>  
Xiuling Cui,<sup>[c]</sup> and Remi Chauvin<sup>\*[a, b, c]</sup>

Dedicated to Professor Marian Mikolajczyk on the occasion of his 80th birthday

**Abstract:** The coordination chemistry of a priori weakly  $\sigma$ -donating nitroaromatic phosphines is addressed through a series of nitro-substituted (*N*-phenyl-benzimidazol-1-yl)di-phenylphosphines in Rh<sup>I</sup> complexes. From a set of seven such phosphines L=L<sub>xyz</sub><sup>(1)</sup> (*x*, *y*, *z*=0 or 1=number of NO<sub>2</sub> substituents at the 5, 6 and *N*-Ph *para* positions, respectively), including the non-nitrated parent L<sub>000</sub> and its dicationic *N*-methyl counterpart L<sub>000'</sub>, three LRhCl(COD) and seven L<sub>2</sub>RhCl(CO) complexes have been obtained in 72–95% yield. Despite of a *cis* orientation of the L and CO ligands, the C=O IR stretching frequency  $\nu_{CO}$  varies in the expected sense, from 1967 ± 1 cm<sup>-1</sup> for L<sub>xy0</sub> to 1978 ± 1 cm<sup>-1</sup> for L<sub>xy1</sub>, and 2005 cm<sup>-1</sup> for L<sub>000'</sub>. The <sup>103</sup>Rh NMR chemical shift  $\delta_{Rh}$  varies

from -288 ppm for L<sub>000</sub> to -316 ± 1 ppm for L<sub>10z</sub> or L<sub>01z</sub>, and -436 ppm for L<sub>000'</sub>. The  $\nu_{CO}$  and  $\delta_{Rh}$  probes thus reveal moderate but systematic variations, and act as “orthogonal” spectroscopic indicators of the presence of nitro groups on the *N*-Ph group and the benzimidazole core, respectively. For the dicationic ligand L<sub>000'</sub>, a tight electrostatic sandwiching of the Rh-Cl bond by the benzimidazole moieties is evidenced by X-ray crystallography (RhCl<sup>δ-</sup>...CN<sub>2</sub><sup>δ+</sup> ≈ 3.01 Å). Along with the LRhCl(CO) complexes, dinuclear side-products (μ-CO)(RhCl)<sub>2</sub> were also obtained in low spectroscopic yield: for the dinitro ligand L=L<sub>011</sub>, a unique 1:6.7 clathrate structure, with dichloromethane as solvate, is also revealed by X-ray crystallography.

## Introduction

In the continuing debate on the fundamental nature of the coordination bond,<sup>[1]</sup> the ligands of some reference Lewis acids (LAs) are commonly classified between the electron-rich and electron-poor categories: for transition metal LAs, this pre-bonding characteristic makes it possible to predict strong or weak ligand-to-metal charge transfer. Beside the long studied class of electron-rich ligands, ranging from alkylphosphines to

diaminocarbenes and onium ylides,<sup>[2]</sup> the class of electron-poor phosphane counterparts has attracted less systematic attention but remains challenging for appraising coordination limits while decreasing the strength of  $\sigma$ -donation.<sup>[3]</sup> The need for electron-poor ligands is, however, more practically motivated by catalysis issues for rate-determining steps requiring a relatively low electron density at a metal center balanced by sufficient stability of the complex. Even weak  $\sigma$ -donation can indeed be compensated by strong  $\pi$ -back bonding, as it happens with phosphites identified as ligands of choice for catalytic transformations such as hydroformylation.<sup>[4]</sup> As esters of phosphorous acid, phosphites are however sensitive to P–O bond protolysis, and two main kinds of more robust electron-deficient triarylphosphine ligands can be distinguished: the electron-poor neutral phosphines, mainly represented by fluoroarylphosphine,<sup>[5]</sup> *N*-heteroarylphosphines (e.g., imidazolophosphines),<sup>[6]</sup> and the highly electron-poor  $\alpha$ -cationic phosphines, such as imidazolio-, diaminocyclopropenio-, or pyridinio-phosphines.<sup>[6a,7,8]</sup> These carbenio-phosphines, optimally described as carbene–phosphenium adducts,<sup>[9]</sup> have been shown to exhibit P-donating ability in ternary C→P→LA coordination motifs,<sup>[7a]</sup> even in the case of the extremely electron-poor  $\alpha$ -dicationic dicyclopropenio-phosphines.<sup>[10]</sup> While cyclopropenio-phosphines give particularly stable Pd complexes acting as efficient catalysts (e.g., for cycloisomerization of enynes),<sup>[7d,11]</sup> imidazolio-phosphines and their complexes are more reactive, un-

dergoing P–C bond cleavage in the presence of weak nucleophiles (such as  $\text{Cl}^-$ ), thus restricting the scope of possible applications.<sup>[9,12]</sup>

With the view to enhancing the electron-deficiency of the parent imidazolophosphines without the detrimental effect of the  $\alpha$ -positive charge, N-methylation of the former ( $\text{CH}_3^+$  N-coordination) could be replaced by CH-substitution with neutral electron-withdrawing groups (Figure 1). Examination of this issue drew the author's attention to the fact that an a priori simple way to make a triarylphosphine ligand more electron-deficient while remaining neutral seems to have been forgotten: alternative to fluorination, nitration should indeed be particularly efficient. Indeed, considering Hammett constants  $\sigma_p$  and  $\sigma_m$  as crude means of comparison of the electron-withdrawing effect of a substituent through an aromatic system,<sup>[13]</sup> one of the largest values is attained for  $\text{NO}_2$  ( $\sigma_m=0.71$ ,  $\sigma_p=0.78$ ), standing close to that of the cationic substituent  $^+\text{NMe}_3$  ( $\sigma_m=0.88$ ,  $\sigma_p=0.82$ ), and much higher than those of other neutral substituents such as F ( $\sigma_m=0.34$ ,  $\sigma_p=0.06$ ),  $\text{CF}_3$  ( $\sigma_m=0.43$ ,  $\sigma_p=0.54$ ) or CN ( $\sigma_m=0.56$ ,  $\sigma_p=0.66$ ).<sup>[14]</sup>

Prior to any coordination chemistry considerations, the oxymoronic redox nature of nitro-substituted arylphosphines can be considered as a basic challenge,<sup>[15]</sup> at least from the thermodynamic standpoint (the nitro-nitroso isomerization  $4\text{-NO}_2\text{-C}_6\text{H}_4\text{-PPh}_2 \rightarrow 4\text{-NO-C}_6\text{H}_4\text{-P(O)Ph}_2$  is calculated to be exothermic by  $\Delta ZPE = -23.2 \text{ kcal mol}^{-1}$ ; see the Supporting Information).<sup>[16]</sup> Direct nitration of aryl-phosphines are prevented by the P-oxidizing potency of the nitronium ion,<sup>[17]</sup> and most of related synthetic efforts have focused on oxidized P=O or P=S precursors.<sup>[18]</sup> Coordination complexes of nitroarylphosphines are actually limited to the formal cases of such P→O or P→S de-

rivatives: to the best of our knowledge, indeed, no experimental example of corresponding P→metal complexes has ever been reported,<sup>[19]</sup> thus unveiling a quite general challenge. While the basic triphenylphosphine series will deserve a natural attention, in particular for the reference (4-nitrophenyl)diphenylphosphine (see Conclusion),<sup>[15b,20]</sup> the forgotten nitration strategy for lowering further the electron deficiency of aromatic phosphine ligands is hereafter addressed within the above-summarized concern in the benzimidazolyl phosphine series (Figure 1 a).

While modern routes to arylphosphines consist in Cu-, Ni- or Pd-catalyzed Ar-P coupling reactions from  $\text{Ar-X} + \text{E-PPh}_2$  ( $\text{X}=\text{I}, \text{Br}, \text{OTf}$ ;  $\text{E}=\text{H}, \text{Ph}, \text{SnBu}_3, \text{Cl}$ ), nitro-ArX substrates are rarely exemplified,<sup>[21]</sup> and have even been claimed to be incompatible with generally efficient conditions.<sup>[22]</sup> Yet, the most employed approach to tertiary phosphines remains based on nucleophilic substitution processes at P centers with lithium or Grignard reactants, as also illustrated in the arene/heteroarene series,<sup>[23]</sup> in particular for imidazole and benzimidazole representatives.<sup>[6e,12b]</sup> For the present objective, (*N*-aryl-1*H*-benzimidazol-2-yl)diphenylphosphines have thus been targeted from the more or less nitrated *NH,N*<sub>2</sub>*CH* benzimidazole precursors **1a–d** by substitution of  $\text{ClPPh}_2$  with lithium salts of *N*-aryl-*N*<sub>2</sub>*CH* derivatives **2a–h** (Figure 1 b). The propensity of nitro-arene/heteroarene substrates to undergo addition or redox processes in the presence of lithium reagents has indeed been reported for alkyl lithiums only.<sup>[24]</sup> Moreover, since *N*-methyl-5-nitro-1*H*-benzimidazol-2-yl lithium has been shown to undergo selective electrophilic chlorination with NCS,<sup>[25]</sup> reaction of the 1*N*-phenyl congener **2b** with the analogous  $\text{Ph}_2\text{P-Cl}$  electrophile appears as a natural possibility to prepare the set of eight

Figure 1. a) top: alternative manners to tune the P- $\sigma$ -donating ability of benzimidazolophosphines towards a Lewis acid (LA): C-nitration vs. N-alkylation (expected order of inductive effects:  $I_0 < I_{\text{NO}_2} < I_+$ ); b) bottom: selected targets and synthetic approach.

more or less nitrated *N*-aryl-1*H*-benzimidazolophosphines **3a–h** (Figure 1). Their coordinating properties were then envisaged to be compared by the  $\nu_{\text{CO}}$  stretching frequencies of carbonyl complexes thereof (LA = Ni(CO)<sub>3</sub> in Figure 1a).<sup>[26]</sup> Instead of Ni(CO)<sub>3</sub> serving to define the Tolman's electronic parameters, LA = RhCl(CO) is here preferred for the sake of comparison with former results on related complexes of chelating bisimidazolophosphines,<sup>[27]</sup> and more generally because of the added value of the complementary <sup>103</sup>Rh NMR probe for rhodium-phosphine complexes.<sup>[28]</sup>

## Results and Discussion

### Synthesis of nitro-benzimidazolophosphines

The four *NH*,*N*<sub>2</sub>*CH* benzimidazole precursors **1a–d** were provided either as commercially available for **1a**, or prepared following known procedures; the nitro derivative **1b** or **1c** (in tautomeric equilibrium) was thus elaborated from 4-nitro-1,2-benzenediamine by condensation of triethylorthoester in the presence of a catalytic amount of TiCl<sub>4</sub> and the dinitro derivative **1d** was obtained by nitration of **1b,c** with fuming HNO<sub>3</sub> in concentrated H<sub>2</sub>SO<sub>4</sub> (see the Experimental Section and cited references).

*N*-Phenylation of **1a** and **1b,c** was implemented by copper-catalyzed C–N coupling from iodobenzene under conditions reported by Buchwald et al.,<sup>[29]</sup> yielding **2a** in 90% yield,<sup>[30]</sup> and the isomers **2b** and **2c** in 64% and 23% yield, respectively, after separation by column chromatography.<sup>[31]</sup> The method however failed to produce **2d** from **1d**, in correlation with the very low *N*-nucleophilicity of **1d** resulting from the cooperative effect of the two nitro groups.

*N*-*p*-Nitrophenylation of **1a–c** was carried out by *S<sub>N</sub>Ar* of 4-fluoro-nitrobenzene, affording the known nitro derivative **2e** in 95% yield,<sup>[30]</sup> and the isomers **2f** and **2g** in 53% and 34% yield, respectively.<sup>[32]</sup> Using the same procedure from **1d**, the trinitro derivative **2h** was isolated in 86% yield (Scheme 1).

**Scheme 1.** Syntheses of nitro-functionalized benzimidazoles (for the 4,5-*X*<sub>2</sub> isomer of **1d**, **1d'**, see the Supporting Information).

Phosphinylation of the lithium salts of **2a–c**–**2e–h** by nucleophilic substitution of ClPPh<sub>2</sub> required optimization of the initial deprotonation step. Inspired by the above-mentioned report on the selective deprotonation and reactivity of the *N*-methyl congener of **2b**,<sup>[25]</sup> the use of lithium diisopropylamide (LDA) as a base in THF was envisaged, with a strict control of the temperature at –78 °C.<sup>[33]</sup> Applied to **2b**, these conditions indeed allowed isolation of **3b** in 83% yield, in the absence of any oxazobenzene side-product (Scheme 2).<sup>[33]</sup> The same procedure gave access in 56% yield to the reference non-nitrated benzimidazolophosphine **3a**, previously reported to be available in 20% yield only under metal-free conditions (in the presence of NEt<sub>3</sub> as a base).<sup>[34]</sup> In summary, application of the LDA procedure to **2a–c**–**2e–g** afforded **3a–c**–**3e–g** in 45–83% yield, while only trace amounts of **3h** were obtained from the trinitro substrate **2h**. The phosphinylation selectivity was first evidenced by NMR spectroscopy by the disappearance of the amidine C<sup>1</sup>H singlet signal at 8.10–8.90 ppm and the appearance of a <sup>31</sup>P{<sup>1</sup>H} singlet signal in the range –21.3/–24.5 ppm.

Single crystals of **3b**, **3c**, **3e** and **3f** deposited from solvent mixtures of pentane and dichloromethane (DCM) were found suitable for X-ray diffraction (XRD) analysis (see the Supporting Information).<sup>[35]</sup> Notably, the structure of the 5-nitrobenzimidazolophosphine **3b** was resolved in the uncommon *P*6<sub>1</sub> space group of the hexagonal system. In all the structures, the C–P distances are virtually identical (1.83 ± 0.01 Å) and the torsion angles between the *N*-Ar and benzimidazole mean planes have a median value of 68.5 ± 1.3°. The amidine sp<sup>2</sup>-C1 atom is found slightly pyramidalized, with a tilting angle of the C–P bond axis versus the imidazole ring mean plane of ca. 4.7 ± 0.3° for **3c** and **3e–f**, but reaching 11.3° for **3b**.

### Coordination complexes of nitro-benzimidazolophosphines

With the view to comparing the coordinating properties of the benzimidazolophosphines through IR  $\nu_{\text{CO}}$  values of RhCl(CO), complexes of type **4** (Scheme 3), **3a–c** and **3e–h** were first sequentially reacted with [Rh(COD)Cl]<sub>2</sub> (for cleavage of the  $\mu$ -Cl

**Scheme 2.** Selective C-phosphinylation of nitro-functionalized benzimidazoles.

**Scheme 3.** Sequential and one-pot, two-step syntheses of RhCl(CO) complexes of nitro-substituted benzimidazolophosphines. From **6x**, initially non-identified side-products denoted as **6x** ( $x = \mathbf{b, c, e-g}$ ) were also obtained (see Figure 3).

bridges; COD = 1,5-cyclooctadiene) before displacement of the COD ligand by a second equivalent of the phosphine and a carbonyl ligand.

Reaction of **3b** with half an equivalent of [Rh(COD)Cl]<sub>2</sub> in DCM for 2 h at room temperature led to the COD complex **4b** in 95% yield. P-Rh coordination was established by the change of the <sup>31</sup>P{<sup>1</sup>H} NMR signal, shifting from -22.88 to +19.00 ppm, and splitting from a singlet to a doublet with a coupling constant of 150.7 Hz characteristic of a <sup>1</sup>J<sub>PRh</sub> coupling. Moving the nitro group from the benzimidazole core in **3b** to the Ar N-substituent in **3e** did not alter the reactivity with the Rh<sup>I</sup> dimer, giving **4e** in 93% yield. Likewise, reaction of the di-nitro benzimidazolophosphine **3f** with [Rh(COD)Cl]<sub>2</sub> gave **4f** in a similar 94% yield. Further displacement of the COD ligand of **4b**, **4e** and **4f** was achieved by adding one additional equivalent of the respective phosphines **3b**, **3e** and **3f**, followed by CO bubbling for 15 min, thus affording the diphosphine RhCl(CO) complexes **5b**, **5e** and **5f** in 74 ± 2% yield (Scheme 3). In each case, another phosphine-rhodium complex numbered as **6b**, **6e** or **6f** was concomitantly formed as an initially non-identified side-product, the structural assignment of

which could be achieved by crystallographic analysis only (see below, Figure 3).

A one-pot procedure was also attempted, providing the target complexes with slightly higher overall yields, as illustrated from **3a**, **3c** and **3g** (Scheme 3). Two equivalents of **3c** were thus treated with half an equivalent of [Rh(COD)Cl]<sub>2</sub> in DCM for 2 h at r.t., and subsequently with bubbling carbon monoxide for 15 min., affording **5c** in 81% yield. The same treatment from **3a** and **3g** provided directly **5a** and **5g** in 79% and 73% yield, respectively. In all cases involving a nitro ligand (not in the case of **5a**), the side-product of initially unknown structure **6x** ( $x = \mathbf{b, c, e-g}$ ) was also observed (see below).

For the sake of reference to the original concern, the RhCl(CO) complex **5a'** of the cationic benzimidazolophosphine **3a'** was also targeted. Treatment of **3a** with one equivalent of methyl triflate (MeOTf) in DCM at -78 °C actually led to the N-methylated target product **3a'** in mixture with the P-methylated isomer **3a''** in a 5:1 ratio, as evidenced by the disappearance of the <sup>31</sup>P NMR signal of **3a** (-24.49 ppm) and appearance of two signals at -15.48 and +14.36 ppm consistent

with the structures of **3a'** and **3a''**, respectively. This lack of N/P selectivity in the reaction of the hard methylating agent MeOTf with imidazolophosphine is unprecedented, but correlated with the absence of a second P center in the monophosphine **3a** as compared to the cases of the *N*-aryl benzimidazolo- and imidazolo-diphosphines BIMINAP (2-(diphenylphosphanyl)-1-[2-(diphenylphosphanyl)naphthalen-1-yl]-1*H*-1,3-benzodiazole) and BIPHIMIP (2-(diphenylphosphanyl)-1-[2-(diphenylphosphanyl)phenyl]-1*H*-imidazole).<sup>[6e, 12b, 36]</sup> Under the same conditions, treatment of the 5-nitrobenzimidazolophosphine **3b** with MeOTf gave a mixture of the *N*- and *P*-methylated isomers **3b'** and **3b''** in a 3:2 ratio according to NMR analysis (see the Supporting Information); this further lowering of N/P selectivity can be interpreted by the electron-withdrawing effect of the nitro group decreasing the electron density of the *N* atom more than that of the more remote *P* atom.

As the two cations **3a'** and **3a''** could not be efficiently separated, the 5:1 mixture was used in coordination experiments. Treatment of this mixture with 0.25 mol. equivalent of [Rh(COD)Cl]<sub>2</sub> with respect to **3a'**, before bubbling carbon monoxide for 15 min allowed the complex **5a'** to be isolated in a high 85% yield after removal of **3a''** by washing the DCM-containing residue with cold pentane (Scheme 4).

The P<sub>2</sub>RhCl(CO) complexes of type **5** have been characterized by <sup>1</sup>H, <sup>13</sup>C, <sup>31</sup>P and <sup>103</sup>Rh NMR and IR spectroscopies (see below). Remarkably, no MS method, among ESI, APCI and MALDI, was found suitable to produce molecular peaks of the complexes, preventing structural confirmation by HRMS: the lability of primary cationic species generated in the MS chamber is actually correlated with the weak donating ability of the monodentate ligands. The structures of **5a–c**, **5f–g** and **5a'** were more precisely determined by XRD analysis of single crystals grown slowly from DCM solutions (Table 1, Figure 2). Nota-

bly, the structure of the dinitro ligand complex **5f** was resolved with the chiral space group *P*2<sub>1</sub>2<sub>1</sub>. In the crystal state, all the complexes were found to exhibit a square planar-like geometry, with a *trans* arrangement of the two phosphine ligands, and an occupation disorder of the facing Cl and CO ligands, except for **5f** and **5a'**. While the Rh–Cl and Rh–C distances vary in the ranges 2.38 ± 0.03 Å and 1.81 ± 0.02 Å, respectively, the C–P distances remain close to 2.31 ± 0.01 Å. The C–O distance, varying in the range 1.14 ± 0.03 Å (Table 1), appears not to be a significant indicator of the global electron-donating ability of the phosphine ligand.<sup>[37a]</sup> This can be ascribed to the *cis*-orientation of the P–Rh–CO bonds, and to the long recognized considerably weaker geometrical *cis*-influence of a *P* ligand on the lengthening of a geminal Rh–L bond (with an

Scheme 4. *N*- vs. *P*-methylation of the benzimidazolophosphine **3a**, and *P*-coordination of the benzimidazolophosphine product **3a'** at a RhCl(CO) center.

**Figure 2.** XRD molecular views of **5a–c**, **5f–g** and **5a'**. Thermal ellipsoids at the 50% probability level. For clarity, hydrogen atoms are omitted. The ellipsoid diagrams of the triflate anions of **5a'** are also omitted. The N-Ph and P-Ph *ipso* atoms reveal a  $\pi$ -stacking interaction: C8–C14  $\approx$  3.26 Å (**5a**), 3.20 Å (**5b**, **5c**), 3.18 Å (**5f**), 3.14 Å (**5a'**); C8–C20  $\approx$  2.24 Å (**5g**); C34–C40  $\approx$  3.14 Å (**5a'**). In the dication **5a'**, the sandwiching of the Cl atom by the benzimidazolium moieties is indicated by the short distances: C11–C1  $\approx$  C11–C27 = 3.01  $\pm$  0.01 Å, C11–N1  $\approx$  C11–N3 = 3.20 Å, C11–N2  $\approx$  C11–N4 = 3.41  $\pm$  0.00 Å C11–C26  $\approx$  C11–C52 = 3.55  $\pm$  0.05 Å.

even weaker correlated influence on the C=O bond length for L=CO) as compared to the corresponding *trans*-influences.<sup>[37b]</sup> For the a priori least donating dicationic ligand **3a'**, the intermediate C–O distance value of 1.14 Å is, however, also correlated with the unique conformational features of the complex **5a'**. In the neutral complexes **5a–c**, **5f–g**, indeed, the ImPh<sub>2</sub>P-(Rh)-PPh<sub>2</sub>Im unit adopts a staggered conformation, with perfectly *anti*-periplanar imidazolyl groups in **5a–c** and **5g** (Im-P-P-Im dihedral angles = 180°), and *synclinal-gauche* imidazolyl groups wrapping the Rh–Cl bond in **5f** (Im-P...P-Im dihedral angle = 45°, N<sub>2</sub>C...Cl  $\approx$  3.28 Å). In contrast, the dicationic complex **5a'** exhibits a perfectly eclipsed conformation of the Rh–Cl bond with both the *syn*-periplanar imidazolyl groups (Im-P...P-Im dihedral angle = 2.8°); the shortness of the N<sub>2</sub>C<sup>+</sup>...Cl<sup>δ-</sup> distances (3.01  $\pm$  0.01 Å) is attributed to the electrostatic effect.

#### Tentative analysis of coordination properties of nitro-benzimidazolophosphines

Disregarding the classical broadness of the <sup>1</sup>H signals of the cyclooctadiene ligand in complexes **4**, all the other signals of NMR spectra of complexes **4** and **5** recorded at room temperature are particularly sharp (see the Supporting Information, section 2, pp. 32–51), ruling out any slow equilibrium between a main *trans* form (found in the crystal state) and significant

proportion of the putative *cis* isomer. The latter is indeed expected to be thermodynamically highly disfavored by the bulkiness of the P environment. Notably, the <sup>31</sup>P coordination shift  $\Delta\delta_{31p}(x) = \delta_{31p}(5x) - \delta_{31p}(3x)$  ( $x = a-g, a'$ ) is found larger for the cationic ligand ( $\Delta\delta_{31p}(a') = 53.6$  ppm) than for the neutral ligands, for which  $\Delta\delta_{31p}$  is found to depend on the presence of NO<sub>2</sub> groups on the benzimidazole core only (Table 2):  $\Delta\delta_{31p} \approx 45.5 \pm 0.1$  ppm for a non-nitrated benzimidazole core ( $x = a, e$ ),  $\Delta\delta_{31p} \approx 46.6 \pm 0.3$  ppm otherwise ( $x = b, c, f, g$ ). At last, the <sup>1</sup>J<sub>RhP</sub> coupling constant does not vary significantly remaining in the range 129.6  $\pm$  1.5 Hz for all the neutral complexes, and just reaching 132.8 Hz for the dicationic complex **5a'**.

In a more classical approach, the IR stretching frequency of the CO co-ligand ( $\nu_{CO}$ ) and <sup>103</sup>Rh, <sup>31</sup>P NMR chemical shifts ( $\delta_{103Rh}$ ,  $\delta_{31p}(5x)$ ) of the (3x)<sub>2</sub>RhCl(CO) complexes **5x** in CD<sub>2</sub>Cl<sub>2</sub> solutions were selected for appraising the coordinating properties of **3x**,  $x = a-g, a'$  (Table 2). The “pre-coordinating” properties of the latter was also tentatively envisaged to be revealed by its <sup>31</sup>P NMR chemical shift in the free state,  $\delta_{31p}(3x)$ .

As previously observed in related RhX(COD)(phosphine) complexes,<sup>[28]</sup> no correlation is observed between  $\delta_{103Rh}(5x)$  and either  $\delta_{31p}(5x)$  or  $\delta_{31p}(3x)$ . P-Coordination to non-metal hard Lewis acids such an oxygen atom is the singlet spin state (promoted oxygen, O\*) was also envisaged in the corresponding phosphine oxides **3xO**,  $x = a-g$ , generated by treatment of **3x** with H<sub>2</sub>O<sub>2</sub> (**3aO** and **3bO** were also isolated and character-

**Table 2.** Selected IR, NMR spectroscopic or crystallographic data for the ligands **3a–c**, **3f, g**, **3a'** or complexes thereof.<sup>[a,b]</sup>

[a] Substitution pattern ( $x = \mathbf{a-g, a'}$ ) of N-phenyl-benzimidazole core as defined in Figure 1 ( $X, Y, Z = \text{H, NO}_2$ ) and Scheme 4 (for **a'**). [b] NMR spectra of solutions in CD<sub>2</sub>Cl<sub>2</sub>; [c] from IR spectra in the solid state recorded by the ATR (attenuated total reflection) technique; [d] chemical shift with respect Rh(acac)<sub>3</sub> with the frequency ratio  $\Xi' = 3.186447\%$ ; [e] chemical shift for the formal frequency ratio  $\Xi = 3.160000\%$ ; [f] the  $^1J_{\text{Rh-P}}$  coupling constants remain similar, varying from 128.3 Hz for **5e** to 132.8 Hz for **5a'**; [g] coordination shift:  $\Delta\delta_{31\text{P}}(\text{x}) = \delta_{31\text{P}}(\mathbf{5x}) - \delta_{31\text{P}}(\mathbf{3x})$ ; [h] from X-ray diffraction data (see Table 2 and the Supporting Information).

for the dicationic complex **5a'** are out of range, but relatively consistent with the expected effects of "electronegative" substituents on the global donating character of the P atom towards the RhCl(CO) center.

The sensitivity of the  $\nu_{\text{CO}}$  value to *p*-nitro-substitution at the N-phenyl group is remarkable (+10 cm<sup>-1</sup> for a remote NO<sub>2</sub> group, nine-bond away from the CO ligands), in particular with regard to the vanishing effect of nitro substitution at the benzimidazole core in spite of  $\pi$ -conjugation with the coordinating P center. Whatever the electronic process at stake (partial  $\pi$ -conjugation and/or  $\sigma$ -inductive attraction through the N-Ar bond), the observation is in line with former observations of a marked effect of *N*-nitroaryl and *N*-fluoroaryl substitution on intrinsic  $\pi$ -accepting ability or catalytic properties of imidazol-2-ylidene ligands.<sup>[38]</sup>

ized: see the Supporting Information); the <sup>31</sup>P NMR shifts of **3xO** remain, however, almost constant at 17.5 ± 0.5 ppm.

The  $\nu_{\text{CO}}$  and  $\delta_{103\text{Rh}}$  parameters thus appear to play complementary roles for appraising the effects of nitro substituents on either the benzimidazole core or pending N-phenyl group, respectively.

Whatever the nitro-decoration of the benzimidazole core, indeed, an N-phenylated ligand gives  $\nu_{\text{CO}} = 1968 \pm 1 \text{ cm}^{-1}$  (**5a–c**) and an N-*p*-nitrophenylated ligand gives  $\nu_{\text{CO}} = 1979 \pm 1 \text{ cm}^{-1}$  (**5e–g**). Using the <sup>103</sup>Rh NMR probe (see the Experimental Section), whatever the N-aryl substituent, the presence of a nitro substituent on the benzimidazole core (at either position 5 or 6) gives  $\delta_{103\text{Rh}} = -315 \text{ ppm}$ , vs.  $\delta_{103\text{Rh}} = -288 \text{ ppm}$  for the non-nitrated reference **5a** (the value for **5e** could, however, not be determined due to solubility issues). The  $\nu_{\text{CO}}$  and  $\delta_{103\text{Rh}}$  values

### Dinuclear nitro-benzimidazolophosphine side products: CH<sub>2</sub>Cl<sub>2</sub>-clathrate complexes

Each of the nitro-containing complexes **5b,c**, **5e–g** (Scheme 3) was actually obtained in mixture with a side-product containing a Rh–P bond, as evidenced by <sup>31</sup>P NMR spectroscopy of the crude material, and denoted as **6b,c**, **6e–g** (see the Experimental Section). The exact structure of these complexes could, however, not be assessed by spectroscopic methods. In the case of the dinitro ligand **3f**, however, crystals of **6f** deposited from a DCM solution of the residue obtained from the supernatant of crystals of **5f** after reaction of **3f** with **4f** (Scheme 3). X-ray diffraction analysis showed a dinuclear structure, where the two Rh centers are in distorted bipyramidal environments, coordinated by a  $\mu$ -CO and two P,N-bridging ligands **3f** (Figure 3). The corresponding structures are assigned

**Figure 3.** Lewis structure of the dinuclear side-products formed along with the target complexes **5b,c**, **5e–g** (Scheme 3; top), crystallographic molecular view of **6f** with thermal ellipsoids at the 50% probability level (bottom left), and free van der Waals gallery available for hosting DCM solvent molecules within the network of molecules of **6f** (bottom right).

to the side-products **6b**, **6c**, **6e** and **6g** obtained from **4b**, **4c**, **4e** and **4g**, respectively.

A search in the CCDC database for similar complexes featuring such a  $[\text{Rh}_2(\mu\text{-CO})\text{Cl}_2]$  core gave 18 related examples, five of them featuring P,N coordination to the Rh centers, with Rh–Rh bonding distances ranging from 2.57 Å to 3.01 Å.<sup>[39]</sup> The Rh–Rh distance of 2.63 Å measured in **6f** is thus quite short, smaller than the average value of 2.68 Å over the series. The Rh–Cl bonds of **6f** (bent from the Rh–Rh axis by ca. 163°) are significantly shorter than all the corresponding bonds within the CCDC sampling (2.36 Å vs. 2.42 to 2.45 Å). The C–O distance of 1.17 Å measured in **6f** is identical to the average value over the CCDC series. The Rh–P bonds of **6f** are found to be quite short (2.21–2.22 Å), and much shorter than in the parent complex **5f** (2.31 Å). The Rh–N bonds are, however, found to be consistently shorter (2.08–2.10 Å).

The crystals of **6f** are actually clathrates, with 6.7 DCM molecules per molecule of **6f**. The high solvent content was first suspected after observing disintegration of isolated crystals in polyisobutene blend oils used as cryo-protectants for XRD analysis (PARATONE or PARABAR 10312; the use of a perfluoropolyether oil, PFO-XR 75, was finally required). The solvate molecules are spread over 12 positions, eight of them being partially occupied and forming a chain with short distances between positions strongly occupied by Cl atoms ( $\text{Cl}\cdots\text{Cl} \approx 3.5$  Å), thus suggesting that the chain cohesion is due to halogen bonding,<sup>[40a]</sup> today widely invoked in crystal engineering.<sup>[40b,c]</sup> Chains of DCM molecules were also proposed to occur in a related dirhodium complex,<sup>[39]</sup> but the extended van der Waals gallery within the crystal network of **6f** (Figure 3) meets more general challenges in the search for metal–organic inclusion compounds of the clathrate type or porous coordination polymers,<sup>[41a]</sup> in particular for DCM guest molecules which are more currently found hosted by organic lattices.<sup>[41b–e]</sup> Within the family of the Werner clathrates, based on a discrete packing of  $\text{MX}_2\text{L}_4$  complexes ( $M$  = divalent transition metal ion,  $X$  = small anionic ligand,  $L$  = pyridine ligand),<sup>[41f]</sup> and related Hoffmann clathrates based on a grid of CN-bridged coordination polymer (initiated by the cadmium(II)- $\text{CCl}_4$  clathrate),<sup>[41g,h]</sup> one may cite the Werner DCM-clathrate  $[\text{Ni}(\text{NCS})_2(3\text{-cyanopyridine})_4] \cdot 2\text{CH}_2\text{Cl}_2$ .<sup>[41i]</sup> More particular examples are the recently described dinuclear clathrates  $[\text{Cd}_2(\mu\text{-L})_2] \cdot \text{CH}_2\text{Cl}_2$  ( $L$  = 4,4'-bis(2-methylimidazol-1-ylmethyl)biphenyl),<sup>[41j]</sup> and  $[\text{Ag}(\text{NO}_3)_2\text{Pt}(\mu\text{-benzothiadiazol-4-ylethynyl})(4\text{-diphenylaminopyridine})] \cdot \text{CH}_2\text{Cl}_2$ .<sup>[41k]</sup>

## Conclusion

The disclosed strategy, upstream based on the use of LDA as the optimal base for the deprotonation of more or less nitrated *N*-aryl benzimidazole precursors dedicated to react with  $\text{ClPPh}_2$ , allowed a pioneering exploration of the coordination chemistry of nitroaromatic phosphines as neutral electron-poor ligands with decreased  $\sigma$ -donating ability. The approach and results open natural prospects in organometallic chemistry such as the synthesis of tri- or tetra-nitro counterparts of the ligands **3**, the design of chelating diphosphine congeners, and the comparison with possible analogous complexes of nitrated

triphenylphosphines such as  $(4\text{-NO}_2\text{-C}_6\text{H}_4)_3\text{P}$  standing as a paradigm. As a preliminary analysis, reduction of the P atom of known *p*-nitrophenylphosphine oxides with the classical  $\text{HSiCl}_3$  reagent is, however, expected to be tricky: in spite of an early report,<sup>[15e]</sup> recent results indeed indicate that competing reduction of the nitro group by  $\text{HSiCl}_3$  could occur, even under milder conditions.<sup>[42]</sup> In an alternative strategy, (4-nitrophenyl)-diphenylphosphine, partly described 40 years ago,<sup>[15b,20]</sup> was targeted from 4-nitro-iodobenzene and  $\text{ClPPh}_2$  but could not be isolated, and further efforts in this direction are naturally envisaged. Nevertheless, targeting the particular category of the benzimidazolylphosphine complexes **4** and **5** gave the opportunity of evidencing unique features such as: (i) empirical binary "orthogonal spectroscopic indicators" of the presence or not of nitro groups on distinct parts of the ligand (the benzimidazole core and the *N*-aryl substituent), based on an observed contrast between two ranges of values separated by ca. 5 times the spectroscopic resolutions:  $10\text{ cm}^{-1}$  and 30 ppm, respectively, for the  $\nu_{\text{CO}}$  and  $\delta_{\text{Rh}}$  probes at the  $\text{RhCl}(\text{CO})$  center; (ii) in the dicationic complex **5a'**, an electrostatic sandwiching of a chloro ligand by two imidazolium rings resulting from a packing effect, and possibly balanced by enhanced polarization of the Rh–Cl bond; (iii) serendipitous finding of an organic–organometallic clathrate of high solvent content (the DCM solvate complex **6f**). A more general occurrence of such features could be sought for in other systems involving other transition metals (Ni, Pd, Pt) and ligands or co-ligands thereof. Finally, beyond coordination chemistry, the results are naturally aimed at exploring the use such complexes in homogeneous catalysis.

## Experimental Section

### General remarks

THF and diethyl ether were dried and distilled over sodium-benzophenone. Pentane and dichloromethane (DCM) were dried with a PureSolv-MD-5 Innovative Technology system for the purification of solvents.  $[\text{Rh}(\text{COD})\text{Cl}]_2$  and other reagents were employed as received from commercial sources, in particular, solutions of *n*BuLi were 2.5 M in hexane. All reactions were carried out under an argon atmosphere by using Schlenk and vacuum line techniques. Column chromatography was carried out on silica gel (60 Å, C.C 70–200  $\mu\text{m}$ ). Previously reported procedures were used for the preparation of the phosphines and their precursors, in particular for the previously described compounds **1b** and **1c**,<sup>[43]</sup> **1d** and **1e**,<sup>[44]</sup> **2a**,<sup>[45]</sup> and **3a**.<sup>[6e,29b]</sup>

### Procedures for the preparation of new compounds

For the characterization of the reported compounds by  $^1\text{H}$ ,  $^{31}\text{P}$ ,  $^{13}\text{C}$  NMR and IR spectroscopies, by mass spectrometry, and by melting point, see the Supporting Information.

**Preparation of 2b and 2c.**<sup>[44]</sup> A mixture of **1b** (2.69 g, 16.5 mmol),  $\text{Cu}^{\text{I}}$  (0.263 g, 1.38 mmol), 1,10-phenanthroline (0.48 g, 2.76 mmol),  $\text{Cs}_2\text{CO}_3$  (9.42 g, 28.9 mmol) was evacuated twice and back-filled with argon in a dried Schlenk tube, then iodobenzene (1.52 mL, 13.8 mmol) and DMF (20 mL) was added with a syringe. The reaction mixture was stirred at  $100^\circ\text{C}$  for 48 h. After the mixture was cooled down to ambient temperature, the solution was filtered on

silica gel, extracted with EtOAc, dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified by column chromatography on silica gel eluted with a 3/2 EtOAc/pentane mixture to deliver **2b** (2.108 g, 8.8 mmol, 64%) and **2c** (0.75 g, 3.1 mmol, 23%) as yellow solids.

**Preparation of 2f and 2g.**<sup>[46]</sup> A mixture of **1b** (1.63 g, 10 mmol) and NaOH (0.40 g, 10 mmol) in 20 mL DMF was treated with 4-nitrofluorobenzene (2.12 mL, 20 mmol) at room temperature under argon. The mixture was stirred at 70 °C for 5 h before addition of water. The resulting suspension was extracted with EtOAc (3 × 40 mL), and the organic layers were combined, dried over MgSO<sub>4</sub> and concentrated to dryness under reduced pressure. Column chromatography of the residue on silica gel eluted with a 3/2 EtOAc/pentane mixture afforded the corresponding products **2f** (1.51 g, 5.3 mmol, 53%) and **2g** (0.97 g, 3.4 mmol, 34%) as yellow solids.

The same procedure from **1e** afforded **2e** as a yellow solid in 95% yield. Starting from **1h**, and changing the chromatographic eluting system to a 1/1 EtOAc/pentane mixture, **2h** was obtained as a yellow solid in 86% yield.

### General procedure for preparation of the nitroaromatic phosphines **3b,c**, **3e-h**

A solution of **2a-c**, **2e-h** (1 equiv) in THF was treated with a solution of freshly prepared LDA (1.2 equiv) at -78 °C. The mixture was slowly warmed up to -40 °C, then stirred for 1 h at this temperature. After cooling back to -78 °C, chlorodiphenylphosphine was added dropwise and the solution was slowly warmed up, then stirred at r.t. for 4 h. After addition of a saturated aqueous NH<sub>4</sub>Cl solution and dilution with DCM, the aqueous layer was separated and the organic layer was dried over MgSO<sub>4</sub> and concentrated to dryness under reduced pressure. The residue was purified by column chromatography on silica gel eluted with a 3/1 DCM/pentane mixture to give the corresponding products as yellow solids (for more details, see the Supporting Information): **3a** (78%), **3b** (83%), **3c** (70%), **3e** (62%), **3f** (77%), **3g** (45%), **3h** (< 5%).

### General procedure for generation of the phosphine oxides **3xO** (x = a-c, e-g)

The phosphine oxides were generated according to a previously reported procedure,<sup>[47]</sup> by treatment of a solution **3x** in THF with H<sub>2</sub>O<sub>2</sub> (3 equiv) at room temperature under TLC monitoring. After addition of NaHCO<sub>3</sub> and Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> solutions, the reaction mixture was separated, and the aqueous layer was extracted with DCM. The combined organic layer was dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated under reduced pressure affording the corresponding phosphine oxide in quantitative <sup>31</sup>P NMR spectroscopic yield without further purification. The products were analyzed by <sup>31</sup>P NMR spectroscopy only (see Table 2), except for **3aO** and **3bO** which were more completely characterized (see the Supporting Information).

### General procedures for the preparation of rhodium complexes

**Method A.** A solution of **3x** (x = b, f, e) and [Rh(cod)Cl]<sub>2</sub> (0.5 equiv) in DCM was stirred at r. t. for 4 h. After concentration under reduced pressure, the residue was washed with pentane and dried to afford the corresponding rhodium complex as brown solids: **4b** (95%), **4e** (93%), **4f** (94%).

A solution of **4x** and the corresponding phosphine **3x** (1 equiv) in DCM was treated with bubbling carbon monoxide for 15 min. After

concentration under reduced pressure, the residue was washed with diethyl ether (or a DCM/pentane mixture) to give the corresponding rhodium complex **5b** (60%), **5e** (74%), **5f** (76%). Minor amounts of the dimeric rhodium complex **6b** (18%), **6e** (14%) or **6f** (15%) were also detected by <sup>31</sup>P NMR spectroscopy of the crude material (approximate spectroscopic yields given). Crystals of **6f** deposited from a DCM solution could be characterized by XRD analysis (see below and the Supporting Information).

**Method B.** A solution of **3x** (x = a, c, g) and [Rh(cod)Cl]<sub>2</sub> (0.25 equiv) in DCM was stirred at r. t. for 4 h. Carbon monoxide was then bubbled through the solution for 15 min. After evaporation of the solvent under reduced pressure, the crude mixture was washed with diethyl ether (or a DCM/pentane mixture) to give the corresponding rhodium complex **5a** (79%), **5c** (81%) or **5g** (73%) as a yellow solid. Minor amounts of the dimeric rhodium complex **6c** (4%) or **6g** (13%) were also detected by <sup>31</sup>P NMR spectroscopy of the crude material (approximate spectroscopic yields given).

**Rhodium complex 5a'.** To a solution of **3a** (152 mg, 0.4 mmol) in DCM (4 mL) at -90 °C was added methyl trifluoromethanesulfonate (45 μL, 0.4 mmol). The mixture was slowly warmed up to -40 °C and stirred for 2 h. After evaporation of the solvent under reduced pressure, the residue was washed with cold pentane, dried under reduced pressure and then analyzed as a 5:1 N<sup>+</sup>Me:P<sup>+</sup>Me mixture of the methylation products of **3a**, which could not be separated. To a solution of this mixture in DCM (10 mL) was added [Rh(cod)Cl]<sub>2</sub> (41 mg, 0.083 mmol), and stirring was pursued at r. t. for 4 h. Carbon monoxide was then bubbled through the solution for 15 min. The solvent was evaporated under reduced pressure, and the residue was washed with diethyl ether to afford **5a'** (130 mg, 68%) as a yellow solid.

### <sup>103</sup>Rh NMR spectroscopy

<sup>103</sup>Rh/<sup>31</sup>P{<sup>1</sup>H} HMQC spectra were recorded on a Bruker AV400 spectrometer, equipped with a three-channel probe H{P}{X}-TBI 5 mm using saturated solutions of **5x** in CD<sub>2</sub>Cl<sub>2</sub> (in the cases of **5e** and **5f**, saturated concentration did not allow achieving sufficient acquisition in available time). A preliminary search for the <sup>103</sup>Rh resonances was performed through <sup>31</sup>P{<sup>1</sup>H} experiments with <sup>103</sup>Rh inversion using a sequence adapted from the literature giving a narrow range for <sup>103</sup>Rh chemical shifts.<sup>[48]</sup> In this range, precise chemical shifts of <sup>103</sup>Rh were measured via an inverse correlation HMQC using both <sup>103</sup>Rh-<sup>31</sup>P coupling constants. The exact spectrometer <sup>1</sup>H frequency of ν<sub>0</sub> = 400.1318 MHz corresponds to the resonance of tetramethylsilane. The <sup>103</sup>Rh frequency ratio Ξ can be assigned to either the formal value Ξ = 3.16% (for which rhodium metal is just an approximate reference giving δ<sub>103Rh} ≈ 0 ppm),<sup>[49]</sup> or to the observable value Ξ' = 3.186447% defined from the real reference Rh(acac)<sub>3</sub> (for which δ<sub>103Rh} = 0 ppm if saturated in CDCl<sub>3</sub> solution).<sup>[50]</sup> Each frequency ratio defines its own chemical shift scale in ppm: δ = (ν - Ξν<sub>0</sub>) / (Ξν<sub>0</sub>) 10<sup>6</sup> and δ' = (ν - Ξ'ν<sub>0</sub>) / (Ξ'ν<sub>0</sub>) 10<sup>6</sup>, where ν is the physical resonance frequency observed for the nominal field of the spectrometer. By elimination of ν, the scales are related by the equation: δ = δ'ξ + (ξ - 1) 10<sup>6</sup>, where ξ = Ξ' / Ξ = 1.008369 (giving δ(Rh(acac)<sub>3</sub>) = 8369 ≈ 8358 ppm for δ'(Rh(acac)<sub>3</sub>) = 0).<sup>[49a]</sup> The δ<sub>103Rh}</sub> values in Table 2 are given in both scales.</sub></sub>

### Crystallographic studies

Intensity X-ray diffraction data from single crystals were collected at low temperature on an Apex2 Bruker diffractometer equipped with a 30 W air-cooled microfocus source (λ = 0.71073 Å) or on an Oxford-Diffraction Gemini (λ = 0.71073 or 1.54180 Å). The structures

were solved using direct methods or SUPERFLIP, and refined by means of least-squares procedures on  $F$  using the programs of the PC version of CRYSTALS. Atomic scattering factors were taken from the International Tables for X-Ray Crystallography.<sup>[51]</sup> All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using a riding model. Absorption corrections were introduced using the program MULTISCAN. For the free phosphines **3b** and **3f**, it was not possible to resolve diffuse electron-density residuals (enclosed solvent molecules). Treatment with the SQUEEZE facility from PLATON resulted in a smooth refinement.<sup>[52]</sup>

## Supporting Information

It includes yields, spectroscopic and other characterizations of all new compounds.  $^1\text{H}$ ,  $^{31}\text{P}$ ,  $^{13}\text{C}$ ,  $^{103}\text{Rh}$ - $^{31}\text{P}\{\text{H}\}$  HMQC NMR spectra and crystallographic data are also provided.

## Acknowledgements

C.Z. thanks the China Scholarship Council for financial support. R.C. thanks the CNRS for half a teaching sabbatical in 2014–2015 and 2015–2016. A determining support was also indirectly provided by the ANR program (ANR-11-BS07-016-01). The authors are also indebted to Dr. Valérie Maraval for efficient logistic management.

## Conflict of interest

The authors declare no conflict of interest.

- [14] Generalization of the Hammett equation, originally defined for X/H-substitution ( $\text{H} \rightarrow \text{X}$ ), to aza-analogation ( $\text{=CH} \rightarrow \text{=N}$ ) and protoaza-analogation ( $\text{=CH} \rightarrow \text{=NH}^+$ ) gives the following values for the corresponding constants:  $\sigma_{\text{m(N)}} = 0.45$ ,  $\sigma_{\text{p(N)}} = 0.76$ ,  $\sigma_{\text{m(NH+)}} = 2.09$  and  $\sigma_{\text{p(NH+)}} = 2.34$ . Comparison with the  $\text{NO}_2/\text{H}$ -substitution values ( $\sigma_{\text{m}} = 0.71$ ,  $\sigma_{\text{p}} = 0.78$ ) indicates that neutral azalogation has a significant, albeit weaker, electron-withdrawing effect, but suggests that  $\text{N}$ -protonation (representative of  $\text{N}$ -alkylation) has a twice stronger effect ( $\sigma_{\text{m(NH+)}} - \sigma_{\text{m(N)}} = 1.64$ ,  $\sigma_{\text{p(NH+)}} - \sigma_{\text{p(N)}} = 1.58$ ). See: C. D. Jonhson, *The Hammett Equation*, pp. 99–101, Cambridge University Press, London, **1973**.

<sup>†</sup> The paper is dedicated to Prof. Marian Mikolajczyk on the occasion of his 80th birthday.

### Table of contents

1. Lists of experimental characterizations
2. Crystallographic data
3. Output data of DFT calculations

## 1. Lists of experimental characterizations

See general procedures used in the main text (sections 4.1 and 4.2.).

The following analytical instruments were used,  $^1\text{H}$ ,  $^{13}\text{C}$ ,  $^{31}\text{P}$  and  $^{103}\text{Rh}$  NMR: Avance 300, Avance 400, Avance 400 HD and Avance 500. NMR chemical shifts  $\delta$  are given in ppm, with positive values to high frequency relative to the tetramethylsilane reference for  $^1\text{H}$  and  $^{13}\text{C}$ , with respect to the  $\text{H}_3\text{PO}_4$  reference for  $^{31}\text{P}$ , and with respect to the formal reference of the frequency ratio  $\mathcal{E} = 3.16\%$  (for values with respect to the  $\text{Rh}(\text{acac})_3$  reference of the frequency ratio  $\mathcal{E}' = 3.186447\%$ , see Table 2 and section 4.3 in the article); coupling constants  $J$  are given in Hertz (Hz). UV-visible absorption: Perkin-Elmer UV-Vis Win-Lab Lambda 950. UV-visible extinction molar coefficients  $\epsilon$  are given in  $\text{L}\cdot\text{mol}^{-1}\cdot\text{cm}^{-1}$  and wavelengths  $\lambda$  in nm. Mass spectra were obtained on a Perkin Elmer Sciex spectrometer (MS/MS API-365). Abbreviations: M.p. = Melting point; M.-D.p. = Melting-decomposition point.

### 1b or 1c. 5-nitro-1H-benzo[d]imidazole

 Brown solid (5.22 g, 32 mmol, 80 %); prepared from 4-nitro-o-phenylenediamine (6.32 g, 40 mmol),  $\text{HC}(\text{OC}_2\text{H}_5)_3$  (6.8 ml, 48 mmol) and  $\text{TiCl}_4$  (0.44 ml, 4 mmol) in EtOH (80 mL). **M.p.** = 210-212 °C.  $^1\text{H}$  NMR (300 MHz, acetone- $d_6$ )  $\delta$ : 12.21 (s, 1H), 8.57 (d,  $J = 2.3$  Hz, 1H), 8.48 (s, 1H), 8.17 (dd,  $J = 8.9, 2.2$  Hz, 1H), 7.81 (d,  $J = 8.9$  Hz, 1H).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz, DMSO- $d_6$ )  $\delta$ : 147.29, 143.08, 142.03, 139.00, 118.11, 115.33, 113.18.

### 1d. 5,6-dinitro-1H-benzo[d]imidazole

 White solid (1.34 g, 6.4 mmol, 66 %); prepared from **1b** (1.6 g, 9.8 mmol) in fuming  $\text{H}_2\text{SO}_4$  (30 mL) and  $\text{HNO}_3$  (15 mL). **M.p.** = 253-255 °C.  $^1\text{H}$  NMR (400 MHz, acetone- $d_6$ )  $\delta$ : 8.71 (s, 1H), 8.40 (s, 2H).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz, acetone- $d_6$ )  $\delta$ : 148.78, 139.07, 113.65.

