# Curriculum Vitae

## ***Xiaoshuang CAI***

*Born in 1989, Nanyang, Henan, China*

*M.Sc. Eng. 2015*

*Grain, Oil and Vegetable Protein Engineering, Faculty of Food Science and Engineering, Wuhan Polytechnic University, CHINA*

### ***Education:***

Chemical engineering, 2015-2019

National Institute of Applied Sciences of Rouen (INSA-Rouen), FRANCE

Grain, oil and vegetable protein engineering, 2012–2015

Faculty of Food Science and Engineering, Wuhan Polytechnic University, CHINA

Master thesis: Gastrointestinal absorption, anti-oxidation mechanisms of Crocetin of Gardenia Jasminoides Ellis on cancer cells.

### ***Project:***

Johan Gadolin Scholarship program: Find the appropriate heterogeneous catalyst for the carbonation of epoxidized vegetable oil, Finland, 2018. (October 2018-March 2019)

PhD Grants from the China Scholarship Council: Co-operation Program with the UT and INSA: Carbonation of vegetable oils, France, 2015.

### ***Experience:***

05/2018–08/2018: Supervision of bachelor student (Matos Manoelito) research project 'Carbonation of fatty acid methyl ester of cottonseed oil' at LSPC, INSA Rouen.

01/2018–06/2018: Assistant-teacher for analysis particles (12 hours).

11/2017–01/2018: Supervision of master students (Boris Kasabov and Baptiste Lefebvre) research project 'Experimental design for monitoring exothermic reactions with calorimetry' at LSPC, INSA Rouen.

02/2017–06/2017: Supervision of master thesis (Wander Y. Perez Sena) 'Kinetic and thermal study of the polymerization of carbonated vegetable oils' at LSPC, INSA Rouen.

05/2016–07/2016: Supervision of master student (Georgiana Alexa) research project 'Risk assessment for the aminolysis of carbonated vegetable oil' at LSPC, INSA Rouen.

# 简 历

蔡小双

1989 年生于中国河南省南阳市

于 2015 年获武汉轻工大学粮食、油脂及植物蛋白工程全日制硕士研究生学位

## 教育背景

---

2012.09 – 2015.07 武汉轻工大学 | 粮食、油脂及植物蛋白工程 | 工学硕士

硕士研究课题 « 梔子源藏花酸的吸收利用及细胞抗氧化机制研究»

2015.10 – 2019.03 法国国立鲁昂应用科学学院 (INSA-Rouen) | 过程工程

## 科研经历

---

2015.10 – 2019.03 法国 UT-INSA/CSC 国际合作项目 « 植物油的碳酸化研究»

2018.10 – 2019.02 芬兰 Johan Gadolin Scholarship 项目 « 植物油的碳酸化的非均相  
催化剂的筛选及应用»

## 教学实践

---

2016.05 – 2016.07 指导研究生(Georgiana Alexa)项目 “棉籽油环氧化反应研究” 及  
“亚麻籽油聚合反应反应过程的热风险评估”

2017.02 – 2017.06 指导研究生(Boris Kasabov and Lefebvre Baptiste)项目 “植物油基  
环碳酸酯的聚合反应的热动力学研究”

2017.11 – 2018.01 指导研究生(Wander Y. Perez Sena)项目 “用量热法监测放热反应  
的实验设计”

2018.01 – 2018.06 试验指导教学 (12 个学时)

2018.05 – 2018.08 指导研究生(Matós Manoelito)项目 “棉籽油脂肪酸甲酯环碳酸化  
反应研究”

## Acknowledgements

The research is the co-operation program with China Scholarship Council and the UT and INSA (France). The majority of this work is performed at the Laboratoire de Sécurité des Procédés Chimiques of INSA de Rouen during the years of 2015-2019. On the occasion of the completion of the thesis, I would like to express my sincere gratitude!

I would like to express my gratitude to the China Scholarship Council (China) for providing me the scholarship, and I would like to express my gratitude to the UT-INSA (France) for the technical support.

I would like to thank my supervisor Dr. Sébastien LEVENEUR for his patient supervision. His scientific knowledge, availability makes this project credible and facilitate in progress. Thank you very much again for your inspiration, support and help over the past three and a half years. From topics of this project conceiving to research plans developing, the results of the experiments discussing to scientific articles co-publishing, and then the first draft of the thesis revising to the final draft determined, every breakthrough in research progress is inseparable from my supervisor's careful guidance and patience. I would like to express my sincere respect!

I would like to thank all the staffs behind the scenes at INSA-Rouen University (France), thank you very much for your timely and great help on my study and my life. I would like to include thanks to every permanent staff from the laboratory LSPC (Laboratoire de Sécurité des Procédés Chimiques): Béchara TAOUK, Lamia VERNIÈRES-HASSIMI, Lionel ESTEL, Alain LEDOUX, Lokmane ABDELOUAHED, Bruno DARONAT, Sylvie POUBELLE, Jean-pierre HEBERT, Raphaël DELAMARE, Giovanna DELAMARE, Axelle TRUFFERT, Fatima ABID, Pereira DE ARAUJO MARIA, Christine DEVOUGE, Jeremy DESHAIS, thank you very much for your encouragement and great help on my study and friendliness. I would like also to thank Nasreddine KÉBIR for helping with the NMR analysis.

I would like to thank Professor Tapio Salmi from Åbo Akademi University for welcoming me at Johan Gadolin Process Chemistry Centre (PCC) and helped with the catalyst screening for the carbonation work. I learned so much from the participation in this project. It makes me well knowledgeable and made my work experience richer. I would like to include my thanks to all the staffs and colleagues at PCC: Pasi TOLVANEN, Pasi VIRTANEN, Kari ERÄNEN, Jani RAHKILA,

Narendra KUMAR, Adrianna FREITES AGUILERA, Soudabeh SAEED, Leolincoln CORREIA. Thank you all for your help and encouragement.

I want to thank all my colleagues in LSPC, Junliu ZHENG, Vivianna CONTRAS, Nassima BENAMARA, Chetna MOHABEER, Emmanuelle VIARD, Yanjun WANG, Marie DÉCULTOT, Xiaojia LU, Elizabeth GARCÍA HERNANDEZ, Wander PEREZ SENA, Jundong WANG, Lilivet UBIERA RUIZ, Luis CÉSAR REYES, etc. All of you are my sunshine and making my French life wonderful. Special thanks to Chetna, you are so intelligent, sincere and kindness. We accompanied each other and became strong together during the past three years. I also want to thank all my friends who have been unequivocally since my days in China and France: Yuan LIU, Yuhui ZHAO, Lulu LIU and Yongshuai CHENG, thanks for accompanies and all the smiles and tears we have shared together. It is my great fortune to be able to meet everyone here. I would like to express my sincere thanks and best wishes to everyone.

I would like to thank my supervisor during my master period, Professor Jingren HE, thank you very much for your teaching and supporting on the road to scientific research. Thanks for giving me the right guidance when I am confused for my future. Thank you for advicing me to go aboard to see the outside world. I would like to thank Doctor Zhenzhou ZHU, thank you very much for your encouragement and help during my application and preparation of the interview for the CSC/UT-INSA program. Also, thanks a lot for all my master colleagues, Lige DUAN, Ning YANG, Minjie KUANG, Shengwen ZHANG, etc. for your encouragement. Thank you all!

I want to thank all the reviewers for my publishments and to include thanks to all the judges of my doctoral thesis defense: Michel CABASSUD, Jean-Marc COMMENGE, Damien HUDEBINE, Valeria CASSON MORENO, Françoise MAUGÉ, thank you very much for your time and valuable advice.

At last, I would like to thank my parents and my family members, thank you very much for your support and companionship. You are always my greatest motivation for my life and my study.

## Remerciements

Ces recherches sont effectuées en collaboration avec le China Scholarship Council (CSC) et UT-INSa en France. La majorité des travaux est effectuée au Laboratoire de Sécurité des Procédés Chimiques (LSPC) de l'INSa de Rouen au cours des années 2015-2019. A la fin d'achèvement de ma thèse, je voudrais exprimer ma sincère reconnaissance.

Je voudrais exprimer ma gratitude au China Scholarship Council (Chine) pour m'avoir fourni la bourse, et je voudrais exprimer ma gratitude à l'UT-INSa (France) pour le soutien technique.

Je souhaite remercier mon superviseur, le Dr Sébastien LEVENEUR, pour sa supervision patiente. Ses connaissances scientifiques, sa disponibilité rendent ce projet crédible et facilitent le progrès. Merci encore pour votre inspiration, votre soutien et vos aides au cours des trois dernières années et demie. Des sujets de ce projet à la conception des plans de recherche, des résultats des expérimentations à la coédition d'articles scientifiques, puis de la première révision de ma thèse à la version finale, chaque percée dans la recherche est indissociable de la direction minutieuse et patience de mon superviseur. Je voudrais exprimer mon respect sincère.

Je souhaite remercier tous les membres du personnel de l'INSa de Rouen (France), qui se trouvent dans les coulisses, merci beaucoup pour votre aide précieuse et efficace dans mon étude et dans ma vie. Je voudrais remercier tous les collaborateurs permanents des laboratoires du LSPC: Béchara TAOUK, Lamia VERNIÈRES-HASSIMI, Lionel ESTEL, Alain LEDOUX, Lokmane ABDELOUAHED, Bruno DARONAT, Sylvie POUBELLE, Jean-pierre HEBERT, Raphaël DELAMARE, Giovanna DELAMARE, Axelle TRUFFERT, Fatima ABID, Pereira DE ARAUJO MARIA, Christine DEVOUGE, Jeremy DESHAIS, merci beaucoup pour vos encouragements et votre aide précieuse dans mon étude et votre gentillesse. J'aimerais remercier Nasreddine KÉBIR pour son aide dans l'analyse par NMR.

Je remercie Professeur Tapio Salmi à l'Université Åbo Akademi de Turku/Åbo, de m'avoir invité à Johan Gadolin Process Chemistry Centre (PCC) et a contribué à la projection de catalyseur pour le travail de carbonatation. J'ai tellement appris de la participation à ce projet. Cela me permet d'avoir de bonnes connaissances et d'enrichir mon expérience de travail. J'aimerais remercier tous les membres du personnel et les collègues du PCC: Pasi TOLVANEN, Pasi VIRTANEN, Kari ERÄNEN, Jani RAHKILA, Narendra KUMAR, Adrianna FREITES AGUILERA,

Soudabeh SAEED, Leolincoln CORREIA, etc. Merci à tous pour votre aide et vos encouragements.

Je voudrais remercier tous mes beaux collègues du LSPC, Junliu ZHENG, Vivianna CONTRAS, Nassima BENAMARA, Chetna MOHABEER, Emmanuelle VIARD, Yanjun WANG, Marie DÉCULTOT, Xiaojia LU, Elizabeth GARCÍA HERNANDEZ, Wander PEREZ SENA, Jundong WANG, Lilivet UBIERA RUIZ, Luis CÉSAR REYES, etc. Vous êtes tous mon rayon de soleil et de faire ma vie française merveilleux dans ce pays étranger. Un merci spécial à Chetna, tu es intelligent, sincère et gentil. Nous nous sommes accompagnés et devenus forts ensemble au cours des trois dernières années. Je tiens aussi à remercier tous mes amis qui ont été sans équivoque depuis mes jours en Chine et en France: Yuan LIU, Yuhui ZHAO, Lulu LIU et Yongshuai CHENG. Merci pour tous les sourires et les larmes que nous avons partagés ensemble. C'est ma grande chance de pouvoir rencontrer tout le monde ici. Je voudrais exprimer mes sincères remerciements et mes meilleurs vœux à tous.

J'aimerais remercier mon superviseur durant ma période de master, Professeur Jingren HE. Merci beaucoup pour votre enseignement et votre soutien sur le chemin de la recherche scientifique. Merci de me advising d'aller à France pour voir le monde extérieur. Je voudrais remercier le Docteur Zhenzhou Zhu. Merci beaucoup pour vos encouragements et votre aide pendant ma candidature et la préparation de l'entretien pour l'application pour le programme CSC / UT-INSA. Merci beaucoup pour tous mes collègues, Lige DUAN, Ning YANG, Minjie KUANG, Shengwen ZHANG, etc. pour vos encouragements. Merci à tous!

Je tiens à remercier tous les relecteurs pour mes publications. Je souhaite remercier tous les juges de ma soutenance de thèse: Michel CABASSUD, Jean-Marc COMMENGE, Damien HUDEBINE, Valeria CASSON MORENO, Françoise MAUGE, merci beaucoup pour votre temps et vos précieux conseils.

Je voudrais remercier mes parents et les membres de ma famille, merci beaucoup pour votre soutien et votre camaraderie. Vous êtes toujours ma plus grande motivation pour ma vie et mes études.

## 致 谢

时光如梭，三年半的博士生涯转眼已接近尾声。回首这三年半以来在法国 INSA-Rouen 的学习生活，心中充满感激。在这里，我得到了诸多祖国同胞和法国同事的关怀，尤其感激导师 Sébastien LEVENEUR 对我的帮助，正是他们的关怀和帮助，使得我的学业顺利完成。在论文完稿之际，我谨向他们表示最真诚的谢意！

诚挚感谢中国留学生基金委与法国 UT-INSA 合作项目为我们提供的这次难得的学习机会，感谢祖国为我们提供的奖学金支持和法国 UT-INSA 提供的科研环境，使我们能够在这里潜心做科研。

衷心感谢我的导师 Sébastien LEVENEUR 博士。孜孜不倦，感谢您在学习和生活上对我的谆谆教诲；亦师亦友，感谢您在科研生活上为我们营造了一个严谨而又和谐的环境。点点滴滴我都会铭记在心。本课题从课题的构思到研究计划的制定、从实验结果的讨论到一篇篇科研成果的共同发表，再到毕业论文初稿的逐章修改直到定稿，每一个环节都离不开导师的耐心阅读和悉心指导。在此论文完成之际，请允许我向您致以诚挚的敬意！

感谢法国国立鲁昂应用科学学院（INSA-Rouen University）每一位辛勤的工作人员，感谢你们曾经的帮助；感谢 LSPC（Laboratoire de Sécurité des Procédés Chimiques）大家庭的每一位优秀的成员：Béchara TAOUK, Lamia VERNIÈRES-HASSIMI, Lionel ESTEL, Alain LEDOUX, Lokmane ABDELOUAHED, Bruno DARONAT, Sylvie POUBELLE, Jean-pierre HEBERT, Raphaël DELAMARE, Giovanna DELAMARE, Axelle TRUFFERT, Fatima ABID, Pereira De Araujo Maria, Christine DEVOUGE, Jeremy DESHAIS, 等等，感谢你们在这三年半以来，在学习和生活中对我的关心、鼓励和帮助。感谢 PBS（Laboratoire Polymères Biopolymères Surface）实验室的 Nasreddine KÉBIR 提供的核磁分析帮助。

感谢芬兰奥博学术大学 Johan Gadolin 化学工艺中心（Johan Gadolin Process Chemistry Center）的 Tapio Salmi 教授邀请并提供宝贵的学习的机会，使得我的专业知识和技能得到了进一步充实。感谢该部门每一位同事：Pasi TOLVANEN, Pasi VIRTANEN, Kari ERÄNEN, Jani RAHKILA, Narendra KUMA, Adrianna FREITES AGUILERA, Soudabeh SAEED, Leolincoln CORREIA, 等等，感谢你们的热情和帮助。

再次感谢 LSPC 部门的所有优秀的博士生们，Junliu ZHENG, Vivianna CONTRAS, Nassima BENAMARA, Chetna MOHABEER, Emmanuelle VIARD, Yanjun WANG, Marie DÉCULTOT, Xiaojia LU, Elizabeth GARCÍA HERNANDEZ, Wander PEREZ SENA, Jundong WANG, Lilivet UBIERA RUIZ, Luis CÉSAR REYES, 等等。在这三年半时间里我们欢笑与共，谢谢大家使我的异国学习生活多姿多彩。同时，感谢一直支持和陪伴我的朋友们，刘媛，赵宇辉，刘璐璐，成永帅，等等，谢谢你们一直以来的陪伴和守候。求学之路，能遇到大家，是我莫大的幸运！

感谢我的研究生导师，武汉轻工大学何静仁教授在科研道路上的指引和鼓励，感谢祝振洲老师在出国申请以及面试期间不遗余力的帮助和指导，使得我有机会能够去看看外面的世界，开阔了我的眼界。感谢实验室所有的同事，段李歌，邝敏杰，杨宁，张胜文，等等。谢谢你们的鼓励和支持。

感谢审阅过所有发表论文的审稿人，特别感谢参与此次毕业答辩的所有评委：Michel Cabassud, Jean-Marc Commenge, Hudebine Damien, Valeria Casson Moreno, Françoise Maugé, 非常感谢您们在百忙之中前来参加我的毕业答辩，以及对论文提出的宝贵意见。

感谢我的父母和家人，感谢你们的默默的支持和陪伴，伴我走过了这么多年漫长求学历程。你们永远是我生活和学习的最大动力，

最后，再次向所有关心和帮助我的人致以诚挚的感谢和永远的祝福。

蔡小双

## Abstract

Nowadays, biomass and carbon dioxide valorization are considered as a helpful solution to the environmental issues of global warming and the depletion of petroleum reserves. Thus, vegetable oils have attracted increasing attention of academic and industrial communities, as one of the potential renewable biomass that can be applied to the production of fossil substitute for sustainable development, owing to their advantages of renewable, sustainable, biodegradable, and universally available with huge feedstock. Among decades of researches, epoxidation and carbonation processes are two popular application methods for vegetable oil valorization.

The conversion of vegetable oils into epoxidized ones is defined by a conversion of unsaturated compound into an epoxide group. So far, the potential application for the production of epoxidized oil in the industrial is the Prileschajew oxidation, which is a well-known conventional way to be used as the commercial production process. This type of epoxidation uses percarboxylic acid as an oxygen carrier, which is formed in situ in the aqueous phase, and then epoxidize the unsaturated groups on the vegetable oils into epoxide groups. During the process, however, this method presents side reaction of ring-opening of the epoxide group. Therefore, the selective epoxidation process conditions need to be optimized in order to minimize the ring-opening reactions. In this study, process parameters including the concentration of acid catalyst (sulfuric acid), reactants (water, epoxide group, hydrogen peroxide, acetic acid) and the reaction temperature have been discussed for the epoxidation and ring opening of vegetable oils. During the kinetic modeling stage, the related kinetic constants for the ring opening reactions were estimated. Based on this model, the ring opening by acetic and peracetic acids was found to be faster than by water and hydrogen peroxide. A semibatch reactor, where hydrogen peroxide and sulfuric acid were added, was found to be the most suitable configuration.

To determine the optimum operating conditions and scale up the epoxidation or carbonation processes, it requires the database of different physicochemical properties, i.e. viscosity, density, refractive index, or specific heat capacity and the evolutions of these properties with the temperature. However, this information is absent in the literature. For this study, the evolution of these properties with temperature and compositions (double bond, epoxide and carbonated groups concentration) was determined for three vegetable oils and their

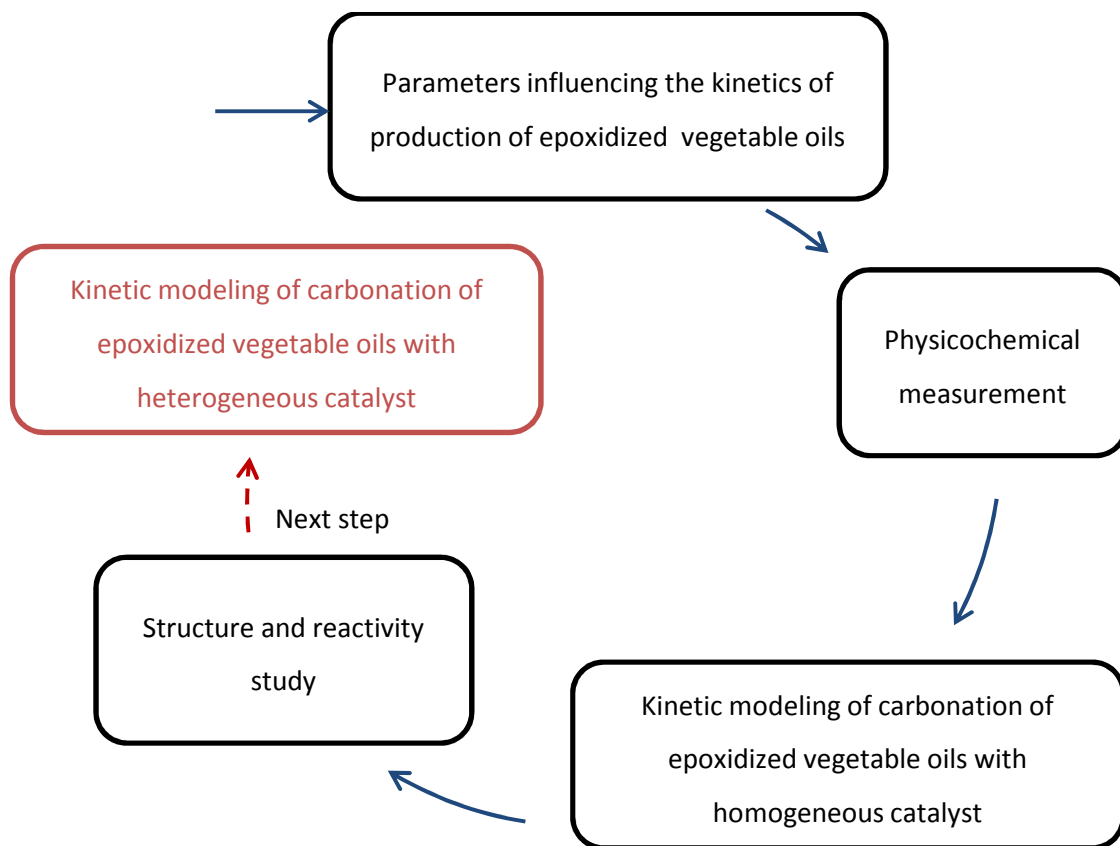

corresponding epoxidized and carbonated forms (cottonseed oil, linseed oil and soybean oil). Density and refractive indices of these oils were found to vary linearly with temperature. Based on the measurement of changes in viscous stresses with shear rates, these oils were found to be Newtonian fluids. It was demonstrated that specific heat capacity follows a polynomial equation of second order with temperature. Based on these results, it was demonstrated that some correlations could be used to predict the evolutions of these physicochemical properties at different composition and temperature based on the knowledge of the property of the pure compounds.

Carbonation of epoxidized vegetable oil is a promising way to prepare bio-based polyols for the production of polyurethane by non-isocyanate route. To promote the use of these feedstocks in industrial scale, kinetic and thermodynamic data are needed for better energy integration and cost optimization. The kinetics of the carbonation of epoxidized cottonseed oil by tetra-n-butylammonium bromide, a homogeneous catalyst, was studied. Reaction parameters, i.e. reaction temperature (110-140°C), reaction pressure (20-50 bar), concentration of catalyst (0.06-0.30 mol.L<sup>-1</sup>) and epoxides (1.67-3.80 mol.L<sup>-1</sup>) were investigated. A kinetic model was developed and the rate constant and activation energy were estimated. The reliability of the kinetic constants was further verified by using Markov chain Monte Carlo method.

In order to investigate the correlation between the reactivities of vegetable oil and its fatty acid building-blocks concerning carbonation reaction, we have compared the kinetics of carbonation of epoxidized cottonseed oil (ECSO) and its epoxidized fatty acid methyl ester (EFAME). Mass transfer and physicochemical properties of these reactions were determined and further applied to estimate the intrinsic rate constants during the kinetic modeling stage. Epoxidized fatty acid methyl ester was found to have higher carbonation reactivity than the one of epoxidized vegetable oil. The rate constant of carbonation of fatty acid methyl ester was estimated to be 1.4 times higher than the one of ECSO. A linear relationship between the carbonation rate constant of epoxidized vegetable oil and its fatty acid methyl ester with temperature was found.

A brief summary of the research strategy is given in the diagram below.

## 摘要

当前，生物质和二氧化碳的废物利用被认为是解决全球变暖和石油储备枯竭的环境问题的有效方法之一。作为潜在的可再生的生物质之一，植物油可用于生产可持续发展的化石替代品。因其具有可再生，可持续，可生物降解特性以及储量巨大且普遍可用的优势，因此越来越受到学术界和工业界的关注。在过去数十年的研究中，环氧化和碳酸化过程是植物油的两种常用应用方法。

**Prileschajew** 环氧化过程是目前常规的商业生产环氧化植物油的方法。该方法以在水相中原位生成的过氧羧酸为氧载体，将植物油的不饱和基团氧化成环氧基团。但是，该方法的缺点是环氧化过程中存在环氧基团开环的副反应，在一定程度上会降低环氧化反应的效率。因此，有必要对环氧化工艺条件进行选择优化以降低开环副反应。因此，该课题研究了环氧化工艺参数，包括酸催化剂（硫酸）的浓度，反应物浓度（水，环氧基团，过氧化氢，乙酸）和反应温度，对环氧化和开环反应的影响。在此基础上，建立反应动力学模型，模拟开环反应的过程并评估相关动力学常数。结果表明，乙酸和过乙酸的开环速度比水和过氧化氢快，而且，通过加入过氧化氢和硫酸的半间歇反应方式是最合适环氧化过程。

为了进一步确定最佳的环氧化植物油加工工艺条件且其实现规模化生产，需要不同植物油的理化性质的数据库，即充分了解粘度，密度，折射率，比热容以及这些数据随温度的变化情况，等等。然而，相关的数据尚且需要补充和完善。鉴于此，本论文初步选择了三种主要植物油（棉籽油，亚麻子油和大豆油）作为研究对象，对这些理化性质随着温度和官能团组分（双键，环氧化基团，碳酸化基团）的变化进行测定和模拟。结果表明，以牛顿流体形式存在的油样，其密度和折射率随温度呈现线性变化，而粘度与温度则为指数函数关系。与此同时，比热容与参考温度下的比热容的比率和温度遵循二阶多项式方程关系。该研究结果为进一步通过相关性来预测理化学性质在不同组成和温度下的演变提供了参考性依据。

环氧化植物油的碳酸化是制备生物基多元醇的最具前景的方法。该产物可以进一步通过非异氰酸酯途径生产聚氨酯。为了促进环氧化植物油的工业规模碳酸化的过程，同样需要相关动力学和热力学数据，以实现更好的能源一体化和优化生产成本。因此，本课题以环氧化棉籽油为代表，采用四丁基溴化铵作为均相催化剂，研究了在均相催化剂催化作用下的碳酸化动力学。根据对碳酸化反应参数，即反应温度（110-140℃），反应压力（20-50bar），催化剂浓度（0.06-0.30mol.L<sup>-1</sup>）和环氧基浓度（1.67-3.80mol.L<sup>-1</sup>）

1) 的研究, 提出了碳酸化反应动力学模型, 并估算了反应速率常数和活化能。利用 Markov chain Monte Carlo 方法进一步验证了动力学参数的可靠性。

为了进一步研究植物油与其对应的脂肪酸结构单元之间在碳酸化反应活性的相关性, 本课题对比研究了环氧化棉籽油及其环氧化脂肪酸甲酯对碳酸化反应活性。基于前期研究过程, 对碳酸化反应的传质过程和反应物及产物的理化学性质进行了测定, 并进一步用于估计动力学反应速率常数。结果显示, 环氧化脂肪酸甲酯具有比环氧化植物油更高的碳酸化反应活性, 其碳酸化速率常数比后者快 1.4 倍。同时, 粘度指标的差异证明了其对二氧化碳在油相中的溶解度发挥重要的作用。

下图简要概述了本课题研究思路。

## Résumé

La valorisation de la biomasse et du dioxyde de carbone est à présent considérée comme une solution aux problèmes environnementaux du réchauffement climatique et l'épuisement des réserves de pétrole. Ainsi, les huiles végétales ont attiré l'attention croissante des milieux universitaires et industriels, comme une source de biomasse potentielle renouvelable qui peut être appliquée à la production de substitut fossile pour un développement durable, due à leurs caractères renouvelables, durables, biodégradables. De plus, cette biomasse est disponible avec une énorme quantité. Durant des décennies de recherches, les processus d'époxydation et de carbonatation sont deux méthodes d'application populaires pour la valorisation des huiles végétales.

La conversion des huiles végétales en huiles époxydées est définie par une conversion d'un composé insaturé en un groupe époxyde. Jusqu'ici, l'oxydation de Prileschajew est la méthode de synthèse plus efficace pour la possible industrialisation du processus d'époxydation de huiles végétales, qui est une manière conventionnelle bien connue à utiliser comme processus de production commerciale. Ce type d'époxydation utilise l'acide percarboxylique comme transporteur d'oxygène qui est formé in situ dans la phase aqueuse, et ensuite époxyde les groupes insaturés des huiles végétales en groupes époxyde. Cependant, cette méthode présente une réaction secondaire d'ouverture du cycle du groupe époxyde au cours du processus. Donc, les conditions du procédé d'époxydation doivent être optimisées afin de minimiser les réactions d'ouverture de cycle. Des paramètres de réaction, y compris la concentration en catalyseur acide (acide sulfurique), réactifs (eau, groupe époxyde, peroxyde d'hydrogène, acide acétique) et la température de réaction, ont été discutés dans cette étude pour l'époxydation et réaction d'ouverture de cycle des huiles végétales. Au cours de la modélisation cinétique, les constantes cinétiques associées pour les réactions d'ouverture du cycle ont été estimées. En se basant sur ce modèle, les réactions d'ouverture du cycle époxyde par les acides acétique et peracétique sont plus rapides que celles de l'eau et du peroxyde d'hydrogène. Un réacteur en mode semi-fermé, avec addition du peroxyde d'hydrogène et de l'acide sulfurique, est la configuration la plus appropriée pour la production d'huiles végétales époxydées.

Pour déterminer les conditions optimales et passer à échelle industrielle dans les procédés d'époxydation et de la carbonatation, il faut connaître différentes propriétés physicochimiques

telles que la viscosité, la densité, l'indice de réfraction, la capacité thermique spécifique et les évolutions de ces données avec la température. Cependant, aucune information sur ces propriétés est disponible dans la littérature. Pour cette étude, l'évolution de ces propriétés ont été déterminées pour trois huiles végétales et leurs dérivés époxydés et carbonates (l'huile de coton, l'huile de lin et l'huile de soja) avec la température et leur composition. La densité et l'indice de réfraction ont été trouvés linéairement dépendants de la température pour les huiles étudiées. La relation entre la contrainte de cisaillement et le taux de cisaillement dans l'étude de viscosité, indique que ces huiles sont des fluides newtoniens. Il a été démontré que la capacité thermique spécifique suit une équation polynomiale du second ordre avec la température.

Sur la base de ces résultats, il a été démontré que certaines corrélations pourraient être utilisées pour prédire les évolutions de ces propriétés physicochimiques à différentes compositions et températures.

Carbonation de l'huile végétale époxydée est une méthode prometteuse pour préparer des polyols biosourcés et ensuite appliquée à la production de polyuréthane par méthode non-isocyanate. Pour promouvoir l'utilisation de ces matières premières dans l'industrie, les données cinétiques et thermodynamiques sont nécessaires pour une meilleure intégration énergétique et une optimisation des coûts. Une étude cinétique de la carbonatation de l'huile de coton époxydée a été menée en présence d'un catalyseur homogène: le bromure de tétran-butylammonium. Des paramètres de réaction comme la température de réaction (110-140 °C), la pression de réaction (20-50 bars), la concentration de catalyseur (0.06- 0.30 mol.L<sup>-1</sup>) et d'époxydes (1.67-3.80 mol.L<sup>-1</sup>) ont été étudiés. Un modèle cinétique a été proposé. La constante cinétique et l'énergie d'activation ont été estimées. La fiabilité des paramètres cinétiques a ensuite été vérifiée en utilisant la méthode de Monte Carlo à chaîne de Markov.

Afin d'étudier la corrélation entre la réactivité d'huile végétale et sa forme estérifiée par le méthanol, nous avons comparé la réactivité de carbonatation de l'huile de coton époxydée et de son ester méthylique d'acide gras époxydé. Transfert de masse et propriétés physicochimiques de ces réactions ont été déterminés, et ensuite, appliqués pour estimer les constantes cinétiques intrinsèques pendant la phase de modélisation cinétique. L'ester méthylique d'acide gras époxydé s'est avéré avoir une réactivité de carbonatation supérieure à celle de l'huile végétale époxydée. La constante de vitesse de carbonatation de l'ester

méthylque d'acide gras a été estimé à 1.4 fois plus grande que celle de l'huile de coton époxydée. Une relation linéaire a été trouvée entre la constante de vitesse de carbonatation de l'huile végétale époxydée et de son ester méthylque d'acide gras avec la température.