### 1d'. 4,5-dinitro-1H-benzo[d]imidazole

 Yellow solid (0.63 g, 3.0 mmol, 31 %); prepared from **1c** (1.6 g, 9.8 mmol) in fuming  $\text{H}_2\text{SO}_4$  (30 mL) and  $\text{HNO}_3$  (15 mL). **M.p.** = 249-251 °C.  $^1\text{H}$  NMR (400 MHz, DMSO- $d_6$ )  $\delta$ : 8.93 (dd,  $J = 2.0, 0.7$  Hz, 1H), 8.80 (d,  $J = 2.0$  Hz, 1H), 8.73 (s, 1H).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz, DMSO)  $\delta$ : 149.51, 141.87, 133.24, 121.40, 114.71.

### 2a. 1-phenyl-1H-benzo[d]imidazole

 Colorless liquid (2.1 g, 10.8 mmol, 90 %); prepared from the mixture of benzimidazole (1.42 g, 12 mmol), iodobenzene (2.04 g, 10 mmol),  $\text{CuI}$  (0.38 g, 2 mmol), 1,10-phenanthroline (0.72 g, 4 mmol) and  $\text{Cs}_2\text{CO}_3$  (6.85 g, 21 mmol) in DMF (20 mL).  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$ : 8.07 (s, 1H), 7.91-7.83 (m, 1H), 7.55-7.47 (m, 3H), 7.46-7.38 (m, 3H), 7.33-7.25 (m, 2H).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz,  $\text{CDCl}_3$ )  $\delta$ : 144.08, 142.26, 136.31, 133.66, 130.00, 127.98, 123.96, 123.67, 122.77, 120.59, 110.46.

### 2b. 5-nitro-1-phenyl-1H-benzo[d]imidazole

 Yellow solid (2.11 g, 8.8 mmol, 64%); prepared from a mixture of **1b** (2.69 g, 16.5 mmol), iodobenzene (2.82 g, 13.8 mmol),  $\text{CuI}$  (0.26 g, 1.4 mmol), 1,10-phenanthroline (0.50 g, 2.8 mmol) in  $\text{Cs}_2\text{CO}_3$  (9.42 g, 28.9 mmol) in DMF (30 mL). **M.p.** = 160-162 °C.  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$ : 8.69 (dd,  $J = 2.2, 0.5$  Hz, 1H), 8.26 (s, 1H), 8.19 (dd,  $J = 9.0, 2.2$  Hz, 1H), 7.60-7.64 (m, 2H), 7.57-7.48 (m, 4H).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz,  $\text{CDCl}_3$ )  $\delta$ : 145.71, 143.98, 143.35, 137.75, 135.17, 130.41, 129.13, 124.26, 119.36, 117.25, 110.60. **HRMS** (ES+) calcd. for  $\text{C}_{13}\text{H}_9\text{N}_3\text{O}_2$ :  $[\text{M}+\text{H}]^+$ , 240.0773, found:  $m/z$  240.0773.

**2c. 6-nitro-1-phenyl-1H-benzo[d]imidazole**

White solid (0.75 g, 3.1 mmol, 23 %); prepared from a mixture of **1c** (2.69 g, 16.5 mmol), iodobenzene (2.82 g, 13.8 mmol), CuI (0.26 g, 1.4 mmol), 1,10-phenanthroline (0.50 g, 2.8 mmol) in Cs<sub>2</sub>CO<sub>3</sub> (9.42 g, 28.9 mmol) in DMF (30 mL). **M.p.** = 162-164 °C. <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>) δ: 8.39 (d, *J* = 2.2 Hz, 1H), 8.31 (s, 1H), 8.19 (dd, *J* = 8.9, 2.2 Hz, 1H), 7.88 (d, *J* = 8.9 Hz, 1H), 7.61-7.64 (m, 2H), 7.55-7.48 (m, 3H). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CDCl<sub>3</sub>) δ: 148.18, 146.67, 144.39, 135.03, 133.19, 130.47, 129.15, 124.26, 120.75, 118.46, 107.56. **HRMS** (ES<sup>+</sup>) calcd. for C<sub>13</sub>H<sub>9</sub>N<sub>3</sub>O<sub>2</sub>: [M+H]<sup>+</sup>, 240.0773, found: *m/z* 240.0779.

**2e. 1-(4-nitrophenyl)-1H-benzo[d]imidazole**

Yellow solid (1.81 g, 7.6 mmol, 95 %); prepared from benzoimidazole (0.94 g, 4 mmol), 1-fluoro-4-nitrobenzene (2.26 g, 8 mmol) and NaOH (0.32 g, 4 mmol) in DMF (10 mL). **M.p.** = 183-185 °C. <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>) δ: 8.50-8.39 (m, 2H), 8.17 (s, 1H), 7.94 – 7.83 (m, 1H), 7.78-7.68 (m, 2H), 7.65-7.55 (m, 1H), 7.44-7.32 (m, 2H). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CDCl<sub>3</sub>) δ: 146.48, 144.42, 141.68, 141.60, 132.77, 125.81, 124.56, 123.69, 123.61, 121.14, 110.29. **HRMS** (ES<sup>+</sup>) calcd. for C<sub>13</sub>H<sub>9</sub>N<sub>3</sub>O<sub>2</sub>: [M+H]<sup>+</sup>, 240.0773, found: *m/z* 240.0778.

**2f. 5-nitro-1-(4-nitrophenyl)-1H-benzo[d]imidazole**

Yellow solid (1.51 g, 5.3 mmol, 53 %); prepared from **1b** (1.63 g, 10.0 mmol), 1-fluoro-4-nitrobenzene (2.82 g, 20 mmol) and NaOH (0.40 g, 10.0 mmol) in DMF (20 mL). **M.p.** = 262-264 °C. <sup>1</sup>H NMR (400 MHz, acetone-*d*<sub>6</sub>) δ: 8.83 (s, 1H), 8.68 (d, *J* = 2.2 Hz, 1H), 8.57 (d, *J* = 8.7 Hz, 2H), 8.33 (dd, *J* = 9.1, 2.2 Hz, 1H), 8.14 (d, *J* = 8.8 Hz, 2H), 7.97 (d, *J* = 9.0 Hz, 1H). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, acetone) δ: 146.49, 144.11, 140.88, 138.95, 125.59, 124.94, 124.51, 119.33, 116.49, 113.73, 111.38. **HRMS** (ES<sup>+</sup>) calcd. for C<sub>13</sub>H<sub>9</sub>N<sub>4</sub>O<sub>4</sub>: [M+H]<sup>+</sup>, 285.0624, found: *m/z* 285.0634.

**2g. 6-nitro-1-(4-nitrophenyl)-1H-benzo[d]imidazole**

Light yellow solid (0.97 g, 3.4 mmol, 34 %); prepared from **1c** (1.63 g, 10.0 mmol), 1-fluoro-4-nitrobenzene (2.82 g, 20 mmol) and NaOH (0.40 g, 10.0 mmol) in DMF (20 mL). **M.p.** = 159-161 °C. <sup>1</sup>H NMR (400 MHz, acetone-*d*<sub>6</sub>) δ: 8.90 (s, 1H), 8.64 – 8.55 (m, 3H), 8.33 – 8.26 (m, 1H), 8.17 (d, *J* = 9.0 Hz, 2H), 8.00 (d, *J* = 9.0 Hz, 1H). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, acetone-*d*<sub>6</sub>) δ: 147.58, 146.49, 125.69, 124.93, 124.51, 120.78, 119.33, 118.48, 116.49, 111.38, 107.69. **HRMS** (ES<sup>+</sup>) calcd. for C<sub>13</sub>H<sub>9</sub>N<sub>4</sub>O<sub>4</sub>: [M+H]<sup>+</sup>, 285.0624, found: *m/z* 285.0631.

**2h. 5,6-dinitro-1-(4-nitrophenyl)-1H-benzo[d]imidazole**

Yellow solid (1.00 g, 3.0 mmol, 86 %); prepared from **1d** (0.74 g, 3.6 mmol), 1-fluoro-4-nitrobenzene (1.01 g, 7.2 mmol) and NaOH (0.14 g, 3.6 mmol) in DMF (7 mL). <sup>1</sup>H NMR (300 MHz, acetone-*d*<sub>6</sub>) δ: 9.07 (s, 1H), 8.60-8.56 (m, 3H), 8.53 (s, 1H), 8.23-8.18 (m, 2H). <sup>13</sup>C{<sup>1</sup>H} NMR (75 MHz, acetone-*d*<sub>6</sub>) δ: 149.49, 125.64, 125.59, 117.95, 109.69. **HRMS** (ES<sup>+</sup>) calcd. for C<sub>13</sub>H<sub>7</sub>N<sub>5</sub>O<sub>6</sub>: [M+H]<sup>+</sup>, 330.0475, found: *m/z* 330.0478.

**3a. 2-(diphenylphosphanyl)-1-phenyl-1H-benzo[d]imidazole**

White solid (0.88 g, 2.3 mmol, 56 %); prepared from **2a** (1.37 g, 7.1 mmol), LDA (10.6 mmol in 10 ml THF) and ClPPh<sub>2</sub> (1.9 ml, 10.6 mmol) in THF (50 mL). **M.p.** = 157-159 °C. <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>) δ: 7.91 (d, *J* = 8.1 Hz, 1H), 7.56-7.48 (m, 4H), 7.46-7.40 (m, 3H), 7.39-7.20 (m, 10H), 7.18 (d, *J* = 7.9

Hz, 1H).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz,  $\text{CDCl}_3$ )  $\delta$ : 154.87 (d,  $J_{\text{CP}} = 10.1$  Hz, C), 144.18 (d,  $J_{\text{CP}} = 2.0$  Hz, C), 137.70, 136.14 (d,  $J_{\text{CP}} = 2$  Hz, C), 134.36, 134.30, 134.15, 129.32 (d,  $J_{\text{CP}} = 2.0$  Hz, CH), 128.79, 128.50 (d,  $J_{\text{CP}} = 7.1$  Hz, CH), 127.92 (d,  $J_{\text{CP}} = 3.0$  Hz, C), 123.48, 122.43, 120.46, 110.26.  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz,  $\text{CDCl}_3$ )  $\delta$ : -24.50. HRMS (ES+) calcd. for  $\text{C}_{25}\text{H}_{19}\text{N}_2\text{P}$ :  $[\text{M}+\text{H}]^+$ , 379.1364, found:  $m/z$  379.1364.

### 3aO. 2-(diphenylphosphoroso)-1-phenyl-1H-1,3-benzodiazole

White solid.  $^1\text{H}$  NMR (400 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$  7.91-7.85 (m, 1H), 7.80-7.74 (m, 4H), 7.55 (m, 2H), 7.45 (m, 4H), 7.40-7.34 (m, 5H), 7.31-7.25 (m, 2H), 7.22 – 7.16 (m, 1H).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$  148.28(d,  $J_{\text{CP}} = 139.4$  Hz, C), 142.76(d,  $J_{\text{CP}} = 17.2$  Hz, C), 137.73(d,  $J_{\text{CP}} = 3.0$  Hz, C), 135.46, 134.32(d,  $J_{\text{CP}} = 21.4$  Hz, C), 132.14(d,  $J_{\text{CP}} = 3.0$  Hz, CH), 131.88(d,  $J_{\text{CP}} = 10.1$  Hz, CH), 131.08, 128.98, 128.90, 128.35(d,  $J_{\text{CP}} = 12.1$  Hz, CH), 127.94, 125.23, 123.35, 120.99, 111.08.  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$  17.23. ### 3c. 2-(diphenylphosphanyl)-6-nitro-1-phenyl-1H-benzo[d]imidazole

Yellow solid (0.30 g, 0.7 mmol, 70 %); prepared from **2c** (0.24 g, 1.0 mmol), LDA (1.2 mmol in 2 mL of THF) and  $\text{ClPPh}_2$  (0.22 ml, 1.2 mmol) in THF (15 mL). **M.p.** = 160-163 °C.  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$ : 8.20 (dd,  $J = 8.9, 2.2$  Hz, 1H), 8.08 (d,  $J = 2.1$  Hz, 1H), 7.91 (d,  $J = 9.0$  Hz, 1H), 7.53 – 7.45 (m, 7H), 7.38 (m, 6H), 7.20 (dt,  $J = 8.2, 1.3$  Hz, 2H).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz,  $\text{CDCl}_3$ )  $\delta$ : 161.74 (d,  $J_{\text{CP}} = 17.2$  Hz, C), 148.11 (d,  $J_{\text{CP}} = 2.0$  Hz, C), 144.11, 137.23, 134.87 (d,  $J_{\text{CP}} = 1.0$  Hz, C), 134.49 (d,  $J_{\text{CP}} = 22.2$  Hz, CH), 133.05 (d,  $J_{\text{CP}} = 6.1$  Hz, C), 129.85, 129.81, 129.68, 128.74 (d,  $J_{\text{CP}} = 8.1$  Hz, CH), 127.74 (d,  $J_{\text{CP}} = 3.0$  Hz, CH), 120.36, 118.24, 107.12.  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz,  $\text{CDCl}_3$ )  $\delta$ : -22.33. HRMS (ES+) calcd. for  $\text{C}_{25}\text{H}_{18}\text{N}_3\text{O}_2\text{P}$ :  $[\text{M}+\text{H}]^+$ , 424.1215, found:  $m/z$  424.1221.

### 3e. 2-(diphenylphosphanyl)-1-(4-nitrophenyl)-1H-benzo[d]imidazole

Yellow solid (0.26 g, 0.6 mmol, 62 %); prepared from **2e** (0.24 g, 1.0 mmol), LDA (1.2 mmol in 2 mL of THF) and ClPPh<sub>2</sub> (0.36 ml, 2 mmol) in THF (15 mL). **M.p.** = 175-178 °C. <sup>1</sup>H NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 8.30-8.22 (m, 2H), 7.84-7.79 (m, 1H), 7.49-7.27 (m, 14H), 7.23-7.17 (m, 1H). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CDCl<sub>3</sub>) δ: 154.56 (d, *J*<sub>CP</sub> = 13.1 Hz, C), 147.33, 144.28, 141.89, 136.92, 134.30 (d, *J*<sub>CP</sub> = 21.2 Hz, CH), 133.40 (d, *J*<sub>CP</sub> = 4.1 Hz, CH), 129.74, 128.72 (d, *J*<sub>CP</sub> = 8.1 Hz, CH), 128.54 (d, *J*<sub>CP</sub> = 19.2 Hz, C), 124.80, 124.21, 123.18, 120.85, 109.74. <sup>31</sup>P{<sup>1</sup>H} NMR (162 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: -23.39. **HRMS** (ES<sup>+</sup>) calcd. for C<sub>25</sub>H<sub>18</sub>N<sub>3</sub>O<sub>2</sub>P: [M+H]<sup>+</sup>, 424.1215, found: m/z 424.1212.

### 3f. 2-(diphenylphosphanyl)-5-nitro-1-(4-nitrophenyl)-1H-benzo[d]imidazole

Yellow solid (0.46 g, 0.9 mmol, 77 %); prepared from **2f** (0.35 g, 1.2 mmol), LDA (1.4 mmol in 2 mL of THF) and ClPPh<sub>2</sub> (0.25 ml, 1.4 mmol) in THF (20 mL). **M.p.** = 190-192 °C. <sup>1</sup>H NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 8.72 (d, *J* = 2.2 Hz, 1H), 8.31-8.24 (m, 2H), 8.20 (dd, *J* = 9.0, 2.2 Hz, 1H), 7.48-7.39 (m, 8H), 7.39-7.32 (m, 4H), 7.22 (dd, *J* = 8.9, 0.5 Hz, 1H). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 159.94 (d, *J*<sub>CP</sub> = 19.2 Hz, C), 147.88, 144.24, 140.98, 140.58, 134.57 (d, *J*<sub>CP</sub> = 21.2 Hz, CH), 132.26 (d, *J*<sub>CP</sub> = 6.1 Hz, C), 131.77 (d, *J*<sub>CP</sub> = 10.1 Hz, C), 130.09, 128.78 (d, *J*<sub>CP</sub> = 8.1 Hz, CH), 128.66 (d, *J*<sub>CP</sub> = 4.0 Hz, CH), 124.97, 119.55, 116.64, 109.88. <sup>31</sup>P{<sup>1</sup>H} NMR (162 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: -21.89. **HRMS** (ES<sup>+</sup>) calcd. for C<sub>25</sub>H<sub>17</sub>N<sub>4</sub>O<sub>4</sub>P: [M+H]<sup>+</sup>, 469.1066, found: m/z 469.1067. C.

### 3g. 2-(diphenylphosphanyl)-6-nitro-1-(4-nitrophenyl)-1H-benzo[d]imidazole

Yellow solid (0.38 g, 0.8 mmol, 45 %); prepared from **2g** (0.50 g, 1.8 mmol), LDA (2.2 mmol in 5 mL of THF) and ClPPh<sub>2</sub> (0.43 ml, 2.2 mmol) in THF (30 mL). **M.p.** = 172-174 °C. <sup>1</sup>H NMR (300 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 8.33-8.25 (m, 2H), 8.23 (dd, *J* = 8.9, 2.2 Hz, 1H), 8.07 (dd, *J* = 2.1, 0.6 Hz, 1H), 7.90 (dd, *J* = 8.9, 0.6 Hz, 1H), 7.49-7.31 (m, 12H). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 161.50 (d, *J*<sub>CP</sub> = 19.2 Hz, C), 148.04 (d, *J*<sub>CP</sub> = 2.0 Hz, C), 147.93, 144.42, 140.40, 136.68, 134.59 (d, *J*<sub>CP</sub> = 21.2 Hz, CH), 132.20 (d, *J*<sub>CP</sub> = 5.1 Hz, C), 131.77 (d, *J*<sub>CP</sub> = 10.1 Hz, C), 130.10, 128.78 (d, *J*<sub>CP</sub> = 8.1 Hz, CH), 128.71 (d, *J*<sub>CP</sub> = 4.0 Hz, CH), 125.05, 120.29, 118.68, 106.64. <sup>31</sup>P{<sup>1</sup>H} NMR (121 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: -21.34. **HRMS** (ES<sup>+</sup>) calcd. for C<sub>25</sub>H<sub>17</sub>N<sub>4</sub>O<sub>4</sub>P: [M+H]<sup>+</sup>, 469.1066, found: m/z 469.1048.

### 3h. 2-(diphenylphosphanyl)-5,6-dinitro-1-(4-nitrophenyl)-1H-benzo[d]imidazole

Yellow solid (trace, < 5%); prepared from **2g** (0.14 g, 0.4 mmol), LDA (0.5 mmol in 2 ml of THF) and ClPPh<sub>2</sub> (0.1 ml, 0.5 mmol) in THF (40 mL). <sup>1</sup>H NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 8.38 (s, 1H), 8.31-8.24 (m, 2H), 7.68 (s, 1H), 7.45-7.41 (m, 6H), 7.39-7.36 (m, 6H). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 148.32, 144.78, 138.00, 134.68 (d, *J*<sub>CP</sub> = 21.2 Hz, CH), 132.64, 132.45, 131.26 (d, *J*<sub>CP</sub> = 5.1 Hz, C), 130.43, 129.02, 128.93 (d, *J*<sub>CP</sub> = 9.1 Hz, CH), 128.66 (d, *J*<sub>CP</sub> = 3.0 Hz, CH), 128.55 (d, *J*<sub>CP</sub> = 7.1 Hz, C), 125.24, 117.68, 107.80. <sup>31</sup>P{<sup>1</sup>H} NMR (162 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: -20.19. **HRMS** (ES<sup>+</sup>) calcd. for C<sub>25</sub>H<sub>16</sub>N<sub>5</sub>O<sub>6</sub>P: [M+H]<sup>+</sup>, 514.0912, found: m/z 514.0916.

### 4b. RhCl(η<sup>2</sup>-C<sub>8</sub>H<sub>12</sub>)(**3b**)

Brown solid (101 mg, 0.18 mmol, 95 %); prepared from **3b** (80 mg, 0.19 mmol) and [Rh(cod)Cl]<sub>2</sub> (47 mg, 0.09 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (4 mL). <sup>1</sup>H NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 8.71 (d,

$J = 2.2$  Hz, 1H), 8.16 (dd,  $J = 9.1, 2.2$  Hz, 1H), 7.84 – 7.74 (m, 5H), 7.57 – 7.53 (m, 3H), 7.44 (dt,  $J = 7.4, 4.2$  Hz, 2H), 7.36 (td,  $J = 7.7, 2.4$  Hz, 5H), 7.10 (d,  $J = 9.0$  Hz, 1H), 5.38 (brs, 2H, CH<sub>cod</sub>), 3.82 – 3.23 (brs, 2H, CH<sub>cod</sub>), 2.30 – 2.18 (brs, 4H, CH<sub>2 cod</sub>), 1.93 (brs, 4H, CH<sub>2 cod</sub>).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz, CD<sub>2</sub>Cl<sub>2</sub>)  $\delta$ : 144.14, 142.13, 141.85 (d,  $J_{\text{CP}} = 10.1$  Hz, CH), 135.53, 135.29 (d,  $J_{\text{CP}} = 12.1$  Hz, CH), 130.78 (d,  $J_{\text{CP}} = 3.1$  Hz, C), 130.53, 130.09, 129.74, 129.54, 128.92, 128.20 (d,  $J_{\text{CP}} = 11.1$  Hz, C), 119.51, 116.96, 111.08, 105.27 (brs, CH<sub>cod</sub>), 78.63 (brs, CH<sub>cod</sub>), 70.92 (brs, CH<sub>cod</sub>), 32.50 (brs, CH<sub>2 cod</sub>), 30.85 (brs, CH<sub>2 cod</sub>), 29.67 (brs, CH<sub>2 cod</sub>).  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz, CD<sub>2</sub>Cl<sub>2</sub>)  $\delta$ : 19.00 (d,  $J_{\text{PRh}} = 150.7$  Hz).

#### 4e. RhCl( $\eta^2$ -C<sub>8</sub>H<sub>12</sub>)(3e)

Brown solid (84 mg, 0.15 mmol, 93 %); prepared from **3e** (69 mg, 0.16 mmol) and [Rh(cod)Cl]<sub>2</sub> (40 mg, 0.08 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (4 mL).  $^1\text{H}$  NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>)  $\delta$ : 8.35-8.18 (m, 2H), 7.83 (ddd,  $J = 10.3, 7.9, 1.8$  Hz, 5H), 7.79-7.69 (m, 2H), 7.45-7.38 (m, 2H), 7.38-7.25 (m, 6H), 7.11 (dd,  $J = 7.3, 1.8$  Hz, 1H), 5.32 (brs, 2H, CH<sub>cod</sub>), 3.43 (brs, 2H, CH<sub>cod</sub>), 2.37-2.15 (brs, 4H, CH<sub>2 cod</sub>), 1.95 (brs, 4H, CH<sub>2 cod</sub>).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz, CD<sub>2</sub>Cl<sub>2</sub>)  $\delta$ : 148.76 (d,  $J_{\text{CP}} = 62.6$  Hz, C), 147.45, 142.96 (d,  $J_{\text{CP}} = 11.1$  Hz, C), 142.09, 137.39, 135.35 (d,  $J_{\text{CP}} = 12.1$  Hz, CH), 131.76 (d,  $J_{\text{CP}} = 10.1$  Hz, C), 130.78 (d,  $J_{\text{CP}} = 3.0$  Hz, CH), 130.32, 129.60, 128.22 (d,  $J_{\text{CP}} = 10.1$  Hz, CH), 124.77, 124.43, 123.50, 120.55, 110.52, 105.57 (brs, CH<sub>cod</sub>), 78.59 (brs, CH<sub>cod</sub>), 71.34 (brs, CH<sub>cod</sub>), 32.48 (brs, CH<sub>2 cod</sub>), 30.87 (brs, CH<sub>2 cod</sub>), 28.84 (brs, CH<sub>2 cod</sub>).  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz, CD<sub>2</sub>Cl<sub>2</sub>)  $\delta$ : 18.81 (d,  $J_{\text{PRh}} = 150.7$  Hz).

#### 4f. RhCl( $\eta^2$ -C<sub>8</sub>H<sub>12</sub>)(3f)

Brown solid (114 mg, 0.19 mmol, 94 %); prepared from **3f** (94 mg, 0.20 mmol) and [Rh(cod)Cl]<sub>2</sub> (49 mg, 0.10 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (4 mL).  $^1\text{H}$  NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>)  $\delta$ : 8.76 (d,  $J = 2.2$  Hz, 1H), 8.33-8.29 (m, 2H), 8.21 (dd,  $J = 9.0, 2.2$  Hz, 1H), 7.81-7.75 (m, 6H), 7.49-7.44 (m, 2H), 7.40-7.33 (m, 4H), 7.17 (d,  $J = 9.0$  Hz, 1H), 5.38 (brs, 2H, CH<sub>cod</sub>), 3.48 (brs, 2H, CH<sub>cod</sub>), 2.49 (brs, 4H, CH<sub>2 cod</sub>), 2.32-2.17 (brs, 4H, CH<sub>2 cod</sub>).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz, CD<sub>2</sub>Cl<sub>2</sub>)  $\delta$ : 147.97, 144.51, 142.18 (d,  $J_{\text{CP}} = 8.9$  Hz, C), 141.07 (d,  $J_{\text{CP}} = 6.1$  Hz, C), 137.83, 135.23 (d,  $J_{\text{CP}} = 12.1$  Hz, CH), 131.80, 131.11 (d,  $J_{\text{CP}} = 3.0$  Hz, CH), 129.50, 128.63, 128.45 (d,  $J_{\text{CP}} = 10.1$  Hz, CH), 124.56, 120.05, 117.21, 110.78, 105.96 (brs, CH<sub>cod</sub>), 78.66 (brs, CH<sub>cod</sub>), 71.52 (brs, CH<sub>cod</sub>), 32.72 (brs, CH<sub>2 cod</sub>), 30.86 (brs, CH<sub>2 cod</sub>), 28.56 (brs, CH<sub>2 cod</sub>).  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz, CD<sub>2</sub>Cl<sub>2</sub>)  $\delta$ : 20.14 (d,  $J_{\text{PRh}} = 152.3$  Hz).

#### 5a. RhCl(CO)(3a)<sub>2</sub>

Yellow solid (146 mg, 0.16 mmol, 79 %); prepared from **3a** (151 mg, 0.4 mmol), [Rh(cod)Cl]<sub>2</sub> (49 mg, 0.10 mmol) and CO (bubbling for 15 min) in CH<sub>2</sub>Cl<sub>2</sub> (10 mL). **M.-D.p.** = 215-217 °C.  $^1\text{H}$  NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>)  $\delta$ : 7.81 (dt,  $J = 8.1, 1.0$  Hz, 1H), 7.78-7.74 (m, 3H), 7.50-7.45 (m, 2H), 7.40-7.37 (m, 4H), 7.33-7.18 (m, 4H), 7.16-7.09 (m, 2H), 7.00-6.89 (m, 3H).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz, CD<sub>2</sub>Cl<sub>2</sub>)  $\delta$ : 149.39, 142.74 (t,  $J_{\text{CP}} = 5.1$  Hz,  $J_{\text{CP}} = 6.1$  Hz, C), 138.50, 135.40, 135.16 (t,  $J_{\text{CP}} = 7.1$  Hz,  $J_{\text{CP}} = 6.1$  Hz, CH), 130.66, 128.91 (d,  $J_{\text{CP}} = 18.1$  Hz, CH), 128.65, 128.16 (t,  $J_{\text{CP}} = 5.1$  Hz,  $J_{\text{CP}} = 6.1$  Hz, CH), 125.71, 124.06, 122.71, 122.43, 120.18, 110.54. The  $^{13}\text{C}$  of CO can't be observed due to poor solubility.  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz, CD<sub>2</sub>Cl<sub>2</sub>)  $\delta$ : 20.85 (d,  $J_{\text{PRh}} = 129.6$  Hz).  $^{103}\text{Rh}\{^1\text{H}\}$  NMR (12.64 MHz, CD<sub>2</sub>Cl<sub>2</sub>)  $\delta$ : -288. **IR:**  $\nu = 1966$  cm<sup>-1</sup> (CO), 742 cm<sup>-1</sup>, 688 cm<sup>-1</sup>.

#### 5b. RhCl(CO)(3b)<sub>2</sub>

Yellow solid (131 mg, 0.13 mmol, 72 %); prepared from **4b** (101 mg, 0.18 mmol), **3b** (76 mg, 0.18 mmol) and CO (bubbling for 15 min) in CH<sub>2</sub>Cl<sub>2</sub> (10 mL). **M.-D.p.** = 226-228 °C. <sup>1</sup>H NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 8.73 (d, *J* = 2.1 Hz, 1H), 8.11 (dd, *J* = 9.0, 2.2 Hz, 1H), 7.78-7.78 (m, 4H), 7.56-7.48 (m, 2H), 7.41 (tt, *J* = 7.1, 1.6 Hz, 4H), 7.30-7.25 (m, 1H), 7.14-7.06 (m, 2H), 7.01 (d, *J* = 9.0 Hz, 1H), 6.98-6.90 (m, 2H). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 144.08, 142.36, 135.08 (t, *J*<sub>CP</sub> = 6.1 Hz, *J*<sub>CP</sub> = 7.1 Hz, CH), 134.40, 131.09, 129.36, 129.25, 128.95, 128.58, 128.44 (t, *J*<sub>CP</sub> = 6.1 Hz, *J*<sub>CP</sub> = 5.1 Hz, CH), 125.22, 119.56, 116.90, 115.36, 110.68; no <sup>13</sup>CO signal was observed due to poor solubility. <sup>31</sup>P{<sup>1</sup>H} NMR (162 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 23.71 (d, *J*<sub>PRh</sub> = 129.6 Hz). <sup>103</sup>Rh{<sup>1</sup>H} NMR (12.64 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: -316. **IR:** ν = 1968 cm<sup>-1</sup> (CO), 1517 cm<sup>-1</sup>, 1495 cm<sup>-1</sup>, 1426 cm<sup>-1</sup>, 1340 cm<sup>-1</sup>, 1279 cm<sup>-1</sup>, 1096 cm<sup>-1</sup>, 1064 cm<sup>-1</sup>, 1003 cm<sup>-1</sup>, 922 cm<sup>-1</sup>, 890 cm<sup>-1</sup>, 821 cm<sup>-1</sup>, 807 cm<sup>-1</sup>, 733 cm<sup>-1</sup>, 694 cm<sup>-1</sup>.

### 5c. RhCl(CO)(3c)<sub>2</sub>

Yellow solid (82 mg, 0.08 mmol, 81 %); prepared from **3c** (85 mg, 0.2 mmol), [Rh(cod)Cl]<sub>2</sub> (25 mg, 0.05 mmol) and CO (bubbling for 15 min) in CH<sub>2</sub>Cl<sub>2</sub> (5 mL). **M.-D.p.** = 283-285 °C. <sup>1</sup>H NMR (500 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 8.16 (dd, *J* = 9.0, 2.2 Hz, 1H), 7.90 (d, *J* = 9.0 Hz, 1H), 7.86 (d, *J* = 2.2 Hz, 1H), 7.77-7.73 (m, 4H), 7.54-7.49 (m, 2H), 7.41 (dd, *J* = 8.4, 7.0 Hz, 4H), 7.32-7.27 (m, 1H), 7.13-7.09 (m, 2H), 6.96 (dd, *J* = 8.3, 7.5 Hz, 2H). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 146.42, 144.58, 137.82, 135.09 (t, *J*<sub>CP</sub> = 7.1 Hz, *J*<sub>CP</sub> = 6.1 Hz, CH), 134.21, 131.12, 129.46, 129.34, 128.90, 128.63, 128.46 (t, *J*<sub>CP</sub> = 5.1 Hz, *J*<sub>CP</sub> = 6.1 Hz, CH), 120.44, 118.30, 113.12, 107.50. <sup>13</sup>CO signal was not observed due to poor solubility. <sup>31</sup>P{<sup>1</sup>H} NMR (162 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 23.88 (d, *J*<sub>PRh</sub> = 131.2 Hz). <sup>103</sup>Rh{<sup>1</sup>H} NMR (12.64 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: -315. **IR:** ν = 1969 cm<sup>-1</sup> (CO), 1514 cm<sup>-1</sup>, 1494 cm<sup>-1</sup>, 1424 cm<sup>-1</sup>, 1334 cm<sup>-1</sup>, 1064 cm<sup>-1</sup>, 873 cm<sup>-1</sup>, 831 cm<sup>-1</sup>, 734 cm<sup>-1</sup>, 687 cm<sup>-1</sup>.

### 5e. RhCl(CO)(3e)<sub>2</sub>

Brown solid (112mg, 0.11 mmol, 74 %); prepared from **4e** (84 mg, 0.15 mmol), **3e** (36 mg, 0.15 mmol) and CO (bubbling for 15 min) in CH<sub>2</sub>Cl<sub>2</sub> (5 mL). **M.-D.p.** = 252-254 °C. <sup>1</sup>H NMR (300 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 7.87 (dt, *J* = 8.2, 0.9 Hz, 1H), 7.78-7.62 (m, 6H), 7.60-7.51 (m, 2H), 7.47-7.41 (m, 4H), 7.37-7.29 (m, 3H), 7.26 (dd, *J* = 7.2, 1.3 Hz, 1H), 7.02-6.93 (m, 1H). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 186.24 (tt, *J*<sub>CP</sub> = 15.2 Hz, *J*<sub>CRh</sub> = 73.7 Hz, CO), 148.79 (t, *J*<sub>CP</sub> = 35.4 Hz, C), 147.46, 142.84 (t, *J*<sub>CP</sub> = 6.1 Hz, C), 140.91, 137.82, 134.79 (t, *J*<sub>CP</sub> = 7.1 Hz, *J*<sub>CP</sub> = 6.1 Hz, CH), 131.22, 129.93, 129.48, 128.57 (t, *J*<sub>CP</sub> = 6.1 Hz, *J*<sub>CP</sub> = 5.1 Hz, CH), 124.75, 124.19, 123.36, 120.56, 110.14. <sup>31</sup>P{<sup>1</sup>H} NMR (121 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 22.29 (d, *J*<sub>PRh</sub> = 128.3 Hz). **IR:** ν = 1979 cm<sup>-1</sup> (CO), 1525 cm<sup>-1</sup>, 1497 cm<sup>-1</sup>, 1435 cm<sup>-1</sup>, 1349 cm<sup>-1</sup>, 1095 cm<sup>-1</sup>, 854 cm<sup>-1</sup>, 820 cm<sup>-1</sup>, 746 cm<sup>-1</sup>, 689 cm<sup>-1</sup>.

### 5f. RhCl(CO)(3f)<sub>2</sub>

Yellow solid (154 mg, 0.14 mmol, 76 %); prepared from **4f** (114 mg, 0.19 mmol), **3f** (89 mg, 0.19 mmol) and CO (bubbling for 15 min) in CH<sub>2</sub>Cl<sub>2</sub> (10 mL). **M.-D.p.** = 280-282 °C. <sup>1</sup>H NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ: 8.77 (d, *J* =

2.1 Hz, 1H), 8.16 (dd,  $J = 9.0, 2.2$  Hz, 1H), 7.77 – 7.72 (m, 4H), 7.69-7.66 (m, 2H), 7.63-7.58 (m, 2H), 7.47 (ddd,  $J = 8.7, 4.9, 1.6$  Hz, 4H), 7.33 – 7.30 (m, 2H), 7.02 (d,  $J = 9.0$  Hz, 1H).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : 185.82 (tt,  $J_{\text{CP}} = 16.2$  Hz,  $J_{\text{CRh}} = 72.7$  Hz, CO), 153.33 (t,  $J_{\text{CP}} = 33.3$  Hz, C), 147.95, 144.46, 141.96 (t,  $J_{\text{CP}} = 6.1$  Hz, C), 141.41, 139.71, 134.78 (t,  $J_{\text{CP}} = 7.1$  Hz,  $J_{\text{CP}} = 6.1$  Hz, CH), 131.68, 129.97, 128.87 (t,  $J_{\text{CP}} = 5.1$  Hz,  $J_{\text{CP}} = 6.1$  Hz, CH), 128.48, 124.39, 120.15, 117.18, 110.37.  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : 24.98 (d,  $J_{\text{PRh}} = 129.6$  Hz). IR:  $\nu = 1980$   $\text{cm}^{-1}$  (CO), 1593  $\text{cm}^{-1}$ , 1520  $\text{cm}^{-1}$ , 1497  $\text{cm}^{-1}$ , 1436  $\text{cm}^{-1}$ , 1339  $\text{cm}^{-1}$ , 1278  $\text{cm}^{-1}$ , 1094  $\text{cm}^{-1}$ , 1068  $\text{cm}^{-1}$ , 988  $\text{cm}^{-1}$ , 886  $\text{cm}^{-1}$ , 854  $\text{cm}^{-1}$ , 820  $\text{cm}^{-1}$ , 736  $\text{cm}^{-1}$ , 688  $\text{cm}^{-1}$

### 5g. RhCl(CO)(3g)<sub>2</sub>

Yellow solid (161 mg, 0.15mmol, 73 %); prepared from **3g** (188 mg, 0.4 mmol),  $[\text{Rh}(\text{cod})\text{Cl}]_2$  (49 mg, 0.10 mmol) and CO (bubbling for 15 min) in  $\text{CH}_2\text{Cl}_2$  (10 mL). **M.-D.p.** = 285-287 °C.  $^1\text{H}$  NMR (400 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : 8.22 (dd,  $J = 9.0, 2.2$  Hz, 1H), 7.96 (d,  $J = 9.0$  Hz, 1H), 7.86 (d,  $J = 2.2$  Hz, 1H), 7.81 – 7.70 (m, 4H), 7.69 – 7.63 (m, 2H), 7.63

– 7.55 (m, 2H), 7.46 (ddt,  $J = 9.0, 7.5, 1.6$  Hz, 4H), 7.33 – 7.26 (m, 2H).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : 184.24 (CO), 148.00, 146.44, 144.93, 139.51, 137.20, 134.79 (t,  $J_{\text{CP}} = 7.1$  Hz, CH), 131.71, 130.03, 128.87 (t,  $J_{\text{CP}} = 5.1$  Hz, CH), 128.66, 128.42, 124.45, 120.89, 118.87, 107.07.  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : 25.01 (d,  $J_{\text{PRh}} = 129.6$  Hz).  $^{103}\text{Rh}\{^1\text{H}\}$  NMR (12.64 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : –315. IR:  $\nu = 1978$   $\text{cm}^{-1}$  (CO), 1811  $\text{cm}^{-1}$ , 1594  $\text{cm}^{-1}$ , 1517  $\text{cm}^{-1}$ , 1426  $\text{cm}^{-1}$ , 1338  $\text{cm}^{-1}$ , 1278  $\text{cm}^{-1}$ , 1094  $\text{cm}^{-1}$ , 1063  $\text{cm}^{-1}$ , 988  $\text{cm}^{-1}$ , 887  $\text{cm}^{-1}$ , 854  $\text{cm}^{-1}$ , 819  $\text{cm}^{-1}$ , 734  $\text{cm}^{-1}$ , 687  $\text{cm}^{-1}$ .

### 5a'. RhCl(CO)(3a')<sub>2</sub>

Yellow solid (130 mg, 0.14 mmol, 68 %); prepared from **3a** (151 mg, 0.4 mmol), MeOTf (45  $\mu\text{L}$ , 0.4 mmol),  $[\text{Rh}(\text{cod})\text{Cl}]_2$  (41 mg, 0.08 mmol) and CO (bubbling for 15 min) in  $\text{CH}_2\text{Cl}_2$  (10 mL). **M.-D.p.** = 240-242 °C.  $^1\text{H}$  NMR (400 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : 8.02 – 7.85 (m, 5H), 7.70 (t,  $J = 7.8$  Hz, 1H), 7.57 (dd,  $J = 15.0, 7.4$  Hz, 3H), 7.53 – 7.40 (m, 5H), 7.35 – 7.22 (m, 4H), 7.03 (d,  $J = 8.4$  Hz,

1H), 4.09 (s, 3H, –CH<sub>3</sub>).  $^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : 183.67 (tt,  $J_{\text{CP}} = 17.2$  Hz,  $J_{\text{CRh}} = 70.7$  Hz, CO), 146.19 (t,  $J_{\text{CP}} = 13.1$  Hz,  $J_{\text{CP}} = 14.1$  Hz, C), 135.63 (t,  $J_{\text{CP}} = 8.1$  Hz, CH), 135.03, 133.52, 133.02, 132.02, 131.51, 130.22 (t,  $J_{\text{CP}} = 6.1$  Hz, CH), 128.28 (d,  $J_{\text{CP}} = 56.6$  Hz, CH), 125.73, 124.52 (t,  $J_{\text{CP}} = 24.2$  Hz,  $J_{\text{CP}} = 25.3$  Hz, C), 122.53, 119.34, 116.15, 113.36 (d,  $J_{\text{CP}} = 3.0$  Hz, CH), 36.55 (t,  $J_{\text{CP}} = 2.0$  Hz, CH<sub>3</sub>).  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : 38.14 (d,  $J_{\text{PRh}} = 132.8$  Hz).  $^{103}\text{Rh}\{^1\text{H}\}$  NMR (12.64 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : –436. IR:  $\nu = 2005$   $\text{cm}^{-1}$  (CO), 1438  $\text{cm}^{-1}$ , 1256  $\text{cm}^{-1}$ , 1149  $\text{cm}^{-1}$ , 1088  $\text{cm}^{-1}$ , 1028  $\text{cm}^{-1}$ , 742  $\text{cm}^{-1}$ , 694  $\text{cm}^{-1}$ .

### 6b-c,e-g: respective dinuclear side-products of 5b-c,e-g

Characterized only by  $^{31}\text{P}$  NMR spectroscopy of the crude final reaction mixture (approximate spectroscopic yields given), and by X-ray crystallography for **6f**:

**6b** (18 %):  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : 43.29 (d,  $J_{\text{PRh}} = 149.0$  Hz).

**6c** (4 %):  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : 43.52 (d,  $J_{\text{PRh}} = 147.4$  Hz).

**6e** (14 %):  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : 41.10 (d,  $J_{\text{PRh}} = 147.4$  Hz).

**6f** (15 %):  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : 43.61 (d,  $J_{\text{PRh}} = 149.0$  Hz). XRD analysis: see section 3.11 of the S.I. below.

**6g** (13 %):  $^{31}\text{P}\{^1\text{H}\}$  NMR (162 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$ : 43.86 (d,  $J_{\text{PRh}} = 148.8$  Hz).

## 2. Crystallographic data

Molecular views below are given for thermal ellipsoids at the 30 % probability level. They are complementary to the corresponding molecular views of Figure 2 and 3 in the main Text. See also Table 1 and the experimental section 4.4 (Crystallographic studies) in the main text.

Δ/σ <sub>max</sub>	0.0039
Refinement on	F
w =	w' × [1 - (ΔF <sub>obs</sub> / 6 × ΔF <sub>est</sub> ) <sup>2</sup> ] <sup>2</sup>
w' =	[P <sub>0</sub> T <sub>0</sub> '(x) + P <sub>1</sub> T <sub>1</sub> '(x) + ...P <sub>n-1</sub> T <sub>n-1</sub> '(x)] <sup>-1</sup> , where P <sub>i</sub> are the coefficients of a Chebychev series in t <sub>i</sub> (x), and x = F <sub>calc</sub> /F <sub>calcmax</sub> .
P <sub>0</sub> - P <sub>n-1</sub> =	0.226 0.938E-01 0.740E-01

**3. Output data of DFT calculations** (see note 16 in the main text)

DFT calculations have been performed at the B3PW91/6-31G(d,p) level, without solvent correction (vacuum), using the Firefly software: a) A. A. Granovsky, *Firefly version 8*, <http://classic.chem.msu.su:gran:firefly:index.html>) which is partially based on the GAMESS (US) source code; b) M. W. Schmidt, K. K. Baldridge, J. A. Boatz, S. T. Elbert, M. S. Gordon, J. H. Jensen, S. Koseki, N. Matsunaga, K. A. Nguyen, S. Su, T. L. Windus, M. Dupuis, J. A. Montgomery, *J. Comput. Chem.* **1993**, *14*, 1347-1363.

Synthesis and supramolecular chemistry of alkyl/  
aryl *carbo*-benzene derivatives

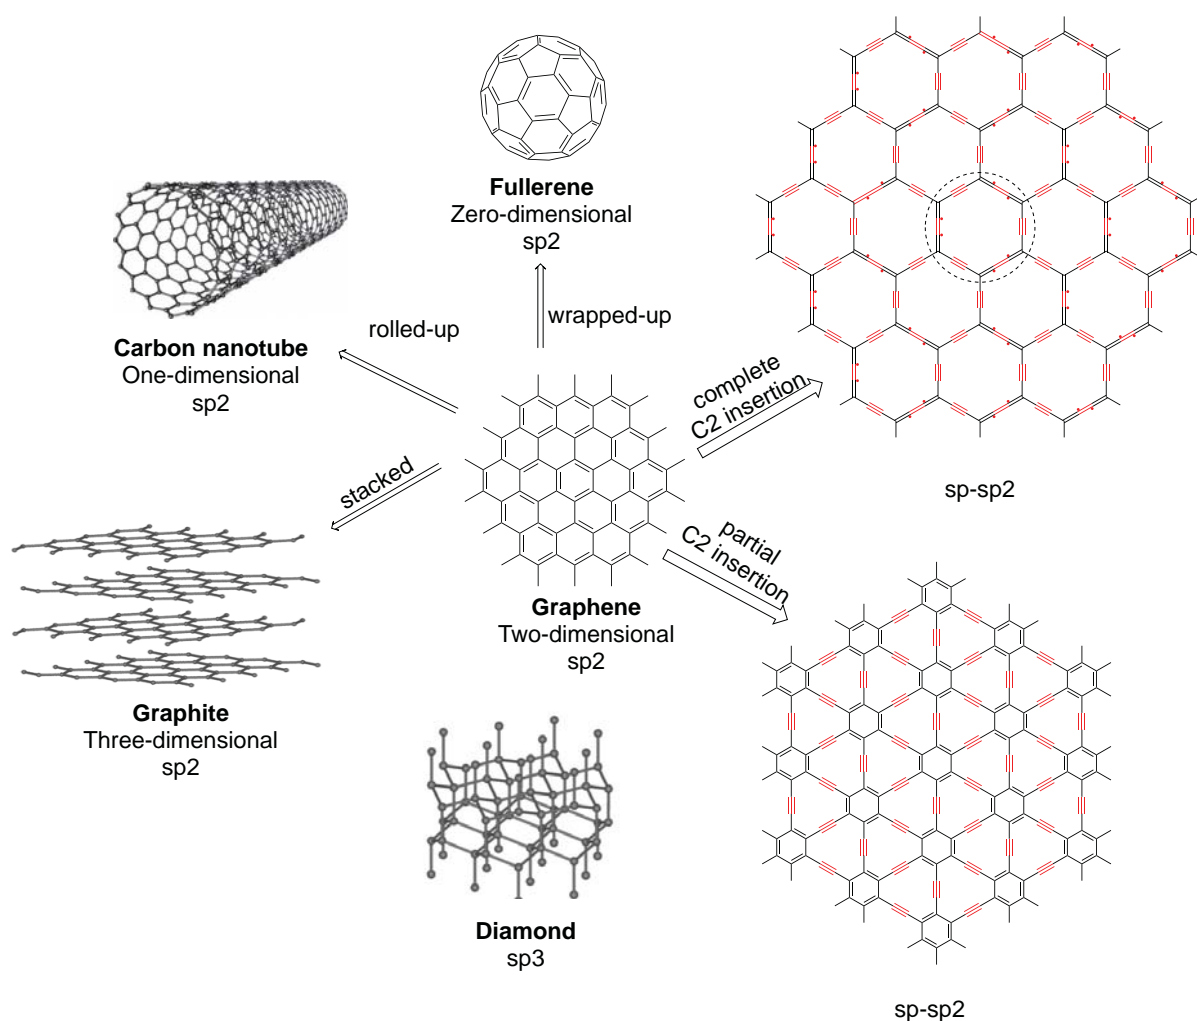

## Chapter 2

Hexaaryl-*carbo*-benzenes revisited: a novel synthetic route, crystallographic data, and prospects of electrochemical behavior

## Introduction & Summary

The carbon element is of paramount importance for the “chemical construction” of life on Earth and is also the basis of organic chemistry. About  $10^7$  different organic molecules and polymers have been synthesized by chemists, their structural diversity being based on stable C-C and C-X bonds, and is accompanied by varieties of chemical and physical properties. Most of them were found to have widespread applications ranging from drugs to materials. Regarding all-carbon molecules and materials, each discovery of a new carbon allotrope was a revolution for materials science, due to their extraordinary electronic and structural properties.<sup>1</sup>

**Figure 1.** Representative allotropic carbon materials with differently hybridized carbon atoms. The  $\alpha$ -graphyne was proposed and studied at the theoretical level only, while all the other carbon allotropes depicted in this figure are known.

Early studies on carbon materials mainly focused on two carbon allotropes: graphite and diamond, which consist of networks of sp<sup>2</sup> and sp<sup>3</sup> hybridized carbon atoms, respectively. The

three-dimensional, layered structure of graphite makes it suitable to be used as a solid lubricant and as a reinforcing additive in carbon fibers.<sup>2</sup> Diamond, featuring the properties of hardness and high refractive index, is mainly used in jewelry and in drilling heads for geological exploration.<sup>1b</sup> Their different applications, based on their distinct chemical and physical properties, drew the attention of the scientific community towards the development of novel carbon materials.

In 1985, Kroto and co-workers disclosed a third allotropic form of carbon, namely, the zero-dimensional Buckminster fullerene or C<sub>60</sub>, made of 60 equivalent sp<sup>2</sup> hybridized carbon atoms, which was fabricated by laser irradiation of graphite.<sup>3</sup> Subsequently, systematic investigations of this new carbon allotrope by chemical methods, such as UV-visible, IR spectroscopies, and mass spectrometry, were reported by Krätschmer *et al.*<sup>4</sup> Fullerene can be considered as a wrapped-up graphene sheet (Figure 1), since these two materials have the same arrangement of carbon atoms. One-dimensional carbon nanotubes, first prepared by Iijima in 1991 using an arc-discharge evaporation method, also exhibit the same sp<sup>2</sup>-hybridized carbon network, and can be regarded as a rolled-up graphene sheet.<sup>5</sup> More recently, the parent of these zero- and one-dimensional carbon allotropes, a graphene sheet, was first obtained by mechanical exfoliation by Geim *et al.* This flat monolayer of carbon atoms densely packed into a honeycomb lattice was described as a two-dimensional material on the basis of investigations of its electronic properties (see Figure 1).<sup>6</sup>

All these sp<sup>2</sup>-hybridized carbon allotropes became attractive for scientists not only for their aesthetically fascinating structure, but also for their prominent properties. Indeed, the  $\pi$ -electron-rich conjugated systems of fullerene, carbon nanotubes and graphene confer them unique and outstanding electronic, mechanical, and thermal properties.<sup>7</sup> For example, functionalized fullerenes were applied as highly efficient electron acceptors in photovoltaic devices.<sup>8</sup> They were also shown to exhibit non-linear optical properties<sup>9</sup> or to act as mesogens for the formation of liquid crystal mesophases<sup>10</sup>. Water-soluble fullerenes decorated with hydrophilic groups were also found to efficiently inhibit HIV-1 protease.<sup>11</sup> Carbon nanotubes were considered for their appealing properties possibly correlated with their helicity, such as their semiconducting or metallic character, which can be potentially used in fine materials, and also their gas storage ability.<sup>12,1d</sup> Although graphene has been developed for only a decade, its unique electronic properties could give rise to applications in integrated circuits,<sup>13</sup> in the domain of energy,<sup>14</sup> and even in anticancer therapy.<sup>15</sup>

The development of new carbon allotropes, having new types of scaffolds made of sp<sup>2</sup>-sp or sp<sup>3</sup>-sp hybridized carbon atoms, is thus a topic of high interest.