Un bref résumé de la stratégie de recherche est donné dans le diagramme ci-dessous.

## LIST OF PUBLICATIONS

The thesis consists of the following publications, which are referred in the doctor thesis.

## 1. Introduction

Dans la première section de ce travail, des études cinétiques de l'époxydation et d'ouverture du cycle oxirane ont été effectués pour optimiser la production d'huile de coton époxydée. L'époxydation d'huile de coton par l'acide peracétique a été étudiée dans un réacteur discontinu. Les constantes cinétiques pour la réaction d'ouverture du cycle oxirane par l'eau, peroxyde d'hydrogène, acide acétique et acide peracétique ont été estimées. Une stratégie adéquate de modélisation pour l'ouverture du cycle oxirane a été bien développé.

Dans la deuxième section, propriétés physicochimiques (viscosité, masse volumique, indice réfraction, capacité calorifique spécifique) ont été mesuré pour trois huiles végétales (huile de soja et de coton et de lin) et des formes modifiées. Des solutions d'huile végétale frais, d'huiles végétales époxydées et d'huiles végétales carbonées ont été synthétisées afin d'évaluer l'effet des groupes de fonctionnel. Il a pu être montré que la masse volumique et l'indice de réfraction de ces huiles varie linéairement avec la température. La viscosité de ces huiles, dont se sont révélés des fluides newtoniens, suit une fonction exponentielle de la température.

Puis, la cinétique de la carbonatation d'huiles végétales époxydées a été exploré afin de déterminer l'effet des différents paramètres de la réaction, comme la pression, la température et la concentration du groupe époxyde. En plus, un modèle cinétique, y compris le transfert massique pour le carbonatation d'huiles végétales époxydées, a été construit.

Dénièrent, des huiles végétales et leurs ester méthylique ont été sélectionnée comme sujet de recherche pour faire une enquête de la relation entre la structure et la réactivité chimique dans des réactions de carbonatation. La relation entre les constantes cinétiques de deux substances différents en structure dans la réaction de carbonatation ont estimées en tenant en compte les propriétés physicochimiques et les paramètres de transfert de masse.

## 2. Objectif

Cette thèse doctorale est centrée sur les réactions d'époxydation et carbonatation des huiles végétales. L'objectif de ce travail a été divisé en quatre parties:

- 1) Une étude cinétique de l'époxydation et l'ouverture du cycle oxirane d'huile végétale;
- 2) Une enquête préliminaire sur les propriétés physicochimiques des huiles végétales (huile de soja, de coton et de lin) et leurs formes modifiées (huiles végétales époxydées et carbonnées).

- 3) Une étude cinétique de la carbonatation des huiles végétales époxydées avec un catalyseur homogène, à savoir bromure de tétra-n-butylammonium (TBABr);
- 4) Une étude de la relation entre la structure et la réactivité chimique dans la réaction de carbonatation des huiles végétales et leurs ester méthylique.

### **3. Résultats et Discussion**

#### **3.1 Influence des réactions d'ouverture du cycle oxirane sur les cinétiques de l'époxydation d'huile de de coton biologique**

L'époxydation d'huile de coton par l'acide peracétique a été étudiée dans un réacteur discontinu. En développant une stratégie de modélisation appropriée, les constantes cinétiques pour la réaction d'ouverture du cycle oxirane par l'eau, peroxyde d'hydrogène, acide acétique et acide peracétique ont été estimées. Le principal objectif de ce travail est de minimiser les réactions secondaires à réaction d'ouverture du cycle oxirane, pour trouver la configuration du réacteur qui convient le mieux. Le présent travail fournit une base pour l'optimisation de technique du traitement d'époxydes à l'avenir.

Ce chapitre est divisé en trois parties: étude cinétique pour l'ouverture du cycle oxirane, modélisation cinétique et la discussion du les distributions de produits d'ouverture du cycle oxirane.

##### **3.1.1 Expériences d'étude cinétique**

Dans cette rubrique, les effets des concentrations d'acide sulfurique, le peroxyde d'hydrogène, acide acétique et acide peracétique ont été enquêté sur la cinétique de la réaction d'ouverture du cycle oxirane. On pourrait conclure:

(1) L'influence de concentration d'acide sulfurique sur la réaction d'ouverture du cycle oxirane implique que la cinétique est plus rapide quand la concentration d'acide sulfurique augmente.

(2) L'influence de concentration du peroxyde d'hydrogène sur la réaction d'ouverture du cycle oxirane suggère que la cinétique augmente légèrement avec la concentration du peroxyde d'hydrogène.

(3) L'influence de concentration d'acide acétique sur la réaction d'ouverture du cycle oxirane suggère que la cinétique accélère quand la concentration d'acide acétique augmente.

##### **3.1.2 Modélisation cinétique**

La section comporte quatre parties: la détermination des coefficients de distribution, la cinétique de différentes réactions, stratégie de bilan de masse et de la modélisation cinétique.

## (1) Détermination des coefficients de distribution

Le Tableau 1 présente le coefficient de distribution calculé d'acide acétique avec différentes concentrations en double liaison, groupes époxyde et produits d'ouverture du cycle oxirane.

Table 1. Coefficient de distribution calculé d'acide acétique  $K_{AA}$

T (°C)	Concentration [mol.L <sup>-1</sup> ]			Acide acétique [mol.L <sup>-1</sup> ]		$K_{AA}$
	[DB] <sub>org</sub>	[Ep] <sub>org</sub>	[RO] <sub>org</sub>	[AA] <sub>org</sub>	[AA] <sub>aq</sub>	
60	4.00	0.00	0.00	0.408	6.048	14.83
50	4.00	0.00	0.00	0.420	6.233	14.83
60	2.33	1.27	0.40	0.507	6.513	12.83
60	2.00	2.00	0.00	0.613	6.730	10.99

Les coefficients de distribution dépendent fondamentalement de la concentration d'époxyde, de double liaison et d'ouverture du cycle oxirane, qui est souvent décrite comme:

$$K_{AA} = A \times [Ep]_{org}^2 + B \times [DB]_{org} + C \times [RO]_{org} \quad (3)$$

Selon le coefficient de distribution calculé d'acide acétique avec différentes concentrations en double liaison, groupes époxyde et produits d'ouverture du cycle oxirane, les valeurs d'A, B et C sont estimés, respectivement, à 0.8938, 3.7075 et 6.875.

Selon Wu et al. (Wu Zhenyu et al., 2016), l'acide performique a été constaté d'être trois fois plus soluble que l'acide formique dans l'époxydation de l'huile de soja. Par analogie, la même logique s'applique pour l'acide acétique et acide performique dans cette étude, donc,  $K_{PAA}=0.33 \times K_{AA}$ .

## (2) Cinétiques de la réaction d'ouverture du cycle oxirane

les taux de la réaction d'ouverture du cycle oxirane par différents nucléophiles sont calculée comme suit :

$$R_{RO \text{ by } AA} = k'_{RO \text{ by } AA} \times [Ep]_{org} \times \frac{[AA]_{aq}}{K_{AA}} \times \frac{[H_3O^+]_{aq}}{[H_2O]_{aq}} \quad (4)$$

$$R_{RO \text{ by } PAA} = k'_{RO \text{ by } PAA} \times [Ep]_{org} \times \frac{[PAA]_{aq}}{K_{PAA}} \times \frac{[H_3O^+]_{aq}}{[H_2O]_{aq}} \quad (5)$$

$$R_{RO \text{ by } W} = k'_{RO \text{ by } W} \times [Ep]_{org} \times [H_3O^+]_{aq} \quad (6)$$

$$R_{RO \text{ by } HP} = k'_{RO \text{ by } HP} \times [Ep]_{org} \cdot [H_2O_2]_{aq} \times \frac{[H_3O^+]_{aq}}{[H_2O]_{aq}} \quad (7)$$

ici que,  $k'_{RO \text{ by AA}}, k'_{RO \text{ by PAA}}, k'_{RO \text{ by W}}$  et  $k'_{RO \text{ by HP}}$  sont égaux à  $\frac{k_{+1}}{k_{-1}} \cdot \frac{K_{H_2O}}{K_{H_3O^+}}, \frac{k_{+1}}{k_{-1}} \cdot \frac{K_{H_2O}}{K_{H_3O^+}},$   
 $\frac{k_{+1}}{k_{-1}} \cdot \frac{K_{H_2O}}{K_{H_3O^+}} \cdot \frac{1}{K_W}$  et  $\frac{k_{+1}}{k_{-1}} \cdot \frac{K_{H_2O}}{K_{H_3O^+}} \cdot \frac{1}{K_{HP}},$  respectivement.

Selon Leveueur et al. (Leveueur et al., 2008), la concentration d'ions d'hydroxonium peut être estimée à partir des concentrations d'acide acétique et d'acide sulfurique, comme :

$$[H_3O^+]_{aq} = \frac{1}{2} \times [H_2SO_4]_{aq} + \sqrt{\frac{[H_2SO_4]_{aq}^2}{4} + 2 \times K_{II}^C \times [H_2SO_4]_{aq} \times [W]_{aq} + K_{AA-diss.}^C \times [AA]_{aq} \times [W]_{aq}} \quad (8)$$

ici que,  $K_{II}^C$  est la deuxième dissociation de l'acide sulfurique (Knopf et al., 2003) and  $K_{AA-diss.}^C$  est la dissociation de l'acide acétique (Sue et al., 2004).

### (3) Bilan de masse

Si on suppose que le transfert de masse est très rapide par rapport à la réaction chimique, le bilan de masse de composés en phase aqueuse (acide acétique, peroxyde d'hydrogène, acide peracétique et eau) et en phase organique (double liaison, groupes époxyde et groupes d'ouverture du cycle oxirane) est défini comme :

En phase aqueuse,

$$\frac{d[AA]_{aq}}{dt} = \left( \alpha + \frac{1-\alpha}{K_{AA}} \right)^{-1} \times \left( -\alpha \times R_{Perh} + (1-\alpha) \times (R_{Ep} - R_{RO \text{ by AA}}) \right) \quad (9)$$

$$\frac{d[HP]_{aq}}{dt} = -R_{Perh} - \frac{(1-\alpha)}{\alpha} \times R_{RO \text{ by HP}} \quad (10)$$

$$\frac{d[PAA]_{aq}}{dt} = \left( \alpha + \frac{1-\alpha}{K_{PAA}} \right)^{-1} \times \left( \alpha \cdot R_{Perh} + (1-\alpha) \times (-R_{Ep} - R_{RO \text{ by PAA}}) \right) \quad (11)$$

$$\frac{d[H_2O]_{aq}}{dt} = R_{Perh} - \frac{(1-\alpha)}{\alpha} \times R_{RO \text{ by H}_2O} \quad (12)$$

En phase organique,

$$\frac{d[DB]_{org}}{dt} = -R_{Ep} \quad (13)$$

$$\frac{d[Ep]_{org}}{dt} = R_{Ep} - R_{RO \text{ by HP}} - R_{RO \text{ by W}} - R_{RO \text{ by AA}} - R_{RO \text{ by PAA}} \quad (14)$$

$$\frac{d[RO]_{org}}{dt} = R_{RO \text{ by HP}} + R_{RO \text{ by W}} + R_{RO \text{ by AA}} + R_{RO \text{ by PAA}} \quad (15)$$

#### (4) Modélisation cinétique et stratégie

Sur la base de cette étude cinétique, dix constantes cinétiques ont été estimées pour la réaction d'ouverture du cycle oxirane ; les constantes cinétiques de l'ouverture du cycle oxirane par l'eau ( $k'_{RO \text{ by } W}$  &  $Ea'_{RO \text{ by } W}$ ), la constante cinétique de l'ouverture du cycle oxirane par le peroxyde d'hydrogène ( $k'_{RO \text{ by } HP}$  &  $Ea'_{RO \text{ by } HP}$ ), la constante cinétique de l'ouverture du cycle oxirane par l'acide acétique ( $k'_{RO \text{ by } AA}$  &  $Ea'_{RO \text{ by } AA}$ ), la constante cinétique de l'ouverture du cycle oxirane par l'acide peracétique ( $k'_{RO \text{ by } PAA}$  &  $Ea'_{RO \text{ by } PAA}$ ) et la constante cinétique de l'époxydation par l'acide peracétique ( $k'_{Ep}$  &  $Ea'_{Ep}$ ). Figure 3 montre une stratégie de la modélisation cinétique. Tableau 2 est la matrice de corrélation pour tous les constantes cinétiques de l'époxydation à  $T_{ref} = 330 \text{ K}$ .

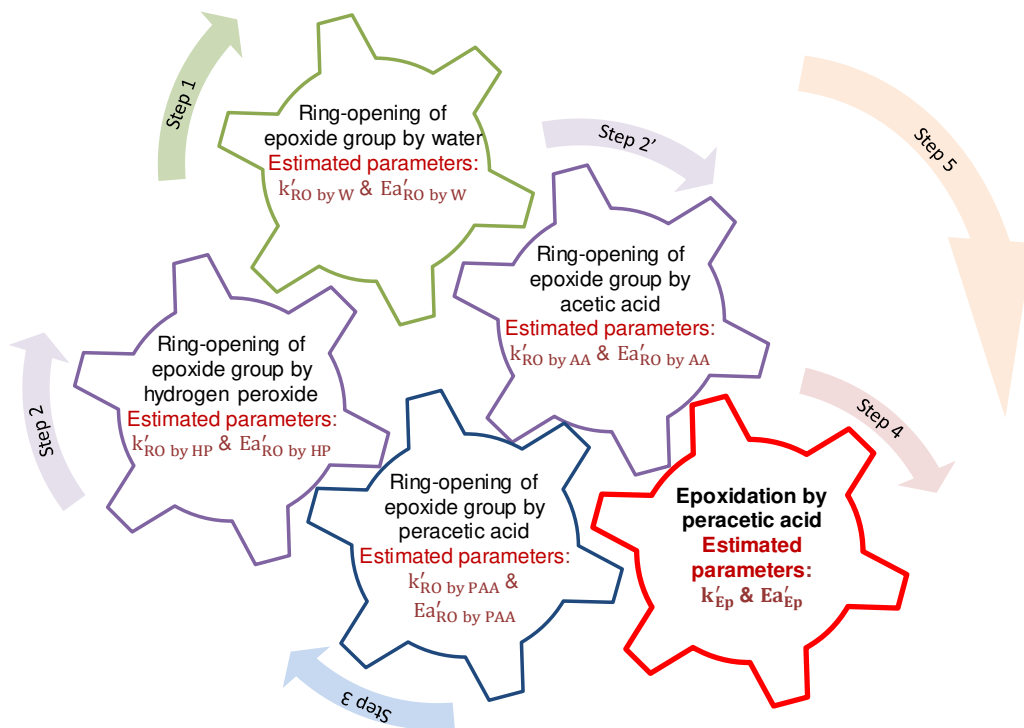

Figure 3. Stratégie de la modélisation cinétique.

Table 2. Constantes cinétiques estimées et données statistiques de l'époxydation de Tref = 330 K.

		Paramètres estimés	Erreur type (%)
$k'_{RO \text{ by } W}$	[L.mol <sup>-1</sup> .s <sup>-1</sup> ]	9.10E-06	19
$Ea'_{RO \text{ by } W}$	[kJ.mol <sup>-1</sup> ]	75200	19.9
$k'_{RO \text{ by } HP}$	[L.mol <sup>-1</sup> .s <sup>-1</sup> ]	1.10E-04	27.9
$Ea'_{RO \text{ by } HP}$	[kJ.mol <sup>-1</sup> ]	104000	22
$k'_{RO \text{ by } AA}$	[L.mol <sup>-1</sup> .s <sup>-1</sup> ]	3.69E-03	9
$Ea'_{RO \text{ by } AA}$	[kJ.mol <sup>-1</sup> ]	53400	20.6
$k'_{RO \text{ by } PAA}$	[L.mol <sup>-1</sup> .s <sup>-1</sup> ]	1.51E-02	11.4
$Ea'_{RO \text{ by } PAA}$	[kJ.mol <sup>-1</sup> ]	51400	26.2
$k'_{Ep}$	[L.mol <sup>-1</sup> .s <sup>-1</sup> ]	3.97E-03	10.2
$Ea'_{Ep}$	[kJ.mol <sup>-1</sup> ]	84200	7.9

En general, les corrélations entre les constantes cinétiques sont négligeables. Toutefois, les corrélations entre les constantes cinétiques de l'ouverture du cycle oxirane par l'eau et le peroxyde d'hydrogène ( $k'_{RO \text{ by } W}$  &  $Ea'_{RO \text{ by } W}$  and  $k'_{RO \text{ by } HP}$  &  $Ea'_{RO \text{ by } HP}$ ) sont élevés. Cette étroite corrélation signifie que la cinétique de l'ouverture du cycle oxirane par ces nucléophiles est plus complexe. Dans le modèle, nous avons supposé que le transfert en masse est rapide, qui pourrait ne pas être le cas pour ces deux molécules.

Afin de déterminer la configuration la plus adaptée pour minimiser les produits de l'ouverture du cycle oxirane. Différentes configurations ont été testées: réacteur discontinu (Batch), réacteur semibatch où le peroxyde d'hydrogène (SemiBatch HP), l'acide acétique (SemiBatch AA), l'acide acétique et l'acide sulfurique sont ajoutées (SemiBatch AA SA), le peroxyde d'hydrogène et l'acide sulfurique (SemiBatch HP SA) sont ajoutées séparément. Selon les constantes cinétiques estimées lors de l'étape de modélisation, la concentration maximale du groupe époxyde, le temps associé ( $t_{max}$ ), et les distributions de produits de l'ouverture du cycle oxirane à cette durée ont été déterminés pour chaque configuration.

Sur la base du modèle cinétique bien construites, l'ouverture du cycle oxirane par l'acide acétique et l'acide peracétique a été trouvé plus rapide que par l'eau et le peroxyde d'hydrogène. Un réacteur semi batch où le peroxyde d'hydrogène et l'acide sulfurique sont ajoutées, a été désignée la configuration la mieux adaptée.

### **3.2 Interactions entre groupes fonctionnels et propriétés physicochimiques: une application pour huiles végétales et leurs formes modifiées (huiles végétales époxydées et carbonnées)**

L'évolution des différentes propriétés physicochimiques a été examinée, comme l'indice de réfraction, la viscosité dynamique, la masse volumique et la capacité calorifique spécifique des huiles végétales, des huiles végétales époxydées et des huiles végétales carbonnées à différentes températures et concentrations des groupes insaturés, époxydés et carbonnés. Trois types des huiles végétales différents ont été sélectionnés: l'huile de coton, l'huile de lin et l'huile de soja. Afin de prédire l'évolution de ces propriétés à différentes concentrations des groupes fonctionnels, nous avons mesuré les propriétés physicochimiques pour différents mélanges d'huile de soja avec ses produits dérivés (huile de soja époxydées et carbonnées).

#### **3.2.1 Indice de réfraction**

À l'évolution des l'indice de réfraction des huiles végétales différents et de leurs dérivés époxydés et carbonnés, il a suggéré que la valeur de l'indice de réfraction dépendent des concentrations des liaisons doubles, groupes insaturés, époxydés et carbonnés. En effet, l'indice de réfraction d'huile de lin et ses dérivés sont supérieurs à l'huile de coton et l'huile de soja et ses dérivés.

#### **3.2.2 Masse volumique**

La valeur de la masse volumique s'avère être sensible aux concentrations des doubles liaisons, des groupes époxydés et carbonnés. La masse volumique des huiles végétales est inférieure à celle de leur formes époxydées et carbonnées. La masse volumique de l'huile de lin a été trouvée supérieure à celle de l'huile de coton et l'huile de soja à des températures variant entre 283.15 K et 353.15 K. Cette tendance était observée aussi pour l'espèce époxydées.

#### **3.2.3 Viscosité**

Les groupes fonctionnels exercent une forte influence sur les valeurs de viscosité. L'évolution de la viscosité dynamique est dans l'ordre suivant :  $\mu(\text{huile végétale}) < \mu(\text{huile végétale époxydée}) < \mu(\text{huile végétale carbonnée})$  à une même température. À 283.15 K, la viscosité de l'huile de lin est 80 mPa.s si l'on compare avec celui de l'huile de coton (120 mPa.s) et l'huile de soja (100 mPa.s). La viscosité d'huile de lin a été observée inférieure que celle des huiles de soja et de coton. De la même façon, on a pu constater que les valeurs de viscosité augmentent considérablement quand le nombre de groupe carbonate augmente.

#### **3.2.4 Capacité calorifique spécifique**

Selon les résultats trouvés de l'évolution de capacité calorifique spécifique des huiles végétales et leurs formes époxydées et carbonées avec la température. Les valeurs des capacités calorifiques spécifiques ont été constatées les mêmes pour les trois composés à des températures variant entre 313.15 K et 383.15 K. Basé sur la variation du  $C_p$  avec la température, qui peut être décrite par une équation polynomiale de deuxième ordre: (Stoessel, 2008)

$$\frac{C_p(T)}{C_p(T_{ref})} = A \times T^2 + B \times T + C \quad (16)$$

ici que,  $T$  est la température;  $T_{ref}$  est la température de référence en Kelvin. Les coefficients A, B et C sont constants. Pour cette étude, la température de référence est 313.15 K.

Les valeurs des coefficients A, B et C pour les huiles végétales ont été estimées, comme il est indiqué au tableau 3. Le coefficient de détermination est plus élevé de 95% ce qui assure la fiabilité de cette étude.

Table 3. L'évolution des coefficients d'A, B et C de Eq. (16) pour les huiles végétales et de leurs dérivés

	$C_p(T) / C_p(T_{ref}=313.15 \text{ K}) = AT^2 + BT + C$		
	A / K <sup>-2</sup> × 10 <sup>-6</sup>	B / K <sup>-1</sup>	C

ELSO	-10.00	0.0091	-0.6965
CLSO	-4.00	0.0043	0.0688

### 3.2.5 Effets de groupes fonctionnels sur les propriétés physico-chimiques

Afin de voir s'il est possible de prédire l'évolution de ces paramètres à différentes concentrations des liaisons doubles, des groupes époxydés et carbonés, nous avons utilisé des solutions mixtes d'huile végétale fraîche, huile végétale époxydée et des huiles végétales carbonées. L'huile de soja et ses formes modifiées ont été fixées comme l'objet de la recherche. Le Tableau 4 indique trois solutions différentes utilisées pour ces expériences.

Tableau 4. Composants de solutions

Solution	Pourcentage de poids w (% fraction massique)		
	SBO	ESBO	CSBO
S1	49.80	50.20	0.00
S2	19.78	19.98	60.24
S3	39.12	31.41	29.47

Les corrélations suivantes sont testées:

$$RI(SX) = w(SBO) \times RI(SBO) + w(ESBO) \times RI(ESBO) + w(CSBO) \times RI(CSBO) \quad (17)$$

$$\rho(SX) = w(SBO) \times \rho(SBO) + w(ESBO) \times \rho(ESBO) + w(CSBO) \times \rho(CSBO) \quad (18)$$

$$\ln\mu(SX) = w(SBO) \times \ln\mu(SBO) + w(ESBO) \times \ln\mu(ESBO) + w(CSBO) \times \ln\mu(CSBO) \quad (19)$$

$$Cp(SX) = w(SBO) \times Cp(SBO) + w(ESBO) \times Cp(ESBO) + w(CSBO) \times Cp(CSBO) \quad (20)$$

ici que, SX est le solution de S1, S2 ou S3.

Les figures 4-7 présentent des exemples de validation des corrélations 17-18 pour l'indice de réfraction (RI), la masse volumique ( $\rho$ ), le logarithme de la viscosité ( $\ln\mu$ ) et la capacité calorifique spécifique (Cp) des différentes solutions de S1, S2 et S3.

•, Données expérimentales; —, Données du modèle.

Figure 7. Ajustement du modèle aux données expérimentales sur la capacité calorifique spécifique de solution S2. •, Données expérimentales; —, Données du modèle.

Selon l'ajustement de la corrélation entre les données expérimentales et les données du modèle d'indice de réfraction ( $n$ ), de la masse volumique( $\rho$ ), du logarithme de la viscosité ( $\ln\mu$ ) et de la capacité calorifique spécifique ( $C_p$ ) sur les différentes solutions S1, S2 et S3, on a pu remarquer que

les données expérimentales (l'indice de réfraction, la densité et la capacité calorifique spécifique) peuvent être précitées fructueusement avec une valeur moyenne globale de l'erreur relative statistique inférieure à 2.5 %. Cependant, la valeur moyenne globale de l'erreur relative statistique de  $\ln\mu$  est supérieur dû au fait que Eq. (19) ne prend pas en compte l'interaction entre les groupes fonctionnels.

### **3.3 Carbonation des huiles végétales époxydées**

Dans cette section, un modèle cinétique de la réaction de carbonatation d'huile de coton époxydée catalysée par TBABr a été proposée. Dans un système de gaz-liquide, il convient de prendre en considération le transfert de masse.

Dans un premier temps, un modèle de transfert massique a été construit afin de pouvoir prédire l'évolution des coefficients de transfert massique volumétrique, des coefficients de Henry, l'avancement de réaction et la température. Ensuite, un modèle cinétique a été proposée à différents niveaux de température, de catalyseur, de concentrations des groupes époxyde et de pression du CO<sub>2</sub>.

#### **3.3.1 Étude cinétique de réaction carbonatation**

L'influence de la pression du CO<sub>2</sub> (20-50bar), la température (110-140°C), la concentration initiale de groupes époxyde (1.67-3.80 mol.L<sup>-1</sup>) et la concentration en catalyseur (0.06-0.3 mol.L<sup>-1</sup>) sur la cinétique de la carbonatation ont été examinées. Les expériences ont été conduites dans des conditions isobarique et isotherme.

##### **(1) Effets de la pression du CO<sub>2</sub>**

La figure 8 montre l'influence de la pression du CO<sub>2</sub> sur la conversion des groupes époxyde à 120 °C. La présence d'une période d'induction est observée lorsque la pression est moins de 30 bar. Ce phénomène avait été observés par North et Pasquale (North and Pasquale, 2009) durant la réaction carbonatation d'oxyde de styrène avec TBABr. Cependant, ils ont remarqué cette période d'induction à basses concentrations de TBABr.

Figure 8. Effets de la pression du CO<sub>2</sub> sur la cinétique de carbonatation à 120°C, [TBABr] = 0.13 mol.L<sup>-1</sup>, [ECSO]<sub>0</sub> = 3.4-3.5 mol.L<sup>-1</sup> et une vitesse de rotation de 500 rpm

(2) Effets de température

La figure 9 montre l'influence de la température sur la cinétique de carbonatation. Comme prévu, le taux de réaction augmente avec la température.

Figure 9. Effets de température sur la cinétique de carbonatation à une concentration de [TBABr] = 0.13 mol.L<sup>-1</sup>, de [ECSO]<sub>0</sub> = 3.4-3.5 mol.L<sup>-1</sup>, 50 bar et une vitesse de rotation de 500 rpm

### (3) Effets de la concentration initiale de groupes époxyde

Figure 10. Effets de la concentration initiale de groupes époxyde de ECSO sur la cinétique de carbonatation à la concentration de [TBABr] à  $0.13 \text{ mol.L}^{-1}$ ,  $110 \text{ }^\circ\text{C}$  et une vitesse de rotation de 500 rpm

La figure 10 révèle l'influence de la concentration initiale des groupes époxyde de ECSO à 47 bar et à  $110 \text{ }^\circ\text{C}$ . Pour faire varier la concentration des groupes époxyde, l'huile pure de coton a été mélangé avec ECSO à différents taux. Lorsque la concentration de ECSO est entre  $2.47$  et  $3.40 \text{ mol.L}^{-1}$ , le comportement cinétique est similaire. Cependant, la cinétique de carbonatation est plus rapide lorsque la concentration de ECSO est à  $1.72 \text{ mol.L}^{-1}$ .

#### (4) Effets de la concentration de catalyseur

Figure 11. Effets de la concentration de catalyseur sur la cinétique de carbonatation à la concentration de  $[ECSO]_0$  à 3.2-3.4 mol.L<sup>-1</sup>, 50 bar, 140 °C et une vitesse de rotation de 500 rpm

La figure 11 montre l'influence de la concentration de catalyseur sur la cinétique de carbonatation à 48 bar. Quand la concentration de catalyseur augmente, la vitesse de réaction s'améliore. L'association de catalyseur dans le groupe oxirane comprend plusieurs étapes qui affectent l'ordre de réaction.

En traçant le logarithme de la vitesse initiale de réaction du ( $\ln(R_{Carbonatation,0})$ ) versus le logarithme de la concentration de catalyseur (Figure 11),

La figure 12 montre que l'ordre de réaction par rapport au catalyseur est probablement égal à 0.5. Le paramètre  $n$  a été estimé lors de la modélisation cinétique dans le but de valider l'observation.

Sur la base des expériences cinétiques, on peut remarquer que la pression du CO<sub>2</sub>, les groupes époxydés et la concentration de TBABr, ainsi que la température de réaction jouent un rôle important sur la cinétique de réaction.

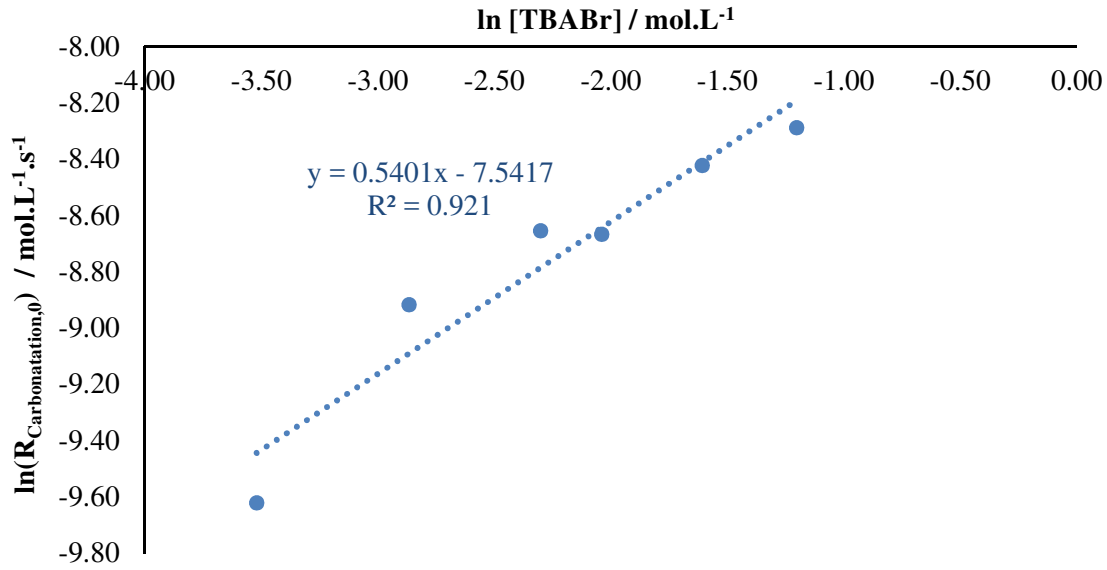

Figure 12.  $\ln(R_{\text{Carbonatation},0})$  versus  $\ln([\text{TBABr}])$  à la concentration de  $[\text{ECSO}]_0 = 3.2\text{-}3.4 \text{ mol.L}^{-1}$ , 50 bar, 140 °C et une vitesse de rotation de 500 rpm

### 3.3.2 Étude de transfert massique de $\text{CO}_2$

Un des objectifs de cette section est la détermination des coefficients de transfert massique entre les phases gazeux et liquide, ainsi comme la solubilité du  $\text{CO}_2$  dans le mélange de réaction. Il est important aussi de vérifier Les variations de ces paramètres en fonction de conversion.

#### (1) Effets de la pression du $\text{CO}_2$

Figure 13. Effet de la pression du  $\text{CO}_2$  sur l'absorption cinétique du  $\text{CO}_2$  dans la solution ECSO à 130 °C et une vitesse de rotation de 500 rpm

La figure 13 présente l'évolution du nombre de moles du CO<sub>2</sub> dans la phase à 130 °C. On a observé qu'à mesure que la pression de CO<sub>2</sub> augmente, la cinétique de carbonatation devient plus rapide.

## (2) Effet de la température

Lorsque la température du liquide augmente, l'absorption du CO<sub>2</sub> est plus rapide mais le nombre de moles du CO<sub>2</sub> absorbé est inférieur (Figure 14).