The structures of graphynes, made of  $sp^2$ - and  $sp$ -hybridized carbon atoms, were proposed in 1987 by Baughman as new bidimensional carbon allotropes.<sup>16</sup> These carbon allotropes have been largely studied at the theoretical level, in particular for their promising electronic and mechanical properties.<sup>17</sup> These expanded graphenic structures are formally obtained by insertion of  $C_2$  units into all the covalent bonds of graphene ( $\alpha$ -graphyne) or a part of them ( $\gamma$ -graphyne) (see Figure 1). This expansion process can be related to the *carbo*-

Figure 2. Carbo-merization process illustrated in the case of the benzene molecule.

merization process defined by R. Chauvin in 1995, and consisting of the formal insertion of  $C_2$  units into all the covalent bonds, or a topologically defined type of bonds, of any parent Lewis structure (Figure 2).<sup>18</sup>  $\alpha$ -Graphyne can thus be also viewed as the *carbo*-mer of graphene, or *carbo*-graphene, its basic constitutive motif is a *carbo*-benzene ring, whose synthesis has been largely studied in our group over the past 20 years (Figure 1).<sup>19</sup> The intrinsic characteristics and properties (stability, aromaticity...) of *carbo*-benzenes, and *carbo*-mers in general, have been largely studied at the theoretical level,<sup>20</sup> and motivate the

synthetic efforts to prepare such expanded molecules. The  $D_{6h}$ -symmetry, hollow discotic character (diameter  $\approx 0.8$  nm), magnetic aromaticity, and conjugated  $\pi$ -electron-rich system of the *carbo*-benzene ring makes it attractive for possible applications in various fields, such as nonlinear optics, electrical conductivity, or liquid crystals. Although the unsubstituted *carbo*-benzene  $C_{18}H_6$  still remains unknown today, more than thirty examples of diversely substituted ring *carbo*-mers of benzene have been described.<sup>19</sup>

All the *carbo*-benzenes are prepared from their corresponding hexaoxy[6]pericyclyne precursors. The term pericyclyne was proposed by L. T. Scott, who described the first fully hydrocarbon representatives in the 1980's (Figure 3. A).<sup>21</sup> A large variety of other cyclic oligoacetylenes have been synthesized,<sup>22</sup> among which are oxygen-substituted pericyclynes (Figure 3, C)<sup>23</sup> or pericyclydienes (Figure 3. B, D, E),<sup>24</sup> cyclic hexaphenylacetylene (Figure 3. G),<sup>25</sup>  $\gamma$ -graphdiyne units (Figure 3. F).<sup>26</sup>

**Figure 3.** Examples of cyclic oligoacetylenes. **F**, **G** are phenylene and acetylene hybrid macrocycles.

The preparation of *carbo*-benzenes calls for the synthesis of hexaoxy[6]pericyclyne precursors, whose six hydroxyl or alkoxy groups are finally removed under reductive and acidic conditions to afford the aromatic  $C_{18}$  macrocycle of *carbo*-benzenes. Several routes were envisioned to prepare these hexaoxy[6]pericyclynes, all of them being based on a key macrocyclization step between a dinucleophile  $X$  and a dielectrophile  $Y$ , the corresponding macrocyclization being then denoted as  $[X+Y]$  (Figure 4).

**Figure 4.** Different macrocyclization strategies developed for the synthesis of hexaalkoxy[6]pericyclyne precursors of *carbo*-benzenes.

The first examples of *carbo*-benzenes were reported by Ueda *et al.*,<sup>27</sup> and their hexaalkoxy[6]pericyclyne precursors were prepared through a [11+7] macrocyclization process. Three octupolar *carbo*-benzenes **a-c** were prepared with this way, including the hexaphenyl-*carbo*-benzene **a**, obtained in 15 steps with a 1% global yield (Figure 4).

In 2007, a new synthetic route based on [14+4] cyclization was proposed for the preparation of the hexaphenyl-*carbo*-benzene **a** in 8 steps and 12% overall yield.<sup>28</sup> The [8+10] macrocyclization approach was later shown to be the most efficient route to prepare quadrupolar *carbo*-benzenes, through the synthesis of a key [6]pericyclynediol precursor **d**, isolated in about 30 % yield by cyclic addition of a C<sub>8</sub> triyne dinucleophile and a C<sub>10</sub> triynediol dielectrophile.<sup>29</sup> Very recently, the yield of this key macrocyclization step was significantly improved up to 48 % by a fine tuning of the concentration, speed of addition of the two reagents, and temperature of the reaction mixture.<sup>30</sup> The [6]pericyclynedione **e**

resulting from the oxidation of [6]pericyclinediol **d** with  $\text{MnO}_2$ , can readily react with various nucleophiles  $\text{R-X}$  ( $\text{X} = \text{Li}$ , or  $\text{MgBr}$ ), thus leading, after a subsequent reductive aromatization step, to a large number of quadrupolar *carbo*-benzenes **f-o** (see Scheme 1). Some of these quadrupolar molecules were found to exhibit remarkable properties, such as, the high single molecular conductance (SMC) of the *p*-dianilinylnyl-*carbo*-benzene **g**,<sup>31</sup> or one- and two-photon absorption properties (OPA and TPA) of the *p*-difluorenylnyl-*carbo*-benzenes **n** and **o**.<sup>32</sup> Among the reported *carbo*-benzenes in the past years, almost half of them were obtained by this method.

**Scheme 1.** Examples of quadrupolar *carbo*-benzenes **f-o** prepared from the [6]pericyclinedione **e**.

However, most of the *carbo*-benzenes suffer from a very limited solubility, thus restricting the scope of potential applications of this new family of compounds. The search for substituents allowing to increase the solubility of these carbon-rich molecules is thus becoming today of crucial importance. The hexaphenyl-*carbo*-benzene **a** was thus first re-prepared and modified in order to improve the solubility. It was also an opportunity to complete its characterization, which was only partially described by Ueda, Kuwatani *et al.*<sup>27</sup> The synthetic route to the known hexaphenyl-*carbo*-benzene **a** was here envisaged by the classically used double addition of two different nucleophiles ( $\text{Ph}^-\text{Li}^+$  and  $\text{Ph}^-\text{MgBr}^+$ ) to the key [6]pericyclinedione **e**. The original synthesis by Ueda *et al.* could thus be improved by shortening the synthetic route (from 15 to 12), and the global yield was increased from 1% to 8%. The synthesis of the expectedly soluble analogue **p** bearing two di-*tert*-butylphenyl substituents was also described and these two hexaaryl-*carbo*-benzenes **a** and **p** could be fully characterized, including by X-ray diffraction analysis and

electrochemistry. The charge transport properties of the hexaphenyl-*carbo*-benzene **a** were also investigated regarding possible applications in organic photovoltaic devices. The extremely low solubility of **a**, however, prevented the formation of thin films of sufficient quality for the measurement of charge transport properties, further evidencing the drawback of the low solubility of *carbo*-benzenes. The replacement of two phenyl groups of **a** with two di-*tert*-butylphenyl groups in **p** was however shown to only slightly increase the solubility of *carbo*-benzene. Nevertheless, efficient solubilizing substituents were recently found, and the synthesis and properties of the corresponding *carbo*-benzenes are described in the Chapter 3 of this manuscript.

# Hexaaryl-*carbo*-benzenes revisited: a novel synthetic route, crystallographic data, and prospects of electrochemical behavior†

Chongwei Zhu,<sup>ab</sup> Carine Duhayon,<sup>ab</sup> Daniel Romero-Borja,<sup>c</sup> José-Luis Maldonado,<sup>c</sup> Gabriel Ramos-Ortiz,<sup>c</sup> Alix Saquet,<sup>ab</sup> Valerie Maraval<sup>\*ab</sup> and Remi Chauvin<sup>†ab</sup>

An improved 12-step synthetic route and full characterization of hexaphenyl-*carbo*-benzene (**4**, 8%) and the *p*-bis-3,5-di-*tert*-butylphenyl homologue (**11**, 4%), are described. The *carbo*-benzene reference **4** is now accurately described in the crystal state by X-ray diffraction analysis in the chiral space group  $P2_12_12_1$ , and in comparison to the less symmetric derivative **11** exhibiting a centro-symmetric packing. According to cyclic voltammetry, both hexaaryl-*carbo*-benzenes **4** and **11** can behave as both reversible potent electron acceptors and standard electron donors, with respective potentials of  $-0.73 \pm 1$  V and  $+1.17 \pm 2$  V/SCE, respectively. Due to their extremely low solubility, solid films of **11** fabricated using the “wet method”, with the initial view of studying charge transport properties, were found to display high roughness.

## 1 Introduction

By January 1995, the title term “*carbo*-benzene” was proposed for **1**, as a putative example of Hückel-aromatic *carbo*-mer,<sup>1</sup> namely a structure devised by  $D_{6h}$  symmetry-preserving  $C_2$ -expansion of the benzene molecule (Fig. 1).<sup>2</sup> In spite of an attempt of synthesis *via* the hexa-oxo-[6]pericyclenediol **2** (itself targeted *via* a [9+9] macrocyclization route from the triynal **3**),<sup>3</sup> the “bare” *carbo*-benzene **1** could not be obtained and remains hitherto experimentally unknown.<sup>4</sup> Exactly at the same time, Ueda *et al.* communicated the synthesis of 3,6,9,12,15,18-hexaphenyldodecahydro[18]-annulene **4** and a few congeners,<sup>5</sup> standing as the first examples of *carbo*-benzene derivatives, in tri- or hexa-substituted versions (Scheme 1). The highly chromophoric compound **4** and its [6]pericyclenetriol precursor **5** were described in more details by the same authors in 1998.<sup>6</sup> The employed route was based on a [11+7] macro-cyclization step, where the bis-terminal tetrayne **6** reacts as a dinucleophile with the skipped bis-ynal **7** as a dielectrophile. The original synthetic route thus consisted of 15 steps, with 1% overall yield, and 59% yield for the  $5 \rightarrow 4$

Fig. 1 Aromatic region of the  $^1\text{H}$  NMR spectra of **4** and **11** in highly diluted  $\text{CDCl}_3$  solutions (400 MHz, 12 h acquisition time).

reductive aromatization step.<sup>5,6</sup> In 2007, the same hexaphenyl-*carbo*-benzene **4** was reported to be also accessible by reductive aromatization of the [6]pericyclenediol **8** or [6]pericyclenetetraol **9**, in 12 or 22% yield, respectively.<sup>7</sup> The precursors **8** and **9** were themselves obtained through [14+4] macro-cyclization processes, in nine steps with 11% overall yield, and eight steps with 12% overall yield, respectively.<sup>8</sup>

A much shorter alternative route would be based on a [8+10] macro-cyclization process and a key [6]pericyclenedione **10**,<sup>9</sup> which more recently proved to be efficient for the synthesis of centro-symmetric tetraphenyl-*carbo*-benzene targets.<sup>10</sup> Application of this method to the preparation of the *carbo*-benzene paradigm **4** is hereafter described, along with the synthesis of the *a priori* more lipophilic *p*-bis-(di-3,5-*tert*-butylphenyl) derivative **11**.

† Electronic supplementary information (ESI) available:  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra, XRD data, SWV and CV voltammograms. CCDC 1503931 and 1518487. For ESI and crystallographic data in CIF or other electronic format see DOI: 10.1039/c7nj00028f

**Scheme 1** Strategies envisaged for the preparation of the unsubstituted *carbo*-benzene **1** (top); known syntheses of hexaphenyl-*carbo*-benzene **4** (bottom).

In the 1998 pioneer report,<sup>6</sup> X-ray diffraction (XRD) analysis of a single crystal of **4** allowed confirmation of the quasi- $D_{6h}$  symmetric structure and provided information on bond distances and bond angles. Nevertheless, the quality of the crystallographic structure was likely not sufficient for deposition of a coordinate listing at the CCDC, where no corresponding cif file is currently available. The challenge of gaining accurate crystallographic data to make a cif file of **4** available at the CCDC is particularly addressed below.

## 2 Results and discussion

The *carbo*-benzene targets **4** and **11** were thus envisaged by reductive aromatization of the [6]pericyclenediols **12** and **13**. The latter were targeted from the known [6]pericyclenedione **10**, respectively, obtainable by oxidation of the corresponding secondary [6]pericyclenediol **14** (Scheme 2).<sup>9</sup> An optimal procedure

**Scheme 2** Synthesis of *carbo*-benzene targets via a [8+10] macro-cyclization route.

for the synthesis of **14** is based on a [8+10] macro-cyclization step involving the  $C_8$  triyne **15** and  $C_{10}$  dialdehyde **16**. As compared to the previously used [11+7] and [14+4] strategies (see the Introduction), the advantage of the [8+10] strategy is its late divergence character: the sensitive dialdehyde **16** is indeed readily obtained from the triyne **15** just before the macro-cyclization step, providing the [6]pericyclenediol **14** in *ca.* 40% yield (see the ESI† for a detailed comparison of the original and improved synthesis strategies).<sup>9</sup> The key [6]pericyclenedione **10** is then obtained by oxidation of **14** with  $MnO_2$ . From **10**, the targets **4** and **11** were prepared in two steps following a procedure previously experienced for the synthesis of other *carbo*-benzenes.<sup>10</sup> The addition of two equivalents of either  $PhLi$  or  $PhMgBr$  to diketone **10** was thus attempted. Treatment of **10** with  $PhLi$  was found to induce opening of the  $C_{18}$  ring, allowing access to the diadduct **12** in a trace amount only. In contrast, the use of  $PhMgBr$  allowed isolation of **12** with a remarkably high 82% yield (Scheme 2). The Grignard reagent was thus also used for anchoring two 3,5-*tert*-butylphenyl groups to **10**, providing the [6]pericyclenediol **13** with 64% yield.

Using a classical procedure,<sup>10</sup> reductive aromatization of **12** and **13** in dichloromethane (DCM) solution with 10 equivalents of  $SnCl_2$  and 20 equivalents of  $HCl \cdot Et_2O$ , followed by neutralization with 1 M aqueous  $NaOH$ , gave the targets **4** and **11** with the same 65% yield. This procedure differs from the original one by the nature of the solvent and the hydrolysis conditions.<sup>6</sup> The results confirm recent observations that the use of DCM as a solvent instead of diethyl ether, along with milder hydrolytic conditions (1 M instead of 10 M  $NaOH$ ), provides higher yields in *carbo*-benzenes, essentially by enhancement of the solubility of both reagents and products.<sup>10</sup> In comparison with the original method,<sup>5,6</sup> not only the yield in **4** of the last reductive elimination step has been improved from 59 to 65%, but also the total number of steps has been reduced from 15 to 12, while the global yield has been increased from about 1% to 8% (see the ESI† for comparative synthesis schemes).

The hexa-aryl-*carbo*-benzenes **4** and **11** have been isolated as poorly soluble dark red solids. The introduction of two *tert*-butyl groups on two phenyl substituents of **4** thus appears to have a limited effect on the solubility of such rigid carbon-rich compounds. Indeed, the solubility of **11** was determined to be *ca.*  $0.46 \pm 0.03 \text{ mg mL}^{-1}$ , namely less than twice the solubility of **4** of *ca.*  $0.29 \pm 0.03 \text{ mg mL}^{-1}$ , in spite of the presence of four *tert*-butyl groups on two of the aromatic substituents of **11**. For comparison, direct anchoring of aliphatic chains at two vertices the  $C_{18}$  macrocycle was recently reported to be much more efficient with the view of increasing the solubility of *carbo*-benzenes.<sup>13</sup>

In spite of this, accurate spectroscopic data could be obtained for both **4** and **11** ( $^1H$  NMR,  $^{13}C$  NMR, UV-vis), thus confirming the data ranges of Ueda *et al.* for **4**.<sup>5,6</sup> In particular,  $^1H$  NMR spectra of **4** and **11** reveal the characteristic deshielding of the *ortho*- $^1H$  nuclei of the aryl substituents resulting from the magnetic anisotropy induced by the strong diatropic  $C_{18}$  ring current (Fig. 1).<sup>1,5-7,10</sup>

The UV-vis absorption spectrum of **4** in chloroform solution confirms the  $\lambda_{max}$  value of 472 nm previously reported (Fig. 2).<sup>6</sup>

Fig. 2 Normalized absorption spectra of **4** and **11** in chloroform solution.

*Carbo*-benzene **11** exhibits an identical spectral profile with the same  $\lambda_{\max}$  value. The molar extinction coefficient of **4** was however measured to be lower than the value initially reported (234 000 vs. 363 000 L mol<sup>-1</sup> cm<sup>-1</sup>).<sup>6</sup> The absorption spectra of **4** and **11** are classical for *carbo*-benzenes, and their common maximum absorption wavelength  $\lambda_{\max} = 472$  nm is a median value of all the reported values, varying from 424 nm for the octupolar triphenyl-*carbo*-benzene,<sup>5,6</sup> to 521 nm for the quadripolar *para*-*N,N*-dimethylaniliny-*l*-tetraphenyl-*carbo*-benzene.<sup>10b</sup>

The structures of **4** and **11** were confirmed by XRD analysis of single crystals deposited from chloroform solutions (Fig. 3 and Table 1).<sup>14</sup> Contrary to the pioneer crystallographic data,<sup>6</sup> the quality of the present crystals of **4** proved to be sufficient for refined resolution, having allowed a new deposition at the CCDC.<sup>14</sup> The same solvate allotropic variety, involving one CHCl<sub>3</sub>

molecule per molecule of **4**, was obtained. Noteworthy, the highly planar centro-symmetric molecule **4** thus crystallizes in the Sohncke chiral space group P<sub>2</sub><sub>1</sub>2<sub>1</sub>2<sub>1</sub>. Crystallization of a highly symmetrical achiral molecule such as **4** in a chiral space group is not common, but examples have been previously reported for other rigid compounds.<sup>15</sup>

Geometrical features of the macrocycle of **4** are typical of generic *carbo*-benzenes, with average sp<sup>2</sup>C–spC and spC–spC bond lengths of 1.39 and 1.22 Å, respectively. The average angle at the sp<sup>2</sup> vertices of the macrocycle is 118.9°. The C<sub>18</sub> ring is slightly distorted: the maximum deviation from planarity is 0.11 Å, while the globally hexagonal shape is not regular, the diameters (between facing sp<sup>2</sup> vertices) varying from 7.79 Å to 8.17 Å. Torsion angles between the phenyl mean planes and the macrocycle mean plane vary from 2.9° to 29.8°. In the crystal of **11**, the molecules pack in a parallel fashion, the distance between the mean planes of two successive *carbo*-benzene macrocycles being 3.62 Å, *i.e.* much larger than in the recently reported first examples of  $\pi$ -stacked *carbo*-benzenes.<sup>13a</sup> No  $\pi$ -stacking is indeed observed here between two C<sub>18</sub> rings, or between a C<sub>18</sub> ring and any C<sub>6</sub> ring of the aryl substituents. Instead of a chlorine atom of the chloroform molecule co-crystallized with **4** (see above), one of the methyl groups of a *tert*-butyl substituent of **11** pointing towards the center of the C<sub>18</sub> ring of the nearest neighbouring molecule: the closest H atom of this methyl group resides 1.43 Å away from the centroid and 1.38 Å from the mean plane of the neighboring C<sub>18</sub> ring (Fig. 4).

The electrochemical behavior of **4** and **11** has also been studied (Table 2). Cyclic (CV) and square-wave (SWV) voltammograms were recorded for **4** and **11** in chloroform solutions (see the ESI†). More conventional DCM solutions could indeed not be used because of an extremely low solubility in this solvent. For a reference dibutyl-*carbo*-benzene exhibiting sufficient solubility

Fig. 4 Views of the crystalline molecular packing of **4** (top) and **11** (bottom) evidencing both the absence of  $\pi$ -stacking between the C<sub>18</sub> rings, and interactions with solvent molecules (for **4**) and between two carbo-benzene molecules (for **11**).

in either solvents, such a solvent change was recently shown to make redox processes less reversible, but keep the redox potential values almost unchanged, thus allowing a comparison between data obtained from either DCM or chloroform solutions.<sup>13b</sup>

While the first reduction process was found to occur reversibly at similar potentials ( $-0.72$  V for **4**,  $-0.74$  V for **11**), the second reduction was found to be irreversible for both compounds (Table 2). These values are consistent with previous values reported for other *para*-diaryl-tetraphenyl-carbo-benzenes, the first reduction occurring between  $-0.75$  and  $-0.85$  V depending on the nature of the aryl groups.<sup>10a,b</sup> This process is however made easier upon substitution of the C<sub>18</sub> ring by acetylenic substituents: the lowest reduction potential (in absolute value) of  $-0.60$  V observed to date for any carbo-benzene was indeed measured for a *para*-bis-fluorenylethynyl-substituted representative.<sup>10f</sup> In the oxidation regime, the first peak potentials of the

two carbo-benzenes have comparable values (1.14 V for **4** and 1.19 V for **11**), but the process was found reversible for **11** only: the oxidation product of **4** indeed undergoes polymerization, leading to a deposit on the electrode. A second non-reversible oxidation process was also observed for **11**. Carbo-benzenes generally undergo irreversible oxidation, most of them leading to a polymeric film on the electrode after the first oxidation process, the latter occurring at potentials between +0.51 and +0.90 V for donor-substituted hexaaryl-carbo-benzenes,<sup>10a,b</sup> and reaching +1.17 V for a fluorenylethynyl-substituted derivative exhibiting a more extended  $\pi$ -conjugation.<sup>10f</sup>

The low first reduction potential value of **4** and **11** (*ca.*  $-0.73$  V) suggests their possible use as electron acceptors, thus as possible alternatives to C<sub>60</sub> (and PCBM) for photovoltaics (the first reduction potential of C<sub>60</sub> is  $-0.55$  V in chloroform).<sup>16</sup> The accessible and possibly reversible character of the first oxidation of **11** (at 1.19 V) might also be compatible with its use as an organic electron donor. However, the very low solubility of these hexaaryl-carbo-benzenes, even that of the slightly more soluble derivative **11**, did not allow preparation of highly regular thin solid films using the “wet method”, thus preventing measurement of their efficiency for charge transport.<sup>17</sup> Indeed, while microscopic optical images clearly show the non-uniformity of the films, AFM measurements showed a film roughness of *ca.* 355 nm (Fig. 5). This entails a poor optical quality of the films, as evidenced by

Fig. 5 Morphology of spin-casted films of **11** (blended with PC<sub>71</sub>BM: 1:1, w/w ratio) on a glass substrate: microscopic optical image taken using a digital camera installed on the AFM instrument used (top), and the AFM image showing the film roughness (rms)  $\sim 355$  nm (bottom). An additional AFM image is available in the ESI.†

their UV-vis absorption spectra exhibiting large light scattering competing with absorption (see the ESI<sup>†</sup>).

### 3 Conclusions

Hexaphenyl-*carbo*-benzene **4** is a fully symmetrical paradigm and model of the *carbo*-benzene family: 20 years after its first description, its synthetic accessibility has been significantly improved through the implementation of a [8+10] macro-cyclization strategy, and its characterization has been completed by accurate crystallographic and electrochemical data. The expected enhancement of solubility upon substitution of **4** by four *tert*-butyl groups was found to be limited, preventing the use of thin films of **11** for charge transport in organic photovoltaics. Nevertheless, the much higher solubility of recently described *p*-dialkyl-tetraphenyl-*carbo*-benzenes<sup>13</sup> allows consideration of their possible use for such applications. The results of the envisaged studies will be communicated in due course.

## 4 Experimental

### 4.1 General remarks

THF, diethyl ether (Et<sub>2</sub>O), pentane and dichloromethane (DCM) were dried using a PureSolv-MD-5 Innovative Technology system for the purification of solvents. All other reagents were used as commercially available. In particular, solutions of PhLi were 1.9 M in dibutyl ether, solutions of PhMgBr were 3 M in diethyl ether, and solutions of HCl were 2 M in diethyl ether. All reactions were carried out under an argon atmosphere using Schlenk and vacuum line techniques. Column chromatography was carried out on silica gel (60 Å, C.C 70–200 μm). Silica gel thin layer chromatography plates (60F254, 0.25 mm) were revealed under UV-light and/or by treatment with an ethanolic solution of phosphomolybdic acid (20%). The following analytical instruments were used, <sup>1</sup>H and <sup>13</sup>C NMR: Avance 400 and Avance 400 HD spectrometers; mass spectroscopy: a Quadrupolar Nermag R10-10H spectrometer; UV-visible: a Perkin-Elmer UV-vis Win-Lab Lambda 950; and NMR chemical shifts are given in ppm with positive values to high frequency relative to the tetramethylsilane reference. Coupling constants *J* are in Hertz. The UV-visible extinction molar coefficient  $\epsilon$  is in L mol<sup>-1</sup> cm<sup>-1</sup> and wavelengths  $\lambda$  in nm.

### 4.2 Experimental procedures and characterization

**4.2.1 Hexaphenylcyclooctadeca-1,2,3,7,8,9,13,14,15-nonaen-5,11,17-triyn-4** (**4**). A solution of [6]pericyclinediol **12** (77 mg, 0.087 mmol) in DCM (50 mL) was treated with SnCl<sub>2</sub> (165 mg, 0.87 mmol) and HCl (0.87 mL, 1.74 mmol, 2 M in Et<sub>2</sub>O) at -78 °C. The mixture was stirred at -78 °C for 10 min, then at room temperature for 25 min. After the addition of aqueous 1 M NaOH (1.74 mL) and filtration through celite<sup>®</sup>, the organic layer was washed with brine three times, dried over MgSO<sub>4</sub>, and concentrated under reduced pressure. The residue was purified by washings with Et<sub>2</sub>O (3 × 5 mL) and pentane (3 × 5 mL) to obtain **4** as a dark violet solid with 65% yield (38 mg, 0.057 mmol).

<sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>)  $\delta$  9.48 (d, *J* = 7.3 Hz, 12H, *o*-C<sub>6</sub>H<sub>5</sub>), 8.01 (t, *J* = 7.7 Hz, 12H, *m*-C<sub>6</sub>H<sub>5</sub>), 7.74 (t, *J* = 7.4 Hz, 6H, *p*-C<sub>6</sub>H<sub>5</sub>). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CDCl<sub>3</sub>)  $\delta$  140.25 (*i*-C<sub>6</sub>H<sub>5</sub>), 130.56 (*o*-C<sub>6</sub>H<sub>5</sub>), 129.92 (*m*-C<sub>6</sub>H<sub>5</sub>), 129.44 (*p*-C<sub>6</sub>H<sub>5</sub>), 118.46 (=C=C=, -C≡C-), 104.53 (=CPh-). HRMS (MALDI-TOF/DCTB): *m/z*: [M + Na]<sup>+</sup> calculated for C<sub>54</sub>H<sub>30</sub>Na: 701.2245, found: 701.2225. UV-vis (CHCl<sub>3</sub>):  $\lambda_{\text{max}}$  = 472 nm ( $\epsilon$  = 234 000 L mol<sup>-1</sup> cm<sup>-1</sup>). Melting-decomposition temperature: 221 °C.

**4.2.2 1,10-Bis(3,5-di-*tert*-butylphenyl)-4,7,13,16-tetraphenylcyclooctadeca-1,2,3,7,8,9,13,14,15-nonaen-5,11,17-triyn-4** (**11**). A solution of [6]pericyclinediol **13** (130 mg, 0.123 mmol) in DCM (100 mL) was treated with SnCl<sub>2</sub> (233 mg, 1.23 mmol) and HCl (1.3 mL, 2.453 mmol, 2 M in Et<sub>2</sub>O) at -78 °C. The mixture was stirred at -78 °C for 20 min, then at room temperature for 15 min. After the addition of 1 M aqueous NaOH (2.6 mL) and filtration through celite<sup>®</sup>, the organic layer was washed with brine three times, dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified by washings with Et<sub>2</sub>O (3 × 5 mL) and pentane (3 × 5 mL) to obtain **11** as a dark red solid with 65% yield (47 mg, 0.052 mmol). <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>)  $\delta$  9.59–9.55 (m, 8H, *o*-C<sub>6</sub>H<sub>5</sub>), 9.45 (d, *J* = 1.7 Hz, 4H, *o*-C<sub>6</sub>H<sub>5</sub>), 7.96 (dd, *J* = 8.1, 7.2 Hz, 8H, *m*-C<sub>6</sub>H<sub>5</sub>), 7.83 (t, *J* = 1.7 Hz, 2H, *p*-C<sub>6</sub>H<sub>5</sub>), 7.72 (t, *J* = 7.3 Hz, 4H, *p*-C<sub>6</sub>H<sub>5</sub>), 1.78 (s, 36H, -C(CH<sub>3</sub>)<sub>3</sub>). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CDCl<sub>3</sub>)  $\delta$  152.55 (*m*-C<sub>6</sub>H<sub>5</sub>), 140.39 (*i*-C<sub>6</sub>H<sub>5</sub>), 130.50 (*o*-C<sub>6</sub>H<sub>5</sub>), 129.85 (*m*-C<sub>6</sub>H<sub>5</sub>), 129.34 (*p*-C<sub>6</sub>H<sub>5</sub>), 127.05 (*i*-C<sub>6</sub>H<sub>5</sub>), 125.02 (*o*-C<sub>6</sub>H<sub>5</sub>), 124.22 (*p*-C<sub>6</sub>H<sub>5</sub>), 118.17 (=C=C=, -C≡C-), 105.63 (=CPh-), 35.55 (-C(CH<sub>3</sub>)<sub>3</sub>), 31.88 (-C(CH<sub>3</sub>)<sub>3</sub>). HRMS (MALDI-TOF/DCTB): *m/z*: [M]<sup>+</sup> calculated for C<sub>70</sub>H<sub>62</sub> 902.4852, found: 902.4787. UV-vis (CHCl<sub>3</sub>):  $\lambda_{\text{max}}$  = 472 nm ( $\epsilon$  = 248 000 L mol<sup>-1</sup> cm<sup>-1</sup>). Melting-decomposition temperature: 230 °C.

**4.2.3 4,7,13,16-Tetramethoxy-1,4,7,10,13,16-hexaphenylcyclooctadeca-2,5,8,11,14,17-hexayne-1,10-diol** (**12**). A solution of [6]pericyclinedione **10** (86 mg, 0.126 mmol) in THF (20 mL) was treated with PhMgBr (0.1 mL, 0.291 mmol) at 0 °C. The reaction mixture was stirred for 1 h at this temperature and 0.5 h at room temperature. After the addition of a saturated aqueous solution of NH<sub>4</sub>Cl, the aqueous layer was separated and extracted with Et<sub>2</sub>O. The combined organic layers were dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified by chromatography on silica gel (pentane:ethyl acetate 4:1) to obtain **12** as a yellow oil with 82% yield (87 mg, 0.104 mmol). <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>)  $\delta$  7.89–7.62 (m, 12H, *o*-C<sub>6</sub>H<sub>5</sub>), 7.49–7.27 (m, 18H, *m*-, *p*-C<sub>6</sub>H<sub>5</sub>), 3.71–3.35 (m, 12H, -OCH<sub>3</sub>), 3.35–3.05 (m, 2H, -OH). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CDCl<sub>3</sub>)  $\delta$  140.90–140.69 (*i*-C<sub>6</sub>H<sub>5</sub>-C(OH)<), 139.49–139.24 (*i*-C<sub>6</sub>H<sub>5</sub>-C(OCH<sub>3</sub>)<), 129.13–128.92 (*p*-C<sub>6</sub>H<sub>5</sub>), 128.73–128.49 (*m*-C<sub>6</sub>H<sub>5</sub>), 126.56–126.40 (*o*-C<sub>6</sub>H<sub>5</sub>-C(OCH<sub>3</sub>)<), 125.78–125.74 (*o*-C<sub>6</sub>H<sub>5</sub>-C(OH)<), 87.22–86.63, 84.65–84.37, 82.96–82.57 (-C≡C-), 72.02–71.91 (>C(OH)Ph), 65.10, 65.07 (>C(OCH<sub>3</sub>)Ph), 53.48, 53.45 (-OCH<sub>3</sub>). **4.2.4 1,10-Bis(3,5-di-*tert*-butylphenyl)-4,7,13,16-tetramethoxy-4,7,13,16-tetraphenylcyclooctadeca-2,5,8,11,14,17-hexayne-1,10-diol** (**13**). A solution of [6]pericyclinedione **10** (165 mg, 0.243 mmol) in THF (20 mL) was treated with 3,5-di-*tert*-butyl-C<sub>6</sub>H<sub>3</sub>MgBr

(0.625 mmol in 1 mL THF) at 0 °C. The reaction mixture was stirred for 1.5 h at this temperature and 0.5 h at room temperature. After the addition of a saturated aqueous solution of NH<sub>4</sub>Cl, the aqueous layer was separated and extracted with Et<sub>2</sub>O. The organic layers were combined, dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified by chromatography on silica gel (pentane : ethyl acetate 4 : 1) to obtain **13** as a yellow oil with 64% yield (165 mg, 0.156 mmol). <sup>1</sup>H NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ 7.93–7.54 (m, 12H, *o*-C<sub>6</sub>H<sub>5</sub>), 7.54–7.24 (m, 14H, *m*, *p*-C<sub>6</sub>H<sub>5</sub>, *p*-C<sub>6</sub>H<sub>3</sub>), 3.70–3.40 (m, 12H, -OCH<sub>3</sub>), 3.36–3.17 (m, 2H, -OH), 1.41–1.22 (m, 36H, -C(CH<sub>3</sub>)<sub>3</sub>). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ 151.41–151.34 (*m*-C<sub>6</sub>H<sub>3</sub>), 139.88–139.68 (*i*-C<sub>6</sub>H<sub>5</sub>), 139.62–139.52 (*i*-C<sub>6</sub>H<sub>3</sub>), 129.08–128.94 (*p*-C<sub>6</sub>H<sub>5</sub>), 128.56–128.46 (*m*-C<sub>6</sub>H<sub>5</sub>), 126.45–126.26 (*o*-C<sub>6</sub>H<sub>5</sub>), 123.34, 123.25 (*p*-C<sub>6</sub>H<sub>3</sub>), 120.24–120.10 (*o*-C<sub>6</sub>H<sub>3</sub>), 87.24–86.94, 84.63–84.37, 82.65–82.54 (-C≡C-), 72.02–71.81 (>C(OH)Ph), 65.77–65.70 (>C(OCH<sub>3</sub>)Ph), 53.37–53.19 (-OCH<sub>3</sub>), 34.96, 34.93 (-C(CH<sub>3</sub>)<sub>3</sub>), 31.20–31.10 (-C(CH<sub>3</sub>)<sub>3</sub>). HRMS (MALDI-TOF/DCTB): *m/z*: [M + Na]<sup>+</sup> calculated for C<sub>74</sub>H<sub>76</sub>O<sub>6</sub>Na: 1083.5540, found: 1083.5476.

### 4.3 Crystal structure determination

Intensity data were collected at low temperature on an Apex2 Bruker diffractometer equipped with a 30 W air-cooled micro-focus source or on an Oxford-Diffraction Gemini (λ<sub>Mo</sub> = 0.71073 Å). The structures were solved using SUPERFLIP, and refined by means of least-squares procedures on *F* using the programs of the PC version of CRYSTALS.<sup>11</sup> Atomic scattering factors were taken from the International Tables for X-ray Crystallography.<sup>12</sup> For **4**, the asymmetric unit consists in a whole *carbo*-benzene molecule. For **11**, it contains half a molecule. Both asymmetric units contain a disordered CHCl<sub>3</sub> solvent molecule. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using a riding model. Absorption corrections were introduced using the program MULTISCAN.

### 4.4 Voltammetric measurements

Voltammetric measurements were carried out using a potentiostat Autolab PGSTAT100 controlled by GPES 4.09 software. Experiments were performed at room temperature in a home-made airtight three-electrode cell connected to a vacuum/argon line. The reference electrode consisted of a saturated calomel electrode (SCE) separated from the solution by a bridge compartment. The counter electrode was a platinum wire of ca. 1 cm<sup>2</sup> apparent surface. The working electrode was a Pt microdisk (0.5 mm diameter). The supporting electrolyte [n-Bu<sub>4</sub>N][PF<sub>6</sub>] was used as received (Fluka, 99% electrochemical grade) and simply degassed under argon. The chloroform solutions used in the electrochemical study was 10<sup>-3</sup> M in *carbo*-benzene and 0.1 M in the supporting electrolyte. Before each measurement, the solutions are degassed by bubbling argon, and the working electrode was polished using a polishing machine (Presi P230). Typical instrumental parameters for recording square-wave voltammograms were: SW frequency *f* = 20 Hz, SW amplitude *E*<sub>sw</sub> = 20 mV, and scan increment Δ*E* = 5 mV.

### 4.5 Solid film fabrication and AFM measurements

Glass substrates were cleaned with ethanol in an ultrasonic bath and were rubbed with alcohol-wetted cotton. Substrates were then dried with clean and dry air and kept at 85 °C over 15 min. Before deposition of the compound layers by spin-casting (blend of 11:PCBM) from a chlorobenzene solution (at 30 mg mL<sup>-1</sup>), substrates were treated with UV oxygen plasma for 5 min. The solution was stirred for 4 h and deposited by spin-coating at 1500 rpm for 30 s in a N<sub>2</sub> glovebox. Morphology, roughness and thickness were analyzed by means of atomic force microscopy (AFM) using a microscope easyscan2 from Nanosurf, with a maximum square scanning area of 110 μm, operating in contact mode under ambient conditions (see the ESI†).

## Acknowledgements

C. Z. thanks the China Scholarship Council for his PhD scholarship. The Toulouse IDEX Emergence program 2014 is acknowledged for funding (*Carbo*-device project). R. C. Thanks the Centre National de la Recherche Scientifique (CNRS) for half a teaching sabbatical in 2015–2016. The authors thank the French-Mexican International Associated Laboratory (LIA) “Molecular Chemistry with Applications in Materials and Catalysis” funded by the CNRS and the CONACyT.

## 2. SWV and CV voltammograms for 4 and 11

Voltammetric measurements were carried out with a potentiostat Autolab PGSTAT100 controlled by GPES 4.09 software. Experiments were performed at room temperature in a home-made airtight three-electrode cell connected to a vacuum/argon line. The reference electrode consisted of a saturated calomel electrode (SCE) separated from the solution by a bridge compartment. The counter electrode was a platinum wire of *ca* 1 cm<sup>2</sup> apparent surface. The working electrode was a Pt microdisk (0.5 mm diameter). The supporting electrolyte [*n*-Bu<sub>4</sub>N][PF<sub>6</sub>] was used as received (Fluka, 99 % electrochemical grade) and simply degassed under argon. The chloroform solutions used in the electrochemical study was 10<sup>-3</sup> M in *carbo*-benzene and 0.1 M in supporting electrolyte. Before each measurement, the solutions are degassed by bubbling argon, and the working electrode was polished with a polishing machine (Presi P230). Typical instrumental parameters for recording square-wave voltammograms were: SW frequency *f* = 20 Hz, SW amplitude *E*<sub>sw</sub> = 20 mV, scan increment *dE* = 5 mV.

## Chapter 3

Lipidic *carbo*-benzenes: molecular probes of magnetic anisotropy and stacking properties of  $\alpha$ -graphyne

## Introduction & Summary

The key [6]pericyclynedione precursor of *para*-disubstituted *carbo*-benzenes is today easily prepared through a nine-step procedure involving a [8+10] macrocyclization reaction between a C<sub>8</sub> triyne and a C<sub>10</sub> triynedial.<sup>1</sup> A series of quadrupolar *carbo*-benzenes bearing various substituents at their *para*-positions, such as anisyl-,<sup>2</sup> fluorenyl-,<sup>3</sup> trimethylsilylethynyl-,<sup>1b,4</sup> and aniliny-,<sup>5</sup> have been synthesized in two steps from this common [6]pericyclynedione precursor. The intrinsic structural and electronic features of the C<sub>18</sub> aromatic ring provide *carbo*-benzenes with remarkable properties and prospects of applications.

Up to now, all the *carbo*-benzenes that were shown to possess outstanding physicochemical properties are quadrupolar representatives, and exhibited single molecule conductance or two-photon absorption properties, depending on the substituents at their *para*-positions.<sup>3,6</sup> Very recently, the use of hexaphenyl-*carbo*-benzene as an electron-acceptor in organic photovoltaics, in replacement of the classically used PCBM C<sub>60</sub> derivative, was also envisaged.<sup>7</sup> However, the extremely poor solubility of this *carbo*-benzene made impossible the preparation of thin films of sufficient quality to be applied in organic photovoltaic devices.<sup>8</sup> The quite low solubility of *carbo*-benzenes generally not only prevents their use in some attractive domains of applications, but also makes them difficult to purify and characterize in solution.

The search for efficient solubilizing substituents appeared therefore to be an inescapable task, which started to be addressed recently in the context of the synthesis of a *carbo*-naphthalene. Indeed, this rigid bis-macrocycle, anticipated to be very poorly soluble, was targeted with eight *para*-pentyphenyl substituents, but their solubilizing effect was shown to be quite limited (Figure 1. D).<sup>9</sup> Similarly, the introduction of two di-*tert*-butylphenyl groups at the *para*-positions of a *carbo*-benzene failed to enhance its solubility (Figure 1, A).<sup>7</sup> The introduction of alkyl groups onto the phenyl substituents of *carbo*-benzenes being poorly efficient to increase their solubility, the direct insertion of aliphatic chains onto the C<sub>18</sub> macrocycle was envisaged. Ueda *et al.* early reported on the synthesis of an octupolar *carbo*-benzene bearing three *tert*-butyl groups alternating with three phenyl groups on the hexagonal C<sub>18</sub> macrocycle (Figure 1. B),<sup>10</sup> and more recently, a series of representatives bearing two, four or six *tert*-butyl groups were prepared, and these substituents were shown to significantly improve the solubility of *carbo*-benzenes in organic solvents.<sup>11</sup> The synthesis of a *p*-diisopropyl-tetraphenyl-*carbo*-benzene was also recently described, and it was found to be

very poorly soluble, the isopropyl groups thus appearing to be much less efficient than *tert*-butyl groups for increasing the solubility (Figure 2. C).<sup>12</sup>

**Figure 1.** Examples of *carbo*-benzene derivatives bearing various alkyl groups.

On the basis of these preliminary results, the direct attachment of linear alkyl chains of variable lengths at the *para*-positions of *carbo*-benzenes was envisaged as a novel approach aiming at improving the solubility of these molecules (see Scheme 1.). A set of lengths of *n*-alkyl chains ( $n = 2, 4, 8, 14, 20$ ) were proposed, and the preparation of the corresponding *carbo*-benzenes was addressed through the classical two-step procedure from the [6]pericyclynedione. The use of alkyl magnesium bromide reagents led to the generation of mixtures of the targeted di-adduct and the reduced mono-adducts, thus allowing for the parallel preparation of series of dialkyl- and mono-alkyl-*carbo*-benzenes respectively. The outcome of the reaction depending on the nature of the nucleophile was also explored in order to determine which reagent gives the highest selectivity in the targeted di-adducts and corresponding quadrupolar *carbo*-benzenes. Three types of alkyl nucleophiles were attempted: alkyl lithium ( $\text{C}^-\text{Li}^+$ ), alkyl halogenomagnesium ( $\text{C}^-\text{MgX}^+$ ,  $\text{X} = \text{Cl}, \text{Br}$ ), and alkyl cerium chloride ( $\text{C}^-\text{CeCl}_2^+$ ), the latter

giving the di-adduct in higher yield, without the reduced product. The physicochemical properties of the obtained *p*-dialkyl-tetraphenyl-*carbo*-benzenes were studied and discussed as a function of the chain length, including solubility, melting-decomposition point, absorption properties, electrochemical behavior and crystal packing.

**Scheme 1.** The synthetic route based on a [6]pericyclonydione for preparation of dialkyl- and monoalkyl-*carbo*-benzenes by using  $\text{RMgBr}$  as a base.

## Supporting Information

**ABSTRACT:** Solubilization of the  $C_{18}$  fundamental circuit of  $\alpha$ -graphyne has been envisaged by decoration with aliphatic chains  $R = n-C_nH_{2n+1}$ . The synthesis and characterization of *p*-dialkyl-tetraphenyl-carbo-benzenes ( $n = 2, 8, 14, 20$ ) are thus presented and compared to the monoalkyl series produced concomitantly. In both series, a dramatic enhancement of solubility in organic solvents ( $CH_2Cl_2$ ,  $CHCl_3$ ) is observed for  $n \geq 8$ , and in the dialkyl series, the melting–decomposition temperature of the solid products is shown to decrease linearly from 208 °C for  $n = 2$  to 149 °C for  $n = 20$ . Fluoroalkyl analogues with  $R = n-C_nH_4F_{13}$  are also described. The products display classical UV–vis electronic spectra of carbo-benzenes in solution ( $\lambda_{max} = 445.5 \pm 1$  nm,  $\epsilon \approx 200\,000$  L·mol<sup>-1</sup>·cm<sup>-1</sup>). They are also characterized by UV–vis absorption in the solid state, which is found to be correlated with the color and crystal packing. The methylene groups of R provide an experimental probe of the magnetic anisotropy and aromaticity of the  $C_{18}$  ring through the progressive NMR shielding of the <sup>1</sup>H nuclei from ca. 4.70 to 1.25 ppm going away from the border of the ring (as far as 8 Å away). All alkyl-carbo-benzenes were also found to be highly crystalline. Seven of them have been characterized by X-ray diffraction analysis and the  $C_{18}$  columnar packing compared in a systematic manner. Crystals of the diethyl and bistetradecyl derivatives, containing no solvent molecule, provided the first examples of direct  $\pi$ -stacking of carbo-benzene rings, with inter-ring distances very close to calculated interlayer distances in AB and ABC  $\alpha$ -graphityne (3.255 and 3.206 Å vs 3.266 and 3.201 Å, respectively).

## 1. INTRODUCTION

Within the continually growing family of  $\pi$ -conjugated carbon allotropes, two main types can be distinguished: the graphenic type based on  $sp^2$ -C atoms only, exemplified by fullerenes, carbon nanotubes (CNTs) and graphene, and the graphynic type based on mixed  $sp^2$ - and  $sp$ -C atoms,<sup>1</sup> exemplified by graphdiyne<sup>2</sup> and the yet unknown  $\alpha$ -,  $\beta$ -,  $\gamma$ -, or 6,6,12-graphynes.

Molecular fragments of either known or unknown, 2D or 3D carbon allotropes, including graphene or  $\alpha$ -graphyne, graphite, or  $\alpha$ -graphityne,<sup>3</sup> are targeted for property promises inherited from the parent pure-carbon material with the view to designing devices made of diverse components (photovoltaic cells, organic light-emitting diodes, field-effect transistors...). In contrast to the nonselective methods employed for the preparation of mixtures of graphenic nanocarbons (arc discharge, laser ablation, chemical vapor deposition),<sup>4</sup> the bottom-up organic synthesis approach allows access to atomically defined molecular fragments containing oligocyclic carbon cores formally extruded from either CNTs and graphene,<sup>5</sup>  $\gamma$ -graphyne,<sup>6</sup>  $\gamma$ -graphdiyne,<sup>7</sup> or  $\alpha$ -graphyne.<sup>8</sup> The decrease of solubility vs the size of the all-carbon core is however a recurring issue requiring recourse to solubilizing substituents of  $sp^2$  vertices at the core periphery. As no

substituent can be attached to  $sp$ -C atoms, the case of graphynic cores is thus particularly challenging. In the case of  $\alpha$ -graphyne, the primary carbon core is the carbo-mer of the  $C_6$  ring of graphene,<sup>9</sup> i.e. a ca. three-times larger  $C_{18}$  ring with a circumscribed nuclear diameter of ca. 8 Å and a van der Waals hole diameter of ca. 5 Å. The corresponding molecular fragments are carbo-benzene derivatives **1** (Figure 1), generally poorly soluble in organic solvents, except in chloroform (albeit to a limited extent).<sup>9b,10</sup> This lack of solubility has prevented systematic studies of chemical properties of carbo-benzenes. For synthesis and yield issues, indeed, most of the carbo-benzenes reported to date are of the type **1a**, bearing at least four phenyl substituents, the remaining two vertices being either unsubstituted (CH) or substituted by other aryl or alkynyl groups. More or less soluble related carbo-meric structures have also been investigated.<sup>10c</sup> Partial saturation of the carbo-benzenic  $C_{18}$  ring to carbo-cyclohexadiene rings or release of its macrocyclic stiffness in carbo-butadienes **3** was thus shown to induce a higher solubility (Figure 1).<sup>10c,d</sup> Although **2** and **3** are easier to handle and characterize, the macro/carbo-aromatic character of carbo-benzenes **1a**, extensively investigated at the

Figure 1. Examples of  $\pi$ -conjugated *carbo*-meric molecules of variable solubility.

theoretical level,<sup>9b,10c</sup> is crucial to provide them with various properties such as unprecedented single-molecule conductance (106 nS with Ar = 4-NH<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>,  $n = 0$ ; vs 2.7 nS for the acyclic analogue 3),<sup>11</sup> high two-photon absorption cross-section (656 GM at 800 nm with Ar = 9,9-dihexyl-9*H*-fluoren-2-yl,  $n = 1$ ),<sup>12</sup> or chemical reversibility of the reduction to pro-aromatic *carbo*-quinoids such as 4 (Ar = 9-hydroxy-2,7-diheptyl-9*H*-fluoren-9-yl,  $n = 0$ ; Ar is here aromatic but not aryl).<sup>13</sup> In the two latter cases and in the case of the *carbo*-naphthalene 5,<sup>8</sup> attachment of alkyl chains on the fluorenyl(idene) or phenyl substituents was required to secure some solubility. Replacement of bare phenyl substituents by alkyl-phenyl groups (alkyl = <sup>*n*</sup>C<sub>5</sub>H<sub>11</sub>, <sup>*t*</sup>Bu) was however observed to have a minor solubilizing effect.<sup>8,10a,b,14</sup> Direct attachment of alkyl chains on the C<sub>18</sub> core while removing two aryl substituents should be a priori a more efficient method with the view to enhancing the solubility of *carbo*-benzene derivatives. Only two alkyl-substituted *carbo*-benzenes have been described to date: an octupolar tri(*tert*-butyl) derivative 1b<sup>10b</sup> and very recently a quadrupolar di(isopropyl) derivative 1c:<sup>15</sup> with branched short (C<sub>2</sub>) alkyl chains, however, none of them is lipidic in nature, and the gain in solubility remains weak. Lipidic *carbo*-benzenes were

therefore envisaged in the quadrupolar series with two *n*-alkyl chains at the para positions (substitution pattern of 1a and 1c). Their synthesis and physicochemical properties (solubility, magnetic aromaticity, light absorption, crystal packing) are hereafter described and discussed.