Pendant la réaction de carbonatation, le transfert massique de CO<sub>2</sub> est affecté par l'évolution de la viscosité du liquide lors de l'augmentation de la concentration de CCSO (Figure 15). Afin de mesurer cette phénomène, une série d'expériences d'absorption du CO<sub>2</sub> a été faite avec CSO, ECSO, CCSO et un mélange de ECSO à 70 wt.% et de CCSO à 30 wt.%.

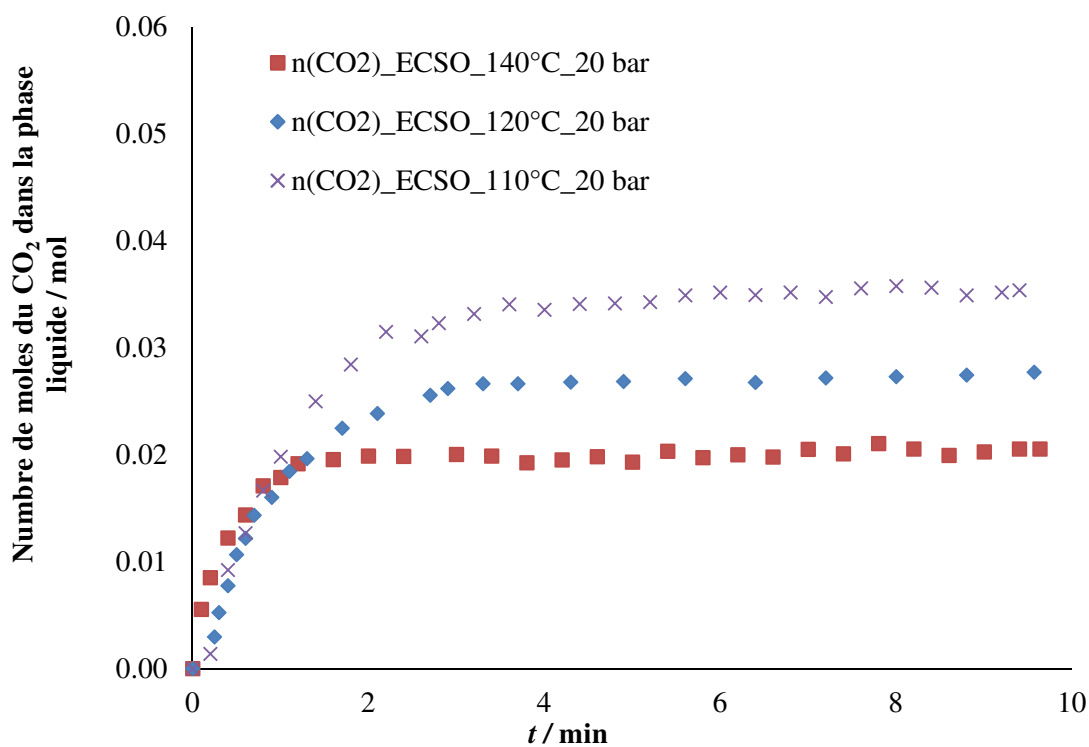

Figure 14. Effet de la température du CO<sub>2</sub> sur l'absorption cinétique du CO<sub>2</sub> dans la solution de ECSO à 20 bar et une vitesse de rotation de 500 rpm

### (3) Effet de les composantes

Figure 15. Effet des composantes sur l'absorption cinétique du CO<sub>2</sub> dans la solution à 20 bar, 120 °C et une vitesse de rotation de 500 rpm

Le figure 15 révèle que l'absorption du CO<sub>2</sub> augmente dans l'ordre suivant: CSO>ECSO> Mélange (70 wt.% ECSO + 30 wt.% CCSO)>CCSO. On peut remarquer que le nombre de moles du CO<sub>2</sub> absorbé dans la phase liquide à l'équilibre augmente dans l'ordre suivant: CSO>CCSO>Mixture>ECSO.

La solubilité de CO<sub>2</sub>  $[CO_2]_{liq}^*$  dans la phase liquide peut être associées à la pression du CO<sub>2</sub> dans la phase gazeuse par le coefficient de Henry ( $He$ ). Ce coefficient dépend des propriétés de la phase liquid et température, et on peut le décrire comme suit:

$$\begin{aligned}
 [CO_2]_{liq}^* &= He_{ECSO} \cdot P_{CO_2} \\
 [CO_2]_{liq}^* &= He_{CCSO} \cdot P_{CO_2} \\
 [CO_2]_{liq}^* &= He_{CSO} \cdot P_{CO_2}
 \end{aligned} \tag{21}$$

ici que,  $He_{ECSO}$ ,  $He_{CCSO}$  et  $He_{CSO}$  représentent les coefficients de Henry pour l'huile de coton époxydée, l'huile de coton carbonnée, et huile de coton pure.

L'évolution de la concentration du CO<sub>2</sub> dans la phase liquide de CSO, ECSO, CCSO suit la loi de Henry à des températures différentes.

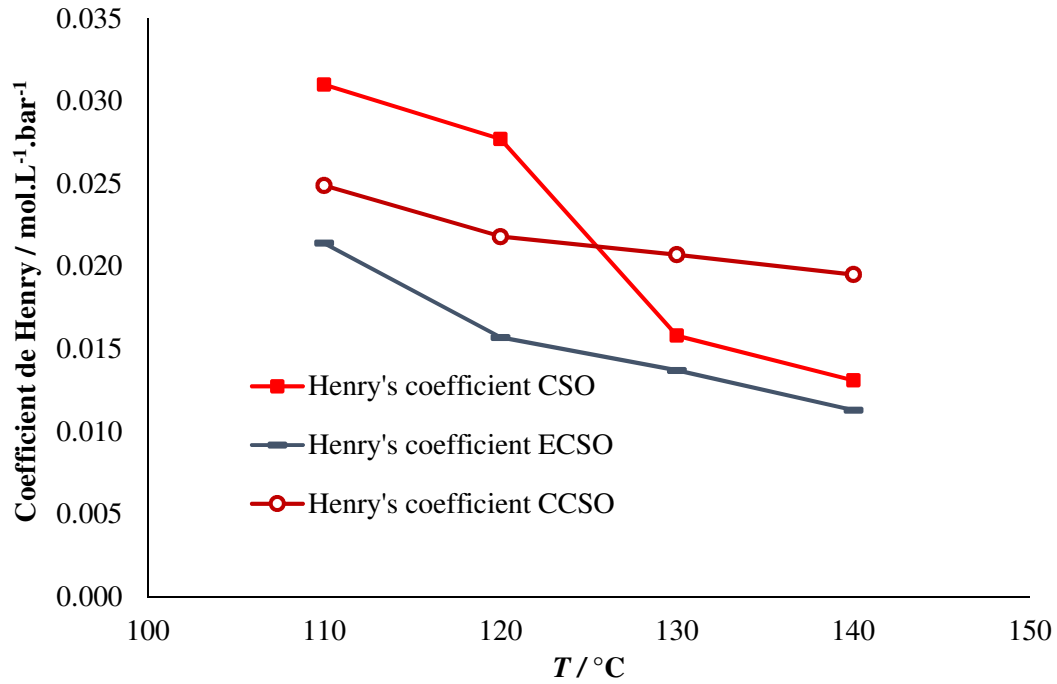

Figure 16. L'évolution de coefficient de Henry versus températures

Le figure 16 montre que la solubilité du CO<sub>2</sub> est plus élevée dans la solution de CSO que la solution de CCSO ou la solution de ECSO à des températures entre 110°C et 120°C. Cependant, à une température supérieure à 130°C, la solubilité du CO<sub>2</sub> augmente dans l'ordre suivant: CCSO>CSO≥ECSO.

En traçant  $\ln\left(\frac{He_{CCSO}(T)}{He_{CCSO}(T_{ref})}\right)$  versus  $\left(\frac{1}{R}\left(\frac{1}{T} - \frac{1}{T_{ref}}\right)\right)$ , il a été vérifié que cette hypothèse est correcte

dans l'intervalle de température expérimentalement.

Figure 17. Courbe de Van't Hoff pour coefficients de Henry de l'huile de coton (CSO), l'huile de coton époxydée (ECSO) et l'huile de coton carbonnée (CCSO)

Le figure 17 montre que la dissolution du CO<sub>2</sub> est plus exothermique dans la solution de CSO ( $\Delta H = -40.406 \text{ kJ.mol}^{-1}$ ) que dans la solution de ECSO ( $\Delta H = -29.03 \text{ kJ.mol}^{-1}$ ) et que dans la solution de CCSO ( $\Delta H = -11.52 \text{ kJ.mol}^{-1}$ ).

#### (4) Modèle du transfert massique

Au cours de l'étape de modélisation du transfert massique, le nombre de moles de CO<sub>2</sub> absorbé dans la phase liquide a été utilisé comme la valeur observable. Les coefficients de transfert massique modifié ( $k_L \cdot a$ ) pour CSO, ECSO et CCSO ont été estimées par une analyse de régression.

L'incertitude du modèle proposé aux données expérimentales est en général satisfaisante. Le coefficient de l'explication dépasse 90%. Le modèle décrit bien les données expérimentales pour l'absorption de CO<sub>2</sub> dans l'huile de coton pure, l'huile de coton époxydée et l'huile de coton carbonnée. Le figures 18 montre un exemple des résultats de la modélisation.

Figure 18. Ajustement du modèle du transfert massique aux observations expérimentales d'absorption du CO<sub>2</sub> dans la phase liquide (huile de coton) à 30 bar, 110 °C et une vitesse de rotation de 500 rpm

Le tableau 5 présente les valeurs estimées pour les coefficients du transfert massique modifié ( $k_L \cdot a$ ). Les erreurs types concernant les paramètres estimés sont inférieures à 2%, ce qui montre la fiabilité du modèle. La matrice de corrélations ne montre pas des corrélations entre les paramètres estimés (Tableau 6).

### 3.3.3 Modèle cinétique

Au cours de l'étape de modélisation cinétique, la concentration du groupe époxydée a été utilisée comme la valeur observable.

Les constantes cinétiques estimées sont le taux constant ( $k_{\text{carbonatation}}$ ) et l'énergie d'activation pour la réaction de carbonatation ( $E_{a_{\text{Carbonatation}}}$ ) et le réaction d'ordre ( $n$ ) sur catalyseur.

Le modèle reproduit les données expérimentales avec efficacité. Le coefficient de l'explication dépasse 95%. Le figure 19 montre que le modèle reproduit les données expérimentales et l'évolution des concentrations du groupe carboné et du CO<sub>2</sub> dans la phase liquide.

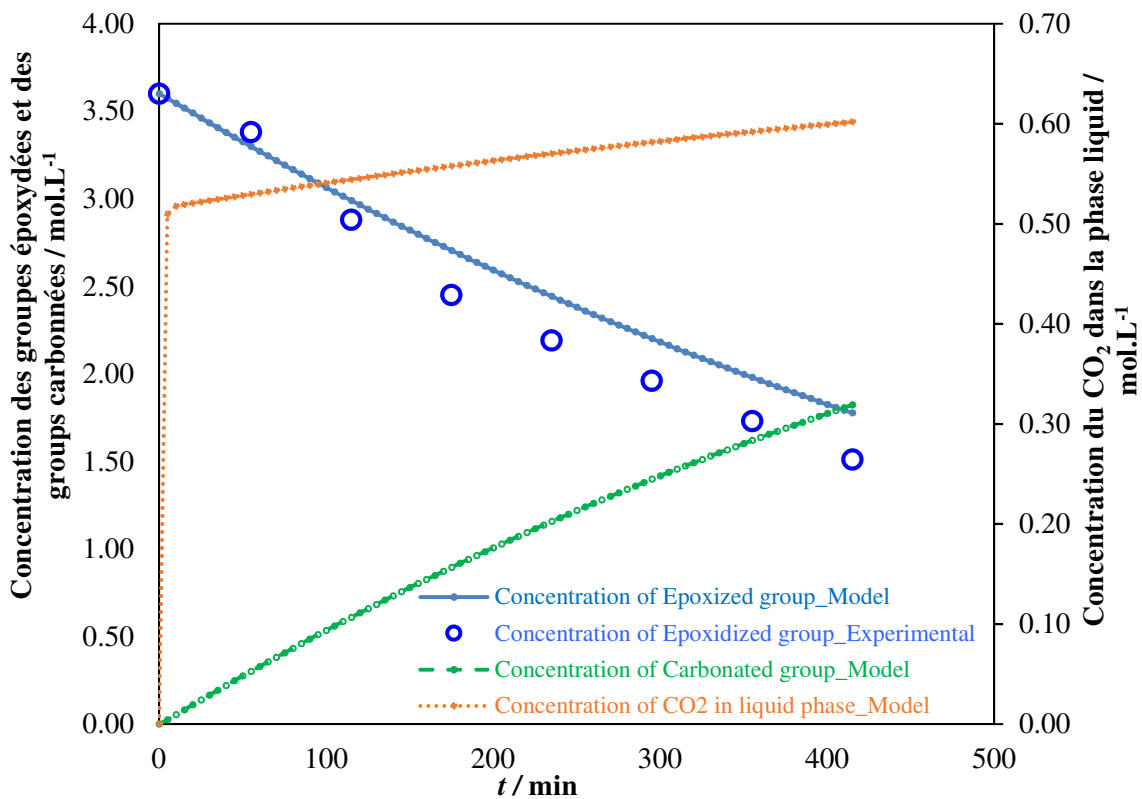

Figure 19. Ajustement du modèle cinétique aux expériences et simulation de l'absorption  $[CO_2]_{liq}$  pour la carbonatation de l'huile de coton époxydée à  $[Ep]$  de  $3.6 \text{ mol.L}^{-1}$ ,  $[TBAB]$  de  $0.13 \text{ mol.L}^{-1}$  et à  $30.6 \text{ bar}$ ,  $120 \text{ }^\circ\text{C}$  et une vitesse de rotation de  $500 \text{ rpm}$

Le Tableau 7 présente les données cinétiques estimées pour la carbonatation de l'huile de coton époxydée. Les écarts-types des constantes de vitesse, d'énergie d'activation et l'ordre de réaction sont inférieur de 20%. Les écarts-types des paramètres cinétiques  $\gamma$  et  $\alpha$  sont relativement élevée. C'est peut-être dû au fait que ces paramètres sont très sensibles à la température.

Tableau 7. Données estimatives et statistiques pour la réaction de carbonatation à  $T_{ref}$  de 403 K

	Estimé	Erreur type	Erreur type %
$k_{Carbonatation}$ [ $L^2 \cdot mol^{-2} \cdot s^{-1}$ ]	1.85E-04	2.94E-05	15.9
$Ea_{Carbonatation}$ [ $J \cdot mol^{-1}$ ]	5.16E+04	3.05E+03	5.9
$n$	5.83E-01	5.19E-02	8.9

$\gamma$ [ $mol \cdot L^{-1}$ ]	8.12E-02	5.02E-02	61.8

Tableau 8 présente la matrice de corrélation pour les paramètres cinétiques. On peut remarquer que les corrélations entre les divers paramètres cinétiques sont d'ordre moyenne. Ceci est dû aux différentes hypothèses formulées.

Tableau 8. Matrice de corrélation

	$k_{Carbonatation}$	$Ea_{Carbonatation}$	$n$	$\alpha$	$\gamma$
$k_{Carbonatation}$	1				
$Ea_{Carbonatation}$	0.56	1			
$n$	0.734	0.196	1		
$\alpha$	0.67	0.603	0.021	1	
$\gamma$	-0.639	-0.561	-0.444	-0.314	1

### 3.4 Structure et réactivité: Comparaison entre l'huiles végétales et esters méthyliques d'huiles végétales

L'objectif de la présente étude est de mesurer l'effet de l'obstacle stérique sur la cinétique de la carbonatation de l'huile de coton, où les centres réactionnels sont situés sur les fragments d'esters méthyliques. A cette fin, une comparaison entre la réactivité de l'huile de coton et ses contreparties des esters méthyliques seront effectués. Afin de mener cette étude, Il est obligatoire de tenir compte des phénomènes de transfert de masse de CO<sub>2</sub> lors du passage d'une phase gazeuse à une phase aqueuse. Ce phénomène est perturbé par les propriétés physico-chimiques du solvant utilisé. La réaction de carbonatation effectuée par avec un catalyseur homogène comme le bromure de tétra-n-butylammonium (TBABr) a été examiné.

#### 3.4.1 Comparaison des propriétés physico-chimiques

##### (1) Comparaison de la masse volumique

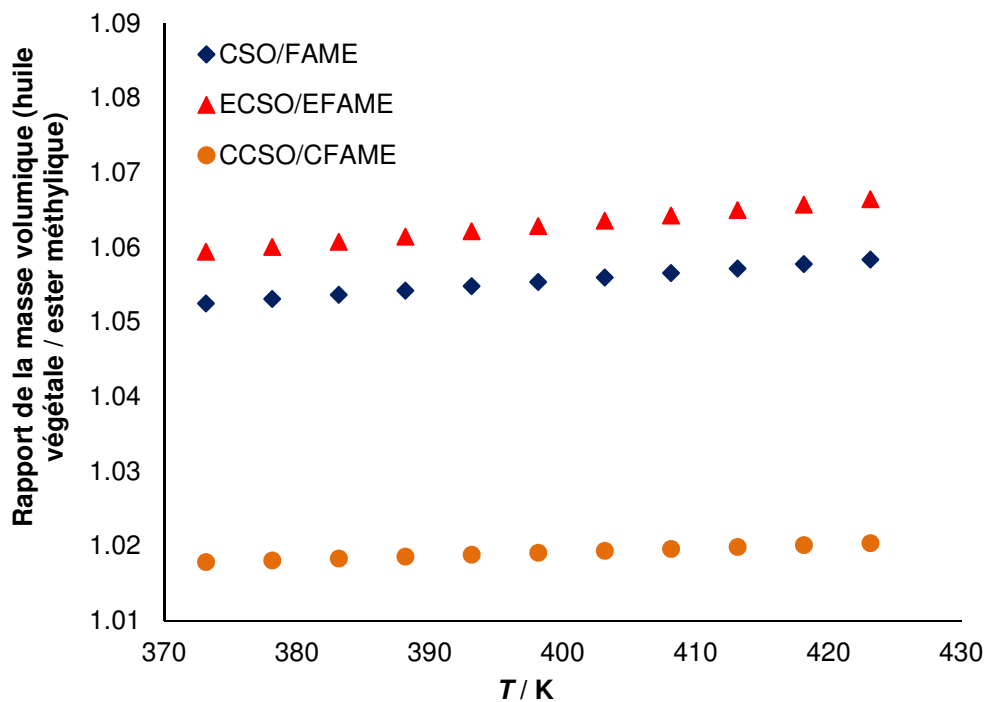

Figure 20. Rapport entre le  $\frac{\rho_{CSO}}{\rho_{FAME}}$ ,  $\frac{\rho_{ECSO}}{\rho_{EFAME}}$  et  $\frac{\rho_{CCSO}}{\rho_{CFAME}}$  en fonction de la température

Figure 20 montre l'évolution des rapports de densité:  $\frac{\rho_{CSO}}{\rho_{FAME}}$ ,  $\frac{\rho_{ECSO}}{\rho_{EFAME}}$  et  $\frac{\rho_{CCSO}}{\rho_{CFAME}}$  en fonction de la

température. Il est remarquable que les rapport de  $\frac{\rho_{CSO}}{\rho_{FAME}}$  et de  $\frac{\rho_{ECSO}}{\rho_{EFAME}}$  sont similaires et sont égaux

à 1.05, tandis que les rapport de  $\frac{\rho_{CCSO}}{\rho_{CFAME}}$  est inférieur et egal à 1.02 a des températures variant entre 100°C et 150°C. Donc, quand le groupe fonctionnel est plus grand, La différence de densité entre l'huile végétale et les esters méthyliques est inférieur.

(2) Comparaison de la viscosité

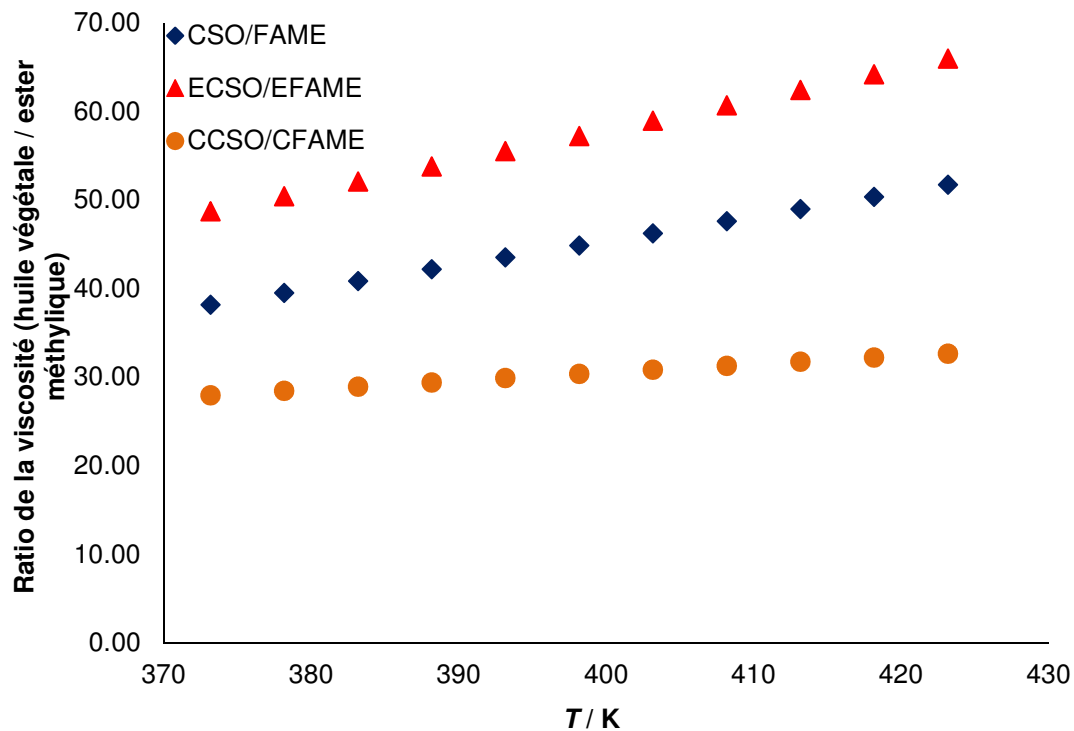

Figure 21. Rapport entre  $\frac{\mu_{CSO}}{\mu_{FAME}}$ ,  $\frac{\mu_{ECSO}}{\mu_{EFAME}}$  et  $\frac{\mu_{CCSO}}{\mu_{CFAME}}$  en fonction de la température

Figure 21 montre l'évolution des rapports de viscosité:  $\frac{\mu_{CSO}}{\mu_{FAME}}$ ,  $\frac{\mu_{ECSO}}{\mu_{EFAME}}$  et  $\frac{\mu_{CCSO}}{\mu_{CFAME}}$  en fonction de la température. À différence de la densité, la différence de viscosité entre l'huile végétale et les esters méthyliques est inférieur est plus prononcé. Nous avons remarqué que les viscosités des l'huile végétale et les esters méthyliques peut être de 20 à 40 fois plus élevée que l'ester méthylique correspondant et ses dérivés. Cette différence illustré le bénéfice d'utiliser l'ester méthylique d'acide gras plutôt que l'huile végétale d'un point de vue de mélange.

### 3.4.2 Comparaison du transfert en masse

Figure 22 montre l'évolution des rapport entre coefficients de Henry:  $\frac{He_{CSO}}{He_{FAME}}$ ,  $\frac{He_{ECSO}}{He_{EFAME}}$  et  $\frac{He_{CCSO}}{He_{CFAME}}$  en fonction de la température. Figure 22 montre que le coefficient de Henry est raisonnable à l'utilisation de CSO/ECSO/CCSO ou FAME/EFAME/CFAME. D'un point de vue thermodynamique, la solubilité du CO<sub>2</sub> dans les dérivés de FAME est plus élevé que les dérivés de CSO, ce qui est à d'avantage cinétique.

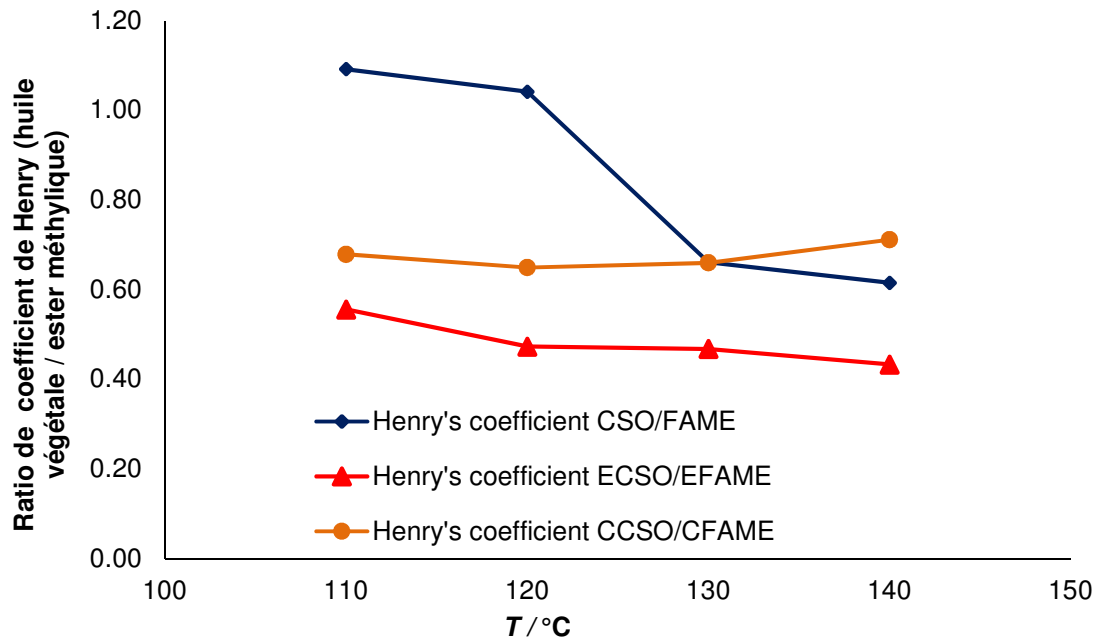

Figure 22. Ratio entre le  $\frac{He_{CSO}}{He_{FAME}}$ ,  $\frac{He_{ECSO}}{He_{EFAME}}$  et  $\frac{He_{CCSO}}{He_{CFAME}}$  en fonction de la température

Les valeurs estimées et leurs erreurs-types sont présentés au tableau 9. On peut voir que leurs erreurs-types sont faibles. Les paramètres de transfert de masse modifiés sont presque les mêmes pour le CFAME et le CCSO, mais ceux des EFAME et FAME sont à 100 fois plus bas que le ECSO et CSO.

Tableau 9. Données statistiques estimés pour les coefficients de transfert de masse modifiés

	Unité	Valeur estimée ( $\times 10^{-6}$ )	Erreur type ( $\times 10^{-8}$ )	Erreur type / %
$(k_L \cdot a)'_{CFAME}$	$\left(\frac{K}{Pa \cdot s}\right)^{-0.5} \cdot \left(\frac{kg \cdot m^{-3}}{Pa \cdot s}\right)^{-0.25} s^{-1}$	1.11	3.0	2.7
$(k_L \cdot a)'_{EFAME}$	$\left(\frac{K}{Pa \cdot s}\right)^{-0.5} \cdot \left(\frac{kg \cdot m^{-3}}{Pa \cdot s}\right)^{-0.25} s^{-1}$	2.59	8.3	3.2
$(k_L \cdot a)'_{FAME}$	$\left(\frac{K}{Pa \cdot s}\right)^{-0.5} \cdot \left(\frac{kg \cdot m^{-3}}{Pa \cdot s}\right)^{-0.25} s^{-1}$	1.14	4.3	3.8

### 3.4.3 Comparaison de cinétiques

Durant l'étape de modélisation cinétique, nous avons estimé la constante de vitesse de la réaction de carbonatation  $k_{\text{carbonatation}}$  et l'énergie d'activation  $E_{\text{carbonatation}}$  pour FAME. La concentration de groupe époxydé a été sélectionné comme la valeur observable.

Figures 23 montre une comparaison entre l'ajustement des modèles cinétique de la carbonatation pour ECSO et EFAME. On peut remarquer que les données d'expérimentation correspondrent très bien aux prévisions des modèles cinétiques. Les deux coefficients explication de la réaction de carbonatation cinétique sont supérieure 95%.

Figure 23. Ajustement des modèles cinétiques de la carbonatation pour ECSO et EFAME à 110°C, 30 bar, à  $[\text{TBABr}]_0$  de  $0.13 \text{ mol.L}^{-1}$  et une vitesse de rotation de 500 rpm

Table 10. Données statistiques estimés à  $T_{\text{ref}}$  de 403 K pour la carbonatation de EFAME

	Valeur estimée	Erreur type	Erreur type %
$(k_{\text{Carbonatation}})_{\text{EFAME}} [\text{L}^2.\text{mol}^{-2}.\text{s}^{-1}]$	$2.57 \times 10^{-4}$	$5.15 \times 10^{-6}$	2.4
$(E_{\text{aCarbonatation}})_{\text{EFAME}} [\text{J}.\text{mol}^{-1}]$	47200	2580	6.4
$(k_{\text{Carbonatation}})_{\text{ECSO}} [\text{L}^2.\text{mol}^{-2}.\text{s}^{-1}]$	$2.07 \times 10^{-4}$	$3.35 \times 10^{-5}$	16.2
$(E_{\text{aCarbonatation}})_{\text{ECSO}} [\text{J}.\text{mol}^{-1}]$	50700	2930	5.8
n	0.584	0.0518	8.9
$\alpha [\text{s}^{-2}]$	0.318	0.0924	29
$\gamma [\text{mol}.\text{L}^{-1}]$	0.078	0.0502	64.3

Le Tableau 10 indique les données cinématiques estimées pour la carbonatation de EFAME. On peut noter que la cinétique de la réaction de carbonatation de EFAME et ECSO sont également du même ordre de grandeur.

Figure 24. La variation de  $\frac{(k_{\text{carbonation}})_{\text{ECSO}}}{(k_{\text{carbonation}})_{\text{EFAME}}}$  en fonction des différentes températures de réaction

Le Figure 24 montre la variation du rapport de constante de vitesse de la réaction de carbonatation de EFAME à différentes températures de réaction. On peut cependant remarquer que il existe une corrélation linéaire entre la ratio de  $\frac{(k_{\text{carbonation}})_{\text{ECSO}}}{(k_{\text{carbonation}})_{\text{EFAME}}}$  et la température. À basses températures, La vitesse de carbonatation de EFAME est à 1.4 fois plus élevée que la vitesse de carbonatation de ECSO, alors que cette différence est plus basse lorsque la température augmente. Donc, on y suggère que il est souvent possible de prévoir la cinétique de la réaction de carbonatation d'huile végétale si les cinétiques de la réaction de carbonatation d'ester méthylique d'acide gras sont connus. Ce résultat montre que l'obstacle stérique joue aussi un rôle lors de la réaction de carbonatation d'huile végétale. Il est possible de trouver la corrélation linéaire entre le rapport de la vitesse de carbonatation et de la température.

#### 4. Conclusion

Cette recherche a été concentrée sur quatre aspects pour la valorisation des huiles végétales:

Premièrement, époxydation cinétiques pour l'époxydation et l'ouverture du cycle oxirane d'huile végétale ont été étudiés dans un réacteur discontinu. En développant une stratégie adaptée de modélisation, les constantes cinétiques ont été estimées pour les réactions de l'ouverture du cycle oxirane par l'eau, le peroxyde d'hydrogène, l'acide peracétique et l'acide acétique. En guise de conclusion, il ressort que l'ouverture du cycle oxirane par l'acide peracétique et l'acide acétique est plus rapide que celles par l'eau, le peroxyde d'hydrogène. Un réacteur semibatch où le peroxyde d'hydrogène et l'acide sulfurique sont constamment ajoutées a été jugé une configuration optimale pour maximiser la concentration du groupe époxyde et réduire la concentration de produits d'ouverture du cycle oxirane.

Deuxièmement, les interactions entre les groupes fonctionnels (double liaison, groupe époxydée et groupe carbonnée) et les propriétés physicochimiques ont été examinées pour les huiles végétales et leurs dérivés époxydés et dérivés carbonnés. L'influence de la température sur les propriétés physicochimiques comme la densité, l'indice de réfraction, la viscosité et la capacité calorifique spécifique ont été discutées. En conclusion, l'indice de réfraction et la densité diminue linéairement lorsque la température augmente. La viscosité de ces huiles est proportionnel à la température. La capacité calorifique spécifique a été jugé relativement constant avec la température. La conversion des groupes époxydés et des groupes carbonnés contribue à une augmentation de la viscosité, ce qui suggère que les composants huileux affecter les paramètres physicochimiques, qui influencent le transfert de masse dans les milieux eau/gaz pendant la réaction de carbonatation. Donc, en s'appuyant sur les évolutions de des composés purs correspondants, les propriétés physicochimiques comme la densité, l'indice de réfraction, la viscosité et la capacité calorifique spécifique des huiles végétales pourrait être prédite.