## 2. RESULTS AND DISCUSSION

### 2.1. Synthesis of Mono- and Dialkyl-*carbo*-benzenes.

The target *p*-di-*n*-alkyl-*carbo*-benzenes were envisaged by reductive aromatization of the corresponding [6]pericyclic diols 6a–e (Scheme 1), themselves envisaged from the [6]pericyclic dione 7,<sup>16</sup> that proved to be a relevant last-but-one pivotal precursor of most quadrupolar *carbo*-benzenes known to date (but not 1c).<sup>9b,10c</sup> Following an optimized procedure, the diketone 7 is obtained as a statistical mixture of five diastereoisomers in 10 steps and ca. 10% global yield from benzoyl chloride and bis-trimethylsilylacetylene, the C<sub>18</sub> ring being formed in a [8 + 10] cyclization step from a C<sub>8</sub> diterminal triyne and the corresponding C<sub>10</sub> triyndial.<sup>16a</sup> The alkyl groups were then introduced by double-nucleophilic attack of 7 with two equivalents of the corresponding alkyl Grignard reagents (in the presence of an optimized excess of three equivalents):

**Scheme 1.** Synthesis of Mono- and Dialkyl-*carbo*-benzenes by Addition of Alkyl or Fluoroalkyl Grignard Reactants to the [6]Pericyclynedione **7**, Followed by Reductive Aromatization of the [6]Pericyclynediol Products **6** and **8** Using Anhydrous SnCl<sub>2</sub><sup>a</sup>

<sup>a</sup>The nonalkylated *carbo*-benzene **12** was previously described, including by X-ray crystallography.

aryl Grignard congeners indeed proved to be optimal nucleophiles for **7**, giving higher yields than the lithium counterparts.<sup>10c</sup> Four alkyl chains R = *n*-C<sub>*n*</sub>H<sub>2*n*+1</sub> differing by a minimal C<sub>6</sub> increment were selected: *n* = 2, 8, 14, 20. The C<sub>8</sub> chain was also considered in the partially fluorinated version R = *n*-C<sub>8</sub>H<sub>4</sub>F<sub>13</sub>. While ethyl and tetradecyl magnesium bromides were used from commercially available solutions, the other Grignard reactants were prepared from the corresponding bromoalkanes. In all cases, the Grignard reaction with **7** led to two main products, always obtained in comparable ratios as mixtures of isomers (Scheme 1). The major product is the diadduct **6a–e** (isolated in 30–45% yield), while the minor one is the monoadduct **8a–e** resulting from the reduction of one of the keto groups of **7** to a carbinol vertex (and isolated in 20–28% yield). Smaller quantities of the known double-reduction product **9** were also obtained in 6–20% yield.<sup>16a</sup> The reducing ability of alkyl Grignard reagents, in particular toward hindered ketones, is due to the presence of a H atom in the β-position, allowing β-elimination leading to the corresponding terminal olefin and “HBr + Mg<sup>0</sup>” as a formal reducing agent. The exact mechanism of the reduction has been largely studied,<sup>17</sup> and several procedures were proposed to enhance the selectivity in addition vs reduction.<sup>18</sup> The recommended use of apolar solvents such as toluene, or additives such as CeCl<sub>3</sub> have been attempted but proved to be inefficient on dialkynylketone substrates such as **7**. Nevertheless, taking advantage of this,

isolation of an extended library of both monoalkyl-[6]-pericyclynediols **8a–e** and dialkyl-[6]pericyclynediols **6a–e** offered the opportunity to target both the dissymmetrical monoalkyl-*carbo*-benzenes **10a–e** and the symmetrical dialkyl-*carbo*-benzenes **11a–e**.

Using a classical treatment with anhydrous SnCl<sub>2</sub> and ethereal HCl, the [6]pericyclynediols **6a–e** and **8a,b,d,e** were converted to the corresponding *carbo*-benzenes **11a–e** and **10a,b,d,e**, isolated in 13–71% yield and 12–40% yield, respectively (Scheme 1).<sup>9b,10a–c</sup> By comparison, the aromatization of **9** was previously reported to give the unsubstituted tetraphenyl-*carbo*-benzene **12**, along with an HCl adduct thereof.<sup>19</sup> The present products were obtained as dark blue-violet solids, giving orange solutions in chloroform. The solubility of the mono- and diethyl representatives **11a** and **10a** in any organic solvent happens to be very low, preventing full characterization of **11a** in solution. As anticipated in the hydrocarbon series, the solubility was found to increase with the chain length from C<sub>2</sub> to C<sub>14</sub> and then to decrease back for C<sub>20</sub>. In contrast, no significant effect on the solubility was observed upon fluorination of the C<sub>8</sub> chain of **11b** into **11e**.

**2.2. NMR Characterization of Mono- and Dialkyl-*carbo*-benzenes.** The mono- and dialkyl-*carbo*-benzenes were characterized by NMR spectroscopy in solution, except **11a**, the poor solubility of which required recourse to the CP-MAS

**Figure 2.** Variation of the  $^1\text{H}$  NMR chemical shifts of the  $\text{CH}_2$  groups of the alkyl chains of **11b–e** vs the  $\text{CH}_2$  rank (top left), variation of the  $^1\text{H}$  NMR chemical shifts of the  $\text{CH}_2$  groups of the alkyl chains of **11b** and parent 1,4-dioctylbenzene<sup>22a</sup> vs the  $\text{CH}_2$  rank (top right),<sup>23</sup> and full  $^1\text{H}$  NMR spectrum of the dioctyl-*carbo*-benzene **11b** in  $\text{CDCl}_3$  (bottom); (\*) acetone; (\*\*)  $\text{CH}_2\text{Cl}_2$ .

technique to record the  $^{13}\text{C}$  NMR spectrum in the solid state (see SI).

The symmetrical *carbo*-benzenes **11a–e** display comparable  $^1\text{H}$  NMR spectral profiles in the aromatic region, with highly deshielded signals for the two *ortho*- $\text{CH}$  nuclei of the four equivalent phenyl substituents resonating at  $9.52 \pm 0.1$  ppm for **11a–d** and 9.44 ppm for the fluorinated derivative **11e**. The  $^1\text{H}$  NMR deshielding outside the macrocycle is experimental evidence of the strong diatropic ring current of *carbo*-benzenes. The corresponding magnetic anisotropy has long been established by calculation of nucleus-independent chemical shifts  $\text{NICS}(x)$ ,<sup>20</sup>  $x$  Å above the centroid of the  $\text{C}_{18}$  ring on the normal to the ring mean plane passing through this center ( $\text{NICS}(0) = -17.9$  ppm for unsubstituted *carbo*-benzene vs  $-8.0$  ppm for benzene).<sup>21</sup> According to the Biot–Savart law, the magnetic deshielding should decrease versus the distance from the ring border, and the aliphatic chains of **11a–e** directly anchored to this border provide a unique experimental probe to appraise the distance effect through the variation of the  $^1\text{H}$  chemical shifts of the  $\text{CH}_2$  groups along the chains. In **11b–d**, containing at least six  $\text{CH}_2$  groups in almost identical local environments, the progressive shielding of the  $\text{C}^1\text{H}_2$  signals away from the  $\text{C}_{18}$  macrocycle is the same for the three compounds and highly regular (Figure 2). The first methylene group (directly connected to the *carbo*-benzene ring and numbered as  $k = 1$ ) thus resonates at very low field, at ca. 4.7 ppm in **11a–d** (4.72 ppm in **11a**; 4.68 ppm in **11b** vs 2.58 ppm in the parent 1,4-dioctylbenzene),<sup>22</sup> while the chemical shift of the next groups (numbered as  $k = 2, 3, \dots$ ) undergoes an exponential decay down to ca. 1.25 ppm.<sup>23</sup> With six or seven methylene groups having significantly different  $^1\text{H}$  chemical shifts, the dioctyl derivative **11b** bears the shortest aliphatic chain serving as an experimental probe of the magnetic

anisotropy of the aromatic *carbo*-benzene macrocycle away from the  $\text{C}_{18}$  ring border (as far as 7.7 Å for  $k = 6$ , 8.9 Å for  $k = 7$ ; see Figure 2 and X-ray crystal structure of **11b**, section 4 and SI).

In **11e**, the two first methylene protons are further deshielded by the neighboring fluorine atoms. The amplitude of the main curve (**11a–d**) shows that the alkyl protons are highly sensitive to the aromatic (diatropic) ring current. No such deshielding effect is observed on the  $^{13}\text{C}$  and  $^{19}\text{F}$  nuclei of the  $\text{CH}_2$  and  $\text{CF}_2$  groups along the alkyl substituents in **11a–d** or **11e**, the corresponding chemical shifts remaining almost unchanged upon aromatization of the [6]pericyclinediol precursors **6a–e**. This is in accordance with earlier recognition of the lower sensitivity of  $^{19}\text{F}$  and  $^{13}\text{C}$  nuclei to ring current effects, as compared to  $^1\text{H}$  nuclei.<sup>24</sup> Although ring current effects in  $^{13}\text{C}$  NMR have been evidenced in particular cases,<sup>25</sup> the  $^{19}\text{F}$  NMR chemical shifts have been more generally considered to be more sensitive to steric than to electronic effects.<sup>26</sup>

In the dissymmetrical monoalkyl series **10a,b,d,e**,  $^1\text{H}$  and  $^{13}\text{C}$  NMR chemical shifts of the  $\text{CH}_2$  groups are identical to those observed for the dialkyl counterparts. The  $^1\text{H}$  nucleus directly connected to the  $\text{C}_{18}$  macrocycle resonates at  $9.81 \pm 0.03$  ppm, which is comparable to the chemical shift of 9.87 ppm for the corresponding nuclei in the unsubstituted tetraphenyl-*carbo*-benzene **12**.<sup>19</sup>

**2.3. Absorption Spectroscopy of Mono- and Dialkyl-*carbo*-benzenes.** The mono- and dialkyl-*carbo*-benzenes **10a,b,d,e** and **11a–e** are highly chromophoric, with molar extinction coefficients in chloroform solution always around  $200\,000 \text{ L}\cdot\text{mol}^{-1}\cdot\text{cm}^{-1}$ , all the measured values being in the range  $185\,000 < \epsilon < 219\,000 \text{ L}\cdot\text{mol}^{-1}\cdot\text{cm}^{-1}$ . Their UV–vis absorption spectra in  $\text{CHCl}_3$  are almost perfectly super-

**Figure 3.** Normalized UV–vis absorption spectra of the monoalkyl-*carbo*-benzenes **10a,b,d,e** (left) and dialkyl-*carbo*-benzenes **11a,b,d,e** (right) in chloroform solution.

<sup>a</sup>Chemical vertical overlap of successive C<sub>18</sub> rings (see Figure 5). <sup>b</sup>Crystals of **11d** obtained from a CHCl<sub>3</sub> solution; approximate values (without esd) determined from the Mercury interface (3.8 version). <sup>c</sup>From ref 19.

impossible and exhibit the classical pattern of *carbo*-benzenes (Figure 3):<sup>9b,10c,12,19</sup> a main band at  $\lambda_{\max} = 446.5 \pm 0.5$  nm in the dialkyl series **11a–e**,  $444.5 \pm 0.5$  nm in the monoalkyl series **10a,b,d,e**, accompanied by three smaller bands at  $502.0 \pm 0.5$ ,  $519.0 \pm 0.5$  (sh), and  $551.5 \pm 0.5$  nm. The presence of one or two alkyl substituents on the C<sub>18</sub> macrocycle has thus a negligible effect on the absorption properties in solution, but the dialkyl-*carbo*-benzenes have different colors in the solid state. For comparison, the UV–vis spectrum of the unsubstituted tetraphenyl-*carbo*-benzene **12** is virtually identical (with  $\lambda_{\max} = 444$  nm).<sup>19</sup> As previously demonstrated,<sup>12</sup> the main one-photon absorption band of *carbo*-benzenes, whatever their substitution pattern, corresponds to two transitions centered on the C<sub>18</sub> rings, analyzable by the Gouterman four-orbital model devised for porphyrins.<sup>27</sup>

The dialkyl-*carbo*-benzenes displaying different colors in the solid state (**11a** and **11c** are dark blue, **11b** is dark violet, and **11d** and **11e** are dark red), the solid UV–vis absorption spectra of the solids were also recorded and found consistent with the observed colors despite the broadness of the bands, with one or two maxima in the range 450–650 nm (analogous spectral shapes are observed for the solid monoalkyl congeners **10a,b,d,e**; see SI). In spite of the structural similarity of the

molecules, different intermolecular interactions in the solid state should thus be invoked to explain the color variation: related crystallochromy, i.e., correlation of the solid state color with the crystal packing as a function of the length of alkyl substituents, was recently reported for a series of tetraalkyltetracenes.<sup>28</sup> A correlation between the crystal packing of **11a–e** and their color in the solid state is tentatively sought for hereafter.

#### 2.4. Crystal Properties of Lipidic *Carbo*-benzenes.

Beyond their lipidic nature, both mono- and dialkyl-*carbo*-benzenes proved to be highly crystalline. Seven representatives, **10b,d** and **11a–e**, could thus be characterized by X-ray diffraction (XRD) analysis of single crystals deposited from DCM or CHCl<sub>3</sub> solutions (Table 1, Figure 4; for **10b** and **10d**, see Figure S1 in the SI).<sup>29</sup> The weak diffracting power of crystals of the fluorinated dioctyl-*carbo*-benzene **11e** limited the acquisition of data but allowed qualitative confirmation of the structure (see SI, Figure S2).

In the dialkyl series **11a–d**, the C<sub>18</sub> ring exhibits a classical quasi-planar quasi-hexagonal conformation (with a maximal deviation of 0.058(2) Å for **11a**) and classical bond lengths (spC=spC  $\approx$  1.22–1.23 Å, sp<sup>2</sup>C=spC  $\approx$  1.37–1.39 Å).<sup>9b,10c</sup> The alkyl carbon chains, stretched in a planar zigzag arrangement,

**Figure 4.** Molecular views of the X-ray crystal structures of the dialkyl-*carbo*-benzenes **11a–d**. Numbering of nonequivalent C atoms indicative of the crystal symmetry. Thermal ellipsoids at the 50% probability level. For clarity, hydrogen atoms and solvent molecules (for **11b** and **11d**) are omitted (for more details, see SI).

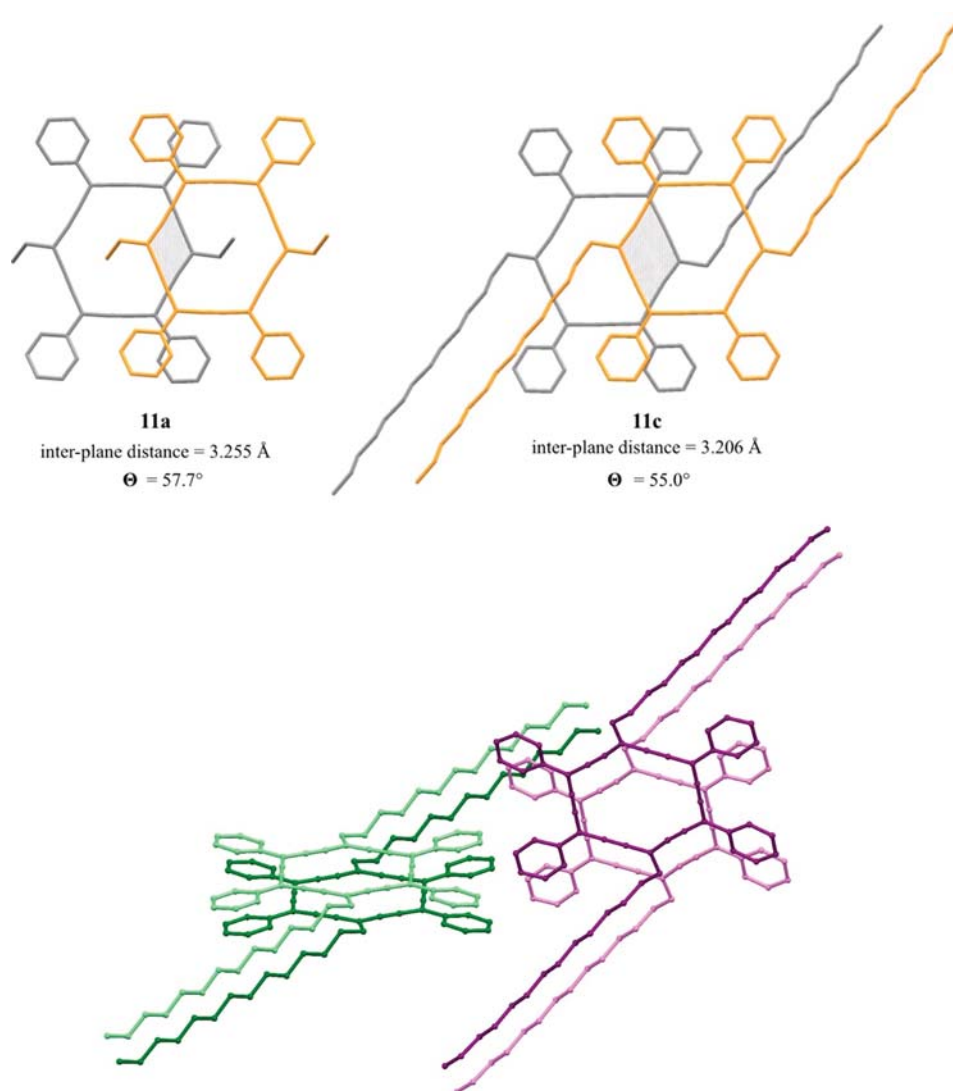

can be coplanar with the  $C_{18}$  macrocycle (dihedral angles of  $6.6(1)^\circ$  for **11b**,  $3.3(1)^\circ$  for **11d**) or not (dihedral angle of  $40.2(2)^\circ$  for **11a**,  $22.0(1)^\circ$  for **11c**). With two fully stretched eicosyl chains, the *carbo*-benzene **11d** is the largest *carbo*-benzenic structure ever described, with a distance of  $57.435(11)$  Å between the two carbon atoms of the  $CH_3$  ends (Table 1).

In the crystal state, the macrocycles of **11a–d** form slanting columnar arrangements, where the distance between the  $C_{18}$  mean planes of two successive *carbo*-benzene molecules varies from 3.206 to 3.398 Å. The deviation from “columnar verticality” ( $\Theta$  = tilting angle between the column axis and the normal to the mean planes) varies from  $55.0^\circ$  for **11c** to  $71.5^\circ$  for **11d**. The first examples of  $\pi$ -stacking between *carbo*-benzene rings are observed in the crystal structures of **11a** and **11c** (Figure 5), where the small  $\Theta$  values allow partial vertical overlap of successive  $C_{18}$  macrocycles separated by distances very close to those calculated for ABC or AB  $\alpha$ -graphityne (2.201–3.266 Å).<sup>3</sup> The maximal extent of vertical overlap is thus attained in crystals of **11c** (top Figure 5), where the distance between the  $C_{18}$  mean planes (3.206 Å) corresponds to the shortest internuclear distances of ca. 3.36 and 3.41 Å occurring between pairs  $sp$ -C and  $sp^2$ -C(Ph) vertices of successive  $C_{18}$  rings, respectively.  $\pi$ -Stacking between phenyl substituents, even at low overlap extent, can also significantly contribute to the stabilization of the tilted columnar arrange-

ment.<sup>30</sup> Nevertheless, the molecular packing indicates significant dispersive intermolecular interactions between tetradecyl chains arranged in a parallel manner: six alternating methylene groups of one chain interact with their closest congeners in the neighboring molecule through  $C\cdots C$  distances in the range 4.50–4.58 Å, revealing an intermolecular van der Waals contact between ideally located H atoms (internuclear  $H\cdots H$  distances of ca. 2.8 Å). The  $\pi$ -stacking between *carbo*-benzene rings is however not merely driven by the London forces between the  $C_{14}$  alkyl chains of **11c**: the same configuration is also observed for the much shorter (not interacting)  $C_2$  alkyl chains of **11a**, with a slightly larger deviation from columnar verticality ( $\Theta$  =  $57.7^\circ$ ) and shortest internuclear distances of ca. 3.29 and 3.55 Å between pairs of  $sp$ -C and  $sp^2$ -C(Ph) vertices in successive  $C_{18}$  rings, respectively.

The  $\pi$ -stacking of  $C_{18}$  rings in crystals of **11a** and **11c** is actually correlated with the absence of cocrystallized solvent molecule. No such stacking is observed in crystals of **11b** ( $\Theta$  =  $65.9^\circ$ ) and **11d** ( $\Theta$  =  $71.5^\circ$ ) containing  $CHCl_3$  and DCM molecules, respectively. In crystals of the dioctyl-*carbo*-benzene **11b**, an interaction between each  $C_{18}$  ring and one  $CHCl_3$  molecule is revealed by a short  $spC_2\cdots ClC$  contact (ca. 3.41 Å), with a  $spC_2\cdots Cl-C$  angle of ca.  $150.8^\circ$ : this arrangement is indicative of a  $\sigma$ -hole-directed  $C-Cl\cdots\pi$  halogen bond, previously evidenced and analyzed in the *carbo*-mer series.<sup>10c,31</sup>

As observed earlier for *o*-tetraphenyl-*carbo*-benzenes,<sup>19</sup> the Cl

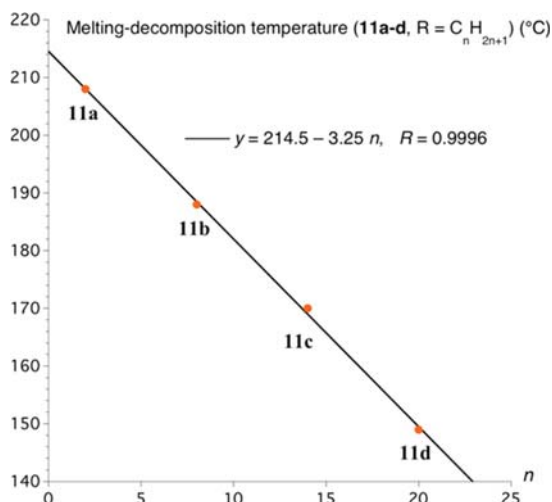

**Figure 5.** Views perpendicular to the C<sub>18</sub> mean planes of **11a** and **11c** in the crystal (top), and perspective view of the 55°-tilted columnar packing of **11c** (bottom), showing the “vertical” overlap of successive C<sub>18</sub> rings illustrative of the one calculated in AB or ABC  $\alpha$ -graphityne.<sup>3</sup>

atom lies very close to the centroid of the C<sub>18</sub> ring (by ca. 1.08 Å). Likewise, no  $\pi$ -stacking of C<sub>18</sub> rings occurs in other crystals of **11d** containing CHCl<sub>3</sub> molecules ( $\Theta = 74.4^\circ$ ): a  $\sigma$ -hole-directed C–Cl $\cdots\pi$  halogen bond between the C<sub>18</sub> ring and one CHCl<sub>3</sub> molecule is revealed by a short spC<sub>2</sub> $\cdots$ ClC contact (ca. 3.40 Å), where the middle of the spC $\equiv$ spC bond is almost aligned with the Cl–C bond axis (spC<sub>2</sub> $\cdots$ Cl–C  $\approx 173.3^\circ$ ), the Cl atom lying quite close to the centroid of the C<sub>18</sub> ring (by ca. 1.78 Å). In crystals deposited from DCM, no C–Cl $\cdots\pi$  halogen bond is observed between DCM and *carbo*-benzene molecules (**10b**, **10d**, **11d**).

On the basis of these analyses, a tentative correlation between the intermolecular interactions and the colors of the dialkyl-*carbo*-benzenes **11a–d** in the solid state can be proposed. The common blue color of solid **11a** and **11c** can be correlated with the comparable extent of  $\pi$ -stacking interactions between the C<sub>18</sub> macrocycles ( $\Theta \approx 55^\circ$ ). Furthermore, the C<sub>2</sub> and C<sub>14</sub> alkyl chains of these two *carbo*-benzenes stretch out of the C<sub>18</sub> ring mean planes, while the carbon chains and the macrocycle are coplanar in all other cases. Also noteworthy, crystals of **11d** and **11b**, red and violet, with and without  $\pi$ -stacking between phenyl substituents,

respectively, exhibit the same space group (*P*-1). The decrease of  $\pi$ -stacking efficiency from **11a** and **11c** to **11d** and **11b** is also correlated with their different colors and UV–vis absorption spectra, the wavelength of the right edge of the broad band decreasing in the same order of magnitude: from ca. 700 nm for **11a** and **11c** to ca. 675 and 660 nm for **11d** and **11b**, respectively (see SI).

As a macroscopic crystal property, the variation of the melting point of the dialkyl-*carbo*-benzenes **11a–e** has been investigated. Although the dark color of the crystals prevented visual monitoring of the melting process, melting–decomposition temperature values could be determined (Table 1). While detectable melting–decomposition points of most nonlipidic *carbo*-benzenes are in the range 200–250 °C,<sup>10c</sup> a regular decrease of this temperature with the chain length *n* is observed: from 208 °C for *n* = 2 to 149 °C for *n* = 20 (Figure 6). Noteworthy, the melting–decomposition temperature of the fluoroctyl derivative **11e** is just slightly higher (196 °C) than that of the octyl analogue **11b** (188 °C). In the hydrocarbon series, extrapolation of the linear fit to very long chains (*n* > 20) suggests possible thermotropic behavior at temperatures compatible with molecular stability.

**Figure 6.** Variation of detectable melting–decomposition temperatures of dialkyl-*carbo*-benzenes vs the chain length  $n$ .

### 3. CONCLUSION

The disclosed series of *carbo*-benzenes combining oxymoronic features of lipidic and aromatic/chromophoric hydrocarbons opens new prospects in the context of *carbo*-benzene and futurist  $\alpha$ -graphyne chemistry.

The dioctyl derivative **11b** bearing the shortest alkyl chain serves as an experimental  $^1\text{H}$  NMR probe of the magnetic aromaticity of the *carbo*-benzene macrocycle, as far as ca. 8 Å away from the  $\text{C}_{18}$  ring border. The octyl chains of **11b** also provide sufficient solubility to allow future studies of the chemical reactivity of the *carbo*-benzene ring, in particular toward metallic ions or small  $\pi$ -electron-rich organic guests to form  $\pi$ -inclusion complexes of various types.<sup>32</sup> The analogue **11e** is the first example of a fluorinated *carbo*-benzene derivative.

The diethyl and bistetradecyl derivatives **11a** and **11c** afford first examples of  $\pi$ -stacking of *carbo*-benzene rings, thus providing experimental evidence of the possible cohesion of  $\alpha$ -graphyne layers in  $\alpha$ -graphityne. The maximum overlap extent is attained in crystals of **11c**, where the distance of 3.206 between stacked  $\text{C}_{18}$  ring planes fits with the calculated interlayer distances of 3.266 and 3.201 Å in AB and ABC  $\alpha$ -graphitynes, respectively.<sup>3</sup>

The bisicosyl derivative **11d** exhibits the lowest melting–decomposition temperature ever reported for a *carbo*-benzene derivative (149 °C). At lower temperature and possibly greater chain lengths ( $n > 20$ ), reversible thermotropic behavior might be envisaged. The columnar packing of dialkyl-*carbo*-benzenes in the crystalline state suggests that liquid crystal properties of putative *carbo*-benzenic mesogens might involve discotic assemblies.

### 4. EXPERIMENTAL SECTION

**4.1. General Remarks.** THF, diethyl ether ( $\text{Et}_2\text{O}$ ), pentane, and dichloromethane (DCM) were dried by filtration under dry argon over two alumina-containing columns. All other reagents were used as commercially available. In particular, commercial solutions of  $n\text{-BuLi}$  were 2.5 M in hexane, solutions of ethylmagnesium bromide were 3 M in THF, and solutions of HCl were 2 M in  $\text{Et}_2\text{O}$ . [6]Pericyclinedione **7** was prepared according to previously published procedures.<sup>16a</sup> All reactions were carried out under an argon atmosphere using Schlenk tubes and vacuum line techniques. Column chromatography was carried out on silica gel (60 Å, CC 70–200  $\mu\text{m}$ ). Silica gel thin layer

chromatography plates (60F254, 0.25 mm) were revealed by treatment with an ethanolic solution of phosphomolybdic acid (20%). NMR chemical shifts are given in ppm with positive values to high frequency relative to the tetramethylsilane reference. Coupling constants  $J$  are given in Hertz; wavelengths  $\lambda$  in nanometers, and UV–vis extinction molar coefficients  $\epsilon$  in  $\text{L}\cdot\text{mol}^{-1}\cdot\text{cm}^{-1}$ .

**4.2. Experimental Procedures.** **4.2.1. General Procedure for the Preparation of Grignard Reagents  $\text{RMgBr}$ ,  $R = n\text{-C}_n\text{H}_{2n+1}$  ( $n = 2, 8, 14, 20$ ),  $n\text{-C}_8\text{H}_4\text{F}_{13}$ .** To a solution of magnesium metal (0.441 mmol, 1 equiv) in THF (0.5 mL) a solution of alkyl bromide (0.530 mmol, 1.2 equiv) was added dropwise at room temperature. The mixture was stirred for 2 h at 50 °C and then cooled to room temperature. The resulting solution of alkylbromomagnesium bromides  $\text{RMgBr}$  was used directly without any further purification.

**4.2.2. General Procedure for the Preparation of Lipidic [6]-Pericyclinediols **6a–e** and **8a–e**.** A solution of [6] pericyclinedione **7** (100 mg, 0.147 mmol) in THF (30 mL) at  $-10$  °C was treated with a freshly prepared solution of  $\text{RMgBr}$  (0.441 mmol in 0.5 mL of THF). The mixture was stirred at  $-10$  °C for 4 h. After treatment with saturated aqueous solution of  $\text{NH}_4\text{Cl}$ , the aqueous layer was separated and extracted by diethyl ether, the organic layers were combined, then dried over  $\text{MgSO}_4$ , and concentrated to dryness under reduced pressure. The residue was purified by chromatography on silica gel to afford the diadduct **6**, the monoadduct **8**, and the double-reduction product **9** as yellow oils.

**4.2.3. General Procedure for Preparation of Lipidic Carbo-benzenes **10a,b,d,e** and **11a–e**.** A solution of [6]pericyclinediol **6** or **8** in DCM was treated with anhydrous  $\text{SnCl}_2$  (10 equiv) and HCl (20 equiv; 2 M in  $\text{Et}_2\text{O}$ ) at  $-78$  °C. The mixture was stirred at  $-78$  °C for 10 min and then at room temperature for 20 min. After treatment with 1 M aqueous NaOH (20 equiv) and filtration through Celite, the organic layer was separated, washed with brine (3 $\times$ ), dried over  $\text{MgSO}_4$ , and concentrated to dryness under reduced pressure. The residue was purified by chromatography on silica gel to give the *carbo*-benzene **11** or **10** as a strongly colored solid.

**4.3. Analytical Characterization.** **4.3.1. Details for the Pericyclinediols **6a**, **8a**, and **9**.** [6]Pericyclinedione **7** (0.147 mmol, 100 mg) was reacted with commercial  $\text{C}_2\text{H}_5\text{MgBr}$  (0.441 mmol, 3 M in THF) in THF (30 mL). Chromatography on silica gel eluted with pentane: $\text{EtOAc} = 4:1$  and then 3:1 gave **6a** (0.067 mmol, 50 mg, 45%) and **8a** (0.042 mmol, 30 mg, 28%) as yellow oils, along with the known bis-secondary [6]pericyclinediol **9** (0.028 mmol, 19 mg, 20%).<sup>16a</sup>

**1,10-Diethyl-4,7,13,16-tetramethoxy-4,7,13,16-tetraphenylcyclooctadeca-2,5,8,11,14,17-hexayne-1,10-diol (6a).**  $^1\text{H}$  NMR (300 MHz,  $\text{CDCl}_3$ )  $\delta$  7.89–7.57 (m, 8H), 7.51–7.28 (m, 12H), 3.69–3.20 (m, 12H), 3.07–2.38 (m, 2H), 2.15–1.85 (m, 4H), 1.27–1.08 (m, 6H).

- (23) If *n* denotes the rank of the CH<sub>2</sub> group (starting from *n* = 1 in *α* position to the C<sub>18</sub> ring), for **11b** a curve fit with an exponential decay gives  $\delta_{\text{H}} \approx 1.256 + 4.995 \exp[-1.333n]$  ppm,  $R \approx 0.994$ ; for the parent dioctylbenzene,<sup>22a</sup> the curve fit gives  $\delta_{\text{H}} \approx 1.250 + 7.184 \exp[-0.734n]$  ppm,  $R \approx 0.999$ .
- (24) Balci, M. *Basic <sup>1</sup>H-<sup>13</sup>C NMR Spectroscopy*; Elsevier: Amsterdam, 2005. On p 285 it is stated “In the <sup>13</sup>C NMR spectroscopy, the ring current effect is less important [than in the <sup>1</sup>H NMR spectroscopy], as it contributes only a little to the total shielding (2 ppm), which is generally hidden by other larger effects”. In absolute value, this effect is in the same range as the one operating in <sup>1</sup>H NMR (2–3 ppm). The relative weakness of the ring current effect in <sup>13</sup>C NMR (also observed in <sup>19</sup>F NMR) can thus also be related to the larger width of the chemical shift windows (220 ppm for <sup>13</sup>C, 350 ppm for <sup>19</sup>F) as compared to the <sup>1</sup>H nucleus (15 ppm).

# Selective access to *p*-dialkyl-*carbo*-benzenes from a [6]pericyclynedione: the *n*-butyl nucleophile model for a metal switch study

Chongwei Zhu, Carine Duhayon, Alix Saquet, Valérie Maraval, and Remi Chauvin

**Abstract:** The synthesis, spectroscopic properties, comparative electrochemical behavior in  $\text{CHCl}_3$  vs  $\text{CH}_2\text{Cl}_2$ , and X-ray crystal structure of *p*-di-*n*-butyl-tetraphenyl-*carbo*-benzene are described. The selectivity of preparation of the ultimate [6]pericyclynediol precursor has been examined by comparing the reactivity of the [6]pericyclynedione substrate with four *n*-Bu- $\text{MX}_n$  nucleophiles involving more or less halogenated metal centers  $\text{MX}_n$  ( $0 \leq n \leq 2$ ): Li, MgBr, MgCl,  $\text{CeCl}_2/\text{LiCl}$ . The cerium reagent is found to be the most efficient, giving approximately twice the yield given by Grignard reagents in the target diadduct (90% vs 51–53%). The dibutyl-*carbo*-benzene product happens to be soluble in both  $\text{CHCl}_3$  and  $\text{CH}_2\text{Cl}_2$ : cyclic voltammograms of either solution exhibit almost identical peak potentials with reduced reversibility of the redox processes in  $\text{CHCl}_3$ .

**Key words:** alkylcerium, alkyne, aromatics, *carbo*-benzene, *carbo*-mer.

**Résumé :** Nous décrivons la synthèse du *p*-di-*n*-butyl-tétraphényl-*carbo*-benzène, ainsi que ses propriétés spectroscopiques, son comportement électrochimique comparatif dans le  $\text{CHCl}_3$  p/r au  $\text{CH}_2\text{Cl}_2$  et sa structure cristalline, déterminée par radiocristallographie. Nous avons examiné la sélectivité de la synthèse du dernier précurseur, le [6]péricyclinediol, en comparant les réactivités d'un substrat précurseur, une [6]péricyclinedione, avec quatre nucléophiles de formule *n*-Bu- $\text{MX}_n$  dont les centres métalliques M sont plus ou moins halogénés, où  $\text{MX}_n$  ( $0 \leq n \leq 2$ ) = Li, MgBr, MgCl,  $\text{CeCl}_2/\text{LiCl}$ . Le réactif à base de cérium s'est révélé le plus efficace, le rendement en diadduit cible étant d'environ le double des rendements obtenus avec les réactifs de Grignard (90 % p/r à 51–53 %). Il se trouve que le dibutyl-*carbo*-benzène généré est soluble tant dans le  $\text{CHCl}_3$  que dans le  $\text{CH}_2\text{Cl}_2$  : les diagrammes de voltampérométrie cyclique des deux solutions présentent des potentiels de crête presque identiques, la réversibilité des processus rédox étant toutefois réduite dans le cas du  $\text{CHCl}_3$ . [Traduit par la Rédaction]

**Mots-clés :** alkylcérium, alcyne, aromatiques, *carbo*-benzène, *carbo*-mère.

## Introduction

Among  $\pi$ -conjugated carbon allotropes and beyond the foremost graphene type, graphynic materials, composed of both  $\text{sp}^2$ -C and  $\text{sp}$ -C atoms, have been considered at the theoretical level<sup>1</sup> but have been more sparingly studied at the experimental level. Nevertheless, several molecular fragments of  $\gamma$ -graphyne,<sup>2</sup>  $\gamma$ -graphdiyne,<sup>3</sup> and even  $\alpha$ -graphyne<sup>4</sup> have been described. A key issue in the synthesis and study of such carbon-rich compounds is their limiting solubility, approaching that of graphite upon increase of the size of the carbon core within a C–H bond periphery. As a solution, peripheral decoration by lipophilic groups is currently envisaged. This can be illustrated by the recent report of a ring *carbo*-mer of naphthalene,<sup>5</sup> with eight *p*-pentylphenyl substituents of the  $\text{C}_{32}$  core having allowed full characterization of this first example of fused polycyclic  $\alpha$ -graphyne fragment, in or from solutions in  $\text{CHCl}_3$ .<sup>4</sup> However, the solubilizing effect of the *p*-pentylphenyl groups appeared limited, even on the smaller *carbo*-benzene congener  $\text{C}_{18}(4-n\text{-C}_5\text{H}_{11}\text{-C}_6\text{H}_4)_6$ . The *carbo*-benzene  $\text{C}_{18}$  ring is actually the smallest cyclic primitive motif of  $\alpha$ -graphyne, and most of the derivatives reported hitherto bear only H, aryl, or alkynyl substituents.<sup>6</sup> Very recently, direct anchoring of alkyl chains at the

$\text{sp}^2$  vertices of the  $\text{C}_{18}$  ring was envisaged in a series of *p*-dialkyl-tetraphenyl-*carbo*-benzenes **1a–1e**, which could be obtained in two steps, namely by addition of alkylmagnesium bromides to the [6]pericyclynedione **2** followed by reductive aromatization of the [6]pericyclynediol products **3a–3e** (Scheme 1).<sup>7</sup> However, the Grignard approach was not found to be selective, and beside the diadducts **3a–3e**, the single and double reductions products **4a–4e** (resulting from the monoadduct) and **5** are also formed. The reducing power of alkyl Grignard reagents is actually known to be due to the presence of a H atom in  $\beta$  position of the Mg atom,<sup>8</sup> but several recommended methods to overcome this effect, e.g., through the change of solvent, failed to improve the reaction outcome. The use of alternative or additive metals should thus be envisaged.

In general nucleophilic addition of  $\text{Nu-MX}_n$  to carbonyl groups, beyond lithium ( $\text{M} = \text{Li}$ ,  $n = 0$ ) and magnesium ( $\text{M} = \text{Mg}$ ,  $n = 1$ ,  $\text{X} = \text{Br}$ ,  $\text{Cl}$ ,  $\text{I}$ ) cations, cerium cations ( $\text{M} = \text{Ce}$ ,  $n = 2$ ,  $\text{X} = \text{Cl}$ ) have also been reported to provide higher selectivity under smooth conditions.<sup>9</sup> In the present context, targeting the [6]pericyclynediols **6a–6b** from the bis-terminal tetrayne **7a–7b** and dialdehyde **8**, while reactions of the  $\text{MgBr}^+$  salts alone appeared almost unproductive (0%–6%),<sup>6a,6b,6h</sup> addition of  $\text{CeCl}_3$  was shown to improve the yield to 12%–14%, likely via the corresponding  $\text{CeCl}_2^+$  salts (Scheme 2).

**Scheme 1.** Last two steps of previous syntheses of *p*-dialkyl-*carbo*-benzenes. The intermediates 2–5 were used as mixtures of stereoisomers.**Scheme 2.** Improvement of a [11+7] macrocyclization from a C11 tetrayne and a C7 dialdehyde through the use of a cerium(III) reagent.

As part of ongoing efforts to improve access efficiency to *carbo*-benzene molecules, the study of the metal effect on the double nucleophilic addition to the diketone **2** has been undertaken for Nu = *n*-Bu, a model nucleophile of intermediate length, with the view to obtaining the hitherto unknown representative *p*-di-*n*-butyl-tetraphenyl-*carbo*-benzene **1f**. This target, bearing both aliphatic and aromatic substituents, is also devised to serve as a standard for electrochemical studies in the *carbo*-benzene series.

## Experimental

### General

THF was dried with a PureSolv MD5 Innovative Technology system for the purification of solvents. All other reagents were used as commercially available. In particular, commercial solutions of *n*-BuLi were 2.5 mol/L in hexane, and solutions of HCl were 2 mol/L in diethyl ether. All reactions were carried out under argon atmosphere using Schlenk tube and vacuum line techniques. Column chromatography was carried out on silica gel (60 Å, 70–200 μm). Silica gel thin layer chromatography plates (60F254, 0.25 mm) were revealed under UV light and (or) by treatment with an ethanolic solution of phosphomolybdic acid (20%). The following analytical instruments were used: <sup>1</sup>H and <sup>13</sup>C NMR spectroscopy: Avance 300, Avance 400, and Avance 400 HD; mass spectrometry: Quadrupolar Nermag R10–10H; UV–vis absorption: Perkin-Elmer UV–vis Win-Lab Lambda 950; X-ray diffraction: Apex2 Bruker, micro-

focus X-ray source (Mo K $\alpha$  radiation). NMR chemical shifts are given in ppm with positive values to high frequency relative to the tetramethylsilane reference. Coupling constants (*J*) are given in Hertz. UV–vis absorption wavelengths ( $\lambda$ ) are given in nanometers, and the corresponding maximum extinction molar coefficient ( $\epsilon$ ) is given in L mol<sup>-1</sup> cm<sup>-1</sup>.

### Crystal structure determination

Intensity diffraction data for **1f** were collected at 100 K. The structure was solved by direct methods using SIR92 and refined by full-matrix least-square procedures on *F* using the programs of the PC version of CRYSTALS.<sup>10</sup> Atomic scattering factors were taken from the International Tables for X-ray Crystallography.<sup>11</sup> All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined using a riding model. Absorption corrections were introduced using the program MULTISCAN.

### Voltammetric measurements

Voltammetric measurements were carried out with a potentiostat Autolab PGSTAT100 controlled by GPES 4.09 software. Experiments were performed at room temperature in a homemade, airtight, three-electrode cell connected to a vacuum/argon line. The reference electrode consisted of a saturated calomel electrode (SCE) separated from the solution by a bridge compartment. The counter electrode was a platinum wire of approximately 1 cm<sup>2</sup>

apparent surface. The working electrode was a Pt microdisk (diameter, 0.5 mm). The supporting electrolyte [*n*-Bu<sub>4</sub>N][PF<sub>6</sub>] was used as received (Fluka, 99% electrochemical grade) and simply degassed under argon. The solutions used in the electrochemical study were 10<sup>-3</sup> mol/L in *carbo*-benzene and 0.1 mol/L in supporting electrolyte. Before each measurement, the solutions were degassed by bubbling argon, and the working electrode was polished with a polishing machine (Presi P230). Typical instrumental parameters for recording square-wave voltammograms were as follows: SW frequency (*f*) = 20 Hz, SW amplitude (*E*<sub>sw</sub>) = 20 mV, and scan increment (*dE*) = 5 mV.

### Experimental characterizations and procedures of new products

#### Characterization of 1,10-dibutyl-4,7,13,16-tetraphenylcyclooctadeca-1,2,3,7,8,9,13,14,15-nonaen-5,11,17-triynyl (1f)

A solution of [6]pericyclinediol 3f (50 mg, 0.063 mmol) in dichloromethane (DCM, 30 mL) was treated with SnCl<sub>2</sub> (120 mg, 0.63 mmol) and HCl (1.26 mmol, 2 mol/L in Et<sub>2</sub>O) at -78 °C. The mixture was stirred at -78 °C for 10 min and then at room temperature for 20 min. After treatment with 1 mol/L aqueous NaOH (1.26 mL) and filtration through Celite®, the organic layer was washed with brine (three times), dried over MgSO<sub>4</sub>, and concentrated under reduced pressure. The residue was purified by chromatography on silica gel (pentane:DCM, 4:1) to give 1f as a dark red solid (25 mg, 0.04 mmol, 63% yield).

<sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>) δ 9.51 (dd, <sup>3</sup>J<sub>HH</sub> = 8.0, <sup>4</sup>J<sub>HH</sub> = 1.2 Hz, 8H, *o*-C<sub>6</sub>H<sub>5</sub>), 7.97 (dd, <sup>3</sup>J<sub>HH</sub> = 8.2, 7.2 Hz, 8H, *m*-C<sub>6</sub>H<sub>5</sub>), 7.73–7.66 (m, 4H, *p*-C<sub>6</sub>H<sub>5</sub>), 4.69 (t, <sup>3</sup>J<sub>HH</sub> = 7.5 Hz, 4H, CH<sub>2</sub>Pr), 3.04–2.92 (m, 4H, CH<sub>2</sub>CH<sub>2</sub>Me), 2.02–1.91 (m, 4H, CH<sub>2</sub>Me), 0.91–0.82 (m, 6H, CH<sub>3</sub>).

<sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CDCl<sub>3</sub>) δ 139.9 (*i*-C<sub>6</sub>H<sub>5</sub>), 129.8 (*o*-C<sub>6</sub>H<sub>5</sub>), 129.8 (*m*-C<sub>6</sub>H<sub>5</sub>), 129.3 (*p*-C<sub>6</sub>H<sub>5</sub>), 122.1, 119.4, 116.0 (=C=C-, C≡C), 106.5 (C-Bu), 103.0 (C-Ph), 40.4 (CH<sub>2</sub>Pr), 34.0 (CH<sub>2</sub>Et), 22.8 (CH<sub>2</sub>Me), 14.3 (CH<sub>3</sub>).

#### Characterization of 1,10-dibutyl-4,7,13,16-tetramethoxy-4,7,13,16-tetraphenylcyclooctadeca-2,5,8,11,14,17-hexayne-1,10-diol (3f)

##### Procedure for the preparation of 3f with *n*-BuMgBr

To a suspension of magnesium turnings (3.2 mg, 0.13 mmol) in THF (0.5 mL) at room temperature was added dropwise *n*-BuBr (0.06 mL, 0.53 mmol). The mixture was stirred for 2 h at room temperature. A solution of [6]pericyclinedione 2 (30 mg, 0.04 mmol) in THF (5 mL) at 0 °C was treated with the freshly prepared solution of *n*-BuMgBr. The mixture was stirred at 0 °C for 3 h before treatment with a saturated aqueous solution of NH<sub>4</sub>Cl. The aqueous layer was extracted with diethyl ether, and the combined organic layers were dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified by chromatography on silica gel (pentane:EtOAc, 5:1, then 3:1) to give the diadduct 3f

(18 mg, 0.0226 mmol, 51% yield), the monoadduct 4f (9 mg, 0.012 mmol, 28% yield), and the known di-reduction diol product 5 (5 mg, 0.007 mmol, 16% yield),<sup>6h,11</sup> as yellow oils.

##### Procedure for the preparation of 3f with *n*-BuMgCl

A solution of [6]pericyclinedione 2 (40 mg, 0.06 mmol) in THF (6 mL) at 0 °C was treated with commercial *n*-BuMgCl (0.18 mmol, 2 mol/L in diethyl ether). The mixture was stirred at 0 °C for 1 h and then at room temperature for 3 h before treatment with a saturated aqueous solution of NH<sub>4</sub>Cl. The aqueous layer was extracted with diethyl ether, and the combined organic layers were dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified by chromatography on silica gel (pentane:EtOAc, 5:1, then 3:1) to give the diadduct 3f as a yellow oil (25 mg, 53% yield).

##### Procedure for the preparation of 3f with *n*-BuLi

A solution of [6]pericyclinedione 2 (40 mg, 0.06 mmol) in THF (6 mL) at -78 °C was treated with *n*-BuLi (0.15 mmol, 2.5 mol/L in hexane). The mixture was stirred while slowly warming up to -30 °C over 1.5 h before addition of an aqueous solution of NH<sub>4</sub>Cl. The aqueous layer was extracted with diethyl ether, and the combined organic layers were dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified by chromatography on silica gel (pentane:EtOAc, 5:1) to give 3f as a yellow oil (33 mg, 0.04 mmol, 70% yield).

##### Procedure for the preparation of 3f with *n*-BuLi and CeCl<sub>3</sub>

To a suspension of CeCl<sub>3</sub> (37 mg, 0.15 mmol) in THF (10 mL) at -78 °C was added *n*-BuLi (0.15 mmol, 2.5 mol/L in hexane), and the resulting mixture was stirred for 0.5 h at this temperature. After treatment with a solution of [6]pericyclinedione 2 (50 mg, 0.0735 mmol) in THF (8 mL) at -78 °C, the mixture was slowly warmed up to -20 °C during 2 h before addition of an aqueous solution of NH<sub>4</sub>Cl. The aqueous layer was extracted with diethyl ether, and the combined organic layers were dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified by chromatography on silica gel (pentane:EtOAc, 5:1) to give 3f as a yellow oil (53 mg, 0.07 mmol, 90% yield).

<sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>) δ 7.81–7.64 (m, 8H, *o*-C<sub>6</sub>H<sub>5</sub>), 7.45–7.30 (m, 12H, *m*-, *p*-C<sub>6</sub>H<sub>5</sub>), 3.73–3.21 (m, 12H, OCH<sub>3</sub>), 3.04–2.51 (m, 2H, OH), 2.10–1.89 (m, 4H, CH<sub>2</sub>Pr), 1.78–1.51 (m, 4H, CH<sub>2</sub>Et), 1.39–1.23 (m, 4H, CH<sub>2</sub>Me), 1.00–0.81 (m, 6H, CH<sub>2</sub>CH<sub>3</sub>).

<sup>13</sup>C{<sup>1</sup>H} NMR (75 MHz, CDCl<sub>3</sub>) δ 139.6–139.3 (*i*-C<sub>6</sub>H<sub>5</sub>), 129.1–129.0 (*p*-C<sub>6</sub>H<sub>5</sub>), 128.5–128.4 (*m*-C<sub>6</sub>H<sub>5</sub>), 126.5–126.4 (*o*-C<sub>6</sub>H<sub>5</sub>), 87.4–87.0, 84.5–84.3, 81.2–80.1 (C=C), 71.9–71.8 (C(OMe)Ph), 63.7 (C(OH)Bu), 53.4–53.3 (OCH<sub>3</sub>), 43.0–42.8 (CH<sub>2</sub>Pr), 26.8–26.5 (CH<sub>2</sub>Et), 22.4–22.3 (CH<sub>2</sub>Me), 14.2–13.9 (CH<sub>2</sub>CH<sub>3</sub>).

HRMS (MALDI-TOF/DCTB) (*m/z*): [M+H]<sup>+</sup> calcd for C<sub>54</sub>H<sub>53</sub>O<sub>6</sub>, 797.3842; found, 797.3771.

## Results and discussion

*p*-Di-*n*-butyl-tetraphenyl-*carbo*-benzene 1f was targeted through the “classical” route, i.e., by reductive aromatization of the corresponding [6]pericyclinediol 3f, itself envisaged from the [6]pericyclinedione 2 and various *n*-Bu-MX<sub>*n*</sub> reagents, MX<sub>*n*</sub> = MgBr, MgCl, Li, CeCl<sub>2</sub> (Scheme 3).<sup>12</sup>

Following previous experiences (Scheme 1), addition of two equivalents of *n*-butylmagnesium bromide to 2 gave 3f in 51% yield, along with the reduced monoadduct 4f and the known bis-secondary [6]pericyclinediol 5,<sup>6h,13</sup> isolated in yields of 28% and 16%, respectively.

Replacing *n*-BuMgBr by *n*-BuMgCl led to the diadduct 3f with a similar 53% yield but without reduction side product, as indicated by the absence of any CHOH <sup>1</sup>H NMR signal in the range of 5–6 ppm. This change in nucleophilic vs redox selectivity can be attributed to the electronegativity-driven higher nucleophilic reactivity of the chlorinated magnesium salt compared with the brominated congener. Traces of the non-reduced mono-ketone

**Scheme 3.** En route and access to *p*-di-*n*-butyl-tetraphenyl-carbo-benzene.

monoadduct were detected by <sup>1</sup>H NMR spectroscopy but could not be separated from other unidentified products, which were likely polymeric in nature.

Addition of two equivalents of *n*-butyllithium to **2** followed by aqueous quenching at -30 °C was found to proceed selectively, allowing the diadduct **3f** to be isolated in 70% yield. This result contrasts with the poor efficiency of the addition of aryllithium reagents to the same diketone **2**, the intermediate lithium alkoxide evolving by retro-additive opening of the macrocycle towards stabilized arylketones such as **9** (Scheme 3).<sup>14</sup> Such a ring opening was not observed with *n*-BuLi, provided that the reaction mixture was quenched at -30 °C.