Ensuite, un modèle de la cinétique pour la carbonatation de l'huile de coton avec un catalyseur homogène du bromure de tétra-n-hexylammonium (TBABr) a été développé. Pendant une étude de cinétique, le phénomène de transfert de masse du  $\text{CO}_2$  a également été pris en compte et l'évolution des paramètres de transfert de masse en fonction de la température et des composants ont été estimées lors d'étape de modélisation pour transfert de masse du  $\text{CO}_2$ . Une expression cinétique pour la carbonatation de l'huile de coton époxydée est dérivé en supposant que la réaction de carbonatation est statique. Les résultats de transfert de masse montrent que la dissolution du  $\text{CO}_2$  est exothermique dans la phase huileuse.

À la dernière étape, une comparaison entre les cinétiques de carbonatation intrinsèques sur l'huile de coton époxydée et les esters méthyliques d'acide gras correspondant a été exécutée avec un catalyseur homogène du bromure de tétra-n-hexylammonium (TBABr). Selon la comparaison des propriétés physicochimiques, on observe une forte influence des groupes fonctionnels (double liaison, groupe époxydée et groupe carbonnée) sur la viscosité, qui est probablement liée à l'obstacle stérique. Les résultats de la comparaison de transfert de masse a démontré que la solubilité du CO<sub>2</sub> dans la phase des dérivés de FAME est plus élevée que des dérivés de CSO, indiquant que le groupe époxyde de FAME époxydée est plus accessible que ceux d'huiles végétales époxydées. Une relation linéaire a été établie entre la constante de vitesse de la réaction de carbonatation d'huile de coton époxydée et de la réaction de carbonatation d'esters méthyliques d'acide gras époxydée. Il suggérerait un moyen possible de prédire la cinétique de la réaction de l'huile végétale sur la cinétique de la réaction d'ester méthylique d'acides gras.

La continuation de cette thèse de doctorat pourraient être: 1) Pour la procédé d'époxydation, une approche fondamentale sont nécessaires pour estimer l'évolution de la période d'induction avant la réaction d'époxydation et la réaction d'ouverture du cycle oxirane; 2) solutions huileuses avec compositions différentes de taux de conversion, qui sont obtenus par la réaction d'époxydation et la réaction de carbonatation, pouvaient être utilisés à la place des solutions mélangées pour examiner l'interaction entre les groupes de fonctions et les propriétés physicochimiques; 3) pour le processus de carbonatation, plus d'huiles végétales

devront être testés de voir si le ratio de  $\frac{(k_{\text{carbonation}})_{\text{EVOs}}}{(k_{\text{carbonation}})_{\text{EFAME}}}$  est toujours semblable.

## Chapter I Literature review

### 1.1 Introduction

Nowadays, due to increasing standards of global environmental awareness, sustainable industrialization based on the renewable resources becomes increasingly popular. It was reported that, 90% of global organic chemicals will come from renewable materials by 2090 (Eissen et al., 2002).

Thus, renewable materials like plant fiber (Ramesh et al., 2017), fat (Alptekin and Canakci, 2010), vegetable oils (Tan and Chow, 2010), wood (Goldstein, 2018), polysaccharides (Kikuchi and Komatsu, 2017) and microspheres (Hossain et al., 2015) are being investigated instead of fossil fuels. Plenty of bio-based products are developed and commercialized, such as alcohols (polyols, glycols, etc.) (Meylan et al., 2015), lubricant (Mikkelsen et al., 2010), stabilizer and plasticizer for polymers (Aresta et al., 2014; Cuéllar-Franca and Azapagic, 2015; Jones et al., 2014; Markewitz et al., 2012; Yang et al., 2012), toughener (Clark et al., 2016), epoxy blends (Cheali et al., 2014) and so on. Among these bio-based green materials, vegetable oils are very popular, due to their huge global feedstock, advantages of renewability, biodegradability, low toxicity and comparably lower cost. During the past decades, these oils have attracted much attention from researchers and chemical industrialists, who have found them to be a renewable source of material for eco-friendly bio-based articles synthesis (Tan and Chow, 2010; Zhang et al., 2017).

Epoxidation and carbonation of vegetable oils were proved to be a good approach to combine biomass and carbon dioxide valorization. Moreover, the capture and utilization of carbon dioxide (CCU) in the chemical field is a promising solution with respect to the global warming issue (Martens et al., 2017). However, to promote the use of vegetable oil and carbon dioxide feedstocks at industrial scale, it is compulsory to gather physicochemical, kinetic and thermodynamic data for better integration and cost optimization.

In this chapter, different species of vegetable oils commonly applied in industry and valorization approaches of carbon dioxide were summarized. It is aimed to give a comprehensive understanding to research background on the application of vegetable oils and valorization of carbon dioxide. Besides, the review mainly focuses on the research advances in epoxidation and carbonation of vegetable oils in terms of chemical structure, preparation, characterization and physicochemical properties.

## 1.2 Vegetable oils

Vegetable oils, known as fats or lipids, are predominantly the mixtures of triglycerides which is the ester derived from glycerol and three fatty acids. Fatty acids can be classified into two species, which are the saturated fatty acids and unsaturated fatty acids. The unsaturated fatty acids consist of monounsaturated fatty acid (myristoleic acid, palmitoleic acid, oleic acid, gadoleic acid, etc.) and polyunsaturated fatty acid (linoleic acid, linolenic acid, stearidonic acid, mead acid, etc.), while the saturated fatty acids comprise of palmitic acid, stearic acid, arachidic acid, behenic acid and lignoceric acid. The majority of vegetable oils are made up of fatty acids with chain length containing more than 16 carbon atoms (Abdullah and Salimon, 2010). Table 1.1 and Table 1.2 present the fatty acid components of vegetable oils which are commonly applied in the industrial areas.

Figure 1.1 General structure of triglyceride of vegetable oil

Vegetable oils are abundant with various resources. Also, advantages of worldwide availability, biodegradability and competitive cost make vegetable oils more attractive. Among all vegetable oils, soybean oil, sunflower oil, rapeseed oil and palm oil are well known as the most common plant oils worldwide, while linseed oil and soybean oil are the most common commercially used oils for chemical industrial productions (Bähr and Mülhaupt, 2012; Fernandes et al., 2018; Fox and Stachowiak, 2007; Saurabh et al., 2011; Sawpan, 2018; Tan and Chow, 2010; Zhang et al., 2017). Furthermore, palm oil was reported to have more benefits than soybean oil for its huge second-world production with competitive price, long shelf life and some other properties (high melting point, slow crystallization properties, oxidation resistance, etc.) (Edem, 2002; Tan and Chow, 2010). However, instead of using edible oils in chemical industry, the non-edible vegetable oils are more attractive alternatives for the future industrial development.

Cottonseed oil refers to the oil extracted from cottonseed kernel. As a by-product of cotton industry, it has around 177 million metric tons of global storages as ending stocks according to the market researchers in 2016/2017 by USDA (United States Department of Agriculture) (USDA, 2010). Also, it is termed as 'heart oil' among the most unsaturated oil, which is composed of more than 70 wt% of unsaturated fatty acid compounds (Dinesh K. Agarwal et al., 2003). The fatty acid components are illustrated in Table 1.1. Thus, it is a promising bio-base material which is potential for chemical structure functionalization and easily accessible and cheap for industrialization.

The advanced oleo-chemistry technologies make it possible by chemically modifying the vegetable oils into polymerizable materials. The modification of vegetable oil can be divided into two distinct ways: the chemical modification of double bonds and the modification of carboxylic acid groups. Double bonds can be modified through epoxidation (Saurabh et al., 2011), metathesis (Meier, 2009), acylation of epoxies (Wu et al., 2018), carbonation (Zheng et al., 2018) or polymerization processes (Pfister et al., 2011), while the fatty acid ester groups can be modified by hydrocracking, saponification or transesterification (Huber and Corma, 2007; Leung et al., 2010). Among these reactions, epoxidation is one of the most significant ones for organic synthesis, since the highly reactive epoxy-containing products formed can also be used as intermediates for other reactions further down the process (acylation of epoxies, carbonation and polymerization processes).

The synthesis approaches and applications of vegetable oils are shown in Figure 1.2 (Behr et al., 2008; Desroches et al., 2014; Rokicki et al., 2015). So far, the potential application of several vegetable oils, like soybean oil, linseed oil, have started to be realized in industrial production (Boyer et al., 2010).

Table 1.1. Chemical structures of mainly fatty acid species

Fatty acid names	IUPAC name <sup>a</sup>	Molecular Formula	Abbreviations <sup>b</sup>
Butanoic acid	Butanoic acid	C <sub>4</sub> H <sub>8</sub> O <sub>2</sub>	4:0
Hexanoic acid	Hexanoic acid	C <sub>6</sub> H <sub>12</sub> O <sub>2</sub>	6:0
Octanoic acid	Octanoic acid	C <sub>8</sub> H <sub>16</sub> O <sub>2</sub>	8:0
Decanoic acid	Decanoic acid	C <sub>10</sub> H <sub>20</sub> O <sub>2</sub>	10:0
Dodecanoic acid	Dodecanoic acid	C <sub>12</sub> H <sub>24</sub> O <sub>2</sub>	12:0
Tetradecanoic acid	Dodecanoic acid	C <sub>14</sub> H <sub>28</sub> O <sub>2</sub>	16:0
Palmitoleic acid	9-Hexadecenoic acid	C <sub>16</sub> H <sub>30</sub> O <sub>2</sub>	16:1
Palmitic acid	Hexadecanoic acid	C <sub>16</sub> H <sub>32</sub> O <sub>2</sub>	16:0
Stearic acid	Octadecanoic acid	C <sub>18</sub> H <sub>36</sub> O <sub>2</sub>	18:0
Dihydroxystearic acid	9,10-Dihydroxystearic acid	C <sub>18</sub> H <sub>36</sub> O <sub>4</sub>	18:0
Oleic acid	9-Octadecanoic acid	C <sub>18</sub> H <sub>34</sub> O <sub>2</sub>	18:1 $\Delta^9$
Ricinoleic acid	12-Hydroxyoctadec-9-enoic acid	C <sub>18</sub> H <sub>34</sub> O <sub>3</sub>	18:1 $\Delta^{12}$
Linoleic acid	9,12-Octadecenoic acid	C <sub>18</sub> H <sub>32</sub> O <sub>2</sub>	18:2 $\Delta^{9,12}$
Linolenic acid	9,12,15-Octadecenoic acid	C <sub>18</sub> H <sub>30</sub> O <sub>2</sub>	18:3 $\Delta^{9,12,15}$
Arachidic acid	Icosanoic acid	C <sub>20</sub> H <sub>40</sub> O <sub>2</sub>	20:0
Paullinic acid	13-Eicosenoic acid	C <sub>20</sub> H <sub>38</sub> O <sub>2</sub>	20:1 $\Delta^{13}$
Erucic acid	13-docosenoic	C <sub>22</sub> H <sub>42</sub> O <sub>2</sub>	22:1 $\Delta^{13}$

<sup>c</sup>Iodine number: the number of grams of iodine consumed by 100g of oil sample.

### 1.3 Biomass and CO<sub>2</sub> valorization

The chemical structure modifications of vegetable oils are effective way to achieve the biomass valorization. Transesterification of vegetable oils (soybean oil, palm oil, cottonseed oil, sunflower oil, rapeseed oil, etc.) is the most promising way to produce biodiesel fuels (Kim et al., 2004; Pinzi et al., 2009; Singh and Singh, 2010). For the production of biodiesel fuels by the transesterification of soybean oil is already industrialized (Fukuda et al., 2001; Körbitz, 1999), and polymerization of vegetable oils, which consists of epoxidation, carbonation and polymerization processes, has been considered as a potential way to produce polyols and polyurethanes (Petrović, 2008). Also, diverse applications from vegetable oil and its epoxidized, carbonated derivatives were made in industry, e.g., epoxidized and carbonated vegetable oils can be used as precursor of lubricant (Panchal et al., 2017) and plasticizer (Thakur et al., 2017), thermoplastic elastomers and thermosetting polymers (Fernandes et al., 2018; Islam et al., 2014).

Carbon dioxide is an example of chemically quite stable waste products. The annual anthropogenic production of CO<sub>2</sub> is 32 Gt, but only 0.2 Gt of CO<sub>2</sub> is used as raw materials in industry (de Haro et al., 2016). The high stability of the carbon dioxide molecule makes its chemical conversion very difficult. How CO<sub>2</sub> should be valorized to be economically and environmentally viable?

Fortunately, carbon dioxide can be used as a reagent in some industrial processes such as production of urea, methanol and inorganic carbonate (Lathi and Mattiasson, 2007). Academic and industrial communities are working on this molecule to turn it into an attractive raw material. Then, it will be possible to develop a circular consumption of CO<sub>2</sub> at industrial scale. The use of CO<sub>2</sub> is well perceived from public (Rodis et al., 2002), and the not-in-my-backyard syndrome could be avoided.

Review articles seem to favor the Carbon Capture and Utilization (CCU) instead of Carbon Capture and Storage (CCS) (Carbonell-Verdu et al., 2016; Jin and Park, 2007; Kolanthai et al., 2015; Rodis et al., 2002; Xia and Larock, 2010). From an economic viewpoint, CCU activities lead to the production of chemicals/fuels which can generate profit. Such business activities could lead to a circular economy based on CO<sub>2</sub>. The only storage of CO<sub>2</sub> in different kinds of reservoir does not generate profit, but the injection of CO<sub>2</sub> to recover oil like in the process of Enhanced Oil Recovery (EOR) might be profitable. From an environmental viewpoint, it is important to store the captured CO<sub>2</sub> for a long-term, CCS technology could overcome this

problem but the risk of leakage is still under debate. The challenge for CCU activity is the development of process with low environmental impact. As noticed by Cuéllar-Franca and Azapagic (Cuéllar-Franca and Azapagic, 2015), CCU technology should privilege the development of materials and products with longer lifetimes, such as polymers (polycarbonate or polyurethane).

The promotion of biomass or/and CO<sub>2</sub> valorization processes involves the knowledge of the kinetics and the thermodynamics of the chemical transformations (Cheali et al., 2014). Indeed, these data are needed for the process design and early conception stages for energy integration and cost evaluation (Souza et al., 2014). Processes based on biomass or CO<sub>2</sub> can be highly energy-demanding, thus one should have a synthetic view on the processes to diminish the energy consumption.

#### **1.4 Epoxidation of vegetable oils**

During the past decades, the use of epoxidized vegetable oils has been popular and more desirable for industrial development (Abdullah and Salimon, 2010; Desroches et al., 2014; Fox and Stachowiak, 2007). They have been widely used in chemical industry, such as plasticizers and stabilizers for environmentally friendly polymers, additives for lubricant, and precursors or intermediates for urethane and so on (Carbonell-Verdu et al., 2016; Chandrasekara et al., 2011; Saurabh et al., 2011; Tan and Chow, 2010). Figure 1.4 illustrates typical products derived from epoxidized vegetable oils, like ring opening products, aminolysis products, hydrolysis products, carbonation products, which could be further used as starting materials for the production of bio-lubricants or additives for lubricants (Karmakar et al., 2017).

Figure 1.3 Typical epoxidized vegetable oil derivatives as additive materials for biolubricants

The epoxidation reaction refers to the functionalization of unsaturated group (double bonds) into epoxide group by using pure oxygen or by using hydrogen peroxide. Chemoenzymatic epoxidation and Prileschajew epoxidation are two main epoxidation processes applied, which are illustrated in Figure 1.5 and Figure 1.6. In this doctoral thesis, I have focused my effort on the Prileschajew method.

Figure 1.4 General structure of epoxidized vegetable oil

According to the related literatures, epoxidation methods can be distinguished by the type of catalyst (homogeneous or heterogeneous catalyst), solvent and Prileschajew method using in-situ or preformed peroxyacids (Goud et al., 2007). Conventional epoxidation (Prileschajew-epoxidation process), chemo-enzymatic epoxidation, metal-catalyzed epoxidation and acidic ion-exchange-resin epoxidation are four main methods used in process (Tan and Chow, 2010).