Finally, the addition of two equivalents of *n*-butylcerium dichloride, assumed to be formed in situ from *n*-BuLi and dry CeCl<sub>3</sub>, to **2** was found to proceed very selectively, affording the [6]pericyclinediol **3f** with a 90% isolated yield. This result is in line with the results disclosed above (M = Li > Mg, X = Cl > Br) and with previous reports on the general use of cerium reagents.<sup>6a,6b,9</sup>

The target **1f** was finally obtained by classical reductive treatment of the [6]pericyclinediol **3f** with SnCl<sub>2</sub> and HCl in DCM.<sup>6</sup> It was isolated with 63% yield as a stable, dark red solid, soluble in chlorinated organic solvents (chloroform and DCM).

Single crystals of **1f** deposited from a DCM solution were analyzed by X-ray diffraction, confirming the anticipated structure (Fig. 1). The C<sub>18</sub> macrocycle of **1f** is quasi-planar with a quasi-regular hexagonal shape, with the maximal deviation from planarity being 0.028 Å. The measured bond lengths in the C<sub>18</sub> ring are classical for a *carbo*-benzene (*sp*C-*sp*C ≈ 1.22–1.23 Å, *sp*<sup>2</sup>C-*sp*C ≈ 1.37–1.38 Å). The *n*-butyl chains exhibit a zigzag arrangement almost perfectly coplanar with the C<sub>18</sub> ring, as previously observed for a few other dialkyl-*carbo*-benzenes.<sup>7a</sup> Two of the phenyl substituents are also quasi-coplanar with the C<sub>18</sub> ring, whereas the two other substituents adopt a torsion angle of approximately 25°. The distance between two successive C<sub>18</sub> mean planes is 3.45 Å, which is longer than the shortest corresponding distance of 3.21 Å measured for the bis-tetradecyl-*carbo*-benzene: no direct π-π stacking between C<sub>18</sub> rings of **1f** is observed in the crystal, where co-crystallized DCM molecules prevent van der Waals contact between nearest macrocycles.<sup>7a</sup>

The dibutyl-*carbo*-benzene **1f** was also characterized by <sup>1</sup>H and <sup>13</sup>C NMR in CDCl<sub>3</sub> solution. The <sup>1</sup>H NMR spectral profile is similar

**Fig. 1.** Molecular view of the X-ray crystal structure of **1f**. Thermal ellipsoids at the 50% probability level. For clarity, hydrogen atoms are omitted.

to those reported for other dialkyl-*carbo*-benzenes, with a strong deshielding at 9.51 ppm of the *o*-CH nuclei of the four equivalent phenyl substituents.<sup>7a</sup> This effect reveals the strength of the diatropic C<sub>18</sub> ring current, which also progressively affects the <sup>1</sup>H signals of the *n*-butyl chain versus the distance of the CH<sub>2</sub> groups to the C<sub>18</sub> ring border, as previously analyzed for other *n*-alkyl-*carbo*-benzenes (Supplementary Fig. S1).<sup>7a</sup>

The UV-vis absorption pattern of **1f** in chloroform solution is typical for dialkyl-tetraphenyl-*carbo*-benzenes (λ<sub>max</sub> = 446 ± 0.5 nm), with one main band at 446 nm, accompanied by three smaller bands at higher wavelengths (Supplementary Fig. S2).<sup>7a</sup> The chro-

**Note:** Supporting electrolyte: solvent + 0.1 mol/L [TBA][PF<sub>6</sub>]; scan rate: 0.2 V/s. The half-wave potential ( $E_{1/2}$ ) = ( $E_p^{\text{red}} + E_p^{\text{ox}}$ )/2, in V/SCE. The separation between the two peak potentials was calculated as follows:  $\Delta E_p = |E_p^{\text{red}} - E_p^{\text{ox}}|$ , in V. The peak current ratio ( $RI_p$ ) =  $|I_p^{\text{ox}}/I_p^{\text{red}}|$ .  $E_p$  values are measured from CV, in V/SCE.

<sup>a</sup>Reversibility is observed at high scan rates only.

<sup>b</sup>The third reduction cannot be observed in CHCl<sub>3</sub> because the solvent is reduced at this potential.

mophoric intensity of **1f** is also classical in this series, with a maximum extinction coefficient of 208 000 L mol<sup>-1</sup> cm<sup>-1</sup>.

The title target **1f** has been selected as a model for an analysis of the solvent effect on the electrochemical behavior of *carbo*-benzene derivatives, which might be not soluble enough in DCM to allow the study of redox properties in this solvent, requiring the use of chloroform instead.<sup>15</sup> For the sake of comparison, solutions of **1f** in both chloroform and DCM were thus investigated by square wave (SW) and cyclic (CV) voltammetry (Table 1).

In the reference DCM solvent, **1f** lends itself to three successive reduction processes, two of them being reversible at  $E_{1/2}^{\text{red}} = -0.82$  V and  $-1.26$  V, these values being comparable with the values previously reported for other *carbo*-benzene derivatives.<sup>6f,6i,15</sup> The aromaticity of the C<sub>18</sub> ring indeed attenuates its sensitivity to substituents.<sup>6f</sup> In chloroform, the two first reductions occur at similar potentials (albeit turning less reversible at  $-0.82$  V and  $-1.32$  V), whereas the third reduction peak occurring at  $E_p^{\text{red}} = -1.98$  V in DCM cannot be detected because of the narrower electrochemical observation window of CHCl<sub>3</sub>, which is reduced at this potential. These results also show that replacement of two aryl substituents by alkyl counterparts has a weak but electronically consistent effect on the reduction potential values ( $-0.72$  V and  $-1.15$  V for hexaphenyl-*carbo*-benzene).<sup>15</sup>

In both solvents, three oxidation processes are also observed at comparable potentials, with a loss of reversibility of the second wave observed in DCM ( $E_{1/2}^{\text{ox}} = +1.63$  V) by passing to chloroform ( $E_p^{\text{ox}} = +1.69$  V).

The influence of the solvent on the redox potentials is thus limited, but affects the reversibility of the processes, possibly because of the higher viscosity and lower dielectric constant of chloroform ( $\eta(\text{CHCl}_3) = 0.537$  mPa·s >  $\eta(\text{DCM}) = 0.413$  mPa·s,  $\epsilon(\text{CHCl}_3) = 4.81 < \epsilon(\text{DCM}) = 8.93$ ). A high dielectric constant indeed favors charge dissociation thus enhancing the conductivity of the electrolytic solution.

## Conclusion

The metal switch study of the reaction of a model alkyl nucleophile with the [6]pericyclinedione **2** brings out the dichlorocerium(III) reagent as the most selective for the production of **3f**. The improvement is particularly eloquent by comparison with the bromomagnesium reagent affording also the double reduction product **5** and the single addition-reduction product **4f** (that could, however, be profitably used for a *carbo*-benzene library purpose).<sup>7a</sup> The synthesis results provide a global increase of the yield of prepara-

tion of *p*-di-*n*-butyl-tetraphenyl-*carbo*-benzene **1f** from 32% to 57% over the two last steps. The cerium method can thus henceforth be envisaged for the synthesis of other alkyl-*carbo*-benzenes.

The disclosed voltammetry results, the first ones in the alkyl-*carbo*-benzene series, indicate that the electrochemical behavior of *carbo*-benzenes is little sensitive to solvent (DCM vs chloroform) and substituent (alkyl vs aryl) effects. More generally, the “hybrid” member of the *carbo*-benzene family **1f**, with two alkyl chain and four phenyl ring substituents, could now serve as a soluble standard for other comparative studies.

#### 1.10. Complete crystal data for 11c

#### 1.11. Complete crystal data for 11d•CH<sub>2</sub>Cl<sub>2</sub>

#### 1.12. Complete crystal data for 11d•CHCl<sub>3</sub>

#### 1.13. Complete crystal data for 11e

#### 1.14. Thermal ellipsoid plots of 10b, 10b2, 10d, 11a, 11b, 11c, 11d

#### 1.15. Solid UV-visible absorption spectra of 10a, b, d, e and 11a-e

#### 1.16. UV-vis absorption spectrum of 1f in CHCl<sub>3</sub>

## 1. Crystallographic data of 11a-d, 10b, 10d, 11e

Crystals of **11a-e**, **10b** and **10d** and were obtained from DCM or chloroform by slow evaporation of the solvent at room temperature. For **10b**, two crystallization processes from the same solvent (DCM) gave allotropic crystals, **10b1** and **10b2**, both triclinic but differing by the content of the asymmetric unit.

### 1.1. Crystal structure determination

Intensity data were collected at low temperature on a diffractometer equipped with a 30W air-cooled microfocus source ( $\lambda = 0.71073 \text{ \AA}$ ). The structures were solved using SUPERFLIP, and refined by means of least-squares procedures on  $F$  using the programs of the PC version of CRYSTALS.<sup>1</sup> Atomic scattering factors were taken from the International Tables for X-Ray Crystallography.<sup>2</sup> The asymmetric unit consists in a whole *carbo*-benzene molecule (with or without solvent), excepting for **10b1** (2 molecules per asymmetric unit), for **11b**, **11c** and **11d**•CHCl<sub>3</sub> (0.5 molecule per asymmetric unit), and for **10b2** (3 molecules per asymmetric unit). Except for **11d**•CH<sub>2</sub>Cl<sub>2</sub> (poorly diffracting), all non-H atoms were refined anisotropically. Crystals of **10b2** were found to be twinned, and data were treated with ROTAX which gave the twin law between the two components (0.75:0.25). Hydrogen atoms were refined using a riding model. Absorption corrections were introduced using the program MULTISCAN.

**Figure S1.** Molecular views of the X-ray crystal structures of the *carbo*-benzenes **10b1** (*top*), **10d** (*middle*) and **11d**·CHCl<sub>3</sub> (*bottom*). 30 % Probability level for the thermal ellipsoids. For clarity, solvent molecules are omitted. All hydrogen atoms are also omitted, except those bonded to the C<sub>18</sub> macrocycle (see full-page figures in Section 2.14, pp 136-142).

#### 1.4. Crystallographic data and refinement parameters for a fluoroalkyl-*carbo*-benzene (**11e**)

Crystals of the *carbo*-benzene **11e** were also obtained from a dichloromethane solution, but the crystals were very small and poorly diffracting. A draft of the structure was obtained in the  $P2_1/c$  space group ( $a = 4.7492(5)$ ,  $b = 30.0592(10)$ ,  $c = 47.2671(14)$  Å,  $\beta = 94.950(3)^\circ$ ,  $V = 20877.7(6)$  Å<sup>3</sup>), with four molecules in the asymmetric unit, making very large the number of parameters to refine, while the

number of measured intensities was very low. The refinement of the model was thus not achieved, but a figure is given, with  $R = 33\%$  (Figure S2).

**Figure S2.** Molecular view of the X-ray crystal structure of **11e**.  $R = 33\%$ .

3D and 2D supramolecular assemblies and  
thermotropic behaviour of a *carbo*-benzenic mesogen

## Introduction & Summary

Liquid crystals (LCs) are extensively applied in various electronic devices that are part of our daily life, such as smartphones, laptops, flat panel TVs. The LC phase, an intermediate state between a crystal state and an amorphous state, is formed by the spontaneous self-organization of mesogenic molecules. Depending on the shape of mesogenic molecules, LCs are commonly classified into two categories: calamitic (rod-like) LCs<sup>1</sup> and discotic (disk-like) LCs.<sup>2</sup> The rod-like mesophase, was first described by Reinitzer at the end of the 19<sup>th</sup> century.<sup>3</sup> Since then, the LCs behavior of linear rod-like shape mesogens have been widely studied and started to lead to applications, in particular in liquid crystal displays (LCDs).<sup>4</sup>

Disk-like liquid crystals (DLCs) have been known only for 40 years, since Chandrasekhar first reported on the formation of discotic mesophases from benzene-hexa-*n*-alkanoate mesogens in 1977.<sup>5</sup> Recently, intense research efforts have been devoted to the development of DLCs due to their potential applications in organic field effect transistors (OFETs), organic light emitting diodes (OLEDs), and organic photovoltaic devices (OPVs).<sup>2, 6</sup> Discotic mesogen molecules typically possess a flat and rigid aromatic core decorated with several flexible aliphatic chains, and allow the formation of two main types of mesophases: nematic and columnar.<sup>2, 4</sup> Lamellar mesophases, whose structure remain still ambiguous today, can also be formed from discotic mesogens.<sup>7</sup> The nematic phase, the simplest and less-ordered LC phase in which the discotic molecules are orientationally arranged with no long-range translational order, already produced industrial applications as optical compensating films aiming to increase the angle of view in LCDs.<sup>8, 6b</sup> When the discotic mesogens arrange into parallel columns, it gives columnar mesophases,<sup>2</sup> whose formation is assumed to be cooperatively induced by central aromatic cores and peripheral side chains of the mesogen. In this mesophase, the core-core intracolumnar distance is quite short (usually 3.5 Å), thus allowing an overlap of the  $\pi$ -orbitals of two adjacent mesogens, whereas the intercolumnar distance is generally longer (about 20-40 Å), depending on the length of the flexible side chains.

The most common aromatic cores for columnar LCs are: macrocyclic or polycyclic compounds possibly containing heteroatoms (N, O, S), such as porphyrins, phthalocyanines, and hexaazatriphenylenes (HATs),<sup>9</sup> triphenylenes or hexa-peri-hexabenzocoronenes (HBCs) (as shown in Figure 1. A-E).<sup>10</sup> Generally, large planar aromatic cores allowing for an extended  $\pi$ -

orbital overlap, are prone to reinforce the stability of the columnar arrangement and the supramolecular order. The dispersive chains attached to the central core also play a significant role in the formation of columnar mesophases. The nature, the number and the position of the chains on the mesogenic core can indeed strongly affect the phase transition temperatures, the solubility of the mesogenic molecules, the intercolumnar distances and the intracolumnar order of the mesophases. The most used flexible side chains for columnar mesogenic molecules cover linear and branched alkyl, alkylphenyl (or alkoxyphenyl) and carboxyl chains.

**Figure 1.** A-E: examples of typical polycyclic mesogenic cores for columnar LCs. F: the *carbo*-benzene ring as first macro-monocyclic newly investigated mesogenic core.

While macro-poly-heterocyclic aromatics, such as porphyrins, were extensively studied as mesogenic cores, no specific attention has been paid to macro-mono-cyclic aromatics. In particular, the *carbo*-benzene C<sub>18</sub> ring, whose macro-aromatic character was often compared to that of the 18- $\pi$ -electrons C<sub>16</sub>N<sub>2</sub> circuits of porphyrins, had not been envisaged as a mesogenic

core before this work. The 18- $\pi$ -electron conjugated *carbo*-benzene ring, three-fold expanded analogue of benzene, with its all-carbon composition, aromatic core, flatness, and strong magnetic anisotropy, represents an attractive new core for the design of DLCs (see Figure 1. F). Furthermore, the hexagonal shape of *carbo*-benzenes makes them an ideal platform for the design of novel series of mesogens, with a possibility to anchor alkyl chains at different positions of the macrocycle. Recently, lipidic *p*-dialkyl-tetraphenyl-*carbo*-benzenes bearing two *n*-alkyl chains of discrete lengths ( $n = 2, 8, 14,$  and  $20$ ) were reported, but none of them was found to exhibit a LC behavior,<sup>11</sup> suggesting that the presence of only two alkyl chains attached to an aromatic C<sub>18</sub> macrocycle is not sufficient to induce the formation of mesophases. Moreover, the melting point (or decomposition point) of most of the *carbo*-benzenes is higher than 200 °C, which is not consistent with the formation of mesophases. The melting point of the recently reported *p*-dialkyl-*carbo*-benzenes was shown to linearly decrease upon increasing the chain lengths, thus implying that the increase of the number of alkyl chains on *carbo*-benzene core could induce a LC behavior. Consequently, two *para*-trialkoxyphenylethynyl-*carbo*-benzenes of different chain lengths ( $n$ -C<sub>12</sub>H<sub>25</sub> and  $n$ -C<sub>18</sub>H<sub>37</sub>) were prepared, and the mesogenic behavior of one of them was studied (see Figure 2.). The formation of a rectangular columnar mesophase at 115 °C was observed, and evidenced by polarized optical microscopy (POM), differential scanning calorimetry (DSC), powder X-Ray diffraction (PXRD) and scanning tunneling microscopy (STM). The lattice constants determined for the 3D lattice were found to be in good agreement with the 2D STM images of the *carbo*-benzene deposited on an HOPG surface.

**Figure 2.** Two designed “*carbo*-mesogen” molecules bearing different chain lengths.

Hexaalkoxy-di(phenylethynyl)-tetraphenyl-*carbo*-benzenes bearing six  $C_nH_{2n+1}$  aliphatic chains ( $n = 12, 18$ ) have been synthesized and characterized, including by single crystal XRD analysis. For  $n = 12$ , a liquid crystal behaviour was observed in the range of 109–130 °C. DSC, POM and PXRD analyses evidenced a rectangular columnar mesophase at 115 °C. The determined 3D lattice constants are consistent with 2D STM images of the so-called “*carbo*-mesogen” deposited on an HOPG surface.

Since the early report by S. Chandrasekhar *et al.* describing mesomorphic properties of a hexasubstituted benzene derivative,<sup>1</sup> a large variety of disc-like  $\pi$ -conjugated rigid cores have been envisaged for the design of discotic-type liquid crystal (LC) mesogens. Such cores have been diversely substituted by two, three, four, six or more dispersion groups, conferring them the self-assembling properties governing the mesophase formation. In the case of extended cores such as discoid polycyclic aromatic hydrocarbons (PAHs), or heterocyclic counterparts, nanosegregation between the aromatic cores and outer aliphatic chains has been shown to act as a driving force for the formation of columnar mesophases.<sup>2</sup> The discoid symmetry order (*so*) of these cores varies from *so* = 3 for triangular triphenylene<sup>3</sup> and its expanded hexadecydrobenzo[12]annulene (DBA) counterparts,<sup>4</sup> to *so* = 4 for tetragonal porphyrin,<sup>5</sup> and up to *so* = 6 for hexagonal hexabenzocoronene (HBC).<sup>6</sup> Most of the latter are thus condensed

polycycles, where the peripheral macrocycle encompasses smaller rings filling the discoid interior (*e.g.* 5 and 13 primitive rings in porphyrin and HBC, respectively). In contrast, due to the decrease of aromaticity *vs.* ring size, the mesogenic properties of macro-monocycles have been sparsely investigated beyond the case of DBA,<sup>4</sup> where rigidity is restored by both double insaturations and benzannulation, albeit for moderate size ( $C_{12}$  ring) and discoid character (*so* = 3). This challenge actually meets former designs of discotic LCs based on larger shape-persistent primitive macrocyclic cores of the oligo-phenylacetylene type.<sup>7</sup> A “tubular” discotic LC devised from a hollow phenylacetylene macrocycle (PAM  $C_{30}$  ring) decorated with six dispersion groups providing the mesogen with a regular hexagonal discoid character (*so* = 6) has thus been evidenced in the range of 144–110 °C.<sup>7a</sup> A larger mesogenic core ( $C_{58}$  ring) filled with intra-annular polar groups was shown to give stable columnar mesophases which were fully characterized at 120 °C or 110 °C.<sup>7b</sup> With the view of gaining insight into the mesogenic properties of truly monocyclic (non-benzannulated) macro-aromatics, the *carbo*-benzene ring of **1** appears to be a relevant candidate (Scheme 1), both in terms of size ( $C_{18}$ , diameter  $\approx$  0.8 nm) and discoid character (*so* = 6). As a three-fold expanded *carbo*-meric version of benzene,<sup>8</sup> the 18- $\pi$ -electron *carbo*-benzene ring is aromatic just as the 6- $\pi$ -electron parent is.<sup>9</sup> This  $C_{18}$  core also possesses other remarkable features, such as an all-carbon composition, an extended flexible flatness, a strong magnetic anisotropy, and a structural/chromophoric analogy with the  $C_{16}N_2$  porphyrin core, thus providing *carbo*-benzene derivatives with unique properties.<sup>10</sup> The same features make the same  $C_{18}$  core also attractive for LC design upon anchoring of selected dispersion groups. Lipidic *carbo*-benzenes  $p$ -( $C_nH_{2n+1}$ )<sub>2</sub> $C_{18}Ph_4$  bearing two *n*-alkyl chains of various lengths ( $n = 2, 8, 14,$  and  $20$ ) at the *para*-positions were recently described,<sup>11</sup> but none of them was found to display any LC behaviour. An increase of the number of dispersion groups is thus here envisaged by anchoring two pyrogallol ether groups at the same *para* positions, and more precisely two long-chain trialkoxyphenylethynyl groups.

The synthesis of the targets **1a** and **1b** was intended from the [6]pericyclynedione **2**,<sup>12</sup> following a method widely used for the

## Communication

**Scheme 1** Synthesis of the hexaalkoxy-di(ethynylphenyl)-tetraphenyl-*carbo*-benzenes **1a** and **1b**, and previously reported reference congeners **5a** and **6**.

preparation of other *para*-disubstituted tetraphenyl-*carbo*-benzenes.<sup>8b,c,11</sup> The precursors of the selected dispersion groups classically used in LC design, the ethynylpyrogallol ethers **3a** and **3b** with alkyl chain lengths of  $n = 12$  and 18, respectively, were prepared from commercially available 5-bromo-1,2,3-trimethoxybenzene.<sup>13</sup> The addition of two equivalents of the bromomagnesium salt of **3a** or **3b** to the diketone **2** afforded the expected [6]pericyclenediols **4a** and **4b** as mixtures of diastereoisomers in 64 and 25% yields, respectively. The low isolated yield of **4b** was due to the tricky procedure required for the purification of such a highly paraffinic molecule. The reaction of **2** with the lithium salt of **3a** (generated with *n*-BuLi) was also attempted, allowing the diadduct **4a** to be obtained in up to 75% yield (Scheme 1). After the treatment of **4a** and **4b** with SnCl<sub>2</sub> and HCl, the *carbo*-benzenes **1a** and **1b** were finally obtained in 58% and 18% yields, respectively (Scheme 1). The two products were isolated as dark blue-violet solids, giving red-violet dichloromethane (DCM) or chloroform solutions. The dodecyl derivative **1a** was however found to be much more soluble than the octadecyl homologue **1b**, the latter dissolving in chloroform only and at a very low concentration. Both <sup>1</sup>H and <sup>13</sup>C NMR spectra of **1b** could however be recorded in CDCl<sub>3</sub> solution at 320 K. A signature of the presence of the aromatic C<sub>18</sub> macrocycle of **1a** and **1b** is the diatropic ring current-induced deshielding of the *ortho*-<sup>1</sup>H nuclei of the phenyl substituents at *ca.* 9.5 ppm, as observed for all aryl-substituted *carbo*-benzenes. Both **1a** and **1b** also exhibit similar UV-vis absorption spectra in chloroform solution, with the same maximum absorption wavelength at 490 nm. In most cases, whatever the solvents and conditions employed, **1a** and **1b** were found to give thin hair-like crystals, or incidentally bipyramidal crystals (see photographs in the ESI<sup>†</sup>), of extremely low diffracting power. Nevertheless, after many attempts, single crystals suitable for XRD analysis were obtained from a chloroform solution of **1a**,

**Fig. 1** Molecular view of the X-ray crystal structure of **1a**, with thermal ellipsoids drawn at the 30% probability level. For clarity, hydrogen atoms are omitted.

thus allowing confirmation of the structure (Fig. 1).<sup>14</sup> Due to weak diffraction intensities and low resolution, non-hydrogen atoms could only be refined with isotropic displacement parameters, but in the absence of any solvate molecule, no disorder is found in the structure, in particular in the dodecyl chains aligned in a parallel manner in parallel triads (approximately along the *a* axis and the *ab* plane).

Mesophases of **1a**, more soluble and available in a larger amount than **1b**, could also be analysed in detail. As a literature reference, the oligophenyleneethynylene (OPE) derivative **5a**, *carbo*-meric parent of **1a** (Scheme 1), was recently reported for its self-assembling properties in solution, but the possible thermotropic LC behaviour of the pure substance was not mentioned.<sup>15</sup> Porphyrinic analogues of type **6** with two or four trialkoxyaryl dispersion groups (Scheme 1) were also reported to exhibit LC behaviour at low temperature.<sup>16</sup>

The phase behaviour of **1a** was investigated by the combination of polarizing optical microscopy (POM), differential scanning calorimetry (DSC), and powder X-ray diffraction (PXRD). Under POM, a viscous birefringent liquid was observed upon heating between 100 and 130 °C (Fig. 2). Further heating was found to give a dark image, indicating either decomposition of **1a** or formation of its isotropic phase, which remained the same upon cooling even to room temperature. The birefringent texture of the viscous liquid upon heating (usually not as indicative as natural textures obtained by cooling a perfect liquid phase, since solid state attributes can remain and interfere) does not show characteristic features for an explicit identification of phases. In the DSC thermogram between 0 and 120 °C, signals can be detected upon

**Fig. 2** Polarizing micrograph of **1a** at 109 °C on heating as a viscous liquid showing birefringent textures indicating the phase to be liquid crystalline (the identity of the LC phase cannot be determined from the POM texture only). Scale: white box length = 50 μm.

heating only, and a phase transition at 109 °C is in accordance with POM observations. Further heating leads to an exothermic signal starting at *ca.* 130 °C, interpretable as the signature of either a recrystallization or a decomposition process.

As no signal is observed in the second or third heating/cooling runs, the initial exothermic signal at 136 °C is ascribed to thermal decomposition. The lowest reported melting–decomposition temperature for a tetraaryl-*carbo*-benzene is just 12 °C higher (148 °C for *p*-dieicosyl-tetraphenyl-*carbo*-benzene),<sup>11</sup> and although most hexaaryl- and dialkynyltetraaryl-*carbo*-benzenes reported to date have been shown to melt or decompose above 200 °C, the “ $\pi$ -frustration” brought by the trialkoxyphenylethynyl groups onto the  $\pi$ -electron-rich C<sub>18</sub> core of **1a** can account for a specific thermal instability.<sup>17</sup> When the DSC thermogram of **1a** is recorded between 0 and 115 °C to avoid thermal decomposition, the non-reproducibility of the signal at 109 °C is ascribed to the thermal history of the virgin crystals (powders). However, after one night annealing at room temperature, a new signal at 55.1 °C appears on heating and a signal at 27.8 °C can be observed on cooling. These DSC data for two cycles between 0 and 115 °C are consistent with POM observations (see the ESI†).

The LC behaviour of **1a** was confirmed by PXRD, allowing investigation of molecular packing patterns in different states. Upon heating the crystalline phase at temperatures above 109 °C and below 130 °C, a wide angle broad halo at 4.7 Å of molten chains evolved, indicating the fluid phase formation.<sup>18</sup> In the small angle regime, signals are simplified by comparison to the complicated patterns of the crystalline phase. The PXRD pattern at 115 °C (Fig. 3) can be indexed to a columnar rectangular (Col<sub>rec</sub>) phase. Detailed analysis of the PXRD data allowed the determination of the two-dimensional lattice constants of the Col<sub>rec</sub> phase at 115 °C (Table 1): *a* = 48.5 Å, *b* = 45.0 Å, and *Z* = 3 (*Z*: number of molecules in a unit cell). No signal could be attributed to the intracolumnar correlation along the *c* axis.

Fig. 3 Powder X-ray diffractogram of **1a** at 115 °C in the LC phase range indicating a columnar rectangular geometry. Left: 2D-XRD; right: 1D-XRD.

Table 1 PXRD data of **1a** at 115 °C (see Fig. 3)

Phase	<i>d</i> -Spacing (Å)		Miller indices	Lattice constants (Å)
	Obsd	Calcd		
Col <sub>rec</sub>	33.01	33.01	11	<i>a</i> = 48.52 <i>b</i> = 45.04
	24.26	24.26	20	
	16.53	16.51	22	
	15.19	15.22	31	<i>Z</i> = 3
	12.10	12.13	40	
	11.37	11.71	41	
	4.68		(Alkyl)	

The 2D lattice constants of the LC phase are consistent with a specific domain in STM images of **1a**, which is primarily revealed as a macrocycle decorated by six phenyl-like groups (Fig. 4). Although the 2D packing is not perfectly regular and compact, it clearly shows a 48 × 43 Å rectangular pattern analogous to the one determined by PXRD analysis. The distances between neighbouring molecules of **1a** are found to be *ca.* 16, 21, 24, and 25 Å. As observed in the single crystal along the *a* axis,<sup>18</sup> the alkyl chains are aligned in a parallel manner with the [0110] direction of the underlying graphite substrate, and are interdigitated between neighbouring molecules, thus locking rotation of the mesogen about the column axes.

A schematic molecular packing deduced from PXRD and STM investigations is shown in Fig. 5. For the 2D lattice, STM resolves 3 chains per molecule of **1a** while the other chains are presumably fluxional in the solution. This is a common packing pattern for alkane-decorated aromatics because of the limited space and insufficient attractions from the substrate.<sup>19</sup> For the 3D columnar phase, the fluxional chains inferred from STM images are likely coplanar with the molecular plane due to van der Waals interactions between alkyl chains of the nearest upper and lower layers (*vide infra*, Fig. 5c).<sup>18</sup>

The macrocyclic cores thus stack face-to-face into columns by  $\pi$ - $\pi$  interactions, assisted by nanosegregation of domains of interdigitated molten side-chains and  $\pi$ - $\pi$  interaction of the peripheral phenyl/phenylethynyl groups. The alkyl chains are arranged in a *trans* manner with respect to the *para*-dialkynyl axis, thus driving an anisotropic in-plane packing by chain interdigitation.

The extended aromatic core of the *carbo*-benzene **1a** (58 sp<sup>2</sup>- or sp-C atoms) is embedded in a 34% more extended oxyparaffinic surrounding (78 sp<sup>3</sup>-CH<sub>2</sub> or O centers). This balance allows a LC behaviour of the pure substance in a rectangular columnar mesophase resulting from unprecedented differential supra-molecular associations around C<sub>18</sub> macro-monocycles. These results open natural prospects for a new generation of functional tubular discotic LCs based on such a type of rigid cores.

#### 1. General remarks

THF, diethyl ether (Et<sub>2</sub>O), pentane and dichloromethane (DCM) were dried with a PureSolv-MD-5 Innovative Technology system for the purification of solvents. All other reagents were used as commercially available. In particular, solutions of *n*-BuLi were 1.6 M or 2.5 M in hexane, solutions of EtMgBr were 3 M in THF, solutions of HCl were 2 M in diethyl ether. All reactions were carried out under argon atmosphere using Schlenk and vacuum line techniques. Column chromatography was carried out on silica gel (60 Å, 70-200 µm). Silica gel thin layer chromatography plates (60F254, 0.25 mm) were revealed under UV-light and/or by treatment with an ethanolic solution of phosphomolybdic acid (20%). The following analytical instruments were used, <sup>1</sup>H and <sup>13</sup>C NMR: Avance 400 and Avance 400 HD spectrometers; mass spectroscopy: TSQ 7000 Thermo Electron and Voyager DE-ST Perceptive Biosystems spectrometers; UV-Visible: Perkin-Elmer UV-Vis Win-Lab Lambda 35; IR: Perkin Elmer 1725. NMR chemical shifts are given in ppm with positive values to high frequency relative to the tetramethylsilane reference. Coupling constants J are in Hertz. UV-Visible extinction molar coefficient ε is in L.mol<sup>-1</sup>.cm<sup>-1</sup> and wavelengths λ in nm. Liquid crystalline properties measurements were conducted by the followings. Differential scanning calorimetry (DSC) was measured on a Perkin-Elmer Pyris1 DSC with heating and cooling rates of 5 and 10 °C min<sup>-1</sup>. Polarizing optical microscopy (POM) was carried out on a Zeiss Axio Imager A1m with a Mettler FP90/FP82HT hot stage system. X-ray powder diffraction data were collected on the wiggler beam line BL17A of the National Synchrotron Radiation Research Center (NSRRC), Taiwan, using a triangular bent Si(111) monochromator and a wavelength of 1.320662 Å. The sample in a 1-mm capillary was mounted on the Huber 5020 diffractometer. An air stream heater is equipped at BL17A beamline and the temperature controller is programmable by a PC with a PID feedback system. Single crystal X-ray diffraction data were collected on a high flux microfocus Rigaku FRX rotating anode at the copper Kα wavelength equipped with a Dectris Pilatus 200K hybrid detector.

## 2. Synthesis procedures and characterization of all new compounds

- Synthesis of the *carbo*-benzenes **1a** and **1b****1,4,10,13-tetraphenyl-7,16-bis((3,4,5-tris(dodecyloxy)phenyl)ethynyl)cyclooctadeca-1,2,3,7,8,9,13,14,15-nonaen-5,11,17-triyne (1a)**

A solution of **4a** (130 mg, 0.065 mmol) in DCM (100 mL) was treated with SnCl<sub>2</sub> (124 mg, 0.653 mmol) and HCl (0.65 mL, 1.31 mmol) at -78 °C. The reaction mixture was stirred for 10 min at -78 °C and for 20 min at rt. After treatment with aqueous 1 M NaOH (1.31 mL) and filtration through celite®, the organic layer was washed with brine three times, dried over MgSO<sub>4</sub> and evaporated under reduced pressure. The residue was purified by chromatography on silica gel (Pentane/DCM 3 : 1) to give the **1a** as a dark blue-violet solid (70 mg, 0.038 mmol, 58%).

<sup>1</sup>H NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ 9.45 (d, *J* = 7.8 Hz, 8H), 7.95 (t, *J* = 7.8 Hz, 8H), 7.73 (m, 4H), 7.31 (s, 4H), 4.24 (t, *J* = 6.5 Hz, 8H), 4.13 (t, *J* = 6.5 Hz, 4H), 1.97 (m, 8H), 1.91 – 1.77 (m, 4H), 1.69 – 1.54 (m, 12H), 1.49 (m, 8H), 1.44 – 1.22 (m, 88H), 0.89 (m, 18H).

<sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CD<sub>2</sub>Cl<sub>2</sub>) δ 153.5, 140.4, 139.0, 130.0, 129.9, 129.8, 120.4, 119.7, 117.1, 113.8, 110.5 (*o*-C<sub>6</sub>H<sub>2</sub>), 104.8, 99.6, 89.7, 84.5, 73.7, 69.4, 32.0 – 22.7 (m), 13.9.

HRMS (MALDI-TOF): *m/z* calcd for C<sub>130</sub>H<sub>174</sub>O<sub>6</sub> [M]<sup>+</sup>: 1831.3310, found: 1831.3165.

UV-Visible (CHCl<sub>3</sub>): λ<sub>max</sub> = 488 nm (ε = 203000 L·mol<sup>-1</sup>·cm<sup>-1</sup>).

**1,4,10,13-tetraphenyl-7,16-bis((3,4,5-tris(octadecyloxy)phenyl)ethynyl)cyclooctadeca-1,2,3,7,8,9,13,14,15-nonaen-5,11,17-triyne (1b)**

A solution of **4b** (60 mg, 0.024 mmol) in DCM (50 mL) was treated with SnCl<sub>2</sub> (46 mg, 0.24 mmol) and HCl (0.24 mL, 0.48 mmol) at -78 °C. The reaction mixture was stirred for 10 min at -78 °C and for 50 min at rt. After treatment with aqueous 1 M NaOH (1.00 mL) and filtration through celite®, the organic layer was washed with brine three times, dried over MgSO<sub>4</sub> and evaporated under reduced pressure. The residue was washed three times with diethyl ether to give the **1b** as a dark blue-violet solid (10 mg, 0.004 mmol, 18%).

<sup>1</sup>H NMR (500 MHz, 318 K, CDCl<sub>3</sub>) δ 9.48 (d, *J* = 7.1 Hz, 8H), 7.97 (t, *J* = 7.1 Hz, 8H), 7.72 (t, *J* = 7.1 Hz, 4H), 7.32, (s, 4H), 4.27 (t, *J* = 6.4 Hz, 8H), 4.19 (t, *J* = 6.4 Hz, 4H), 2.00 (m, 8H), 1.90 (m, 4H), 1.64 (m, 12H), 1.51 (m, 12H), 1.39-1.29 (m, 156H), 0.91 (m, 18H).

<sup>13</sup>C{<sup>1</sup>H} NMR (125 MHz, CDCl<sub>3</sub>) δ 153.5, 140.8, 139.4, 130.1, 129.7, 120.9, 119.0, 117.3, 114.3, 111.2, 104.9, 99.3, 89.9, 84.8, 73.8, 69.7, 31.9-29.3 (m), 26.2, 22.6, 14.0, 14.0.

HRMS (MALDI-TOF): *m/z* calcd for C<sub>166</sub>H<sub>246</sub>O<sub>6</sub> [M]<sup>+</sup>: 2335.8944, found: 2335.8909.

UV-Visible (CHCl<sub>3</sub>): λ<sub>max</sub> = 488 nm (ε = 187000 L·mol<sup>-1</sup>·cm<sup>-1</sup>).

- Synthesis of the tris-alkoxy-5-ethynylbenzene derivatives **3a** and **3b**

The 1,2,3-tris-octadecyloxy-5-ethynylbenzene **3b** was prepared according to the procedure previously described for the synthesis of the 3,4,5- tris-dodecyloxy-5-ethynylbenzene **3a** (Scheme S1).<sup>[1]</sup>

Scheme S1. Synthesis of the trialkoxy-phenylacetylenes **3a** and **3b**.

**5-Bromo-1,2,3-tris(dodecyloxy)benzene (1a)**

$^1\text{H}$  NMR (400 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$  6.68 (s, 2H), 3.96 (t,  $J = 6.5$  Hz, 4H), 3.92 (t,  $J = 6.5$  Hz, 2H), 1.90 – 1.82 (m, 2H), 1.82 – 1.75 (m, 4H), 1.69 (m, 2H), 1.51 – 1.40 (m, 8H), 1.28 (m, 42H), 0.91 – 0.87 (t,  $J = 6.5$  Hz, 9H).

#### 5-Bromo-1,2,3-tris(octadecyloxy)benzene (1b)

$^1\text{H}$  NMR (300 MHz,  $\text{CDCl}_3$ )  $\delta$  6.68 (s, 2H), 3.96-3.90 (m, 6H), 1.85-1.71 (m, 6H), 1.47 (m, 6H), 1.30 (bs, 84H), 0.90 (t,  $J = 6.5$  Hz, 9H).  
 $^{13}\text{C}\{^1\text{H}\}$  NMR (400 MHz,  $\text{C}_6\text{D}_6$ )  $\delta$  154.3, 138.1, 115.6, 110.3, 73.1, 68.8, 32.0, 30.6, 29.9, 29.8, 29.8, 29.5, 29.4, 29.3, 26.4, 26.1, 22.8, 14.0.

HRMS (MALDI-TOF):  $m/z$  calcd for  $\text{C}_{60}\text{H}_{113}\text{O}_3\text{Br}$  [ $\text{M}^+$ ]: 960.7873, found: 960.7908.

#### Trimethyl((3,4,5-tris(dodecyloxy)phenyl)ethynyl)silane (IIa)

$^1\text{H}$  NMR (300 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$  6.65 (s, 2H), 3.93 (td,  $J = 6.5, 3.2$  Hz, 6H), 1.78 (dt,  $J = 8.3, 6.4$  Hz, 4H), 1.69 (dt,  $J = 8.6, 6.6$  Hz, 2H), 1.53 – 1.42 (m, 6H), 1.29 (bs, 48H), 0.92 – 0.86 (m, 9H), 0.24 (s, 9H).

#### Trimethyl((3,4,5-tris(octadecyloxy)phenyl)ethynyl)silane (IIb)

$^1\text{H}$  NMR (300 MHz,  $\text{CDCl}_3$ )  $\delta$  6.69 (s, 2H), 3.97 (m, 6H), 1.84-1.75 (m, 6H), 1.52-1.47 (m, 6H), 1.30 (bs, 84H), 0.92 (t,  $J = 6.5$  Hz, 9H), 0.27 (s, 9H).

HRMS (MALDI-TOF):  $m/z$  calcd for  $\text{C}_{65}\text{H}_{122}\text{O}_3\text{Si}$  [ $\text{M}^+$ ]: 978.9163, found: 978.9242.

#### 1,2,3-Tris(dodecyloxy)-5-ethynylbenzene (3a)

$^1\text{H}$  NMR (400 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$  6.69 (s, 2H), 3.93 (m, 6H), 3.04 (s, 1H), 1.78 (m, 4H), 1.70 (m, 2H), 1.46 (m, 6H), 1.28 – 1.32 (m, 48H), 0.91 – 0.86 (t,  $J = 6.5$  Hz, 9H).

#### 1,2,3-Tris(dodecyloxy)-5-ethynylbenzene (3b)

$^1\text{H}$  NMR (300 MHz,  $\text{CDCl}_3$ )  $\delta$  6.71 (s, 2H), 3.97 (m, 6H), 3.01 (s, 1H), 1.84-1.75 (m, 6H), 1.48-1.45 (m, 6H), 1.28 (bs, 84H), 0.90 (m, 9H).

$^{13}\text{C}\{^1\text{H}\}$  NMR (75 MHz,  $\text{CDCl}_3$ )  $\delta$  152.9, 139.5, 116.4, 110.7, 84.0, 75.7, 73.5, 69.1, 31.9, 30.3, 29.8, 29.7, 29.6, 29.6, 29.4, 29.3, 26.1, 26.1, 22.7, 14.1.

HRMS (MALDI-TOF):  $m/z$  calcd for  $\text{C}_{62}\text{H}_{114}\text{O}_3$  [ $\text{M}^+$ ]: 906.8768, found: 906.8758.

#### - Synthesis of the [6]pericyclic diols **4a** and **4b**

#### 3,6,12,15-Tetramethoxy-3,6,12,15-tetraphenyl-9,18-bis((3,4,5-tris(dodecyloxy) phenyl)ethynyl)cyclooctadeca-1,4,7,10,13,16-hexayne (**4a**)

A solution of **3a** (174 mg, 0.26 mmol) in THF (40 mL) was treated with *n*-BuLi (0.09 mL, 0.22 mmol) at  $-78$  °C. The mixture was stirred for 20 min at  $-78$  °C and 20 min at rt, before dropwise addition at  $-78$  °C of a solution of **2** (60 mg, 0.09 mmol) in THF (4 mL). The reaction mixture was allowed to warm up to room temperature slowly and then stirred for 8 h. After treatment with an aqueous saturated solution of  $\text{NH}_4\text{Cl}$ , the aqueous layer was extracted with diethyl ether. The combined organic layers were washed with brine, dried over  $\text{MgSO}_4$ , and evaporated under reduced pressure. The residue was purified by chromatography on silica gel (Pentane/EtOAc 10 : 1, then 4 : 1) to give **4a** as a yellow oil (132 mg, 0.066 mmol, 75%).

$^1\text{H}$  NMR (400 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$  7.79 – 7.67 (m, 8H), 7.46 – 7.35 (m, 12H), 6.76 – 6.61 (m, 4H), 4.05 – 3.83 (m, 12H), 3.66 – 3.36 (m, 14H), 1.78 (m, 8H), 1.73 – 1.66 (m, 4H), 1.51 – 1.42 (m, 12H), 1.29 (m, 96H), 0.88 (t,  $J = 6.7$  Hz, 18H).

$^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz,  $\text{CD}_2\text{Cl}_2$ )  $\delta$  153.0, 139.8, 139.5 – 139.1 (m), 129.2 – 129.1 (m), 128.6 – 128.5 (m), 126.5 – 115.1 (m), 110.2, 84.5 – 83.6 (m), 80.5 – 80.4 (m), 73.5, 71.7, 69.1, 54.7 – 53.3 (m), 32.0 – 22.3 (m), 22.6, 22.3, 13.4.

HRMS (MALDI-TOF):  $m/z$  calcd for [ $\text{M}^+$ ]  $\text{C}_{134}\text{H}_{188}\text{O}_{12}$ : 1989.4101, found: 1989.4075.

#### 3,6,12,15-Tetramethoxy-3,6,12,15-tetraphenyl-9,18-bis((3,4,5-tris(octadecyloxy) phenyl)ethynyl)cyclooctadeca-1,4,7,10,13,16-hexayne (**4b**)

A solution of **3b** (300 mg, 0.33 mmol) in THF (30 mL) was treated with EtMgBr (0.11 mL, 0.33 mmol) at 0 °C. The mixture was stirred for 20 min at 0 °C and 2 h at rt, before dropwise addition at 0 °C of a solution of **2** (100 mg, 0.147 mmol) in THF (5 mL). The reaction mixture was allowed to warm up slowly to rt and then stirred overnight. After treatment with an aqueous saturated solution of  $\text{NH}_4\text{Cl}$ , the aqueous layer was extracted with diethyl ether. The combined organic layers were washed with brine, dried over  $\text{MgSO}_4$ , and evaporated under reduced pressure. The residue was purified by chromatography on silica gel (Hexane/EtOAc 9 : 1) to give **4b** as a yellow oil (90 mg, 0.036 mmol, 25%).

$^1\text{H}$  NMR (300 MHz,  $\text{CDCl}_3$ )  $\delta$  7.81-7.74 (m, 8H), 7.40-7.37 (m, 12H), 6.72 (m, 4H), 4.00-3.97 (m, 12H), 3.69-3.42 (m, 14H), 1.83-1.77 (m, 12H), 1.49 (m, 12H), 1.29 (bs, 168H), 0.91 (m, 18H).

$^{13}\text{C}\{^1\text{H}\}$  NMR (75 MHz,  $\text{CDCl}_3$ )  $\delta$  153.0, 139.5-138.8 (m), 129.2, 128.6-128.4 (m), 126.7-126.5 (m), 115.4, 110.5, 84.6-84.3 (m), 84.0-83.7 (m), 80.6-80.2 (m), 73.5, 71.9, 69.2, 53.6, 53.5, 32.0, 29.7-29.6 (m), 29.4-29.3 (m), 26.1, 22.7, 14.1.

MS (MALDI-TOF):  $m/z$  2495 [ $\text{M}-\text{H}$ ] $^+$  (20), 2519 [ $\text{M}+\text{Na}$ ] $^+$  (25), 2535 [ $\text{M}+\text{K}$ ] $^+$  (100).

### 3. Absorption spectra of 1a and 1b

Combined normalized UV spectra of **1a** and **1b** in chloroform solution

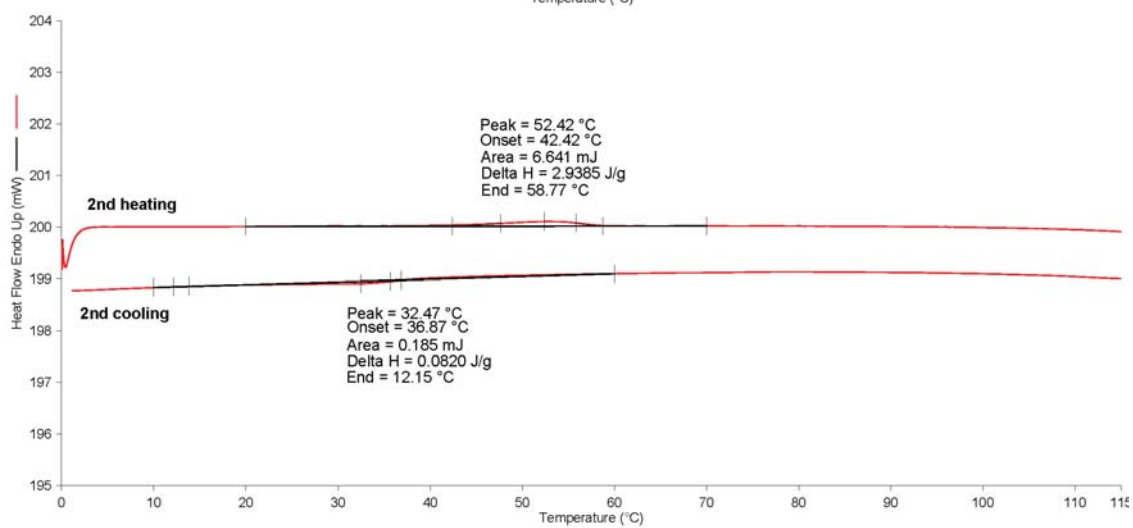

### 4. DSC thermograms of 1a

From top to bottom: 1st and 2nd cycles between 25 and 200 °C; 1st, 2nd cycles between 0 and 115 °C, and 3rd cycle (annealed at rt for one night) between -35 and 115 °C.

With heating up to 115 °C, the signal at 109 °C observed in the first heating is not reproducible. This is ascribed to the thermal history of the virgin crystals (powders). However, after one night annealing at room temperature, a new signal at 55.1 °C appears on heating and a signal at 27.8 °C can be observed on cooling. POM observations between 0 and 115 °C for two cycles are consistent with the DSC data.

5. Variable temperature powder X-ray diffractograms of 1a upon heating (left: 2D; right: 1D)

## 6. Photographs of crystals of 1a

These bipyramidal crystals were obtained by slow evaporation of the solvent from a chloroform solution, but in spite of their relatively large size they proved unsuitable for XRD analysis with standard diffractometers (see section 8).

## 7. Crystallographic data for 1a

Small crystalline plates of poor quality were obtained from a chloroform solution of **1a**. Due to the low diffractive power of the crystals, data collections were performed on a high flux microfocuss Rigaku FRX rotating anode at the copper  $\text{K}\alpha$  wavelength equipped with a Dectris Pilatus 200K hybrid detector at 100 K. The diffractive power was quite low for crystals of poor quality. The structure was solved direct methods and refined by means of least-square procedure on  $F$  by using CRYSTALS. Absorption correction was performed by using a multiscan procedure. Due to the weak diffraction intensities and low resolution, non-hydrogen atoms could be refined only with isotropic displacement parameters. *Phenyl* were refined as rigid groups. Surprisingly, the compound crystallizes without any interstitial solvent molecule. Crystals were found to be inherently twinned. Data were treated with ROTAX which gave the twin law between the two components (0.87 : 0.13).<sup>[2]</sup> Refinement of the final model led to an imperfect but reasonable solution and confirmed the structure of **1a** (Figure 1 below).

$\text{C}_{130}\text{H}_{174}\text{O}_6$ , pink red plate,  $M = 1832.81 \text{ g}\cdot\text{mol}^{-1}$ , monoclinic,  $a = 49.45(2)$ ,  $b = 15.293(11)$ ,  $c = 7.3526(14) \text{ \AA}$ ,  $\beta = 91.49(3)$ ,  $V = 5558(2) \text{ \AA}^3$ ,  $T = 100 \text{ K}$ , space group  $P2_1/c$ ,  $Z = 2$ ,  $\mu(\text{Cu K}\alpha) = 0.490 \text{ mm}^{-1}$ , 13385 reflections measured and 4780 unique ( $2\theta_{\text{max}} = 102.6^\circ$ ,  $R_{\text{int}} = 0.086$ ), 2434 reflexions [ $I > 2.5 \sigma(I)$ ] used in all calculations.  $R = 0.2493$ ,  $R_w = 0.2680$ .

CCDC 1546671 contains the supplementary crystallographic data for this paper. The data can be obtained free of charge from the Cambridge Crystallographic Data Centre via <http://www.ccdc.cam.ac.uk/getstructures>.

**Figure 1.** Molecular view of the X-ray crystal structure of **1a**, with thermal ellipsoids drawn at 30 % probability level. For clarity, hydrogen atoms are omitted.

## **Chapter 5**

*Carbo-bi- and -ter-phenyls: OPE ring  
carbo-mers*

## Introduction & Summary

After Ratner's initial theoretical report in 1974,<sup>1</sup> molecular electronics became a hot research topic, which considerably attracted the interest of the scientific community.<sup>2</sup> It is today well known that  $\pi$ -conjugated organic molecules having small HOMO-LUMO gap can potentially find applications in molecular electronic devices.<sup>3</sup> Over the past few decades, many efforts were thus devoted to the development of novel organic molecules as alternative components in electronic devices aiming at miniaturization of integrated circuits in replacement of silicon-based circuits.<sup>4</sup> As compared to traditional inorganic semiconductors (silicon),  $\pi$ -conjugated organic molecules including oligomers and polymers have many advantages: a) low production costs, b) easy processability, and c) tunable optical and electronic properties through modifications of the molecular structures.<sup>5</sup>

Oligo(phenylene-ethynylene)s (OPEs) molecular wires were considered as model compounds to give insight into the structural and electronic properties of the corresponding poly(phenylene-ethynylene)s (PPEs) polymers.<sup>6</sup> Due to their remarkable optical and electronic properties, OPEs also found applications in a wide range of domains such as in organic light-emitting devices,<sup>7</sup> chemosensors,<sup>8</sup> molecular electronic switches,<sup>9</sup> and nonlinear optical materials.<sup>10</sup> Though numerous studies on the synthesis and charge transport properties of OPEs were implemented in the past decades,<sup>6b, 9, 11</sup> fabricating a molecular integrated circuit applicable in devices still remains today challenging. Charge transport properties of molecular wires hinge not only on physical factors, such as temperature, molecule-electrode interfaces, but also on the chemical nature of the molecule, including its conjugation, redox characteristics, molecular length and substitution.<sup>12</sup> In general, the charge transport is enhanced for molecules having a flat and rigid organic core with an extended  $\pi$ -conjugation and a low redox potential.<sup>6,13</sup>

The 18- $\pi$ -electrons *carbo*-benzene ring, three times larger but three times less energetically aromatic than its parent 6- $\pi$ -electrons benzene ring,<sup>14</sup> was recently shown, through the study of the quadrupolar *p*-dianilinylnyl-*carbo*-benzene, to exhibit an unprecedented ten times higher single molecule conductance (SMC) than comparable molecules of similar size.<sup>15</sup> This high conductance, but also the rigidity, flatness, and  $\pi$ -electron-richness of *carbo*-benzenes encouraged the design of a series of ring *carbo*-mers of oligo(phenylene-ethynylene)s (*carbo*-OPEs). The preparation of one *carbo*-OPE<sub>2</sub> (skeleton *carbo*-mer of biphenyl) and two *carbo*-OPE<sub>3</sub> (skeleton *carbo*-mers of terphenyl) were thus envisaged. In

order to enhance the predicted low solubility of these *carbo*-OPEs, two *n*-octyl substituents were introduced at the two ends of the *carbo*-OPEs backbone, and the four phenyl groups of the central C<sub>18</sub> macrocycle of one *carbo*-OPE<sub>3</sub> were additionally replaced by four *para*-*n*-pentylphenyl groups.<sup>16</sup>

Synthetic routes based on mono-addition processes onto the key [6]pericyclynedione precursor were applied to the preparation of the three *carbo*-OPEs. The *carbo*-OPE<sub>2</sub>, made of two *carbo*-benzene units connected to each other by an ethynyl bridge, was first synthesized with 7 % global yield from the [6]pericyclynedione (Scheme 1.). Two *carbo*-OPE<sub>3</sub> derivatives, first examples to date of molecules made of three *carbo*-benzene rings, were prepared through two different strategies. These three molecules were fully characterized by <sup>1</sup>H, <sup>13</sup>C NMR and UV-visible spectroscopy, HRMS (MALDI-TOF technique), and electrochemistry. Two *carbo*-OPEs were also characterized by X-ray diffraction analysis of single crystals deposited from chloroform. The *carbo*-OPE<sub>3</sub> compounds were found to exhibit very low first reduction potentials ( $-0.42 \pm 0.03$  V/SCE), unprecedented in the *carbo*-mer series. Additionally, theoretical investigations of the aromaticity of the *carbo*-benzene rings of this series of *carbo*-OPEs ( $s = 1 - 4$ ) were also carried out by DFT calculations of the NICS values at the center of each macrocycle.

**Scheme 1.** The designed synthetic routes for preparation of *carbo*-OPEs

## Carbo-bi- and -ter-phenyls: OPE ring carbo-mers

Chongwei Zhu,<sup>[a,b]</sup> Albert Poater,<sup>[c]</sup> Carine Duhayon,<sup>[a,b]</sup> Brice Kauffmann,<sup>[d]</sup> Alix Saquet,<sup>[a,b]</sup> Valérie Maraval,<sup>\*[a,b]</sup> Remi Chauvin<sup>\*[a,b]</sup>

**Abstract:** Ring carbo-mers of oligo(phenylethynyl)enes (OPE $n$ ,  $n = 0-2$ ), made of  $C_2$ -catenated  $C_{18}$  carbo-benzene rings, have been synthesized and characterized by NMR and UV-vis spectroscopy, crystallography and voltammetry. Analyses of crystal and DFT-optimized structures show that the  $C_{18}$  rings preserve their individual aromatic character according to structural and magnetic criteria (NICS indices). Carbo-terphenyls ( $n = 2$ ) are reversibly reduced at much higher potential  $E_{1/2}^{red1}$  ( $\approx -0.42$  V/SCE) than the corresponding carbo-benzene ( $-0.83$  V/SCE), thus revealing salient inter-ring  $\pi$ -conjugation. An accurate linear fit of  $E_{1/2}^{red1}$  vs the DFT LUMO energy suggests a notably higher value ( $-0.30$  V/SCE) for a carbo-quaterphenyl congener ( $n = 3$ ). Increase with  $n$  of the effective  $\pi$ -conjugation is also evidenced by a red shift of two of the three main visible light absorption bands, all being assigned to TDDFT-calculated excited states, one of them restricting to a HOMO $\rightarrow$ LUMO main one-electron transition.

Oligo( $p$ -phenylene)s (OPP $n$ )<sup>[1]</sup> and oligo( $p$ -phenylethynylene)s (OPE $n$ )<sup>[2]</sup> ( $n > 0$ ) are  $\pi$ -conjugated hydrocarbon ribbon-wires widely used in the design of molecular materials with topical electronic properties, such as electrical conductance at the molecular level.<sup>[1d,2a]</sup> Their common phenylene brick provides stability, but also local insulating character due to its intrinsic aromaticity. The latter can however be "diluted" by embedding OPP sections within polycyclic aromatic scaffolds, such as pyrene or hexabenzocoronene (HBC) cores also bringing enhanced rigidity ("super-OPP").<sup>[3]</sup> Such rigid extension can also be achieved by replacing phenylene rings of OPEs by porphyrinylethynylene moieties.<sup>[4]</sup> In either case, the macrocyclic framework is filled by smaller  $C_6$ -benzenic or  $C_4N$ -pyrrolic circuits. In a homogeneous series of bis-dianilinyll derivatives, the hollow  $C_{18}$  carbo-benzene macrocycle has been shown to provide a much higher conductivity (106 nS over 2.0 nm) than the

diethynylbenzene, HBC or porphin congeners ( $10 \pm 4$  nS over  $1.7 \pm 0.3$  nm).<sup>[5]</sup> This specificity can be attributed to the three time weaker energetic aromaticity of the carbo-benzene ring as compared to benzene parent.<sup>[6]</sup> Beyond this, the accessibility of OPP carbo-mers, or OPE ring carbo-mers, appears as a natural challenge (Figure 1). After a recent report of the first molecule containing two carbo-benzene rings in the fused mode, a carbo-naphthalene,<sup>[7]</sup> counterparts in the catenated mode through acetylene linkers are thus devised from the known carbo-benzene **1**,<sup>[8]</sup> as the carbo-biphenyl and carbo-terphenyl targets **2** and **3**. The  $n$ -octyl ends, and  $n$ -pentyl lateral chains of **3b**, were selected with the view to enhancing solubility and processability. Beyond known dioctyl-OPP $n$  parents,<sup>[9,10]</sup> dioctyl-OPE2 was employed for the syntheses of substituted acenes and blue-emitting conjugated polymers applicable in organic semiconducting materials.<sup>[11,12]</sup> Liquid crystal and charge carrier properties of dioctyl-OPE3 were also reported.<sup>[13]</sup>

**Figure 1.** Target design:  $R^i$  = stabilizing/solubilizing substituents at four  $sp^2$  vertices.

The synthesis of **2** was undertaken from the [6]pericyclynedione **4**<sup>[14]</sup> and octyl-[6]pericyclynone **5** using procedures previously implemented for the preparation of **1**.<sup>[8]</sup> In parallel, similar methods were applied to the sequential preparation of the ethynyl-[6]pericyclynol **6**, [6]pericyclynediol **7** and dimethyl diether **8**, isolated in 42 % yield over three steps by the optimized route (see ESI). Deprotonation of **8** with LiHMDS in the presence of **5** led to crude bis-[6]pericyclynediol **9** as an intractable mixture of isomers, which, under treatment with  $\text{SnCl}_2/\text{HCl}$ , afforded the carbo-biphenyl **2** as a stable black solid, with 18 % yield over two steps.

## COMMUNICATION

Scheme 1. Synthesis of a *carbo*-biphenyl.

The synthesis of *carbo*-terphenyls **3a-b** was addressed *via* a similar strategy first aiming at the preparation of the respective tris-[6]pericyclic precursors **10a-b** (Scheme 2).

Scheme 2. Synthesis of *carbo*-terphenyls (HMDS = hexamethyldisilazane).

The most efficient method implemented for the preparation of **10a** (see ESI) was resumed for the preparation of **10b**. The pentyphenyl [6]pericyclic precursor **11** was first obtained from the known triene **12** and dialdehyde **13** by a two-step procedure adapted from the one used for the phenyl congener **4** (see ESI).<sup>[7]</sup> In the presence of LiHMDS, addition of two equivalents of **8** to **4** and **11** thus afforded the respective primary targets **10a** and **10b**. The latter could not be isolated in pure form, but their direct treatment with SnCl<sub>2</sub>/HCl, gave **3a** and **3b** as poorly soluble black solids in 20 % and 9 % yields over two steps, respectively. The three *carbo*-OPEs **2** and **3a-b** were found to be stable under air at room temperature for at least several weeks. As expected, **3b** was found to be significantly more soluble than **3a**. In all the cases, the <sup>1</sup>H NMR signals of the *ortho*-H nuclei of the aryl substituents are highly deshielded in two separate sets: those of the external phenyl groups (adjacent to octyl substituents) resonate at  $\delta \approx 9.5$  ppm as in the *carbo*-benzene **1**,<sup>[8]</sup> while those of the internal aryl groups occur at lower field ( $\delta \approx 9.8$  ppm). This extra-deshielding can be attributed to the combined effects of the diatropic ring currents of both the geminal and vicinal C<sub>18</sub> rings. The signals of the octyl CH<sub>2</sub> groups resonate at similar chemical shifts as in **1**.<sup>[8]</sup> The magnetic aromaticity of **1**, **2** and **3a-b** was further analyzed in a systematic manner by calculation of nucleus independent chemical shifts (NICS;<sup>[15]</sup> see below).

The structure of **2** and **3b** were confirmed by X-ray diffraction (XRD) analyses of single crystals obtained by slow evaporation of nitrobenzene or chloroform solutions (Figure 2 and ESI).<sup>[16]</sup>

Figure 2. Crystallographic molecular views of **2** (from nitrobenzene: top, ellipsoid shown at 30 % probability) and **3b** (from chloroform: bottom, ellipsoid shown at 50 % probability).<sup>[16]</sup> For XRD analysis of crystals of **2** deposited from chloroform, see ESI.

In the *carbo*-biphenyl **2**, the two C<sub>18</sub> rings are quite puckered, with deviation from the mean planes,  $\Delta$ , up to 0.17 Å. These mean planes form an angle of 34.5(1)° through a bent C<sub>4</sub> acetylenic bridge of ca 4.05 Å long (bending angle *ba* = 169.8°). The C1-C10 diagonal of one macrocycle forms an angle of 24.3° with the projection of the C1'-C10' diagonal of the other macrocycle in the mean plane of the former (see ESI). In the *carbo*-terphenyl **3b** the

## COMMUNICATION

three C<sub>18</sub> ring are closer to planarity ( $\Delta = 0.05$  Å and 0.09 Å for the central and external rings, respectively), with dihedral angles values  $\theta = 35.63(3)^\circ$  and  $0^\circ$  (parallel external C<sub>18</sub> mean planes). The C<sub>4</sub> bridges (4.03 Å) are also closer to linearity ( $ba = 177.9^\circ$ ), while the three C<sub>18</sub> centroids are perfectly aligned. The central macrocycle displays a significantly shrunk C1-C1' axial diagonal (7.23(1) Å vs  $8.21 \pm 0.10$  Å for C7-C7' and C4-C4'), while the external counterparts are more regular hexagons (diagonal distances =  $7.98 \pm 0.11$  Å). Crystallographic features of **2** and **3b** were found preserved in the isolated state by DFT calculation (see below).

The UV-vis absorption spectra of **2**, **3a** and **3b** exhibit three main absorption bands, one of them in the far red-region (661–743 nm). These spectra are thus quite different from those of **1** (Figure 2), with, however, a similar intense band between 435 and 457 nm (447 nm for **1**), the maximum molar extinction coefficient remaining around 200 000 L·mol<sup>-1</sup>·cm<sup>-1</sup>. While the spectrum of **2** presents two bands of identical intensities at 435 and 542 nm, the weaker most blue-shifted band of **3a** and **3b** is actually split in two shoulders of similar intensities.

Figure 3. UV-vis absorption spectra of **1**, **2**, **3a-b** (CHCl<sub>3</sub> solutions).

The *carbo*-OPEs **2** and **3a-b** were also studied by cyclic voltammetry (CV) and square-wave voltammetry (SWV) (Table 1). They were found to be much more readily reduced than the reference *carbo*-benzene **1**, the first and second absolute reduction potentials decreasing regularly with the global  $\pi$ -conjugation extent, up to  $E_{1/2} = -0.39$  V for **3a** (vs  $-0.83$  V for **1**).

Table 1. Voltammetric data for the three *carbo*-OPEs **1**, **2**, **3a** and **3b**.

	Reduction			Oxidation	
	$E_p$ red <sup>4b</sup>	$E_p$ red <sup>3b</sup>	$E_{1/2}$ or $E_p$ red <sup>2</sup>	$E_{1/2}$ red <sup>1a</sup>	$E_{1/2}$ or $E_p$
<b>1</b>			-1.31 <sup>b</sup>	-0.83	1.20 <sup>a</sup>
<b>2</b>		-1.20	-0.76 <sup>a</sup>	-0.58	1.22 <sup>b</sup>

<b>3b<sup>c</sup></b>	-1.04 <sup>d</sup>	-0.87 <sup>d</sup>	-0.52 <sup>d</sup>	-0.45	1.16 <sup>b</sup>

**Note:** supporting electrolyte: CHCl<sub>3</sub> + 0.1 mol/L [TBA][PF<sub>6</sub>]; scan rate: 0.2 V/s; half-wave potential  $E_{1/2} = (E_p^{red} + E_p^{ox})/2$  in V/SCE. <sup>a</sup> Reversible process. <sup>b</sup> Irreversible process. <sup>c</sup> Measurements performed after deposition of the compound on the working electrode by dipping it in a DCM solution of **3a** or **3b** (see section 3 in ESI). <sup>d</sup> Observed by SWV only.

In contrast, increasing the  $\pi$ -conjugation extent from **1** to **3a-b** has a negligible effect on the first oxidation potential, remaining in the range  $1.18 \pm 0.04$  V. The first reduction process is reversible in all cases, while the first oxidation is reversible for the *carbo*-benzene **1** only.

The structures of **1**, **2** and **3a** in vacuum were optimized at the B3PW91/6-31G(d,p) DFT level without symmetry constraint (see ESI) in the singlet spin state (the singlet-triplet gap still mounting to 20 kcal/mol for **2**). The long known [6]pericyclinedione **4**<sup>[14b]</sup> has also been calculated for the first time (as a *trans-cis-trans*, stereoisomer: see ESI, Figure S8). A tractable model of **4** was devised by truncating the four central pentyl chains to four methyl groups in **3b'**. Calculated bond lengths and C<sub>18</sub>-Ph dihedral angles reproduced crystallographic data within experimental errors, fitting with current values in the *carbo*-benzene series (Csp-Csp  $\approx 1.236 \pm 0.003$  Å, Csp-Csp<sup>2</sup>  $\approx 1.382 \pm 0.005$  Å, C-Ph  $\approx 1.480 \pm 0.002$  Å). Perfectly linear C<sub>4</sub> bridges are found 0.05 Å longer (4.05 Å) than the C<sub>18</sub> ring edges, with shorter Csp-Csp (1.220 Å) and longer Csp-Csp<sup>2</sup> (1.417 Å) bonds. The calculated structure of the quaterphenyl **14** ( $n = 3$ , R<sup>1</sup> = Ph in Figure 1) exhibits similar features, confirming the structural "*carbo*-aromatic" character of the individual macrocycles.<sup>[6]</sup> All the C<sub>18</sub> rings were found nearly planar ( $\Delta \leq 0.053$  Å) in a staggered conformation:  $\theta = 29.9^\circ$  for **2**,  $\theta = 30.8^\circ$  for **3a** with external rings staggered by  $2\theta = 61.6^\circ$  ( $\theta = 38.5 \pm 0.5^\circ$  for the parent OPEs), deviation from co-planarity being due to steric repulsion between phenyl substituents (replacing the Ph groups of **2**, **3a-b** and **14** by H atoms leads to equilibrium structures of perfect C<sub>2h</sub> symmetry). Successive C<sub>18</sub> rings are calculated to be quite free-rotating about the C<sub>4</sub> bridges, with a barrier of *ca* 1.7 kcal/mol through both orthogonal ( $\theta \approx 90^\circ$ ) and eclipsed ( $\theta \approx 0^\circ$ ) transition states (see full conformational analysis in ESI). Planar rigidification of the *carbo*-biphenyl core of **2** has also been theoretically envisaged by double Ph-Ph oxidative coupling and by embedding in a *carbo*-pyrene frame (see section 4.6.3 in ESI and Figure S13).

The magnetic aromaticity of the macrocycles can be appraised by the NICS values calculated at either the ring center (NICS(0)) or 1 Å above (NICS(1)). As previously reported, starting from C<sub>18</sub>H<sub>6</sub> or C<sub>18</sub><sup>t</sup>Bu<sub>6</sub>, the NICS(0) value decreases upon substitution with phenyl groups from *ca* -18 ppm to -13.5 ppm for C<sub>18</sub>Ph<sub>6</sub>, through -14.6 ppm for C<sub>18</sub>Ph<sub>4</sub><sup>t</sup>Bu<sub>2</sub>.<sup>17</sup> The values -14.9 ppm for C<sub>18</sub>Ph<sub>4</sub>Oct<sub>2</sub> **1** (Tables 2 and S6) is thus consistent with this trend. In **3a**, **3b'** and **14**, the NICS values are *ca* 1 ppm higher for the central rings than for the external counterparts, which is consistent with the general trend (both CC-C<sub>18</sub> and Ph substituents are  $\pi$ -conjugating). The C<sub>18</sub> rings thus preserve their intrinsic magnetic anisotropy/aromaticity in *carbo*-OPE wires.

As in all the *carbo*-benzenes calculated to date, the near-frontier MOs (NFOs) are of out-of-plane  $\pi$  symmetry (Table S9, Figures S4-S7). For **3a-b'**, while the HOMO and LUMO are delocalized over the three macrocycles, six NFOs of higher or lower energy are localized on either the central or external macrocycles ("central MOs" or "external MOs", respectively; Figure S6). Consistently with the donating character of alkyl substituents, the energies of the central NFOs increase by *ca* 0.005 Ha (0.14 eV) from **3a** to **3b'** (or a vertical model thereof), while their rank changes from HOMO-3 to HOMO-1 and from LUMO+1 to LUMO+4 (Figure S6, Table S10). In contrast, the energy variation of the external NFOs is negligible (0.02 eV) and that of the delocalized NFOs is intermediate (0.07 eV), with the same HOMO-LUMO gap for **3a** and **3b'** (1.7 eV).

Calculation of the excited states |Si> ( $i = 1-50$ ) at the TDDFT level shows that the three excitations of greatest oscillator strengths correlate with the observed spectra as  $\lambda_{\text{exptl}} \approx 0.76 \lambda_{\text{calcd}} + 94$  nm (Table 2, Table S8, Figure S3A). The wavelength of the most red-shifted band also correlates quite accurately with the

## COMMUNICATION

HOMO→LUMO gap over the series (Figure S3B): this is confirmed by the CI expansion of the corresponding excitation consisting mainly in a HOMO→LUMO one-electron transition (62 % of |S2> for **1**, 67 % of |S3> for **2**, 70% of |S1> for **3a**, **3b'** and **14**: see section 4.8 in ESI). The intermediate band of **2**, **3a** and **3b** (in the range 542-557 nm) is assigned to a more complex excitation (|S9>, |S19 and |S24>, respectively). As previously reported for other carbo-benzenes,<sup>[18]</sup> the interpretation of the most blue-shifted band (around 450 nm) within the Gouterman model (devised for porphyrins) applies to **1** and can be generalized to **2**, **3a** and **3b** (excitations involving two one-electron transitions from {HOMO-1, HOMO} to {LUMO, LUMO+1}).<sup>[19]</sup> Although not experimentally detected, fluorescence properties have also been calculated (Table S8). The carbo-quaterphenyl target **14** is thus predicted to exhibit strong absorption and emission propensity in the near infrared region (at 937 and 1254 nm, with  $f \approx 3$  and 4.8, respectively).

**Table 2.** DFT calculated electronic and magnetic properties of **1**, **2**, **3a**, **3b** or **3b'**, and **4** (B3PW91/6-31G(d,p) level) vs experimental data.

<b>14</b>	-0.186	-0.128	(0.30)	786	-	937.4 (3.0)	13.6/12.4	12.4/11.3	

a) HOMO and LUMO energies in Ha (see complete NFO data in Table S9); b) first reduction potential in V/SCE (Table 1), extrapolated value in brackets; c) chemical hardness  $\eta = E_{\text{LUMO}} - E_{\text{HOMO}}$ , in a.u. (Table S5); d) observed strongest absorptions in nm (Figure 3), stars (\*) denote  $\lambda_{\text{max}}$  values; e) in nm for TDDFT-calculated excited states,  $f$  = absorption oscillator strength (Table S8); f) calculated in ppm within the GIAO formalism. The NICS(0) and NICS(1) values of the phenyl substituents vary in the ranges  $-6.3 \pm 0.4$  and  $-8.4 \pm 0.4$  ppm, respectively, vs  $-9.8$  and  $-11.4$  ppm for benzene (see Tables S6-S7).

Finally, a remarkable linear fit of the first reduction potential with the LUMO energy of **1**, **2**, **3a-b'** is evidenced (Figure 4):  $E_{1/2\text{red}} = -3.32 - 23.52 E_{\text{LUMO}}$  (in V/SCE vs a.u.). By extrapolation, a reduction potential of  $-0.30$  V is thus predicted for the carbo-quaterphenyl **14** ( $E_{\text{LUMO}} = -0.128642$  a.u.).

**Figure 4.** Linear fit of the measured first (reversible) reduction potential with the DFT-calculated LUMO eigenvalue.

Along the lines developed in the Introduction, the availability and stability of the carbo-OPEs **2**, **3a** and **3b** open natural prospects in molecular electronics, in particular for comparison with parent OPE wires and accessing longer wires such as **14**. On this occasion, first compounds containing three carbo-benzenes rings were isolated (**3a-b**). Functionalization of the carbo-OPE termini, e.g. by amino groups, is the next challenge.

**Abstract:** Ring carbo-mers of oligo(phenylethynyl)enes (OPEs) containing C<sub>2</sub>-catenated C<sub>18</sub> carbo-benzene rings have been synthesized from a key [6]pericyclynedione, and characterized by <sup>1</sup>H, <sup>13</sup>C NMR and UV-vis absorption spectroscopy, X-ray diffractometry, and voltammetry. Analyses of crystal and DFT-optimized structures show that the C<sub>18</sub> rings preserve their individual carbo-aromatic character according to both structural and magnetic criteria (NICS indices). Carbo-terphenyls are however found to be reversibly reduced at much higher potential  $E_{1/2}^{\text{red1}}$  ( $-0.42 \pm 0.03$  V/SCE) than the parent mono-carbo-benzene ( $-0.83$  V/SCE). Over the series, an accurate correlation between  $E_{1/2}^{\text{red1}}$  and the DFT-calculated LUMO energy, suggests an even lower value for a theoretical carbo-quaterphenyl congener ( $0.30$  V/SCE). Extended  $\pi$ -conjugation is also revealed by three main absorption bands from the blue to the far-red regions, two of which can be interpreted, by single one-electron excitations in frontier orbitals, and by TDDFT-calculated low lying excited states.

## 1. Experimental Procedures

## 1.1. General remarks

THF, diethyl ether (Et<sub>2</sub>O), pentane and dichloromethane (DCM) were dried with a PureSolv-MD-5 Innovative Technology system for the purification of solvents. All other reagents were used as commercially available. In particular, commercial solutions of LiHMDS were 1 M in THF, solutions of *n*-BuLi were 2.5 M in hexane and 1.6 M in THF, solutions of *t*-BuLi were 1.6 M in pentane, solutions of ethylmagnesium bromide were 3 M in THF, solutions of octylmagnesium bromide were 3 M in THF, solutions of ethynylmagnesium bromide were 0.5 M in THF, solutions of HCl were 2 M in diethyl ether, SnCl<sub>2</sub> was anhydrous. Silica gel (60 Å, C.C 70-200 μm) was used for column chromatography. Silica gel thin layer chromatography plates (60F254, 0.25 mm) were revealed under UV-light and/or by treatment with an ethanolic solution of phosphomolybdic acid (20%). The following analytical instruments were used, 1D (<sup>1</sup>H, <sup>13</sup>C) and 2D (<sup>1</sup>H-<sup>13</sup>C HSQC, <sup>1</sup>H-<sup>13</sup>C HMBC) NMR: Avance 300, Avance 400, Avance 400 HD and Avance 600 spectrometers; Mass spectroscopy: Quadrupolar Nermag R10-10H spectrometer; UV-Visible: Perkin-Elmer UV-Vis Win-Lab Lambda 950; All the <sup>1</sup>H and <sup>13</sup>C signals were assigned according to chemical shifts, spin-spin coupling constants, splitting patterns, signal intensities, and 2D NMR experiments; NMR chemical shifts are given in ppm with positive values to high frequency relative to the tetramethylsilane reference. Coupling constants *J* are in Hertz. UV-Visible extinction molar coefficient  $\epsilon$  is in L·mol<sup>-1</sup>·cm<sup>-1</sup> and wavelengths  $\lambda$  in nm.

## 1.2. Synthesis and characterization of new compounds

**1-octyl-10-[2-(10-octyl-4,7,13,16-tetraphenylcyclooctadeca-1,2,3,7,8,9,13,14,15-nonaen-5,11,17-triyn-1-yl)ethynyl]-4,7,13,16-tetraphenylcyclooctadeca-1,2,3,7,8,9,13,14,15-nonaen-5,11,17-triyne (2)**

A solution of crude dodecaoxy-[6,6]peribicyclyne **9** (40 mg) in DCM (40 mL) was treated with anhydrous SnCl<sub>2</sub> (98 mg, 0.514 mmol) and HCl (0.51 mL, 1.023 mmol) at -78 °C. The reaction mixture was stirred at -78 °C for 15 min, then at room temperature for 20 min. After treatment with a 2 M aqueous NaOH solution (0.51 mL), the solution was filtrated through celite<sup>®</sup>. The organic layer was washed with brine, dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified on silica gel by column chromatography (pentane/DCM 3:1, then 2:1) to give **2** (12 mg, 0.009 mmol, 18 % over 2 steps) as a black solid.

<sup>1</sup>H NMR (600 MHz, CDCl<sub>3</sub>)  $\delta$  9.80 (d, *J* = 7.4 Hz, 8H, H<sup>21</sup>), 9.50 (d, *J* = 7.4 Hz, 8H, H<sup>14</sup>), -8.00 (t, *J* = 7.4 Hz, 8H, H<sup>22</sup>), 7.96 (t, *J* = 7.4 Hz, 8H, H<sup>15</sup>), 7.74 (t, *J* = 7.1 Hz, 4H, H<sup>23</sup>), 7.67 (t, *J* = 7.1 Hz, 4H, H<sup>16</sup>), 4.68 (t, *J* = 7.6 Hz, 4H, H<sup>8</sup>), 3.01 (quint., *J* = 7.7 Hz, 4H, H<sup>7</sup>), 1.96 (quint., *J* = 7.6 Hz, 4H, H<sup>6</sup>), 1.73 (quint., *J* = 7.6 Hz, 4H, > H<sup>5</sup>), 1.48 (quint., *J* = 7.4 Hz, 4H, H<sup>4</sup>), 1.35 (m, 8H, H<sup>3</sup>, H<sup>2</sup>), 0.89 (t, *J* = 7.0 Hz, 6H, H<sup>1</sup>).

<sup>13</sup>C{<sup>1</sup>H} NMR (151 MHz, CDCl<sub>3</sub>)  $\delta$  139.7 (C<sup>13</sup>), 139.6 (C<sup>20</sup>), 130.3 (C<sup>15</sup>, C<sup>21</sup>), 130.0 (C<sup>16</sup>), 129.9 (C<sup>14</sup>, C<sup>22</sup>), 129.5 (C<sup>23</sup>), 122.3 (C<sup>10</sup>), 10-8.8 (C<sup>9</sup>), 105.8 (C<sup>19</sup>), 103.7 (C<sup>12</sup>), 99.7 (C<sup>26</sup>), 82.9 (C<sup>27</sup>), 120.6, 120.5, 119.3, 117.1, 113.7 (C<sup>11, 17, 18, 24, 25</sup>), 40.9 (C<sup>8</sup>), 32.0 (C<sup>7</sup>), 31.8 (C<sup>6</sup>), 29.8 (C<sup>5</sup>), 29.6 (C<sup>4</sup>), 29.4 (C<sup>3</sup>), 22.7 (C<sup>2</sup>), 14.1 (C<sup>1</sup>).

HRMS (MALDI-TOF/DCTB): *m/z*: [M]<sup>+</sup> calculated for C<sub>102</sub>H<sub>74</sub>: 129-8.5791, found: 129-8.5802.

UV-vis (CHCl<sub>3</sub>):  $\lambda$  = 435 ( $\epsilon$  191000), 542, 661.

**1,10-bis[2-(10-octyl-4,7,13,16-tetraphenylcyclooctadeca-1,2,3,7,8,9,13,14,15-nonaen-5,11,17-triyn-1-yl)ethynyl]-4,7,13,16-tetraphenylcyclooctadeca-1,2,3,7,8,9,13,14,15-nonaen-5,11,17-triyne (3a)**

A solution of crude octadecaoxy-[6,6]peritricyclyne **10a** (50 mg) in DCM (50 mL) was treated with anhydrous SnCl<sub>2</sub> (120 mg, 0.630 mmol) and HCl (0.63 mL, 1.260 mmol) at -78 °C. The reaction mixture was stirred at -78 °C for 15 min, then at room temperature for 20 min. After treatment with a 2 M aqueous NaOH solution (0.630 mL), the solution was filtrated through celite<sup>®</sup>. The organic layer was washed with brine, dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified on silica gel by column chromatography (pentane/DCM 3:1 then pure CHCl<sub>3</sub>), the elution was collected and evaporated under rotovap, the product was rinsed with pentane and Et<sub>2</sub>O on glass fiber to give pure **3a** (13 mg, 0.007 mmol, 20 % from **4**), as a black solid.

<sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>)  $\delta$  9.86 – 9.72 (dd, *J* = 7.5 Hz, 16H, H<sup>21</sup>, H<sup>34</sup>), 9.53 – 9.47 (d, *J* = 7.5 Hz, 8H, H<sup>14</sup>), -8.05 – 7.95 (m, 24H, H<sup>15</sup>, H<sup>22</sup>, H<sup>35</sup>), 7.79 – 7.77 (t, *J* = 6 Hz, 4H, H<sup>36</sup>), 7.74 – 7.71 (quint., *J* = 6 Hz, 4H, H<sup>16</sup>, H<sup>23</sup>), 4.69 (t, *J* = 7.5 Hz, 4H, H<sup>8</sup>), 3.02 (quint., *J* = 7.6 Hz, 4H, H<sup>7</sup>), 1.96

(quint.,  $J = 7.7$  Hz, 4H,  $H^6$ ), 1.74 (quint.,  $J = 7.4$  Hz, 4H,  $H^5$ ), 1.49 – 1.45 (m, 4H,  $H^4$ ) 1.37 – 1.34 (m, 8H,  $H^3$ ,  $H^2$ ), 0.90 – 0.88 (m, 6H,  $H^1$ ).

$^{13}\text{C}\{^1\text{H}\}$  NMR (151 MHz,  $\text{CDCl}_3$ )  $\delta$  139.9 ( $\text{C}^{33}$ ), 139.8 ( $\text{C}^{20}$ ), 139.6 ( $\text{C}^{13}$ ), 130.5 – 130.4 ( $\text{C}^{34}$ ,  $\text{C}^{21}$ ,  $\text{C}^{22}$ ), 130.2 – 130.0 ( $\text{C}^{14}$ ,  $\text{C}^{15}$ ,  $\text{C}^{23}$ ,  $\text{C}^{35}$ ,  $\text{C}^{36}$ ), 129.7 ( $\text{C}^{16}$ ), 122.5 ( $\text{C}^{10}$ ), 109.1 ( $\text{C}^9$ ), 10–6.4 ( $\text{C}^{19}$ ), 10–6.1 ( $\text{C}^{32}$ ), 103.9 ( $\text{C}^{12}$ ), 120.9 – 113.8 ( $\text{C}^{11}$ , 17, 18, 24, 25, 30, 31, 37), 94.6 ( $\text{C}^{29}$ ), 8–8.6 ( $\text{C}^{26}$ ), 83.5 – 81.8 ( $\text{C}^{27}$ ,  $\text{C}^{28}$ ), 41.1 ( $\text{C}^8$ ), 32.1 ( $\text{C}^7$ ,  $\text{C}^6$ ), 31.9 ( $\text{C}^5$ ), 29.9 ( $\text{C}^4$ ), 29.5 ( $\text{C}^3$ ), 22.9 ( $\text{C}^2$ ), 14.3 ( $\text{C}^1$ ).

HRMS (MALDI-TOF/DCTB):  $m/z$ :  $[\text{M}+\text{Na}]^+$  calculated for  $\text{C}_{146}\text{H}_{94}\text{Na}$ : 1869.7253, found: 1869.7404.

UV-vis ( $\text{CHCl}_3$ ):  $\lambda = 440, 550$  ( $\epsilon$  218000), 73–8.

#### Alternative strategy for the synthesis of **3a**.

The carbo-terphenyl **3a** was also prepared by the procedure outlined in Scheme S1a.

Scheme S1a. Alternative synthesis of the carbo-OPE **3a**.

#### 1,10-bis[2-(10-octyl-4,7,13,16-tetraphenylcyclooctadeca-1,2,3,7,8,9,13,14,15-nonaen-5,11,17-triyn-1-yl)ethynyl]-4,7,13,16-tetraphenylcyclooctadeca-1,2,3,7,8,9,13,14,15-nonaen-5,11,17-triyn-1,10-diyne (**3a**)

A solution of crude **S3** (17 mg) in DCM (50 mL) was treated with anhydrous  $\text{SnCl}_2$  (40 mg, 0.210 mmol) and HCl (0.21 mL, 0.042 mmol) at  $-78^\circ\text{C}$ . The reaction mixture was stirred at  $-78^\circ\text{C}$  for 15 min, then at room temperature for 20 min. After treatment with a 1 M aqueous NaOH solution (0.630 mL), the solution was filtrated through celite®. The organic layer was washed with brine, dried over  $\text{MgSO}_4$  and concentrated under reduced pressure. The residue was purified with the identical manipulations as above to give **3a** (3.5 mg, 0.002 mmol, 8 % from **S2**) as a black solid.

#### 1,10-diethynyl-4,7,13,16-tetramethoxy-4,7,13,16-tetraphenylcyclooctadeca-2,5,8,11,14,17-hexayne-1,10-diol (**S1**)

A solution of **4** (130 mg, 0.191 mmol) in THF (30 mL) was treated with ethynylmagnesium bromide (0.8 mL, 0.400 mmol) at  $0^\circ\text{C}$ . The solution was stirred for 1 h at  $0^\circ\text{C}$ , then overnight at room temperature. After treatment with saturated aqueous  $\text{NH}_4\text{Cl}$ , the aqueous layer was extracted with EtOAc, and the combined organic layers were dried over  $\text{MgSO}_4$  and concentrated under reduced pressure. The residue was purified by chromatography over silica gel (pentane/EtOAc 3:1) to give **S1** (133 mg, 0.182 mmol, 95%) as a pale yellow solid foam.

$^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.76 – 7.66 (m, 8H,  $o\text{-C}_6\text{H}_5$ ), 7.41 – 7.33 (m, 12H,  $m\text{-}, p\text{-C}_6\text{H}_5$ ), 3.72 – 3.03 (m, 14H,  $-\text{OCH}_3$ ,  $-\text{OH}$ ), 2.90 – 2.52 (m, 2H,  $-\text{C}\equiv\text{CH}$ ).

$^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz,  $\text{CDCl}_3$ )  $\delta$  139.0 – 13–8.8 ( $i\text{-C}_6\text{H}_5$ ), 129.2 – 129.0 ( $p\text{-C}_6\text{H}_5$ ), 12–8.6 – 12–8.5 and 12–6.5 – 12–6.4 ( $o\text{-}, m\text{-C}_6\text{H}_5$ ), 84.5 – 79.8 ( $-\text{C}\equiv\text{C}-$ ), 72.5 – 72.4 ( $-\text{C}\equiv\text{CH}$ ), 71.8 ( $>\text{C}(\text{OMe})\text{Ph}$ ), 60.4 ( $>\text{C}(\text{OH})\text{C}\equiv\text{CH}$ ), 54.0 – 53.5 ( $-\text{OCH}_3$ ).

#### 3,12-diethynyl-3,6,9,12,15,18-hexamethoxy-6,9,15,18-tetraphenylcyclooctadeca-1,4,7,10,13,16-hexayne **S2**

A solution of **S1** (183 mg, 0.250 mmol) in THF (30 mL) was treated with  $n\text{-BuLi}$  (0.31 mL, 0.500 mmol) at  $-78^\circ\text{C}$ . The reaction mixture was stirred for 10 min before addition of MeI (0.093 mL, 1.500 mmol) at the same temperature. The solution was slowly warmed up to  $-25^\circ\text{C}$  before addition of anhydrous DMSO (0.035 mL, 0.500 mmol). Then the reaction was allowed to slowly warm up to room temperature under stirring overnight. After treatment with the distilled water, the aqueous layer was extracted with  $\text{Et}_2\text{O}$ , the combined organic layers were dried over  $\text{MgSO}_4$ , and concentrated under reduced pressure. The residue was purified by silica gel column chromatography (pentane/EtOAc 4:1) to give **S2** (185 mg, 0.243 mmol, 97%) as a pale yellow foamed solid.

$^1\text{H NMR}$  (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.77 – 7.70 (m, 8H, *o*- $\text{C}_6\text{H}_5$ ), 7.41 – 7.35 (m, 12H, *m*-, *p*- $\text{C}_6\text{H}_5$ ), 3.66 – 3.37 (m, 18H,  $-\text{OCH}_3$ ), 2.75 – 2.69 (m, 2H,  $-\text{C}\equiv\text{CH}$ ).

$^{13}\text{C}\{^1\text{H}\}$  NMR (101 MHz,  $\text{CDCl}_3$ )  $\delta$  139.2 – 13.8.9 (*i*- $\text{C}_6\text{H}_5$ ), 129.2 – 129.0 (*p*- $\text{C}_6\text{H}_5$ ), 12.8.6 – 12.8.5 and 12.6.5 – 12.6.4 (*o*-, *m*- $\text{C}_6\text{H}_5$ ), 84.8 – 77.9 ( $-\text{C}\equiv\text{C}-$ ), 73.3 – 73.0 ( $-\text{C}\equiv\text{CH}$ ), 71.9 – 71.8 ( $>\text{C}(\text{OMe})$ ), 53.6 – 53.0 ( $-\text{OCH}_3$ ).

HRMS (MALDI-TOF/DCTB):  $m/z$ :  $[\text{M}]^+$  calculated for  $\text{C}_{50}\text{H}_{36}\text{O}_6$ : 732.2512, found: 732.2499.

**1-(2-{10-[2-(1,10-dihydroxy-4,7,13,16-tetramethoxy-10-octyl-4,7,13,16-tetraphenylcyclooctadeca-2,5,8,11,14,17-hexayn-1-yl)ethynyl]-1,4,7,10,13,16-hexamethoxy-4,7,13,16-tetraphenylcyclooctadeca-2,5,8,11,14,17-hexayne-1,10-diol (S3)}**

To a solution of **S2** (29 mg, 0.038 mmol) in THF (15 mL) was added LiHMDS (0.228 ml, 0.228 mmol) at  $-78^\circ\text{C}$ . After stirring for 1 h at this temperature, a solution of **5** (60 mg, 0.076 mmol) in THF (10 mL) was added at  $-78^\circ\text{C}$ . The resulting mixture was stirred for 1 h at  $-78^\circ\text{C}$  and overnight at room temperature. After treatment with a saturated aqueous solution of  $\text{NH}_4\text{Cl}$ , the aqueous layer was extracted with EtOAc, and the combined organic layers were dried over  $\text{MgSO}_4$  and concentrated under reduced pressure. The residue was purified by silica gel column chromatography (pentane/EtOAc 4:1 then 3:1), to give a fraction of not pure **S3** (32 mg, ca 36% yield) as a yellow solid foam.

### 1-ethynyl-4,7,13,16-tetramethoxy-10-octyl-4,7,13,16-tetraphenylcyclooctadeca-2,5,8,11,14,17-hexayne-1,10-diol (7)

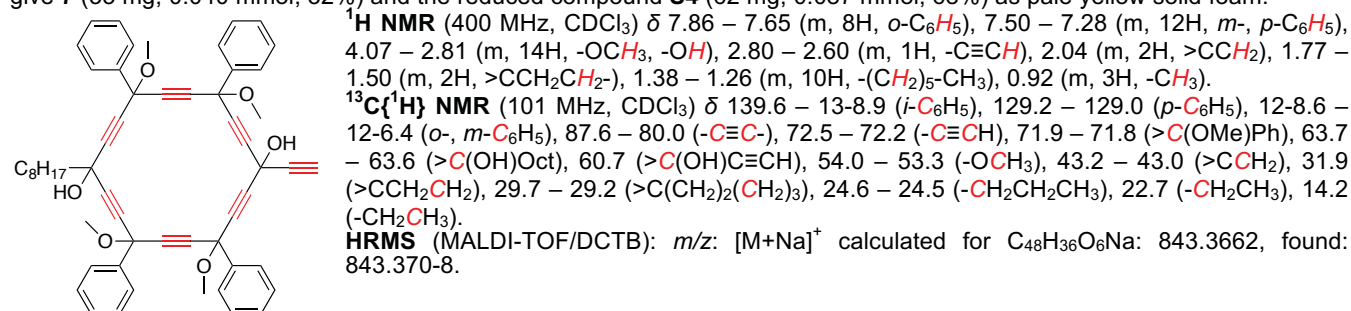

**Scheme S1b.** Alternative routes and methods to **7** and **8** from **4**.

**Method A** (Scheme S1b). To a solution of **5** (118 mg, 0.148 mmol) in THF (15 mL) was added ethynylmagnesium bromide (0.88 mL, 0.444 mmol) at 0 °C. The mixture was stirred for 1 h at 0 °C and overnight at room temperature. After treatment with a saturated aqueous solution of  $\text{NH}_4\text{Cl}$ , the aqueous layer was extracted with EtOAc, and the combined organic layers were dried over  $\text{MgSO}_4$  and concentrated under reduced pressure. The residue was purified by silica gel column chromatography (pentane/EtOAc 3:1) to give **7** (100 mg, 0.123 mmol, 83%) as a pale yellow foamed solid.

**Method B** (Scheme S1b). A solution of **6** (180 mg, 0.255 mmol) in THF (40 mL) was treated with freshly prepared *n*- $\text{C}_8\text{H}_{17}\text{Li}$  (0.765 mmol in  $\text{Et}_2\text{O}$ ) at  $-78$  °C. The reaction mixture was slowly warmed up to  $-30$  °C in 2 h under stirring. After treatment with a saturated aqueous solution of  $\text{NH}_4\text{Cl}$ , the aqueous layer was extracted with EtOAc, and the combined organic layers were dried over  $\text{MgSO}_4$  and concentrated under reduced pressure. The residue was purified by silica gel column chromatography (pentane/EtOAc 3:1) to give **7** (192 mg, 0.233 mmol, 92%) as a pale yellow foamed solid.

**Preparation of *n*- $\text{C}_8\text{H}_{17}\text{Li}$ .** To a solution of  $\text{C}_8\text{H}_{17}\text{I}$  (0.362 mL, 2mmol) in  $\text{Et}_2\text{O}$  (4 mL) was added dropwise *t*-BuLi (2.4 mmol, 1.5 ml, 1.6 M) at  $-78$  °C. The reaction mixture was stirred for 1 h at  $-78$  °C and 0.5 h at room temperature. The resulting solution was used directly without further purification.<sup>[1]</sup>

**Method C** (Scheme S1b). A solution of **6** (90 mg, 0.128 mmol) in THF (10 mL) was treated with *n*- $\text{C}_8\text{H}_{17}\text{MgBr}$  (0.1 mL, 0.2 mmol) at 0 °C. The mixture was stirred for 1 h at 0 °C and overnight at room temperature. After treatment with a saturated aqueous  $\text{NH}_4\text{Cl}$ , the aqueous layer was extracted with EtOAc, and the combined organic layers were dried over  $\text{MgSO}_4$  and concentrated under reduced pressure. The residue was purified by silica gel column chromatography (pentane/EtOAc 3:1) to give **7** (33 mg, 0.040 mmol, 32%) and the reduced compound **S4** (62 mg, 0.087 mmol, 68%) as pale yellow solid foam.

### 1-ethynyl-4,7,13,16-tetraphenylcyclooctadeca-2,5,8,11,14,17-hexayne-1,10-diol (S4)

**3-ethynyl-3,6,9,12,15,18-hexamethoxy-12-octyl-6,9,15,18-tetraphenylcyclooctadeca-1,4,7,10,13,16-hexayne (8)**

A solution of **7** (190 mg, 0.231 mmol) in THF (30 mL) was treated with *n*-BuLi (0.29 mL, 0.460 mmol) at -78 °C. The mixture was stirred for 10 min at this temperature before addition of MeI (0.083 mL, 1.340 mmol). The solution was slowly warmed up to -25 °C before addition of anhydrous DMSO (0.033 mL, 0.463 mmol). Then, the mixture was allowed to warm up to room temperature under stirring overnight. After treatment with the distilled water, the aqueous layer was extracted with Et<sub>2</sub>O, and the combined organic layers were dried over MgSO<sub>4</sub>, and concentrated under reduced pressure. The residue was purified by silica gel column chromatography (pentane/EtOAc 5:1) to give **8** (178 mg, 0.210 mmol, 91%) as a pale yellow foamed solid.

<sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>) δ 7.88 – 7.64 (m, 8H, *o*-C<sub>6</sub>H<sub>5</sub>), 7.43 – 7.35 (m, 12H, *m*-, *p*-C<sub>6</sub>H<sub>5</sub>), 3.73 – 3.30 (m, 18H, -OCH<sub>3</sub>), 2.83 – 2.60 (m, 1H, -C≡CH), 2.02 (m, 2H, >CCH<sub>2</sub>), 1.77 – 1.54 (m, 2H, >CCH<sub>2</sub>CH<sub>2</sub>-), 1.31 (m, 10H, -(CH<sub>2</sub>)<sub>5</sub>-CH<sub>3</sub>), 0.91 (m, 3H, -CH<sub>3</sub>).

## SUPPORTING INFORMATION

**1,10-bis[2-(1,4,7,10,13,16-hexamethoxy-10-octyl-4,7,13,16-tetraphenylcyclooctadeca-2,5,8,11,14,17-hexayne-1-yl)ethynyl]-4,7,13,16-tetramethoxy-4,7,13,16-tetrakis(4-pentylphenyl)cyclooctadeca-2,5,8,11,14,17-hexayne-1,10-diol (10b)**

To a solution of **8** (68 mg, 0.080 mmol) in THF (15 mL) was added LiHMDS (0.100 mL, 0.100 mmol) at -78 °C. After stirring for 1 h at this temperature, the mixture was treated with a solution of **11** (35 mg, 0.036 mmol) in THF (10 mL) at -78 °C. The resulting solution was stirred for 1 h at the same temperature and overnight at room temperature. After treatment with a saturated aqueous solution of NH<sub>4</sub>Cl, the aqueous layer was extracted with EtOAc, and the combined organic layers were dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified by silica gel column chromatography (pentane/EtOAc 5:1 then 3:1) to give a fraction of not pure **10b** (42 mg, about 41% yield) as a yellow foamed solid.

<sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>) δ 7.78 – 7.51 (m, 24H, *o*-C<sub>6</sub>H<sub>5</sub>, *o*-C<sub>6</sub>H<sub>4</sub>), 7.47 – 7.19 (m, 24H, *m*-, *p*-C<sub>6</sub>H<sub>5</sub>), 7.15 – 7.02 (m, 8H, *m*-C<sub>6</sub>H<sub>4</sub>), 3.99 – 2.74 (m, 50H, -OCH<sub>3</sub>, -OH), 2.58 – 2.47 (m, 8H, C<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>), 2.04 – 1.94 (m 4H, >CCH<sub>2</sub>), 1.63 – 1.48 (m, 12H, C<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>CH<sub>2</sub>, >CCH<sub>2</sub>CH<sub>2</sub>), 1.27 (brs, 36H, -(CH<sub>2</sub>)<sub>5</sub>-CH<sub>3</sub>, C<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>CH<sub>2</sub>(CH<sub>2</sub>)<sub>2</sub>), 0.87 (brs, 18H, -CH<sub>3</sub>).

HRMS (MALDI-TOF/DCTB): *m/z*: [M+Na]<sup>+</sup> calculated for C<sub>182</sub>H<sub>184</sub>O<sub>18</sub>Na: 2680.3380, found: 2680.349-6.

**Two step synthesis of the tetrapentylated [6]pericyclynedione 11**

**Scheme S2.** Synthesis of the tetrapentylated [6]pericyclynedione **11**.

**4,7,13,16-tetramethoxy-4,7,13,16-tetrakis(4-pentylphenyl)cyclooctadeca-2,5,8,11,14,17-hexayne-1,10-diol (S5)**

To a solution of triyne **12**<sup>[2]</sup> (355 mg, 0.780 mmol) in THF (50 mL) was added EtMgBr (0.52 mL, 1.560 mmol) at 0 °C. The mixture was stirred for 15 min at 0 °C, then for 2 h at r. t. The resulting solution, and a solution of dialdehyde **13**<sup>[2]</sup> (400 mg, 0.780 mmol) in THF (50 mL) were added simultaneously (addition rate: 6 mL/h) into a 1 L round bottom flask containing THF (400 mL) under stirring at room temperature. The mixture was stirred for 15 h at room temperature before treatment with a saturated aqueous solution of NH<sub>4</sub>Cl. The aqueous layer was extracted with EtOAc, and the combined organic layers were dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified by silica gel column chromatography (pentane/Et<sub>2</sub>O 3:1 then 2:1) to give **S5** (269 mg, 0.279 mmol, 36 %) as a pale yellow solid foam.

<sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>) δ 7.77 – 7.50 (m, 8H, *o*-C<sub>6</sub>H<sub>4</sub>), 7.18 (m, 8H, *m*-C<sub>6</sub>H<sub>4</sub>), 5.44 – 5.16 (m, 2H, >CHOH), 3.64 – 3.31 (m, 12H, -OCH<sub>3</sub>), 2.88 – 2.43 (m, 10H, -CH<sub>2</sub>, -OH), 1.61 (m, 8H, -CH<sub>2</sub>-CH<sub>2</sub>), 1.38 – 1.28 (m, 16H, -(CH<sub>2</sub>)<sub>2</sub>-), 0.89 (m, 12H, -CH<sub>2</sub>CH<sub>3</sub>).

<sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CDCl<sub>3</sub>) δ 144.1 – 144.0 (*p*-C<sub>6</sub>H<sub>4</sub>), 13-6.6 – 13-6.4 (*i*-C<sub>6</sub>H<sub>4</sub>), 12-8.6 – 12-6.4 (*o*-, *m*-C<sub>6</sub>H<sub>4</sub>), 84.3 – 82.1 (-C≡C-), 71.7 (>C(OMe)Ph), 53.4 – 53.3 (-OCH<sub>3</sub>), 52.4 – 52.3 (>CHOH), 35.6 (-CH<sub>2</sub>), 31.5 (-CH<sub>2</sub>CH<sub>2</sub>), 31.0 (-CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>), 22.5 (-CH<sub>2</sub>CH<sub>3</sub>), 14.0 (-CH<sub>2</sub>CH<sub>3</sub>).

## 2. X-ray diffraction analysis

### 2.1. General remarks

Data collections were performed on a high flux microfocus Rigaku FRX rotating anode at the copper  $\text{K}\alpha$  wavelength equipped with a Dectris Pilatus 200K hybrid detector at low temperature. The diffractive power of the crystals was quite low for these very small crystals. The structures were solved using SUPERFLIP, and refined by means of least-squares procedures on F using the programs of the PC version of CRYSTALS. Atomic scattering factors were taken from the international tables for X-ray crystallography. Absorption correction was performed by using a multiscan procedure.

For **3b**, all non-hydrogen atoms were refined anisotropically. For the two structures of **2** (**2**• $\text{CHCl}_3$  and **2**• $\text{PhNO}_2$ ), due to the weak diffraction intensities and low resolution, non-hydrogen atoms could be refined only with isotropic displacement parameters.

For the crystals of **2**• $\text{CHCl}_3$ , phenyl rings were refined as rigid groups and it was not possible to resolve diffuse electron-density residuals (enclosed solvent molecules). Treatment with the SQUEEZE facility from PLATON resulted in a smooth refinement.<sup>[3]</sup> Hydrogen atoms were refined using a riding model. Absorption corrections were introduced using the program MULTISCAN.

### 2.2. Crystallographic data and refinement parameters for **2** (from $\text{CHCl}_3$ or $\text{PhNO}_2$ ) and **3b**

### 3. Electrochemical data

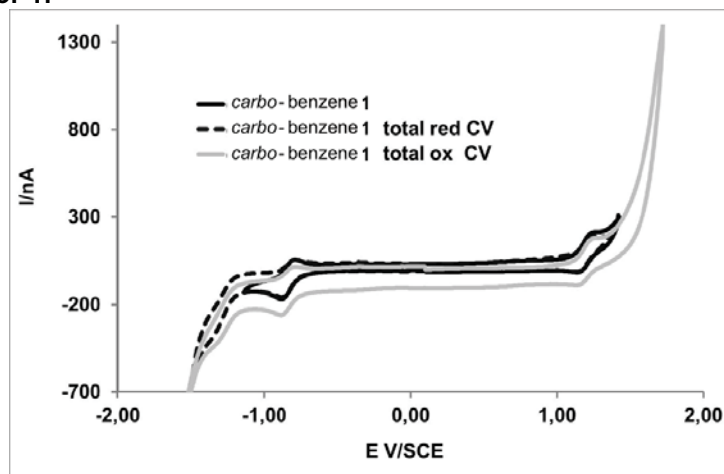

Voltammetric measurements were carried out with a potentiostat Autolab PGSTAT100. Experiments were performed at room temperature in a homemade airtight three-electrode cell connected to a vacuum/argon line. The reference electrode consisted of a saturated calomel electrode (SCE) separated from the solution by a bridge compartment. The counter electrode was a platinum wire of ca 1 cm<sup>2</sup> apparent surface. The working electrode was a Pt microdisk (0.5 mm diameter). The supporting electrolyte [<sup>n</sup>Bu<sub>4</sub>N][PF<sub>6</sub>] (Fluka, 99% puriss electrochemical grade) was used as received and simply degassed under argon. HPLC grade chloroform was used. The solutions used during the electrochemical studies were typically 10<sup>-3</sup> M in compound and 0,1 M in supporting electrolyte. Before each measurement, the solutions were degassed by bubbling Ar and the working electrode was polished with a polishing machine (Presi P230).

Compounds **3a** and **3b** being very poorly soluble in chloroform and more soluble in DCM, a small amount of these *carbo*-OPEs was dissolved in few drops of DCM and deposited on the platinum working electrode by dipping. The covered electrode was then immersed in a chloroform solution of the supporting electrolyte just before running the measurement.

## 4. DFT-computational studies and theoretical analyses

### 4.1. Computational details

All the DFT static calculations have been performed at the GGA level with the Gaussian09 set of programs,<sup>[4]</sup> using the B3PW91 functional of Becke, Perdew and Wang.<sup>[5]</sup> The electronic configuration of the molecular systems was described with the 6-31G(d,p) basis set for H, C, and O (6-31G\*\* keyword in Gaussian) during geometry optimizations performed without symmetry constraint.<sup>[6]</sup> The isolated stationary points were characterized by analytical frequency calculations. All NICS and UV-vis absorption or emission calculations were calculated with the same 6-31G(d,p) basis set.

Time dependent density functional theory (TDDFT) calculations were focused on singlet excited states. Both the DFT and TDDFT geometry optimization of the singlet ground state and singlet first excited state were performed without symmetry constraints, in vacuum for the DFT ground state. Solvent effects, based on the polarizable continuum solvation model PCM using dichloromethane as a solvent, were taken into account in the TDDFT calculation of UV-vis absorption or emission spectra.<sup>[7]</sup> The atomic contribution of single atoms to the molecular orbitals was performed in the framework of the Mulliken population analysis.

Bearing on conceptual DFT,<sup>[8]</sup> the chemical potential  $\mu$  for a  $N$ -electron system of total electronic energy  $E$  is defined as the first derivative of  $E$  vs  $N$  at a fixed external (nuclear) potential  $v$ :  $\mu = (\partial E / \partial N)_v$ ; it is identified to the negative of electronegativity  $\chi$  ( $\mu = -\chi$ ). The molecular hardness  $\eta$  is defined as the corresponding second derivative:<sup>[9]</sup>  $\eta = (\partial^2 E / \partial N^2)_v$  (on the basis of the Taylor expansion of  $E$  vs  $n$ , a factor 1/2 was originally proposed in the alternative definition  $\eta' = 1/2 (\partial^2 E / \partial N^2)_v$ ).<sup>[10]</sup> In numerical applications,  $\mu$  (the Fermi level) and  $\eta$  (the HOMO-LUMO gap) are calculated by finite difference formulas, which, at the first order, are equivalent to the Koopmans' approximation for ionization potential and electron affinity.<sup>[11]</sup>

$$\mu \equiv \left( \frac{\partial E}{\partial N} \right)_v \cong \frac{1}{2} (\varepsilon_L + \varepsilon_H), \quad \eta \equiv \left( \frac{\partial^2 E}{\partial N^2} \right)_v \cong \varepsilon_L - \varepsilon_H$$

where  $\varepsilon_H$  and  $\varepsilon_L$  denote the energies of the highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO), respectively.

Electrophilicity  $\omega$  is the ratio of the chemical potential squared to twice the hardness; a principle of electrophilicity equalization of the constituting atoms within a molecule has been proposed:<sup>[12]</sup>

$$\omega = \frac{\mu^2}{2\eta}$$

### 4.2. Chemical potential, hardness and electrophilicity (Table S5)

**Table S5.** HOMO, LUMO and corresponding electronic indices in the Koopmans' approximation.

Energies in a.u.	HOMO $\varepsilon_H$	LUMO $\varepsilon_L$	chemical potential $\mu$	chemical hardness $\eta$	electrophilicity $\omega$
Unsubstituted <i>carbo</i> -benzene <b>C<sub>18</sub>H<sub>6</sub></b>	-0.21411	-0.10637	-0.1602	0.1077	0.1192
<b>1</b>	-0.19017	-0.10562	-0.1479	0.0846	0.1294
<b>2</b>	-0.18878	-0.11666	-0.1527	0.0721	0.1617
<b>3a</b>	-0.18701	-0.12429	-0.1557	0.0627	0.1931
<b>3b'</b>	-0.18467	-0.12199	-0.1533	0.0627	0.1875
<b>14</b>	-0.18642	-0.12835	-0.1574	0.0581	0.2133
[6]pericyclynedione <b>4</b>	-0.25109	-0.09387	-0.1725	0.1572	0.0946

As outlined in the main text, data listed in Table S5 show that the chemical hardness, or HOMO-LUMO gap, decreases very regularly with  $n$  ( $\eta \approx 0.102 - 0.019 n + 0.002 n^2$ ,  $R = 1.000$ ).

The electrophilicity is found to be mainly determined by the LUMO energy ( $\omega \approx -0.261 - 3.67 \varepsilon_L$ ,  $R = 0.994$ ), i.e. the electron affinity as measured by the first reduction potential  $E_{1/2}^{\text{red1}}$  (which is indeed shown to vary linearly with  $n$ : see main text). Electrophilicity also varies in the opposite sense of electronegativity: the decrease of electronegativity vs  $n$  can be interpreted as a decrease of the *global* aromaticity, while the local aromaticity of the C<sub>18</sub> rings, as quantified by NICS(0) values, remains the same over the series (see below).

As expected, the pericyclynedione **4** with restricted  $\pi$ -conjugation appears highly electrophilic and hard.

#### 4.3. Nucleus-independent chemical shifts (NICS)

The aromaticity of the C<sub>18</sub> cores and C<sub>6</sub> rings of **1**, **2**, **3a-b'** and **14** were evaluated by the corresponding NICS(0)/NICS( $\pm 1$ ) values (section 4.1, Table S6) and compared with the bare *carbo*-benzene reference (C<sub>18</sub>H<sub>6</sub>).

**Table S6.** Calculated NICS values (in ppm) for the C<sub>18</sub> and C<sub>6</sub> rings of the *carbo*-OPEs **1**, **2**, **3a-b'**, **14** and the unsubstituted reference C<sub>18</sub>H<sub>6</sub>, at the B3PW91-6-31G(d,p) level (GIAO formalism).

## SUPPORTING INFORMATION

As previously observed,<sup>[13]</sup> substitution of the "bare carbo-benzene" C<sub>18</sub>H<sub>6</sub> results in an increase of the NICS(0) value, albeit much weaker by alkyl groups than by phenyl group: +0.15 ppm per <sup>t</sup>Bu or <sup>i</sup>Pr group vs +0.77 ppm per Ph group (+0.03 ppm per F atom), at the B3PW91/6-31+G (d,p) level. Assuming the same coefficient for <sup>n</sup>Oct groups, the predicted value for **1** would be -14.7 ppm, so very close to the calculated value of -14.9 ppm at the B3PW91/6-31G (d,p) level.

Upon increasing the number of C<sub>18</sub> units in the carbo-OPE<sub>n</sub> from *n* = 2 to *n* = 4, the external rings exhibit lower NICS values (*ca* -13.7/-12.5 ppm) than the central rings (*ca* -12.4/-11.4 ppm). The phenyl substituents display similar values whatever their value, but are slightly more deshielded (at *ca* -6.0 ppm) in external position (in  $\gamma$  position from the *n*-octyl chains) than in internal positions (at *ca* -6.5 ppm).

For comparison, the NICS(0)/NICS( $\pm$ 1) values of the unsubstituted OPE parents were also calculated. As in the carbo-OPE series, the external rings exhibit lower NICS values ( $\leq$  -9.0/-10.7 ppm) than the central rings (*ca* -8.3/-10.1 ppm).

Perfluorination of the OPE parents was also considered. As previously observed, fluorination of the benzene ring results in a dramatic decrease of the NICS(0) value (down to -17 ppm), along with a negligible decrease of NICS(1) value due to a decrease of the paratropic ring current in the sigma system induced by the electron-withdrawing effect of the fluorine atoms (Table S7).<sup>[13b,14]</sup> Although the NICS value increases again quickly upon further partial defluorination, for *n*  $\geq$  2, the external rings exhibit lower NICS values ( $\leq$  -15.2/-11.0 ppm) than the central rings (*ca* -13.5/-10.3 ppm).

**Table S7.** Calculated NICS values (in ppm) for the C<sub>6</sub> rings of unsubstituted OPE<sub>n</sub>, Ph-[C $\equiv$ C-4-C<sub>6</sub>H<sub>4</sub>]<sub>n</sub>-H, and perfluorinated F<sub>6+4n</sub>-OPE<sub>n</sub>, C<sub>6</sub>F<sub>5</sub>-[C $\equiv$ C-4-C<sub>6</sub>F<sub>4</sub>]<sub>n</sub>-F, *n* = 0-3, at the B3PW91-6-31G(d,p) level (GIAO formalism).

## 4.4. Excited states and UV-vis absorption/emission spectra

Data for the first fifty excited states of the *carbo*-OPEn **1**, **2**, **3a**, **3b'**, **14**, and [6]pericyclinedione **4** are detailed in section 4.8. As a general trend both the absorption and emission wavelengths of maximum oscillator strength  $f$ , and the corresponding  $f$  values themselves, increase with  $n$  (Table S8).

**Table S8.** TDDFT-calculated absorption and emission spectra of **1-4**, **14** (B3PW91/6-31G(g,p)). See section 4.8.

• Ground state NFOs of *carbo*-benzene **1** and *carbo*-biphenyl **2** (Figure S4)Figure S4. FMOs of unsubstituted *carbo*-benzene  $C_{18}H_6$  ( $D_{6h}$ ) and **1**, and *carbo*-biphenyl **2** (B3PW91-6-31G(d,p)).

• Ground state NFOs of *carbo-terphenyls* **3a** and **3b** (Figure S5)

While the HOMO and LUMO of **3a** are found delocalized over the three C<sub>18</sub> rings, six NFOs are strongly localized on either the central or external C<sub>18</sub> rings, and thus called "central" or "external" NFOs, respectively. Substituting the four central phenyl rings of **3a** by methyl groups in **3b'** (instead of pentyl chains in **3b**) results in a shift of the ranks of central FMOs: HOMO-1 and LUMO+4 in **3b'** are thus placed as HOMO-3 and LUMO+1 in **3a**, respectively. The relative energy shift is as expected from the electron-donating effect of the methyl groups.

**Figure S5.** FMOs of **3a** and **3b** (B3PW91-6-31G(d,p)); in the boxes: central NFOs with shifted rank from **3a** to **3b'**.

With the view to appraising the pure electronic effect of alkyl-substitution independently from conformational effects, a vertical model **3b\*** of **3b'** (and **3b**) was devised by truncating the four pentyl chains of **3b** to methyl groups in the calculated equilibrium conformation of **3a**. As observed above for the equilibrium structures of **3a** and **3b'**, the energies of the occupied and unoccupied central NFOs increase by *ca* 0.005 Ha (0.14 eV) from **3a** to **3b'**, while their rank changes from HOMO-3 to HOMO-1 and LUMO+1 to LUMO+4, respectively (Table S10).. In contrast, the energy variation of the external MOs is negligible (0.02 eV), while that of the delocalized MOs is intermediate (0.07 eV). The HOMO-LUMO gaps of **3a** and **3b'** are the same (1.7 eV).

**Table S10.** FMOs of **3a** the vertical model **3b\*** of **3b'** (and **3b**) is the same conformation as **3a** (B3PW91-6-31G(d,p) level), showing the electronic origin of the rank shifting of the central NFOs from **3a** to **3b'**(<sup>\*,\*</sup>).

### • NFOs of the [6]pericyclynedione **4**

The [6]pericyclynedione **4** has long been used as a pivotal precursor of quadrupolar tetraphenyl-carbo-benzenes. The gas-phase equilibrium structure of one of its stereoisomers (*trans-cis-trans*, the most stable one, among five) has been calculated for the first time; its structure and NFOs are displayed Figure S8.

**Figure S8.** FMOs of the most stable stereoisomer of the *carbo*-[6]pericyclynedione **4** (B3PW91-6-31G(d,p) level).

#### 4.6. Conformational analysis and comparison between catenation and fusion of *carbo*-benzene rings.

##### 4.6.1. Conformational analysis of the *carbo*-biphenyl 2

In the nearly  $C_2$ -symmetric equilibrium geometry of **2**, optimized without symmetry constraint, the *carbo*-benzene rings are nearly planar but not coplanar, with a dihedral angle of ca  $\theta_{\text{eq}} \approx 30^\circ$  (see main text). The rotation about the ethynylene linker, monitored through the dihedral angle variable  $\theta$  for a  $sp^2C-sp^2C-(spC)_2-sp^2C-sp^2C$  sequence, is quite free, with a barrier of ca 1.7 kcal/mol for two quasi-iso-energetic transition states TS1 and TS2, at  $\theta_{\text{TS1}} = 0^\circ$  ( $E_{\text{TS1}} = 1.8$  kcal/mol) and  $\theta_{\text{TS2}} \approx 90^\circ$  ( $E_{\text{TS2}} = 1.6$  kcal/mol: see Figure S9). In TS1, it is noteworthy that the macrocycle mean planes are almost parallel but not the same (non-coplanar  $C_{18}$  rings): the mean distances between the eighteen C atoms of a ring and the mean plane of the other ring are 0.82289 Å and 0.82267 Å, so almost equal, as also indicated by the angle between the mean planes of  $0.66^\circ$  only (Figure S9).

The partial de-conjugation between the  $C_{18}$  rings (slanting of the axis of the almost perfectly linear  $C_4$  connector  $sp^2C-spC-spC-sp^2C$  by  $9.3^\circ$  out of the  $C_{18}$  ring mean) is actually due to a folding by  $7.7^\circ$  of the prow and stern of the  $C_{18}$  rings in a half-chair-like conformation. The latter thus undergo some intrinsic structural de-aromatization dictated by steric repulsion between the facing *ortho*-phenyl substituents (the dihedral angles of ca  $19^\circ$  between the corresponding  $C_6$  mean planes and the attached  $C_{18}$  ring mean plane indeed guaranty stabilizing residual  $\pi$ -conjugation between them).

**Figure S9.** Views of the rotation transition states about the ethynylene linkers in the *carbo*-biphenyl **2**. *Top*: orthogonally staggered TS2 ( $\theta_{\text{TS2}} \approx 90^\circ$ ,  $E_{\text{TS2}} = 1.6$  kcal/mol); *bottom*: pseudo-eclipsed TS1 ( $\theta_{\text{TS2}} = 0^\circ$ ,  $E_{\text{TS2}} = 1.8$  kcal/mol) with a local average distance between the two  $C_{18}$  ring mean planes of ca 0.82 Å.

The complete rotation profile ( $E$  vs  $\theta$ ) displays no other local extremum (Figure S10), showing that the leading energy costs are equivalently due to steric repulsion between the four internal phenyl groups (in TS1) and complete disruption of  $\pi$ -conjugation through the  $C_2$  connector (in TS2).

**Figure S10.** Rotation profile about the ethynylene linkers of the *carbo*-biphenyl **2** ( $E$  in kcal/mol vs a dihedral angle  $\theta$  defined as shown in Figure S9)

The same features were observed from the calculation of the rotation about the ethynylene linkers of the *carbo*-terphenyl **3a**.

For comparison, the parent OPE<sub>n</sub>, Ph-[C≡C-4-C<sub>6</sub>H<sub>4</sub>]<sub>n</sub>-H, display similar equilibrium dihedral angles (39.1 for *n* = 2, 38.0° for *n* = 3). As expected, even on the basis of steric effects only, the perfluorinated parents F<sub>6+4n</sub>-OPE<sub>n</sub>, C<sub>6</sub>F<sub>5</sub>-[C≡C-4-C<sub>6</sub>F<sub>4</sub>]<sub>n</sub>-F exhibit greater dihedral angles (56.6° for *n* = 2, 56.0° for *n* = 3).

#### 4.6.2. Steric effects vs inter-ring π-conjugation in *carbo*-OPEs

Geometry optimization while constraining dihedral angles between all the successive C<sub>18</sub> rings to vanish in a "co-flip" TS-like eclipsed conformation gave destabilizations of 1.7, 3.0 and 5.7 kcal/mol vs the respective equilibrium structures of **2**, **3a** and **14**. Under such a constraint, as observed for **2**, the C<sub>18</sub> rings are neither coplanar nor individually planar: the central C<sub>18</sub> rings of **3a** and **14** adopt a chair-like conformation where the prow and the stern, in quasi-parallel mean planes, are folded by ca 4.0-4.5° from the central square bearing the four phenyl groups (see section 4.6.1, and Figures S9 and S11). This gives an average cost of 1.7 kcal/mol per C<sub>18</sub> ring pair for the steric effects to compete with π-conjugation through the C<sub>2</sub> connectors.

**Figure S11.** Side view of the TS-like pseudo-eclipsed conformation of the *carbo*-terphenyl **3a** (optimized under the constraint of simultaneously vanishing particular dihedral angles between successive C<sub>18</sub> rings).

The NICS(0)/NICS(1) values of the corresponding planar structures **2-eclipsed**, **3a-eclipsed** and **14-eclipsed** were found to not change significantly (i.e. by 0.1-0.2 units) from the values of the equilibrium geometry for **2**, **3a** and **14**, respectively (see section 4.3 and Tables S6 and S11).

**Table S11.** NICS values (in ppm) for the C<sub>18</sub> rings of the *carbo*-OPEs **1**, **2**, **3a** **14** with constrained eclipsing C<sub>18</sub> rings (vanishing dihedral angles), calculated at the B3PW91-6-31G(d,p) level with the GIAO formalism.

rings	constrained geometry with co-planar C <sub>18</sub> rings (vs equilibrium geometry)					
	<b>2-eclipsed</b> (vs <b>2</b> at equil.)		<b>3a-eclipsed</b> (vs <b>3a</b> at equil.)		<b>14-eclipsed</b> (vs <b>14</b> at equil.)

				12.3 (12.4)		11.3 (11.3)
C <sub>18</sub>					13.5 (13.6)	12.4 (12.4)
						12.2 (12.4)

Addressing the issue of the through-ring π-conjugation driving force in the absence of steric counter-effect, the phenyl rings of **2**, **3a** and **14** have been replaced by simple hydrogen atoms in **2H**, **3H** and **14H**, respectively: starting optimization without any symmetry constraint led to equilibrium structures of perfect C<sub>2h</sub> symmetry. For **14H** (Figure S12), the external and internal NICS(0)/NICS(1) values are -16.5/-15.1 and -15.2/-13.9 ppm, respectively.

**Figure S12.** Perfectly  $C_{2h}$ -symmetric equilibrium geometry of the *carbo*-quaterphenyl **14H** without phenyl substituent; level of calculation: B3PW91-6-31G(d,p).

#### 4.6.3. From *carbo*-biphenyl to *carbo*-pyrene

With the view to appraising the experimental possibility to force co-planarity between the  $C_{18}$  ring of *carbo*-terphenyl **2**, the theoretical tetra-dehydrogenated Scholl product **2-H<sub>4</sub>** was calculated (see Figure S13).

**Figure S13.** Embedding the free-rotating  $C_{38}$  *carbo*-OPE1 motif of *carbo*-biphenyl **2** in the  $C_{54}$  core of *carbo*-pyrenes. Calculated equilibrium structures at the B3PW91/6-31G(d,p) level. NICS(0)/NICS(1) values, calculated at the same level, are indicated for the  $C_{18}$  rings (see Table S12).

The resulting C<sub>16</sub> cyclo-meta-phenyleneethynylene rings were however found to remain non-planar - albeit more than in **2**, see section 4.2 -, with unchanged NICS(0)/NICS(1) values of the C<sub>18</sub> rings (-13.7/-12.5 ppm: Table S12).

To restore a Hückel aromaticity count in the added peri-condensed rings, the C<sub>16</sub> macrocycles were formally replaced by C<sub>18</sub> macrocycles in **2+(C-H)<sub>4</sub>** and *meta*-benzannelation was finally deleted in *carbo*-pyrenes derivatives **cbpyr-R**, R = Ph, H. The NICS(0)/NICS(1) values of the original catenated (distal) C<sub>18</sub> rings decrease significantly to -16.4/-15.1 ppm for R = Ph and -16.8/-15.4 ppm for R = H (Table S12). Meanwhile, the NICS(0)/NICS(1) values of the added fused (central) C<sub>18</sub> rings are more than twice smaller, at -6.4/-6.1 ppm for R = Ph and -8.6/-8.1 ppm for R = H, witnessing a very weak *carbo*-aromatic character.

Eigenvalues of DFT-calculated NFOs of the ground state in vacuum are listed in Table S13, and TDDFT-calculated absorption and emission spectra in dichloromethane (using the PCM method) are reported in Table S14.

**Table S12.** Calculated NICS values (in ppm) for the C<sub>18</sub> and C<sub>6</sub> rings of the *carbo*-OPEs **1**, **2**, **3a-b'**, **14** and the unsubstituted reference C<sub>18</sub>H<sub>6</sub>, at the B3PW91-6-31G(d,p) level (GIAO formalism).

# Chapter 6

From endo-aromatic hemi-butatriene to bridging  
[3]cumulene units: *carbo*-barrelenes and *carbo*-stilbenes

## Introduction & Summary

Over the past few decades,  $\pi$ -conjugated polyacetylenic macrocyclic chromophores drew chemist's attention for their peculiar structural, electronic, and optical properties.<sup>1</sup> In *carbo*-mer chemistry, besides the most studied *carbo*-benzenes, the design and synthesis of new types of expanded molecules belonging to this family are still active. Very recently, the multi-step synthesis of a *carbo*-naphthalene, the smallest fused polycyclic fragment of  $\alpha$ -graphyne (or *carbo*-graphene),<sup>2</sup> was reported by our group.<sup>3</sup> In this context, the design and synthesis of tricyclic *carbo*-mers of the strained barrelene (bicyclo[2.2.2]-2,5,7-octatriene) was envisaged, the parent barrelene being indeed a fascinating structure with potential applications in various domains. Since the first report of barrelene by Zimmerman in 1960,<sup>4</sup> many of its derivatives were described and studied for their structural and electronic properties,<sup>5</sup> and substituted representatives were also used as ligands in catalysis,<sup>6</sup> or for their ability to trigger photo-generated rearrangements.<sup>7</sup>

The expanded *carbo*-barrelene, with its triple  $\pi$ -electron-rich conjugated system, is attractive not only for its possible optical and electronic properties, but also because its three-dimensional hollow structure can be viewed as a shape-persistent organic cage that could encapsulate small molecules or ions. In the recent years, the use of molecular containers as hosts able to encapsulate small guests<sup>8</sup> have attracted a great interest due to the wide range of related applications such as the stabilization of unstable species,<sup>9</sup> molecular recognition and separation,<sup>10</sup> discrimination of chiral molecules,<sup>11</sup> reactors,<sup>12</sup> sensors,<sup>13</sup> crystal growth,<sup>14</sup> and catalysis.<sup>15</sup> Cage compounds are generally categorized into two classes: (i) supramolecular cages built by self-organization of small molecules;<sup>16</sup> (ii) covalent cages built by organic synthesis. This second class is much less exemplified than the first one, whose prominent representatives are metal-organic frameworks (MOFs) fabricated by coordination between metal ions and rigid organic ligands,<sup>17</sup> and supramolecular cages assembled through hydrogen bonding.<sup>18</sup>

Covalent organic cage molecules are relatively rare as compared to their supramolecular counterparts,<sup>19</sup> their construction indeed requiring multistep synthesis with low overall yields sometimes. In spite of this drawback, their hollow rigid structures still remain attractive because of the higher stability of these covalent assemblies, which could find applications in the domain of molecular recognition of chiral guests,<sup>20</sup> as receptors or sensors.<sup>21</sup> Fullerene C<sub>60</sub>

and its derivatives were for example largely studied as covalent cages for the encapsulation of dihydrogen.<sup>22</sup>

Here, the synthesis of cage-like *carbo*-barrelenes made of three dialkynylbutatriene moieties covalently connected to each other through two  $sp^3$  hybridized vertices was envisaged. The synthetic strategy designed for the preparation of these tricyclic compounds is based on the cyclizing double nucleophilic addition of one equivalent of triyne to the key [6]pericyclynedione in the presence of LiHMDS as base, followed by a reductive and acidic treatment under optimized conditions. Two *carbo*-barrelenes and a partially reduced bis-butatrienic derivative were isolated as highly soluble brown-yellow chromophores and sufficiently stable to be fully characterized by  $^1\text{H}$ ,  $^{13}\text{C}$  NMR and UV-visible spectroscopy, HRMS (MALDI-TOF technique), and by square-wave and cyclic voltammetry. They were also shown to crystallize at low temperature, and single crystals of three molecules deposited from *n*-heptane were found to be suitable for X-ray diffraction analysis. In addition, one of the isolated *carbo*-barrelene was selected as a model molecule for the study of its encapsulation ability. The small  $\text{NH}_4^+$  cation was first envisaged as a guest, despite the absence of clear experimental evidence of encapsulation up to now, theoretical calculations suggested that an interaction should occur between these two partners ( $\Delta E_{\text{tot}} = -44.4$  kcal/mol). Further experiments are in progress in order to study the ability of *carbo*-barrelene cage as host for small molecules or ions.

Inspired by the isolation of a side-product from the addition of the triyne to the [6]pericyclynedione (see Figure 1), the synthesis of expanded stilbenes, or *carbo*-stilbenes, was envisioned. The photo-isomerization property of the parent stilbene (1,1-diphenylethylene), leading to a large number of applications as dyes, in optical devices,<sup>23</sup> and even in biomedicine,<sup>24</sup> indeed motivated the synthesis and study of the expanded  $\pi$ -conjugated *carbo*-stilbene, which could also exhibit interesting electronic and optical properties. Two *carbo*-stilbenes could be prepared through an optimized synthetic strategy, but their unexpected extremely poor solubility prevented their full characterization. Nevertheless, they could be characterized by  $^1\text{H}$  NMR and UV-visible spectroscopy, HRMS (MALDI-TOF technique), and square-wave and cyclic voltammetry. The  $^1\text{H}$  NMR spectra and DFT calculations revealed the formation of a mixture of the *trans*- and *cis*- isomers for this two *carbo*-stilbenes, but no evidence of *cis-trans* interconversion were observed by variable temperature  $^1\text{H}$  NMR experiments in the range 25 °C to 55 °C.

**Abstract.** The synthesis and spectroscopic, diffractometric and electrochemical properties of novel types of bis-C<sub>18</sub>-bicyclic derivatives of *carbo*-benzene, *carbo*-barrelenes and *carbo*-stilbenes, are described. The possible cage behaviour of *carbo*-barrelenes is explored for various guest candidates, in particular among H-bond donors.

### Introduction

[n]Cumulenes are fascinating molecules that were particularly studied for their bond-length alternation (BLA), and for the decrease vs n of the barrier of rotation about their cumulenic axis, corresponding to a *R/S* enantiomerization for even n, to a *cis (Z)/trans (E)* stereoconversion for odd n.<sup>[1]</sup> The [3]cumulene, or butatriene, motif, *carbo*-mer of the alkene motif, has been more largely considered because of its higher stability as compared to longer homologues.<sup>[2]</sup> The stability of isolated di- and tetra-alkynylbutatrienes was shown to be highly substituent-dependent, in particular with respect to the steric bulkiness.<sup>[3]</sup> In the series of n-oligobutatrienylethynyls (OBEs), ω-dialkynyl-*carbo*-butadienes (OBE2) were also shown to be quite stable when protected by bulky silyl groups,<sup>[4]</sup> while ω-dialkynyl-*carbo*-hexatrienes (OBE3) could be isolated and stored in the solid state only.<sup>[5]</sup> In *carbo*-mers of benzene, the alternating butatriene and butyne edges of the resonating Kekule forms are further stabilized by their resulting globally hemi-butatrienic character.<sup>[4]</sup> In non-aromatic *carbo*-mers of 1,3-cyclohexadienes,<sup>[6]</sup> two butatrienes are "simply" conjugated to each other through the ethynylene linker as in *carbo*-butadienes, with a similar moderate stabilizing

effect.. In this report, the use of the ethynylbutatrienylethynylene (EBE) motif as a bridging unit was envisaged in two kinds of *carbo*-meric targets: (i) *carbo*-barrelenes, in which three EBEs bridge two  $sp^3$ -C vertices in a pericondensed bmacrocycle, and (ii) *carbo*-stilbenes, in which a single EBE bridges two  $sp^2$ -C vertices of two *carbo*-benzene rings. The parent barrelene molecule, first described by Zimmerman in 1960,<sup>[7]</sup> was later studied in diversely substituted versions for structural and electronic properties,<sup>[8]</sup> but also for uses as a ligand in catalysis<sup>[9]</sup> and for its ability to undergo photo-generated rearrangements.<sup>[10]</sup> The *carbo*-barrelene derivatives targeted hereafter are attractive for their possible electronic properties, their three conjugated bridges being indeed promising of high charge transport properties, even through the  $sp^3$ -C bridgehead junctions.<sup>[11]</sup> The hollow three-dimensional *carbo*-barrelene framework also suggest possible cage behavior for hosting small molecules or ions, e.g. by several H-bonds to triple bonds to prevent too facile escape through the relatively wide apertures of the capsule of elongated triangular bipyramidal shape.. In spite of tricky synthesis, rigid covalent cages remain indeed attractive for their higher stability as compared to supramolecular counterparts.<sup>[12]</sup> Regarding the *carbo*-stilbene targets, the parent stilbene molecules have been thoroughly studied for their chromophoric and photo-isomerization properties, allowing prospects of applications in optical devices and in biomedicine, for example.<sup>[13]</sup> Upon replacement of the central ethenylene  $C_2$  unit of stilbene by an EBE  $C_8$  unit in the *carbo*-stilbene, conditions of isomerization should *a priori* require milder conditions. Dialkynylbutatrienes are indeed known to undergo rather facile *Z/E* isomerization and to exhibit minor thermodynamic preference for either the *E* or *Z* isomer due to the absence of steric interactions between remote substituents in  $\delta$  positions,<sup>[3c, 14]</sup> Consequently, the anchorage effect of two very large tetraphenyl-*carbo*-benzenic substituents on either phenomena deserves to be studied.

### Results and discussion

The preparation of the *carbo*-barrelenes **1** and **2** was envisaged from the [6]pericyclynedione **3**,<sup>[15]</sup> key precursor of the synthesis of *para*-disubstituted *carbo*-benzenes.<sup>[16]</sup> Various bases were tested for the formation of the intermediate tricyclic diol **4a**, by di-addition of the triyne dinucleophile **5** to the macrocyclic diketone **3** (Scheme 1). While the use of ethylmagnesium bromide and *n*-butyllithium failed to produce the diol **4a**, it could be isolated with 31 % yield using LiHMDS. This base was thus applied to the preparation of the tricyclic diol **4b**,

obtained by addition of the triyne **6** to the same diketone **3**. This optimal procedure led however to the formation of the monocyclic side-products **7a,b** and/or **8a,b**.

**Scheme 1.** Synthesis of the tricyclic precursors **4a** and **4b** of *carbo*-barrelenes.

The treatment of **4a** with SnCl<sub>2</sub> and HCl in dichloromethane at low temperature allowed isolating, after optimization of the amounts of reagents, temperature and reaction time, the *carbo*-barrelene **1** with 28 % yield, as a brown solid. The moderate stability of this first *carbo*-barrelene, possibly due to its two trialkynylcarbinol vertices, motivated their prior transformation into the corresponding methyl ethers in **9a,b**. The treatment of this diethers with the optimal reductive and acidic conditions devised for the preparation of **1** allowed obtaining the *carbo*-barrelene **2** and the partially reduced compound **10**, isolated with 30 % and 17 % yield respectively (Scheme 2). All attempts at formation of the third butatriene unit of the dissymmetrical *carbo*-barrelene **11** by using either a large excess of SnCl<sub>2</sub> and HCl, or harsher reaction conditions failed. The donating *tert*-butyl groups make more difficult the formation of the corresponding butatriene moiety, as it was previously observed for the synthesis of *tert*-butyl substituted *carbo*-benzenes,<sup>[17]</sup> and is here competing with the decomposition of the targeted *carbo*-barrelene **11**, which could not be obtained.

**Scheme 2.** Synthesis of the *carbo*-barrelenes **1** and **2**, and of the partially reduced derivative **10**.

The three isolated tricyclic compounds **1**, **2** and **10** were found to be highly soluble in most of the classical organic solvents, allowing their full characterization by <sup>1</sup>H and <sup>13</sup>C NMR spectroscopies in solution. The two *carbo*-barrelenes **1** and **2** display comparable <sup>1</sup>H NMR spectral profile in the aromatic region, the six equivalent phenyl groups giving a doublet for the *ortho*-H and two triplets for the *meta*- and *para*-H resonating between 7.8 and 7.3 ppm, namely in the classical range for aromatic H-nuclei on isolated butatrienes, and thus much less deshielded than the signals of aromatic H-nuclei on butatriene units included into a *carbo*-benzene ring. In the proton NMR spectrum of the partially reduced compound **10**, the four phenyl groups are also equivalent and give signals at similar chemical shifts as in **1** and **2**, but two types of methoxy groups are observed, a singlet at 3.74 ppm counting for six protons and corresponding to the two equivalent methoxy groups occupying the vertices of the tricycle, and two singlets at 3.57 and 3.56 ppm also counting for six protons and corresponding to the methoxy groups of the two diastereoisomers of the non-reduced di-*tert*-butyl-dimethoxy-

butyne edge of **10**. The full assignment of the  $^1\text{H}$  and  $^{13}\text{C}$  spectra could be performed by 2D-NMR experiments (see ESI).

The absorption properties of the three tricyclic chromophores were studied in chloroform solutions. The two *carbo*-barrelenes **1** and **2** exhibit identical UV-visible spectra, with a main intense absorption band at  $\lambda_{\text{max}} = 401$  nm, while the one of **10** is slightly bathochromically shifted at  $\lambda_{\text{max}} = 418$  nm, these values being consistent with the maximum absorption wavelengths of previously reported isolated dialkynyldiphenylbutatrienes (Figure 2).<sup>[3d]</sup> These three derivatives are much less chromophoric than *carbo*-benzenes ( $\epsilon$  often higher than  $200\,000\text{ L}\cdot\text{mol}^{-1}\cdot\text{cm}^{-1}$ ), with molar extinction coefficients lower than  $100\,000\text{ L}\cdot\text{mol}^{-1}\cdot\text{cm}^{-1}$ .

**Figure 2.** Normalized UV-vis absorption spectra of the bis- and tris-butatrienic derivatives **1**, **2** and **10** in chloroform solutions.

The *carbo*-barrelenes **1** and **2**, and the partially reduced derivative **10** were also characterized by X-ray diffraction analysis of single crystals deposited from *n*-heptane or DCM solutions (Figure 3). Solvent molecules were found in the crystal lattice of **1** and **2**, but not at the center of the tricyclic cage, the DCM molecule being too large to enter inside the hole of the *carbo*-barrelene host. A disorder was observed in the structure of the partially reduced derivative **10**, due to the presence of the two diastereoisomers related to the non-reduced edge in the crystal.

**Figure 3.** Molecular views of the X-ray crystal structures of the *carbo*-barrelenes **1** and **2**, and of the partially reduced derivative **10**. Thermal ellipsoids at the 30 % probability level. For clarity, unnecessary hydrogen atoms and solvent molecules (for **1** and **2**) are omitted (for more details see ESI).

The electrochemical behavior of **1** and **10** was studied by cyclic and square-wave voltammetry in chloroform solution (Table 1). The two products exhibited two reduction processes and one oxidation process, none of them being reversible. The values of the reduction and oxidation potentials being quite different for the two products, the processes probably occur at different locations of the molecules. The partially reduced *carbo*-barrelene derivative **10** was found to be both the most difficult to reduce and the most difficult to oxidize, with higher values of potentials in absolute value as compared to **1**.

<b>10<sup>a</sup></b>	- 1.11	- 1.28	-	1.61	-	-

**Table 1.** Voltammetric data for the three *carbo*-barrelene derivatives **1** and **10** in V/SCE. Supporting electrolyte: CHCl<sub>3</sub> + 0.1 mol/L [TBA][PF<sub>6</sub>]; scan rate: 0.2 V/s; <sup>a</sup> Measurements performed after deposition of the compound on the working electrode by dipping it in a DCM solution of **10** (see SI for more details).

The isolation of traces amounts of the side-products **8a** and **8b** during the synthesis of the tricyclic precursor of *carbo*-barrelenes **4a** and **4b** motivated the search for a more efficient way to produce these monocyclic adducts, which can be seen as intermediates of the preparation of *carbo*-mers of stilbene **12a** and **12b**. The straightforward addition of two equivalents of the known [6]pericyclonone **13** to one equivalent of the triyne **5** or **6** giving

only traces amounts of the bicyclic product **14a** and **14b**, the use of a sequential synthetic strategy, through the intermediates **8a** and **8b** was envisaged (Scheme 3).<sup>[8c]</sup>

**Scheme 3.** Attempts at straightforward synthesis of *carbo*-stilbene precursors **14a,b**.

The optimal use of 1.5 equivalent of triene **5** or **6** and 1.1 equivalent of EtMgBr as base for one equivalent of **3** allowed obtaining the targeted monoadducts **8a** and **8b** as main products, accompanied by small quantities of the diadducts **7a** and **7b**, along with some unreacted **3** and **5** or **6**. The monoketones **8a** and **8b** were then treated with n-octyllithium to give the diols **15a** and **15b**, which were subsequently dimethylated into **16a** and **16b** respectively. Finally, addition of these precursors to the monoketone **13** in the presence of LiHMDS allowed isolating with reasonable yields the bis-macroyclic precursors **17a** and **17b**, and the corresponding *carbo*-stilbenes **12a** and **12b** after a reductive and acidic treatment with SnCl<sub>2</sub> and HCl (Scheme 4). These two *carbo*-stilbenes were isolated as black solids and were found to be very poorly soluble, despite the presence of an octyl chain, previously shown to be an efficient solubilizing substituent,<sup>[16c]</sup> at each side of the molecule, and the presence of two *t*-butyl groups on the central butatriene unit of **12b**, also recently described to increase the solubility of *carbo*-benzenes.<sup>[17]</sup>

**Scheme 4.** Synthesis of the *carbo*-stilbenes **12a** and **12b**.

The very low solubility of these two *carbo*-stilbenes **12a** and **12b** prevented their full characterization. In particular, it was almost impossible to record <sup>13</sup>C NMR spectra of sufficient quality to be described. Nevertheless, <sup>1</sup>H and COSY <sup>1</sup>H-<sup>1</sup>H NMR of the two compounds could be performed, and <sup>1</sup>H-<sup>13</sup>C HSQC and HMBC experiments at 600 MHz at 45 °C were also realized on the slightly more soluble derivative **12b**, thus allowing to propose an assignment of the <sup>1</sup>H NMR signals, although it was made difficult by the duplication of all the

signals due to the presence in both samples of a mixture of the *cis* and *trans* isomers of the central butatriene unit of the *carbo*-stilbenes, the ratio between the *trans* and *cis* isomers being about 52:48 for **12a** and 56:44 for **12b** (Figure 4 and ESI).

**Figure 4.** Aromatic region of the  $^1\text{H}$  NMR of the *carbo*-stilbenes **12a** (bottom) and **12b** (top) in  $\text{CDCl}_3$  (500 MHz; 55  $^\circ\text{C}$ ).

In both spectra, some highly deshielded signals above 9 ppm, characteristics of the *ortho* H-nuclei of the aryl substituents of *carbo*-benzenes, were observed, but a shielded triplet at 6.5 ppm also appeared. This latter signal was attributed to the *cis*-isomer of *carbo*-stilbenes, some of the phenyl substituents of one *carbo*-benzene ring being indeed in this isomer in the shielding cone of the other aromatic macrocycle, and *vice-versa*. This phenomenon being observed for both *carbo*-stilbenes, these shielded signals cannot be assigned to the phenyl substituents on the butatriene unit.

The absorption properties of the two *carbo*-stilbenes **12a** and **12b** were studied in chloroform solutions. They exhibit comparable UV-visible spectra with two intense absorption bands at  $459 \pm 4$  and  $550 \pm 3$  nm followed by a smaller band at higher wavelength (Figure 5). These spectral profiles are very similar to that of the *carbo*-biphenyl **19**,<sup>[18]</sup> in which the two *carbo*-benzenes are conjugated to each other not through a diethynylbutatriene

linker, but through a short ethynyl linker (Figure 5). As expected, the longer  $\pi$ -conjugated linker of the *carbo*-stilbenes **12a** and **12b** induce a bathochromic shift of their absorption bands as compared to those of the *carbo*-biphenyl **19**. The stronger effect was observed on the small absorption bands at high wavelength with a red shift of 74 nm from the *carbo*-biphenyl **19**, having the shortest  $\pi$ -conjugated skeleton, to the *carbo*-stilbene **12a** exhibiting the largest  $\pi$ -conjugated system through additional delocalization with the two phenyl substituents of the central butatriene bridge as compared to **12b**.

**Figure 5.** Normalized UV-visible absorption spectra of the two *carbo*-stilbenes **12a** and **12b** and of the *carbo*-biphenyl **19** in chloroform solutions.

The electrochemical behavior of the *carbo*-stilbene **12b** was also studied by square-wave and cyclic voltammetry, while **12a** appeared to be too poorly soluble to give satisfactory results. For solubility reasons, the measurements were performed after deposition of the compound on the working electrode by dipping in a DCM solution of **12b**. Because of this unconventional method of analysis, will the first oxidation and reduction potentials only be

discussed. In these conditions, a quasi-reversible reduction process was observed at  $E_{1/2} = -0.65$  V/SCE, and an irreversible oxidation was evidenced at 1.11 V/SCE. These results are in agreement with those previously obtained for the *carbo*-biphenyl **19**, exhibiting a first reduction potential at - 0.58 V/SCE.<sup>[18]</sup> The low reduction potentials of both **12b** and **19** are consistent with their extended  $\pi$ -conjugated systems.

11. The macro-aromatic *carbo*-benzene ring was reported to exhibit an unprecedented single molecule conductance as compared to molecules of similar length. The conductance being known to be higher for non aromatic molecules, and to increase with the number of parallel p-conjugated systems, the non aromatic *carbo*-barrelene presenting three parallel conduction pathways of similar structure as those of the *carbo*-benzene appears thus as a very promising target for the study of charge transport properties. a) Z. ## 1. General remarks

THF, diethyl ether (Et<sub>2</sub>O), pentane and dichloromethane (DCM) were dried with a PureSolv-MD-5 Innovative Technology system for the purification of solvents. All other reagents were used as commercially available. In particular, commercial solutions of LiHMDS were 1 M in THF, solutions of *n*-BuLi were 2.5 M in hexane and 1.6 M in THF, solutions of HCl were 2 M in diethyl ether, SnCl<sub>2</sub> was anhydrous. Silica gel (60 Å, C.C 70-200 μm) was used for column chromatography. Silica gel thin layer chromatography plates (60F254, 0.25 mm) were revealed under UV-light and/or by treatment with an ethanolic solution of phosphomolybdic acid (20%). The following analytical instruments were used, <sup>1</sup>H and <sup>13</sup>C NMR: Avance 300, Avance 400, Avance 400 HD, Avance 500 and Avance 600 spectrometers; Mass spectroscopy: Quadrupolar Nermag R10-10H spectrometer; UV-Visible: Perkin-Elmer UV-Vis Win-Lab Lambda 950; IR: Perkin-Elmer Spectrum 100 FT-IR spectrometer; Dual Syringe Infusion Pump was used for macrocyclization reactions. All the <sup>1</sup>H and <sup>13</sup>C signals were assigned according to chemical shifts, spin-spin coupling constants, splitting patterns, signal intensities, and 2D NMR experiments; NMR chemical shifts are given in ppm with positive values to high frequency relative to the tetramethylsilane reference. Coupling constants *J* are in Hertz. UV-Visible extinction molar coefficient  $\epsilon$  is in L·mol<sup>-1</sup>·cm<sup>-1</sup> and wavelengths  $\lambda$  in nm. IR frequency  $\nu$  in cm<sup>-1</sup>.

## 2. Experimental procedures and characterizations

### 2.1. General procedure A for the preparation of 9a and 9b.

A solution of diol **4a** or **4b** (1 eq.) in THF was treated with *n*-BuLi (2 eq. 1.6 M in THF) at -78 °C. The reaction mixture was stirred at this temperature for 10 min before addition of MeI (6 eq.). The solution was slowly warmed up to -25 °C, and then anhydrous DMSO (2 eq.) was added. The resulting mixture was warmed up to room temperature and stirred overnight. After treatment with distilled water, the aqueous layer was extracted with Et<sub>2</sub>O, the combined organic layers were dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified by silica gel column chromatography.

### 2.2. General procedure B for the preparation of 4a and 4b.

A solution of triyne **5** or **6** (1 eq.) in THF was treated with LiHMDS (4eq. 1 M in THF) at -78 °C. The reaction mixture was stirred for 1 h at this temperature. This solution, and a solution of [6]pericyclynedione **3** (1eq.) in THF were added simultaneously to a round-bottom flask (500 ml) filling with THF at -78 °C (rate of addition: 20 mL/h). The resulting mixture was slowly warmed up to room temperature and stirred overnight. After treatment with a saturated solution of NH<sub>4</sub>Cl, the solution was carefully concentrated under reduced pressure, and then extracted with EtOAc. The organic layer was dried over MgSO<sub>4</sub> and concentrated under reduced pressure, before purification of the residue by silica gel column chromatography.

### 2.3. General procedure C for the preparation of *carbo*-barrelene derivatives.

A solution of **4a**, **9a** or **9b** (1 eq.) in DCM was treated with anhydrous SnCl<sub>2</sub> (15 eq.) and HCl (6 eq., 2 M in Et<sub>2</sub>O) at -78 °C. The reaction mixture was stirred for 15 min at this temperature, and then slowly warmed up to -10 °C during 1.5 h and stirred at this temperature for more 1 h. After addition of aqueous NaOH (6 eq., 2 M), the reaction mixture was filtrated through celite® and washed with a saturated NaCl solution. The organic layer was dried over MgSO<sub>4</sub> and concentrated under reduced pressure, before purification of the residue by flash silica gel column chromatography to give **1**, **2** and **10** respectively.

### 2.4. General procedure D for the preparation of **8a** and **8b**.

A solution of triyne **5** or **6** (1.5 eq.) in THF was treated with EtMgBr (1.1 eq., 1 M) at 0 °C. The mixture was stirred for 15 min at this temperature and 2 h at room temperature, and dropwise added to a solution of [6]pericyclynedione **3** (1 eq.) in THF at 0 °C. The reaction mixture was stirred overnight at room temperature. After treatment with the distilled water, the aqueous layer was extracted with Et<sub>2</sub>O, the combined organic layers were dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified by silica gel column chromatography.

### 2.5. General procedure E for the preparation of **15a** and **15b**.

To a solution of **8a** or **8b** (1 eq.) was slowly added freshly prepared octyllithium (4 eq.) at -78 °C. The mixture was stirred for 30 min at -78 °C and then slowly warmed up to -30 °C during 2 h. After treatment with a saturated aqueous NH<sub>4</sub>Cl solution, the aqueous layer was extracted with EtOAc, and the combined organic layers were dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified by silica gel column chromatography.

### 2.6. General procedure F for the preparation of **16a** and **16b**.

A solution of **15a** or **15b** (1 eq.) in THF was treated with *n*-BuLi (2 eq.) at -78 °C. The reaction mixture was stirred for 10 min and then MeI (6 eq.) was added at the same temperature. Anhydrous DMSO (2 eq.) was added at -25 °C, and the reaction mixture was warmed up to room temperature and stirred overnight. After treatment with the distilled water, the aqueous layer was extracted with Et<sub>2</sub>O, the combined organic layers were dried over MgSO<sub>4</sub> and concentrated under reduced pressure. The residue was purified by silica gel column chromatography.

### 2.7. General procedure G for the preparation of **17a** and **17b**.

A solution of **16a** or **16b** (1 eq.) in THF was treated with LiHMDS (6 eq.) at -78 °C. The reaction mixture was stirred for 1 h at this temperature, and then transferred to a solution of **13** (1.2 eq.) in THF at -78 °C. The resulting solution was slowly warmed up to room temperature and then stirred overnight. After treatment with a saturated aqueous NH<sub>4</sub>Cl solution, the aqueous layer was extracted with EtOAc, and the combined organic layers were dried over MgSO<sub>4</sub>, and concentrated under reduced pressure. The residue was purified by silica gel column chromatography.

### 2.8. General procedure H for the preparation of **12a** and **12b**.

A solution of **17a** or **17b** (1 eq.) in DCM was treated with anhydrous SnCl<sub>2</sub> (25 eq.) and HCl (50 eq.) at -78 °C. The reaction mixture was stirred for 20 min at this temperature and then for 2 h at 0 °C. After neutralization with aqueous NaOH solution (50 eq.), the mixture was filtrated through celite®, and then washed with a saturated NaCl solution. The organic layer was dried over MgSO<sub>4</sub>, and concentrated under reduced pressure. The residue was purified by washing with pentane and Et<sub>2</sub>O and filtration through glass fiber to give **12a** or **12b** respectively as black solids.

### **1,10-dimethoxy-4,7,13,16,21,24-hexaphenylbicyclo[8.8.8]hexacos-4,5,6,13,14,15,21,22,23-nonaen-2,8,11,17,19,25-hexayne (1)**

### 3. X-ray diffraction analysis

X-ray data were collected at low temperature on APEX2 Bruker or Gemini Oxford Diffraction diffractometers. The structures were solved using SUPERFLIP, and refined on F by means of least-squares procedures on F using the programs of the PC version of CRYSTALS. Atomic scattering factors were taken from the international tables for X-ray crystallography. Absorption correction was performed by using a multiscan procedure. All non-hydrogen atoms were refined anisotropically. The H atoms were refined using riding constraints. For **10**, the non-reduced butyne edge is disordered, permitting the presence of the two enantiomers in the asymmetric unit.

## 4. 2D and variable temperature $^1\text{H}$ NMR for the *carbo*-stilbene 12a and 12b.

### 4.1 Variable temperature $^1\text{H}$ NMR (500 MHz) spectra of 12a

$^1\text{H} - ^1\text{H}$  HSQC NMR (600 MHz) spectrum of 12a at 55 °C:

**$^1\text{H}$  -  $^{13}\text{C}$  HSQC NMR (600 MHz) spectrum of 12b at 45 °C:**

**The  $^1\text{H}$  -  $^{13}\text{C}$  HMBC NMR (600 MHz) spectrum of 12b at 45 °C:**

# **General Conclusion**

## General Conclusion

As proposed in the General Introduction, the thesis has been divided into two independent parts and six chapters. In a consistent summary, the first part mainly focused on the synthesis of nitro-aromatic phosphines and their coordination chemistry in Rh<sup>I</sup> complexes, while the second part described the synthesis of a series of aliphatic *carbo*-benzenes derivatives, the physico-chemical properties of which were investigated systematically with a view to related applications.

More precisely, in the first part and first chapter, an efficient strategy based on the use of LDA as an optimal base was developed for the preparation of nitro-aromatic phosphines, this method might be extended to the preparation of other nitro-substituted heteroaromatic phosphines, e.g. containing a O- or S-heterocycle. In a set of Rh<sup>I</sup> complexes of such nitro-substituted (*N*-phenyl-benzimidazol-1-yl)diphenylphosphines L, the moderate but systematic variations of the C=O IR stretching frequency and <sup>103</sup>Rh NMR chemical shift of *trans*-L<sub>2</sub>Rh<sup>I</sup>Cl(CO) complexes revealed that neutral nitro-aromatic phosphines are weakly σ-donating P-ligands. As an unexpected observation, crystals of dinuclear side-products Rh<sub>2</sub>Cl<sub>2</sub>(μ-CO)(μ<sub>N,P</sub>-L)<sub>2</sub> happened to be organometallic clathrates with high solvent content (dichloromethane), opening options in the design of organometallic frameworks for host-guest chemistry. In the future, Rh<sup>I</sup> complexes of the newly designed nitro-aromatic phosphines, or simpler versions thereof such as tris(nitrophenyl)phosphines, e.g. (4-NO<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>)<sub>3</sub>P, would deserve to be tested in homogeneous catalysis.

In the second part of the thesis dealing with *carbo*-mer chemistry, the second chapter describes the synthesis of the long known hexaphenyl-*carbo*-benzene, and its previously unknown *p*-bis-3,5-di-*tert*-butylphenyl homologue, through an [8+10] macro-cyclization strategy (instead of [14+4] or [11+7]) allowing a dramatic improvement of the global yield from 1 % to 8 %. Accurate crystallographic and electrochemical data completed the characterization of the hexaphenyl *carbo*-benzene reference. Attachment of four *tert*-butyl

groups on two phenyl substituents of the C<sub>18</sub> macrocycle was found to have a very limited effect on the solubility of *carbo*-benzenes, the low solubility being the main general drawback limiting the processability, and thus applications, of *carbo*-benzenes. Application in organic photovoltaics was also envisaged in collaboration with Mexican partners, but the remaining very poor solubility of the tetra *tert*-butyl homologue of the C<sub>18</sub>Ph<sub>6</sub> standard prevented the formation of the required high quality thin films, thus stimulating the search for more efficient solubilizing substituents; in this context, the design of dialkyl-*carbo*-benzenes was proposed in the next section.

The third chapter discloses the synthesis and physical properties of *p*-dialkyl-tetraphenyl-*carbo*-benzenes bearing two *n*-aliphatic chains R = C<sub>n</sub>H<sub>2n+1</sub>, directly anchored to the C<sub>18</sub> ring (n = 2, 4, 8, 14, 20). The addition of RMgBr nucleophiles to the [6]pericyclynedione resulted in the simultaneous formation of the di-adduct and reduced mono-adduct, thus allowing the parallel synthesis of the quadrupolar dialkyl- and dipolar monoalkyl-*carbo*-benzenes. The use of RMgCl or RLi/CeCl<sub>3</sub> nucleophiles was found to prevent the formation of the reduced derivatives. A remarkable enhancement of the solubility of the two series of mono- and dialkylated *carbo*-benzenes was observed for n ≥ 8. In the crystal state, the first evidence of direct π-stacking of *carbo*-benzene rings was observed for the diethyl and bis-tetradecyl-derivatives, thus providing experimental evidence of possible attractive arrangement of α-graphyne layers into the theoretical 3D carbon allotrope α-graphityne. In the dialkyl series, a linear decrease of the melting-decomposition temperatures vs n was observed. Furthermore, even if slanted, the columnar arrangements of dialkyl-*carbo*-benzenes in the crystalline state suggest that discotic mesophases and liquid crystals could be obtained upon structural tuning of candidate *carbo*-benzenic mesogens.

The fourth chapter focuses on the design of mesogenic *carbo*-benzenes and exploration of their liquid crystal (LC) properties. Two hexaalkoxy-di(phenylethynyl)-tetraphenyl-*carbo*-benzenes bearing six alkyl chains R = C<sub>n</sub>H<sub>2n+1</sub> (n = 12, 18) were synthesized and fully characterized, including by X-ray diffraction analysis of a single crystal for one of them. The mesogenic behavior of the more soluble hexadodecyl-substituted *carbo*-benzene was studied

in depth by Taiwanese collaborators. The formation of a rectangular columnar mesophase at 115 °C was evidenced by POM, DSC, PXRD and HR-STM experiments. These results pave the way for the development of a new generation of discotic columnar LCs based on the large, rigid and hollow C<sub>18</sub> *carbo*-benzene core. Improvement of LC properties by modifications of the length and number of aliphatic chains, and/or substitution pattern of the hexagonal macrocycle (quadrupolar *vs* octupolar), can henceforth be confidently envisaged.

In the fifth chapter, a multi-step synthesis of *carbo*-OPE<sub>2</sub> and *carbo*-OPE<sub>3</sub> wire models, composed of two or three *carbo*-benzene rings catenated through ethylene linkers, was described. Despite a limited solubility, they could be fully characterized, including by single crystal XRD analysis and electrochemistry. The *carbo*-OPE<sub>3</sub>, or "*carbo*-terphenyls", were found to exhibit the lowest first reduction potential ever measured in the *carbo*-mer family ( $-0.42 \pm 0.03$  V/SCE). Results of computational studies at the DFT level, undertaken by a Spanish collaborator, allowed appraisal of the magnetic aromaticity of *carbo*-OPEs: calculated NICS values revealed that the C<sub>18</sub> rings preserve their individual *carbo*-aromatic character in such oligomers. The more extended *carbo*-quaterphenyl was also calculated and predicted to have an extremely low first reduction potential ( $-0.31$  V/SCE) and an extremely wide UV-vis absorption range (440-738 nm). These results open natural prospects of applications of *carbo*-OPE wires in molecular electronics.

In the last chapter, the synthesis of two new types of skeletal *carbo*-mers, derivatives of *carbo*-benzenics as containing two butatrienic C<sub>18</sub> rings, aromatic or not, in the peri-condensed fused mode or catenated mode, namely *carbo*-barrelenes and *carbo*-stilbenes, respectively. They were prepared by double addition of triyne dinucleophiles to one or two equivalents of the key tetraphenyl-[6]pericyclynedione, acting as a di- or mono-electrophile, respectively. In the peri-condensed case, two shape-persistent *carbo*-barrelenes and a partially reduced bis-butatrienic derivative were obtained upon treatment of the peribicyclic bis-adducts with SnCl<sub>2</sub>. Although sensitive to temperature, they were found sufficiently stable to be kept for a few weeks at ambient temperature without decomposition, and to be fully characterized, in particular by single crystal XRD analysis. The ability of such hollow 3D

organic structures to encapsulate  $\text{NH}_4^+$  guest was explored both computationally and experimentally: though clear experimental evidence of encapsulation is still missing, investigations are still in progress, and attempts at encapsulation of other small guests, amongst X–H... $\pi$ C hydrogen bond donors, are envisaged. In the catenated case, two *carbo*-stilbene compounds bearing phenyl or *tert*-butyl substituents at the butatrienic unit bridging the two *carbo*-benzene rings were prepared. Their extremely poor solubility prevented a full characterization, but  $^1\text{H}$  NMR spectroscopy allowed evidencing the formation of mixtures of *cis* (*Z*) and *trans* (*E*) isomers in ratios close to 1:1. Studies of the photo-isomerization propensity of *carbo*-stilbenes will be implemented in the future.

In summary, the thesis work covers two quite distinct research fields: organometallic coordination chemistry and acetylenic organic synthesis. About 40 final products, including 33 organic compounds and 7  $\text{Rh}^{\text{I}}$  complexes were obtained, isolated and characterized, the structures of 27 of them having been determined by X-ray crystallography. Noteworthy as a formal meeting point of the two fields, the sterically hindered bases LDA and LiHMDS played pivotal roles in the preparation of both nitro-aromatic phosphines and *carbo*-benzene derivatives, *carbo*-OPEs, *carbo*-barrelenes, and *carbo*-stilbenes. In terms of synthesis versatility, 24 *carbo*-benzenes were synthesized from the key [6]pericyclinedione precursor. The observed enhancement of solubility upon direct substitution of the  $\text{C}_{18}$  macrocycle by *n*-alkyl chains also paves the way for improving the processability in solution of larger *carbo*-meric molecules, such as long *carbo*-OPE wires.

Finally, the disclosed results open prospects of applications in many various fields as: catalysis, clathrate and host-guest chemistry, organic photovoltaics, liquid crystal design, electro-conductive molecular electronics, and photochemistry.

## **Résumé en français**

## Résumé en français

La thèse est divisée en deux parties portant sur des spécialités expérimentales distinctes, à savoir la chimie du phosphore et de coordination d'une part (pour la catalyse homogène) et d'autre part la chimie organique acétylénique des composés riches en carbone (pour la physique).

La première partie, correspondant au premier chapitre, concerne la conception de nouveaux types de ligands pour des applications spécifiques en catalyse homogène. La famille des ligands faiblement électro-donneurs a été considérée, avec une focalisation sur les phosphines pauvres en électrons et leur coordination avec des centres Rh(I) acides de Lewis. L'étude des nitro-arylphosphines, très peu développée, a donc été initiée avec la synthèse de N-aryl benzimidazolodiphénylphosphines nitrées sur différentes positions des substituants aryle et/ou benzimidazolyle, ainsi que leur complexation avec du Rh(I). La rétro-donation  $\pi$  des ligands ciblés dans les complexes de Rh(I) a été évaluée par des méthodes analytiques complémentaires que sont le blindage en RMN du  $^{103}\text{Rh}$  et la fréquence d'élongation CO en infra-rouge.

La seconde partie, correspondant aux chapitres 2 à 6, porte sur la chimie des acétyléniques et en particulier sur les dérivés macro-aromatiques à motifs cumulènes de types *carbo*-mères tels que les *carbo*-benzènes,<sup>1</sup> avec l'objectif de fournir de nouvelles connaissances fondamentales et des perspectives d'applications de ces dérivés. Plus précisément, les efforts ont été dirigés vers la mise en évidence du rôle des interactions supramoléculaires soit au niveau local dans des complexes hôte-invité, soit à longue distance dans des auto-assemblages de dérivés de *carbo*-benzènes. Différentes cibles ont donc été imaginées dans cet objectif, et sont présentées dans les 5 chapitres composant la deuxième partie du manuscrit.

### **1. Les phosphines nitroaromatiques comme ligands faiblement P-donneurs : la série N-aryl-benzimidazolyle dans des complexes RhCl(CO)**

Les ligands peuvent être classés en deux catégories : les ligands pauvres et les ligands riches en électrons. Alors que les ligands phosphines riches en électrons, tels que les arylphosphines à substituants électro-donneurs,<sup>2</sup> les alkylphosphines,<sup>3</sup> les imidazol-2-ylidènamino-phosphines<sup>4</sup> ou les phosphinophosphinidènes,<sup>5</sup> ont été beaucoup étudiés, les représentants pauvres en électrons n'ont été que peu explorés. L'efficacité spécifique des ligands phosphane déficients en électrons dans des réactions catalysées par des métaux de transitions, comme la métathèse

des oléfines ou l'hydroformylation, a pourtant longtemps attiré l'attention des chimistes.<sup>6</sup> Les P-ligands pauvres en électrons sont généralement conçus suivant différentes approches :

- substitution du squelette des triarylphosphines par des groupements accepteurs tels que CF<sub>3</sub> ou CN,<sup>7</sup>
- introduction de liaisons P-O exerçant un effet électro-accepteur sur l'atome de phosphore libre ou complexé par effet inductif (-I),<sup>8</sup>
- introduction d'une charge positive au voisinage de l'atome de phosphore, rendant ainsi sa paire libre moins disponible,<sup>9</sup>
- remplacement des substituants aryle des phosphines neutres par des groupes hétéroaryle pouvant exercer un effet électro-attracteur (-M) sur l'atome de phosphore par  $\pi$ -donation de la paire libre du P dans l'orbitale antiliante  $\pi^*$  de l'hétérocycle.<sup>10</sup>

Dans l'objectif d'augmenter encore le caractère pauvre en électrons d'hétéroarylphosphines tout en conservant leur caractère neutre, l'utilisation de substituants accepteurs a été considérée à travers l'étude du cas du groupement nitro. Une série de (*N*-phényl-benzimidazol-1-yl)diphénylphosphines portant un nombre variable de groupes NO<sub>2</sub> sur les cycles phényle ou benzimidazolyle a donc été préparée en présence de LDA comme base optimale, et les complexes *trans*-L<sub>2</sub>Rh<sup>I</sup>Cl(CO) correspondants ont été obtenus suivant deux stratégies (Schéma 1).

**Schéma 1.** Méthode générale de préparation des ligands (*N*-phényl-benzimidazol-1-yl)diphénylphosphine à substituants nitro et des complexes de Rh(I) correspondants.

La fréquence d'élongation de la bande C=O en spectroscopie infra-rouge et le déplacement chimique en RMN du <sup>103</sup>Rh ont été utilisés comme sondes pour mesurer le caractère électro-donneur des ligands phosphorés synthétisés, qui se sont avérés être très faiblement  $\sigma$ -donneurs

en comparaison des ligands non-nitrés correspondants et des dérivés cationiques N-méthylbenzimidazolium.<sup>11</sup>

## 2. Les hexaaryl-carbo-benzènes revisités : nouvelle voie de synthèse, donnés cristallographiques et comportement électrochimique

L'élément carbone est d'une importance primordiale dans la construction chimique de la vie sur Terre et il est également à la base de la chimie organique. Environ  $10^7$  molécules organiques et polymères ont été synthétisés par les chimistes, leur diversité structurale étant basée sur des liaisons C-C et C-X stables, et accompagnée par de nombreuses propriétés chimiques et physiques. Leurs applications sont très variées, allant des médicaments aux matériaux.

Les premières études sur les matériaux carbonés ont principalement porté sur deux allotropes du carbone : le graphite et le diamant, correspondant à des réseaux d'atomes de carbone hybridés  $sp^2$  et  $sp^3$  respectivement. La structure tridimensionnelle en couches du graphite lui confère des applications comme lubrifiant solide et comme additif pour renforcer les fibres de carbone.<sup>12</sup> Le diamant, avec sa dureté et son indice de réfraction élevé, est quant à lui principalement utilisé en joaillerie et dans les têtes de forage pour l'exploration géologique.<sup>13</sup> Ces différentes applications, basées sur les propriétés chimiques et physiques distinctes de ces deux allotropes du carbone, ont attiré l'attention de la communauté scientifique vers le développement de nouveaux matériaux carbonés.

Après la première synthèse en 1985 du Buckminster fullerene,<sup>14</sup> formé de 60 atomes de carbone équivalents hybridés  $sp^2$ , les nanotubes de carbone, composés d'atomes de carbone de même hybridation, ont commencé à être étudiés en 1991.<sup>15</sup> Plus récemment, le « parent » de ces deux allotropes du carbone, un feuillet de graphène, a été synthétisé pour la première fois par Geim et al.<sup>16</sup> Ce réseau bidimensionnel d'atomes de carbone arrangés en nid d'abeilles a été étudié notamment pour ses propriétés électroniques, mais il présente également des propriétés mécaniques et thermiques exceptionnelles.<sup>17</sup> Les structures des graphynes, composés d'atomes de carbone hybridés  $sp$  et  $sp^2$ , proposées par Baughman en 1987,<sup>18</sup> ont été largement étudiés au niveau théorique. Ces graphènes expansés sont formellement obtenus par insertion d'unités  $C_2$  dans toutes les liaisons covalentes du graphène ( $\alpha$ -graphyne) ou dans une partie d'entre elles ( $\gamma$ -graphyne), et peuvent donc être formellement obtenus par le processus de *carbo*-mérisation, défini en 1995, et consistant en l'insertion d'unités  $C_2$  dans toutes les liaisons covalentes, ou dans une partie topologiquement définie des liaisons d'une structure de Lewis parente.<sup>19</sup> L' $\alpha$ -graphyne peut donc être considéré comme le *carbo*-mère du graphène,

ou *carbo*-graphène, dont les motifs constitutifs de base sont des cycles *carbo*-benzènes, largement étudiés dans l'équipe depuis 20 ans. La symétrie  $D_{6h}$ , le caractère discotique creux, l'aromaticité magnétique et le système conjugué riche en électrons  $\pi$  du cycle *carbo*-benzène le rend attractif pour de possibles applications dans de nombreux domaines tels que l'optique non linéaire<sup>20</sup> ou la conductivité électrique.<sup>21</sup> Bien que le représentant non substitué  $C_{18}H_6$  soit encore inconnu, plus de 30 *carbo*-benzènes diversement substitués ont été décrits.<sup>1</sup>

Tous les *carbo*-benzènes sont préparés à partir de précurseurs hexaoxy[6]péricyclines,<sup>22</sup> dont les six substituants hydroxyle ou alkoxy sont éliminés dans des conditions acides et réductrices dans une dernière étape conduisant à la formation du macrocycle aromatique en  $C_{18}$ .<sup>1</sup> Différentes voies de synthèse, toutes basées sur une étape clé de macrocyclisation notée [X+Y] entre un dinucléophile X et un diélectrophile Y, ont été envisagées pour préparer ces hexaoxy[6]péricyclines (Schéma 2).<sup>23</sup>

**Schéma 2.** Différentes stratégies de macrocyclisation développées pour la synthèse des précurseurs hexaoxy[6]péricyclines de *carbo*-benzènes.

Les premiers exemples de *carbo*-benzènes dont le représentant hexaphénylé de référence, décrits par Ueda *et al*, ont été obtenus par une stratégie de cyclisation de type [11+7].<sup>24</sup> En 2007, une nouvelle voie d'accès à l'hexaphényl-*carbo*-benzène basée sur une macrocyclisation [14+4] a été proposée,<sup>23</sup> avant la mise au point de l'approche [8+10], qui a été montrée comme étant la plus efficace pour préparer les *carbo*-benzènes quadripolaires, via la synthèse d'un [6]péricyclynediol clé résultant de l'addition d'un triyne dinucléophile en C<sub>8</sub> sur un dialdéhyde diélectrophile en C<sub>10</sub>.<sup>25</sup> Le diol macrocyclique ainsi obtenu peut facilement être oxydé en dicétone, qui peut alors conduire en deux étapes, une addition nucléophile suivie d'une aromatisation réductrice, à de nombreux *carbo*-benzènes quadripolaires (Schéma 3).<sup>1</sup>

**Schéma 3.** Méthode générale de synthèse des *carbo*-benzènes quadripolaires.

La plupart des *carbo*-benzènes souffrent d'une solubilité limitée réduisant le champ d'applications possibles. La recherche de substituants permettant d'augmenter la solubilité de cette famille de molécules riches en carbone devient donc aujourd'hui d'une importance cruciale. L'hexaphényl-*carbo*-benzène a donc été re-préparé afin de définir la solubilité de cette molécule de référence, ce qui a permis de compléter sa caractérisation qui n'avait été que partiellement décrite par Ueda et Kuwatani,<sup>24</sup> mais également d'augmenter le rendement global de sa synthèse tout en diminuant le nombre d'étapes.<sup>26</sup> La préparation d'un analogue *a priori* plus soluble à substituants 3,5-di-*tert*-butylphényle a été effectuée en deux étapes à partir de la [6]péricyclynedione, et il a également été entièrement caractérisé, mais l'effet de ces substituants sur la solubilité des *carbo*-benzènes s'est avérée très faible.<sup>26</sup>

### 3. *Carbo*-benzènes lipidiques : sondes moléculaires de l'anisotropie magnétique et des propriétés d'empilement de l' $\alpha$ -graphyne

La recherche de substituants solubilisants efficaces a été amorcée récemment dans le cadre de la synthèse d'un *carbo*-naphtalène dont la solubilité avait été anticipée comme très faible. Sa préparation a donc été entreprise en version octa-substituée par des groupements 4-

pentylphényle,<sup>27</sup> mais l'effet de ces derniers sur la solubilité est apparu limité, tout comme celui des groupements 3,5-di-*tert*-butylphényle.<sup>26</sup> L'introduction de chaînes alkyles sur les substituants phényle des *carbo*-benzènes ayant peu d'influence sur leur solubilité, l'insertion directe de chaînes aliphatiques sur le cycle en C<sub>18</sub> a alors été envisagée. Alors que les substituants *iso*-propyl n'améliorent pas la solubilité,<sup>28</sup> les groupements *tert*-butyl directement insérés sur le macrocycle ont récemment été montrés augmenter de façon significative la solubilité des *carbo*-benzènes dans les solvants organiques.<sup>29</sup>

Sur la base de ces résultats préliminaires, l'insertion directe de chaînes alkyles linéaires de longueurs variables sur les positions *para* des *carbo*-benzènes a été envisagée comme nouvelle approche visant à améliorer la solubilité de ces molécules. Une série de longueurs de chaînes (n = 2, 4, 8, 14, 20) a été proposée, et les *carbo*-benzènes correspondants ont été préparés suivant la méthode classique en deux étapes à partir de la [6]péricyclynedione. L'utilisation de réactifs bromures d'alkyl magnésium a conduit à la formation de mélanges des diadduits ciblés et des mono-adduits réduits, permettant ainsi la préparation parallèle de séries de dialkyl- et de monoalkyl-*carbo*-benzènes (Schéma 4). Le résultat de la réaction en fonction de la nature du nucléophile utilisé a également été exploré afin de déterminer quel réactif conduit à la plus grande sélectivité en diadduit. Trois types de nucléophiles ont été envisagés : alkyl lithien (C<sup>-</sup>Li<sup>+</sup>), alkyl halomagnésien (C<sup>-</sup>MgX<sup>+</sup>, X = Cl, Br), et alkyl cérien (C<sup>-</sup>CeCl<sub>2</sub><sup>+</sup>), ce dernier donnant le diadduit avec un rendement élevé, sans formation observée de produit de réduction.<sup>30</sup> Les propriétés physico-chimiques, telles que la solubilité, la température de fusion-décomposition, les propriétés d'absorption, le comportement électrochimique et l'empilement cristallin des dialkyl-*carbo*-benzènes obtenus ont été étudiées et discutées en fonction de la longueur de chaîne.<sup>31</sup>

**Schéma 4.** Synthèse des dialkyl- et monoalkyl-*carbo*-benzènes à partir de la [6]péricyclonédione en utilisant  $\text{RMgBr}$  comme base.

#### 4. Assemblages supramoléculaires 3D et 2D et comportement thermotropique d'un mésogène de type *carbo*-benzène

Les cristaux liquides sont présents dans de nombreux dispositifs électroniques faisant partie intégrante de notre vie quotidienne, comme les smartphones, les ordinateurs portables et les écrans de télévision. La phase cristal liquide, qui est un état intermédiaire entre l'état cristallin et l'état amorphe, est formée par l'auto-organisation spontanée de molécules mésogènes. Suivant la forme de ces molécules mésogènes, les cristaux liquides sont communément classés en deux catégories : calamitiques (mésogènes en forme de bâtonnets)<sup>32</sup> et discotiques (mésogènes en forme de disque).<sup>33</sup> Les premières mésophases calamitiques ont été décrites par Reinitzer au début du 20<sup>ème</sup> siècle,<sup>34</sup> et depuis, le comportement cristal liquide de mésogènes linéaires en forme de bâtonnet a été largement étudié et a conduit à des applications concrètes, notamment dans les affichages à cristaux liquides (LCD).<sup>35</sup>

Les cristaux liquides discotiques sont connus depuis que Chandrasekhar a décrit la formation de mésophases de ce type par des mésogènes de type benzène hexasubstitué il y a une quarantaine d'années.<sup>36</sup> Récemment, les cristaux liquides discotiques ont fait l'objet d'intenses recherches pour leurs applications potentielles dans les transistors organiques à effet de champ, dans les diodes électroluminescentes organiques et dans les dispositifs photovoltaïques organiques.<sup>33,37</sup> Les mésogènes discotiques présentent typiquement un cœur

rigide et plat aromatique décoré par plusieurs chaînes aliphatiques flexibles, et ils conduisent à la formation de deux principaux types de mésophases : nématiques et colonnaires.<sup>33,35</sup> Des mésophases lamellaires, dont la structure reste ambiguë encore aujourd'hui, peuvent aussi être formées par des mésogènes discotiques.<sup>38</sup> Dans les mésophases colonnaires, les mésogènes s'organisent en colonnes parallèles, dont la formation est induite par des interactions coopératives à la fois des cœurs aromatiques centraux et des chaînes latérales qui les entourent. Dans ces mésophases, les distances cœur-cœur intra-colonnaires sont généralement courtes (environ 3,5 Å), permettant un recouvrement des orbitales  $\pi$  de deux mésogènes adjacents, alors que les distances inter-colonnaires sont généralement plus grandes (de l'ordre de 20 à 40 Å) et dépendent de la longueur des chaînes flexibles. Les cœurs aromatiques les plus communément utilisés pour l'élaboration de cristaux liquides à mésophases colonnaires sont des dérivés macro-polycycliques pouvant contenir des hétéro-atomes (N, O, S) tels que les porphyrines, les phthalocyanines, les hexaazatriphénylènes (HAT),<sup>39</sup> les triphénylènes ou les hexa-péri-hexabenzocoronènes (HBC).<sup>40</sup> De façon générale, les cœurs aromatiques étendus plans permettant un bon recouvrement des orbitales  $\pi$  sont susceptibles de renforcer la stabilité de l'arrangement colonnaire et l'ordre supramoléculaire. Les chaînes dispersives attachées au cœur central jouent aussi un rôle important dans la formation des mésophases colonnaires. La nature, le nombre et la position de ces chaînes sur le cœur mésogène peuvent fortement modifier les températures de transition de phase, la solubilité des molécules mésogènes, les distances inter-colonnaires et l'ordre intra-colonnaire des mésophases. Les chaînes flexibles les plus utilisées sont des chaînes alkyles linéaires ou branchées, des groupes alkylphényle ou alkoxyphényle.

Alors que les macro-poly-hétérocycles aromatiques tels que les porphyrines ont été largement considérés comme cœur mésogène, aucune attention n'a été portée aux macro-monocycles aromatiques. En particulier, le cycle *carbo*-benzène en  $C_{18}$ , dont le caractère macro-aromatique est souvent comparé aux circuits en  $C_{16}N_2$  à 18 électrons  $\pi$  des porphyrines, n'avait jamais été envisagé comme cœur mésogène avant ce travail. Pourtant, le cycle *carbo*-benzène à 18 électrons  $\pi$  délocalisés, analogue trois fois expansé du benzène, représente un nouveau type de cœur attractif pour l'élaboration de cristaux liquides discotiques. De plus, la forme hexagonale des *carbo*-benzènes en font une plateforme idéale sur laquelle il est possible d'insérer des chaînes alkyles sur différentes positions. Les *para*-dialkyl-*carbo*-benzènes lipidiques portant deux chaînes alkyle linéaires récemment décrits ne présentent pas de comportement cristal liquide, suggérant que la présence de deux chaînes sur le cœur mésogène

n'est pas suffisante pour induire la formation de mésophases.<sup>31</sup> Deux *para*-trialkoxypényléthynyl-*carbo*-benzènes ayant différentes longueurs de chaînes ont donc été préparés ( $n\text{-C}_{12}\text{H}_{25}$  et  $n\text{-C}_{18}\text{H}_{37}$ ), et le comportement mésogène de l'un d'entre eux a été étudié. La formation d'une mésophase colonnaire rectangulaire à 115 °C a été mise en évidence par microscopie optique à lumière polarisée (POM), par calorimétrie différentielle à balayage (DSC), par diffraction des rayons X sur poudre (PXRD) et par microscopie à effet tunnel (STM). Les constantes mesurées pour le réseau 3D ont été trouvées être en accord avec les images STM du réseau 2D obtenu en déposant une solution de *carbo*-mésogène sur une surface de HOPG (Figure 1).<sup>41</sup>

**Figure 1.** Molécules *carbo*-mésogènes portant des chaînes alkyle de longueurs différentes.

### 5. *Carbo*-bi- and -ter-phényles : *carbo*-mères de cycle de [n]OPE

Suite au rapport initial par Ratner en 1974,<sup>42</sup> l'électronique moléculaire est devenu un sujet de recherche incontournable qui a considérablement attiré l'intérêt de la communauté scientifique.<sup>43</sup> Il est aujourd'hui reconnu que les molécules organiques  $\pi$ -conjuguées ayant un petit gap HOMO-LUMO peuvent potentiellement trouver des applications dans des dispositifs électroniques moléculaires.<sup>44</sup> Durant les dernières décennies, de nombreux efforts ont porté sur le développement de nouvelles molécules organiques pouvant être utilisées dans des dispositifs électroniques en remplacement des circuits à base de silicium dans le but de miniaturiser les circuits intégrés.<sup>45</sup> Les molécules organiques  $\pi$ -conjuguées parmi lesquels les oligomères et les polymères ont de nombreux avantages tels que de faibles coûts de production, une mise en œuvre simple, et surtout la possibilité de modifier leur structure moléculaire afin de moduler les propriétés optiques et électroniques.<sup>46</sup>

Les fils moléculaires oligo(phénylène-éthynylène)s (OPE) ont été considérés comme modèles pour l'étude des propriétés structurales et électroniques des polymères poly(phénylène-éthynylène) correspondants.<sup>47</sup> Les remarquables propriétés optiques et électroniques des OPE ont conduit à des applications dans de nombreux domaines tels que dans

les diodes organiques électroluminescentes,<sup>48</sup> les chimiosenseurs,<sup>49</sup> les interrupteurs moléculaires<sup>50</sup> ou les matériaux pour l'optique non-linéaire.<sup>51</sup> Malgré les nombreux travaux visant à synthétiser des OPE pour l'étude de leurs propriétés de transport de charge, fabriquer un circuit intégré moléculaire applicable dans des dispositifs reste aujourd'hui un défi.<sup>50,52</sup> Les propriétés de transport de charge de fils moléculaires ne dépendent pas seulement de facteurs physiques tels que la température ou de l'interface molécule-électrode, mais aussi de la nature chimique de la molécule et en particulier de sa conjugaison, de ses caractéristiques redox, de sa longueur et de ses substituants.<sup>53</sup> En règle générale, le transport de charge est amélioré dans les molécules rigides, présentant un système  $\pi$ -conjugué étendu et un potentiel redox faible.<sup>46,54</sup>

Le cycle *carbo*-benzène à 18 électrons  $\pi$  délocalisés, trois fois plus grand mais trois fois moins aromatique au niveau énergétique que son parent benzène à 6 électrons  $\pi$ ,<sup>55</sup> a récemment été montré, à travers l'étude du *p*-dianilinyll-*carbo*-benzène, présenter une conductance moléculaire sans précédent de 106 nS, soit dix fois plus grande que celle de molécules comparables de mêmes dimensions.<sup>56</sup> Cette conductance élevée, associée à la rigidité, la planéité et la richesse en électrons  $\pi$  des *carbo*-benzènes, a encouragé l'élaboration d'une série de *carbo*-mères de cycle d'OPE (*carbo*-OPE). La préparation d'un *carbo*-OPE<sub>2</sub> (*carbo*-mère de squelette du biphenyle) et de deux *carbo*-OPE<sub>3</sub> (*carbo*-mères de squelette du terphenyle) a alors été envisagée. Afin de les rendre solubles, ces trois cibles ont été conçues avec des chaînes *n*-octyle solubilisantes aux deux extrémités de leur squelette  $\pi$ -conjugué. De même, l'un des *carbo*-terphenyle a été ciblé avec des chaînes pentyle sur les quatre substituants phényle du macrocycle central.

Des voies de synthèse basées sur des procédés de mono-addition nucléophile sur la [6]péricyclonedione ont été utilisées pour préparer ces *carbo*-OPE (Schéma 4). Le *carbo*-OPE<sub>2</sub> a été synthétisé avec un rendement de 7 % à partir de la [6]péricyclonedione. Les deux *carbo*-OPE<sub>3</sub>, premiers exemples de molécules composées de trois cycles *carbo*-benzènes, ont été préparés suivant deux stratégies différentes. Ces trois *carbo*-OPE ont été entièrement caractérisés par RMN <sup>1</sup>H et <sup>13</sup>C, par spectroscopie UV-visible, par spectrométrie de masse et par électrochimie. Deux d'entre eux ont également été caractérisés par diffraction des rayons-X sur des monocristaux obtenus à partir de solutions dans le chloroforme. Les *carbo*-OPE<sub>3</sub> présentent un très faible potentiel de première réduction ( $0,42 \pm 0,03$  V/SCE), sans précédent en série *carbo*-mère. Des études théoriques ont également été réalisées afin d'évaluer l'aromaticité des cycles *carbo*-benzènes de cette série de *carbo*-OPEN ( $n = 1 - 4$ ) à travers la détermination des valeurs de NICS au centre de chaque macrocycle (calculs DFT).<sup>57</sup>

Schéma 4. Stratégies de synthèse des *carbo*-OPE.

## 6. Des héli-butatriènes endo-aromatiques aux unités [3]cumulènes pontants : *carbo*-barrélènes et *carbo*-stilbènes

Au cours des dernières décennies, les chromophores macrocycliques polyacétyléniques  $\pi$ -conjugués ont attiré l'attention des chimistes pour leurs propriétés structurales, électroniques et optiques remarquables.<sup>58</sup> En chimie des *carbo*-mères, au-delà des *carbo*-benzènes qui sont les plus étudiés, l'élaboration et la synthèse de nouveaux types de molécules expansées de cette famille est encore aujourd'hui un sujet de recherche active dans l'équipe. Par exemple, la synthèse multi-étapes d'un *carbo*-naphtalène, plus petit fragment polycyclique fusionné d' $\alpha$ -graphyne (ou *carbo*-graphène), a été récemment décrite.<sup>27</sup> Dans ce contexte, la synthèse de *carbo*-mères tricyclique du barrélène tendu (bicyclo[2.2.2]-2,5,7-octatriène) a été envisagée, le barrélène parent étant lui-même attractif, non seulement pour sa structure particulière, mais aussi pour ses possibles applications dans divers domaines. Depuis le premier rapport sur le barrélène par Zimmerman en 1960,<sup>59</sup> de nombreux dérivés du barrélène ont été décrit et étudiés

pour leurs propriétés électroniques,<sup>60</sup> pour leurs applications en catalyse<sup>61</sup> et pour leur capacité à subir des réarrangement photo-induits.<sup>62</sup>

Le *carbo*-barrélène, avec son triple système  $\pi$ -conjugué riche en électrons, est attractif non seulement pour ses possibles propriétés optiques et électroniques, mais aussi parce que sa structure tridimensionnelle creuse peut être considérée comme une cage organique rigide pouvant éventuellement encapsuler de petites molécules ou ions. Ces dernières années, l'utilisation de molécules comme conteneurs hôtes capables d'encapsuler de petits invités a fait l'objet d'intenses recherches,<sup>63</sup> en particulier pour les nombreuses applications qui découlent de cette propriété telles que la stabilisation d'espèces instables,<sup>64</sup> la reconnaissance moléculaire,<sup>65</sup> la discrimination de molécules chirales,<sup>66</sup> la croissance de cristaux<sup>67</sup> ou la catalyse<sup>68</sup> par exemple. Les composés cages sont en général classés en deux catégories : les cages supramoléculaires formées par auto-organisation de petites molécules<sup>69</sup> et les cages covalentes obtenues par synthèse organique.<sup>70</sup> Les cages covalentes, dont la construction requiert des synthèses multi-étapes aux rendements parfois faibles, sont donc plus rares que leurs homologues supramoléculaires. Malgré ce désavantage, les structures creuses rigides covalentes restent attractives pour leur plus grande stabilité ouvrant des possibilités d'applications comme hôte chiral,<sup>71</sup> comme récepteur ou comme capteur.<sup>72</sup> Le fullerène C<sub>60</sub> et ses dérivés ont été par exemple largement étudiés en tant que cages covalentes pouvant encapsuler le dihydrogène.<sup>73</sup>

Ici, la synthèse de *carbo*-barrélènes, possibles cages covalentes composées de trois unités dialcynylbutatriènes connectées entre elles par deux sommets hybridés sp<sup>3</sup>, a été envisagée par double addition nucléophile cyclisante d'un équivalent de triyne sur la [6]péricyclodione en présence de LiHMDS comme base, suivie d'une étape d'élimination réductrice. Deux *carbo*-barrélènes et un dérivé partiellement réduit bis-butatriénique ont été isolés sous forme de solides brun-jaunes très solubles et suffisamment stables pour pouvoir être caractérisés par RMN, spectroscopie UV-visible, spectrométrie de masse et électrochimie (Schéma 5). Ils ont également été caractérisés par analyse par diffraction des rayons-X sur des monocristaux obtenus à basse température.<sup>74</sup> Le cation NH<sub>4</sub><sup>+</sup> a été envisagé comme invité pour ce nouveau type de cage covalente dans des travaux préliminaires. A ce jour, aucune preuve expérimentale claire d'encapsulation de NH<sub>4</sub><sup>+</sup> dans le *carbo*-barrélène n'a pu être mise en évidence, mais des calculs théoriques suggèrent qu'une interaction stabilisante devrait se produire entre ces deux molécules ( $\Delta E_{\text{tot}} = -44.4$  kcal/mol).

**Schéma 5.** Stratégies de synthèse des *carbo*-barrélènes et des *carbo*-stilbènes.

Inspirée par la formation d'un produit secondaire lors de la synthèse des *carbo*-barrélènes, la préparation de *carbo*-stilbènes a été envisagée (Schéma 5). La propriété de photo-isomérisation des dérivés du stilbène parent (1,1-diphényléthène), conduisant à de nombreuses applications comme colorant, dans des dispositifs optiques<sup>75</sup> et même en biomédecine,<sup>76</sup> a en effet motivé la synthèse et l'étude de *carbo*-stilbènes, qui pourraient aussi s'avérer présenter des propriétés optiques et électroniques intéressantes. Deux *carbo*-stilbènes ont été préparés suivant une stratégie de synthèse optimisée, mais leur très faible solubilité n'a pas permis leur entière caractérisation. Ils ont cependant pu être caractérisés par RMN <sup>1</sup>H, spectroscopie UV-visible, spectrométrie de masse et électrochimie. Les spectres RMN <sup>1</sup>H ont montré la formation d'un mélange des deux isomères *cis*- et *trans*- des *carbo*-stilbènes, mais aucune évidence d'interconversion *cis-trans*, souvent observée pour les dialcynylbutatriènes,<sup>77</sup> n'a pu être détectée par RMN à température variable entre 25 et 55 °C.<sup>74</sup>

Ce travail de thèse couvre deux thèmes de recherche distincts : la chimie organométallique de coordination, et la chimie organique de synthèse. Une quarantaine de produits finaux, dont 33 composés organiques et sept complexes de  $Rh^I$  ont été obtenus, isolés et caractérisés. La structure de 27 d'entre eux a pu être confirmée par analyse par diffraction des rayons X.

On peut remarquer un point commun formel entre ces deux thématiques de recherche, qui est le rôle clé des bases encombrées LDA et LiHMDS dans la préparation des phosphines nitro-aromatiques d'une part, et des *carbo*-benzènes, *carbo*-OPEs, *carbo*-barrélènes et *carbo*-stilbènes d'autre part. En termes de versatilité de synthèse, 24 *carbo*-benzènes ont été préparés à partir du précurseur [6]péricyclonedione clé. L'augmentation de la solubilité observée par substitution directe du macrocycle par des chaînes alkyles devrait permettre de manipuler plus facilement des molécules *carbo*-mères plus étendues, comme de longs films moléculaires *carbo*-OPE.

Enfin, ces résultats ouvrent des perspectives d'applications dans différents domaines tels que la catalyse, la chimie hôte-invité des clathrates, le photovoltaïque organique, l'élaboration de cristaux liquides, l'électronique moléculaire et la photochimie.

## Résumé

Le manuscrit est divisé en six chapitres et deux parties indépendantes, la première étant consacrée à l'étude de l'effet de substituants nitro sur des ligands phosphines aromatiques (L). Une série de (N-phényl-benzimidazol-1-yl)diphénylphosphines substituées par 1 à 3 groupes nitro à différentes positions des noyaux N-phényle et benzimidazolyle, a été synthétisée, et comparée au parent non nitré et à l'homologue N-méthyl-benzimidazolium cationique. Dans les complexes trans-L<sub>2</sub>Rh<sup>I</sup>Cl(CO) correspondants, des variations faibles mais systématiques de la fréquence d'élongation C=O IR et du déplacement chimique RMN <sup>103</sup>Rh fournissent une quantification empirique des effets régio-spécifiques des substituants nitro sur le caractère donneur global du ligand. Les produits secondaires dinucléaires (μ-CO)(LRhCl)<sub>2</sub> donnent des cristaux de clathrate uniques à teneur élevée (6,7:1) en solvate de dichlorométhane.

La deuxième partie, regroupant cinq chapitres, concerne l'étude de nouveaux types de *carbo*-mères fortement π-conjugués, principalement conçus pour pallier la faible solubilité limitante du noyau *carbo*-benzène. La synthèse et la caractérisation des hexaaryl-*carbo*-benzènes de référence sont revisitées. Une voie de synthèse en 12 étapes améliorée du dérivé hexaphényle connu et de l'homologue *p*-bis-3,5-di-*tert*-butylphényle est décrite. Les deux *carbo*-benzènes ont été entièrement caractérisés, en particulier par analyse par diffraction des rayons X et par électrochimie. Leur utilisation dans les cellules solaires photovoltaïques organiques s'est avérée freinée par leur faible solubilité empêchant la formation de couches minces de haute qualité.

Le troisième chapitre porte sur une série de *p*-dialkyl-tétraphényl-*carbo*-benzènes à deux chaînes aliphatiques R = C<sub>n</sub>H<sub>2n+1</sub>, n = 2, 4, 8, 14, 20. Leur synthèse basée sur l'addition nucléophile de RMgBr sur la [6]péricyclynedione clé conduit à la fois aux dialkyl- et mono-alkyl-*carbo*-benzènes réduits, le processus de réduction étant supprimé en utilisant un réactif RLi/CeCl<sub>3</sub>. Une augmentation spectaculaire de la solubilité dans les solvants chlorés a été observée pour n ≥ 8. Un empilement π-π direct des cycles en C<sub>18</sub>, guidé par les forces de dispersions aliphatiques, a été montré pour la première fois dans la structure cristalline du dérivé bis-tétradécyle, appuyant l'existence de l'allotrope du carbone 3D α-graphityne (*carbo*-mère putatif du graphite).

Le quatrième chapitre décrit deux trialkoxyaryléthynyl-tétraphényl-*carbo*-benzènes et l'étude des propriétés mésogènes de l'un d'entre eux. Une mésophase rectangulaire colonnaire, mise en évidence à 115 °C par des analyses DSC, POM et PXRD, ouvre des perspectives pour une étude systématique des cristaux liquides apparentés. Les constantes du réseau 3D sont cohérentes avec les images STM 2D du *carbo*-mésogène sur HOPG.

Le cinquième chapitre décrit trois *carbo*-mères de squelette de bis- et ter-phényles, conçus pour leur relation aux fils moléculaires OPP ou OPE. Un *carbo*-terphényle a montré un très faible potentiel de réduction (-0,39 V/SCE), sans précédent en série *carbo*-mère.

Dans le dernier chapitre, de nouveaux types de *carbo*-mères sont illustrés: les *carbo*-barrélènes et les *carbo*-stilbènes. Leur préparation repose sur l'addition de triyne dinucléophiles sur un ou deux équivalents d'un précurseur [6]péricyclyne(di)one. Dans la série tricyclique, deux *carbo*-barrélènes non macro-aromatiques et un dérivé bis-butatriénique partiellement réduit, se sont révélés suffisamment stables pour permettre une caractérisation complète, y compris par cristallographie. Le rôle de cage d'un *carbo*-barrélène vis-à-vis de petites molécules telles que NH<sub>4</sub><sup>+</sup>, même si elle n'a pas encore été clairement établie, a été étudiée théoriquement et expérimentalement. Les *carbo*-stilbènes ont été obtenus sous forme de mélanges. En l'absence d'analyse cristallographique, ils ont été attribués aux diastéréoisomères *cis* et *trans* sur la base de la spectroscopie RMN <sup>1</sup>H et des calculs DFT.

**Mots clés:** ligands phosphine nitroaromatiques, [6]péricyclynes, *carbo*-benzènes aliphatiques, cristaux liquides, *carbo*-barrélène, *carbo*-stilbène, *carbo*-oligo-phénylène(éthynylènes)

## Abstract

The manuscript is divided into six chapters and two independent parts, the first part being dedicated to the investigation of the effect of nitro substituents on aromatic phosphine ligands (L). A series of (*N*-phenyl-benzimidazol-1-yl)diphenylphosphines substituted with 1 to 3 nitro groups at different positions of the *N*-phenyl and benzimidazolyl cores, were synthesized, and compared with the non-nitrated parent and cationic *N*-methyl-benzimidazolium counterpart. In the corresponding *trans*-L<sub>2</sub>Rh<sup>I</sup>Cl(CO) complexes, prepared in two steps and fully characterized, moderate but systematic variations of the C=O IR stretching frequency and <sup>103</sup>Rh NMR chemical shift provide an empirical quantification of regio-specific effects of the nitro-substituents on the global donating character of the P-ligand. Dinuclear (μ-CO)(LRhCl)<sub>2</sub> side-products were shown to give unique clathrate crystals with a high content (6.7:1) of dichloromethane solvate.

The second part, gathering five chapters, concerns the study of new types of highly π-conjugated *carbo*-mers, primarily devised to palliate the limiting poor solubility of the aromatic C<sub>18</sub> *carbo*-benzene core. The synthesis and characterization of reference hexaaryl-*carbo*-benzenes are revisited. An improved 12-step synthetic route to the long known hexaphenyl derivative and *p*-bis-3,5-di-*tert*-butylphenyl homologue is described. Both *carbo*-benzenes were fully characterized, in particular by X-ray diffraction analysis and electrochemistry. Their use in organic photovoltaic solar-cells was found to be hampered by their very low solubility preventing the formation of high quality thin films.

The third chapter focusses on a series of *p*-dialkyl-tetraphenyl-*carbo*-benzenes with two aliphatic chains R = C<sub>n</sub>H<sub>2n+1</sub>, n = 2, 4, 8, 14, 20. The synthetic route based on nucleophilic addition of RMgBr to a key [6]pericyclynedione ultimately led to both the dialkyl- and reduced monoalkyl-*carbo*-benzenes, the reduction process being found suppressed by using a RLi/CeCl<sub>3</sub> reactant. A dramatic enhancement of solubility in chlorinated solvents was observed for n ≥ 8. A direct π-π stacking of C<sub>18</sub> rings, driven by aliphatic dispersions forces, could be evidenced for the first time in the X-ray crystal structure of the bis-tetradecyl derivative, giving experimental support to the existence of the α-graphityne 3D carbon allotrope (putative *carbo*-mer of graphite).

The fourth chapter describes two trialkoxyarylethynyl-tetraphenyl-*carbo*-benzenes and the study of the mesogen properties of one of them. A columnar rectangular mesophase, evidenced at 115 °C by DSC, POM and PXRD analyses, opens prospects for a systematic study of related liquid crystals. The 3D lattice constants are consistent with 2D STM images of the *carbo*-mesogen deposited on HOPG.

The fifth chapter reports on three skeletal *carbo*-mers of bis- and ter-phenyls, devised for their acquaintance with OPP or OPE molecular wires. A *carbo*-terphenyl was found to exhibit a very low first reduction potential (-0.39 V/SCE), unprecedented in the *carbo*-mer series.

In the last chapter, new types of *carbo*-mers are exemplified: *carbo*-barrelenes and *carbo*-stilbenes. Their preparation relies on the addition of triyne dinucleophiles to either one or two equivalents of a [6]pericyclyne(di)one precursor. In the tricyclic series, two non-macroaromatic *carbo*-barrelenes and one partially reduced bis-butatrienic derivative, both containing two *sp*<sup>3</sup>-C bridgeheads, were found to be sufficiently stable to allow full characterization, including by crystallography. The cage-ability of a *carbo*-barrelene toward small molecules such as NH<sub>4</sub><sup>+</sup>, albeit not clearly proven yet, was investigated both theoretically and experimentally. The *carbo*-stilbene product was evidenced as an unseparated mixture of two isomers. In the absence of crystal of suitable quality for crystallography, they were assigned to the *cis* and *trans* diastereoisomers on the basis of <sup>1</sup>H NMR spectroscopy and DFT calculations.

**Key words:** nitroaromatic phosphine ligands, [6]pericyclynediones, aliphatic *carbo*-benzenes, liquid crystals, *carbo*-barrelene, *carbo*-stilbene, *carbo*-oligo-phenylene(ethynylenes)