Of all the epoxidation methodologies, Prileschajew epoxidation is the most extensively studied method, which is the reaction of epoxidizable unsaturated group with percarboxylic acid formed in situ (Tan and Chow, 2010). Since this method is clean and effective, especially since the percarboxylic acid is easily prepared and is inexpensive, this method has been the commercial applied method to produce epoxides from the corresponding olefins (French, 1967; Turco, 2011). Firstly, percarboxylic acid (formic acid or acetic acid) was produced in situ from carboxylic acid and hydrogen peroxide in the aqueous phase with or without catalyst (H<sub>2</sub>SO<sub>4</sub>, HNO<sub>3</sub>, H<sub>3</sub>PO<sub>4</sub>, etc.), and then the percarboxylic acid transfers into the organic phase to epoxidize the unsaturated groups on the olefins and release the carboxylic acid. One of the main drawbacks for this epoxidation approach is that the epoxidized group is highly reactive and can undergo ring opening side reactions by different nucleophiles (Cai et al., 2018). Also, the kinetics of ring opening reaction is dependent to the pH of the reaction mixture. When pH is low, the protonation of epoxide group favors ring opening reaction (Campanella and Baltanás, 2005). It is essential to investigate the different ring opening reaction kinetics in order to minimize the ring opening. However, researches concerning this part are relatively scarce.

Figure 1.5 Prileschajew epoxidation mechanisms of vegetable oil

Chemoenzymatic epoxidation is defined as ‘self-epoxidation’, which is referring to the double bonds in unsaturated fatty acid is epoxidied with the enzymatically self-formed peroxy acid (Tan and Chow, 2010; Tiran et al., 2008; Warwel and Rüschen. Klaas, 1995), as shown in Figure 1.6.

Figure 1.6 Chemoenzymatic epoxidation mechanisms of vegetable oil

*Candida antarctica* lipase enzyme (Novozym 435) is the mostly used enzymatic catalyst during this kind of epoxidation. It works efficiently with high yield of epoxides because of the lower side reaction of ring opening and the simplified separation process for products. However, besides of less than 2% of byproduct (peracids), this process is limited to the type of unsaturated fatty acid (internal or terminal position of carboxylic acid) (Warwel and Rüschen. Klaas, 1995). It was reported that epoxidation of double bonds existing in unsaturated fatty acids with internal carboxylic acid are supposed to be more efficient than the ones with terminal carboxylic acid. Because of the low stability of the lipase catalyst, either hydrogen peroxide or alcohol could inactivate the lipid catalyst during the catalytic procedure (Abdullah and Salimon, 2010).

Metal-catalyst epoxidation is the epoxidation of olefins with hydrogen peroxide under the existence of metal catalyst, such as titanium, tungsten, molybdenum, rhenium and also the metal-based nanocatalysts (Blanckenberg and Malgas-Enus, 2018; Sheldon and Van Doorn, 1973). Compared to the Prileschajew epoxidation, chemoenzymatic epoxidation reaction system could be conducted under mild conditions (room temperature) with high selectivity and achieves almost quantitative yield. For example, it was mentioned that the selectivity of epoxidized unhindered alkenes can be achieved over 90% after 3 hours of epoxidation, which is faster than the other epoxidation reactions. Also, heterogeneous catalytic system simplifies

the separation issue of catalyst. Catalysts like Ti(IV)-grafted silica catalysts, Tungsten-based catalyst, transition metal complexes, amorphous TiSiO<sub>2</sub> and alumina are currently developed to be efficient alternative to improve epoxidation process (Abdullah and Salimon, 2010; Campanella and Baltanás, 2004; Di Serio et al., 2012; Santacesaria et al., 2011; Saurabh et al., 2011; Sepulveda et al., 2007).

Acidic ion-exchange-resin epoxidation is the epoxidation of olefins using in-situ generated peroxyacid (peroxyacetic acid or peroxyformic acid) and in the presence of ion exchange resin. Amberlite IR 120H is commonly used acidic ion exchange resin to catalyze the kinetics of perhydrolysis, which is the reaction between H<sub>2</sub>O<sub>2</sub> and carboxylic acid. Investigations on the epoxidation approach shows that the efficiency of transferring unsaturated groups into epoxides varies from the types of feed stock (Saurabh et al., 2011), and the ring opening side reactions can be reduced by using this epoxidation process (Goud et al., 2007; Petrović et al., 2002).

Among these four epoxidation methods mentioned above, Prileschajew epoxidation is the most widely used process, which has already achieved commercial importance, for example, the production of epoxidized soybean oil with percarboxylic acid has already achieved the industrial production scale and the product is significantly to be used as bio-based poly(vinyl chloride) (PVC) plasticizer (Hosney et al., 2018; Turco, 2011). A number of vegetable oils listed in Table 1.2 have already been well studied as the substrates for epoxidation, such as soybean oil (Bhalerao et al., 2018; Petrović et al., 2002), linseed oil (Ishimura and Yoshida, 2015) and cottonseed oil (Cai et al., 2018; Carbonell-Verdu et al., 2016; Dinda et al., 2008). The common feature of these oils is that they have high content of unsaturated bonds as indicated by iodine values in Table 1.2. Several typically literatures were discussed below, shown the influences of epoxidation factors on the epoxidation kinetics.

Dinda, et al. (Dinda et al., 2008) investigated the epoxidation kinetics of cottonseed oil by peroxy-carboxylic acid formed in-situ. It was reported that, under the experimental conditions, this reaction is exothermic with -11.04 kcal.mol<sup>-1</sup> of reaction enthalpy. Also, sulfuric acid was proved to be the most effective catalyst among different inorganic acids. The catalytic effectiveness order for different catalysts is sulfuric acid > phosphate acid > nitric acid > hydrochloric acid. It was suggested that 60°C is the optimized temperature to perform epoxidation reactions. Besides, acetic acid was proved to be superior to formic acid because of its more effective oxygen carrier behavior than formic acid for the in-situ epoxidation of cottonseed oil. However, in the study of Petrović, et al. (Petrović et al., 2002), they have

pointed out an opposite opinion that formic acid works more efficient than acetic acid for the epoxidation of soybean oil at 40°C and 60°C.

Cai et al. (Cai et al., 2008) worked on the epoxidation kinetics of different vegetable oils by peracetic acid generated in-situ with the existence of sulfuric acid as catalyst. The epoxidation effectiveness order for different vegetable oils is soybean oil > corn oil > sunflower oil. It was worth mentioning that the activation energy varies with fatty acid components in vegetable oil, higher linoleic acid content will limit the epoxidation reaction. Moreover, the optimized reaction temperature is 75°C, while 45°C is considered to be a temperature that helps stabilize the epoxide group.

The effect of triacyl-glycerol components on epoxidation kinetics was investigated by Yan et al. (Yan et al., 2018), in which they have prepared epoxidized vegetable oils with performic acid but without the inorganic acid catalysts. By testing the epoxidation of three vegetable oils (linseed oil, high-oleic form and commodity form of soybean oil), they found that linolenic acid can be epoxidized more rapidly than oleic acid. Moreover, the epoxidation of high-oleic soybean oil undergoes faster than the epoxidation of linseed oil, which has higher content of double bonds, suggesting that the epoxidation kinetics are also limited by diffusion aspect.

Both Petrović et al. (Petrović et al., 2002) and Goud et al. (Goud et al., 2006) have studied the influences of factors, like reaction temperature, molar ratio of reactant, catalyst type and the mixing speed, on the epoxidation process by using in-situ formed percarboxylic acid. They have got the same conclusion that moderate temperature within 55-65°C is suitable for the epoxidation. What is more, Goud et al. have pointed out that higher temperature and catalyst concentration of sulfuric acid will shorten the reaction time to get higher epoxide contents with glycol due to cleavage.

Zheng, et al. (Zheng et al., 2016) have studied the epoxidation of cottonseed oil using performic acid in a semi-batch reactor. They have proposed a kinetic model based on the kinetics of peroxidation of formic acid, epoxidation of cottonseed oil and ring opening of epoxidized oil. Also, during kinetic modeling stage, the epoxidation of oleic acid, linoleic contents have been considered. It was found that ring opening of epoxide group by performic acid is faster than formic acid and water.

To produce the epoxidized vegetable oil, three-neck flask batch reactor and glass jacket reactor are commonly used to conduct the reaction and semi-batch process procedure is

avored, for which, there are three configurations to add the reactants during epoxidation reaction, as illustrated below:

Configuration 1 is that vegetable oil, carboxylic acid (formic acid or acetic acid) with/without inorganic catalyst were mixed and preheated before aqueous  $H_2O_2$  was added drop-wise (Dinda et al., 2008).

Configuration 2 is that peroxyacid (performic acid or peracetic acid) was prepared with carboxylic acid (formic acid or acetic acid) and aqueous  $H_2O_2$  in the presence of inorganic catalyst, and then being added in into the soybean oil slowly. (Cai et al., 2008)

Configuration 3 is that vegetable oil, aqueous  $H_2O_2$  were mixed and preheated before acid (formic acid or acetic acid) was added drop-wise (Zheng et al., 2016).

In our work, epoxidation of cottonseed oil using peracetic acid was studied. Based on the kinetic model developed, we found that semi-batch reactor where hydrogen peroxide and sulfuric acid were added is the most suitable configuration. Also, according to the estimated kinetic constants for the ring opening reactions by water, hydrogen peroxide, acetic acid and peracetic acid, ring opening by acetic acid and peracetic acid were found to be faster than by water and hydrogen peroxide. This part of work has been published in literature of Cai, et al. 2018 (Cai et al., 2018).

### 1.5 Carbonation of vegetable oils

In recent decades, the growth emission of carbon dioxide in the atmosphere is still the main incentive to the 'global warming'. Meanwhile, according to the situation of the modern consumption of petroleum, it was forecasted that the remaining petroleum reserves will be exhausted in 2056 (Miloslavskiy et al., 2014). Thus, the pressure of world ecological legislation and the risk linked to petroleum consumption has forced industry to switch to "green technology" through using renewable raw materials such as vegetable oils (Adhvaryu and Erhan, 2002; Ogunniyi, 2006). Carbonated vegetable oils have attracted special attentions, because it is synthesized from carbon dioxide and vegetable oils. However, the carbonated product is still under its laboratory research stage, rather than at industrial scale production. The carbonation products are widely regarded as substitutes for fossil derivatives for the production of non-isocyanate polyurethanes and polyvinylchloride and so on (Mehta et al., 2015; Rokicki et al., 2015; Sawpan, 2018).

Figure 1.7 General structure of carbonated vegetable oil

Carbonation of vegetable oils is referring to the incorporation of carbon dioxide into the epoxide group with catalyst, thus to produce a five membered cyclic carbonates (as shown in Figure 1.8). According to the operating conditions, the processing procedures can be classified into three categories: atmospheric pressure synthesis through coupling carbon dioxide with epoxide oils (Z. Hu et al., 2018; Meléndez et al., 2007), pressurized synthesis in autoclaves (Cai et al., 2017; Zheng et al., 2018) and supercritical synthesis with supercritical carbon dioxide (M. Doll and Z. Erhan, 2005). According to catalytic system, carbonation can be classified into homogeneous and heterogeneous reaction systems. During the past decades, various catalysts have been developed (Table 1.3). Several homogeneous catalysts have been used, such as quaternary ammonium (Li et al., 2008), ionic liquid (Bobbink and Dyson, 2016; Narra et al., 2016), organocatalyst (Büttner et al., 2017) and crown ether complexes (Desens and Werner, 2016). Several heterogeneous catalysts have been used such as silica supported ionic liquid (Bähr and Mülhaupt, 2012), metal-organic frameworks (Babu et al., 2017; Y. L. Hu et al., 2018; Li et al., 2008; Wang et al., 2012; Wu et al., 2016) and other novel catalysts (Onyenkeadi et al., 2018) have attracted significant attention due to its high catalytic activity and high efficiency.

Table 1.3. Literature review for the carbonation of epoxidized vegetable oils with catalysts

Oil source	Catalyst system		Carbonation conditions	Yield (%)	References
ESBO	5% (mol percent per epoxide group) of tetrabutylammonium bromide (TBABr)	Homogeneous	110°C, atmosphere pressure, 70h	94	(Tamami et al., 2004)
ESBO	5% (mol percent per epoxide group) of tetrabutylammonium bromide (TBABr)	Homogeneous	100°C, 10.3 MPa of supercritical CO <sub>2</sub> , 40h	100	(M. Doll and Z. Erhan, 2005)
ESBO	3% (mol percent per epoxide group) of T tetrabutylammonium bromide / Tin(IV) chloride pentahydrate (TBABr/SnCl <sub>4</sub> ·5H <sub>2</sub> O, 3:1)	Homogeneous	140°C, 1.5 MPa of CO <sub>2</sub> , 30h	98.6	(Li et al., 2008)
ESBO	5% (mol percent per epoxide group) of tetrabutylammonium bromide / water (TBABr/H <sub>2</sub> O, 3:1)	Homogeneous	120°C, atmosphere pressure, 70h	79	(Mazo and Rios, 2013)
Epoxidized methyl ricinoleate	32.55% (mol percent per epoxide group) of scandium (III) trifluoromethanesulfonate	Homogeneous	Room temperature, atmosphere pressure, 8h	90	(Narra et al., 2016)
1,2-butylene oxide	2% (mol percent per epoxide group) of 1,3-Bis(2,6-diisopropylphenyl)imidazole-2-ylidene/ potassium iodide /18-crown-6 (1:1:1)	Homogeneous	100°C, 1.0 MPa of CO <sub>2</sub> , 3h	81	(Desens and Werner, 2016)
ESBO	3% (mol percent per epoxide group) of tetrabutylammonium bromide (TBABr) or silica supported 4-pyrrolidinopyridinium iodide (SiO <sub>2</sub> -4(I))	Heterogeneous	140°C, 3.0 MPa of CO <sub>2</sub> , 20h (TBABr), 48h (SiO <sub>2</sub> -4(I))	100	(Bähr and Mülhaupt, 2012)

Oil source	Catalyst system		Carbonation conditions	Yield (%)	References
ESBO	Pt doped H <sub>3</sub> PW <sub>12</sub> O <sub>40</sub> /ZrO <sub>2</sub>	Heterogeneous	150°C, 1.0MPa of CO <sub>2</sub> , 30h	93	(Wang et al., 2012)
Epoxidized SBO FAMES	Polyethylene glycol 400-embedded-potassium Bromide	Heterogeneous	120°C, 3.0MPa of CO <sub>2</sub> , 20h	99	(Liu et al., 2018)
ELSO	5% (mol percent per epoxide group) of Ortho-hydroxy- triphenyl-phosphonium bromide	Heterogeneous	80°C, 2.5MPa of CO <sub>2</sub> , 24h	88	(Büttner et al., 2017)
Propylene oxide	Carboxymethyl cellulose supported 1-hydroxypropyl-3-n-butyl imidazolium chloride and Niobium(V) chloride (HBimCl-NbCl <sub>5</sub> /HCMC)	Heterogeneous	130°C, 1.5MPa of CO <sub>2</sub> , 3h	87.8	(Wu et al., 2016)
Propylene oxide	Zinc naphthalate (4,4'-Bipyridine)/ tetrabutylammonium bromide / water (Zn <sub>2</sub> (NDC) <sub>2</sub> (4,4'-bipy)/TBAB/H <sub>2</sub> O)	Heterogeneous	Room temperature, 1.2MPa of CO <sub>2</sub> , 18h	97	(Babu et al., 2017)
Propylene oxide	5.9% (mol percent per epoxide group) of [P <sub>12,4,4,4</sub> ]Br/MIL-53(Cr) (MIL: Materials of Institut Lavoisier) ( 1:28)	Heterogeneous	100°C, 1.0MPa of CO <sub>2</sub> , 2h	98	(Hu et al., 2018)
Butylene oxide	10% (w/w) of Ceria, lanthana and zirconia graphene oxide (Ce-La-Zr/GO) nanocomposite catalyst	Heterogeneous	125°C, 7.5MPa of CO <sub>2</sub> , 20h	64	(Onyenkeadi et al., 2018)
Epichlorohydrin	0.75% (w/w) of Li-doped MgO catalyst (Li-MgO)	Heterogeneous	130°C, 4.0MPa of CO <sub>2</sub> , 4h	97	(Rasal et al., 2018)

Table 1.3 presents a literature review on the major development of catalytic synthesis of carbonated vegetable oils from epoxidized vegetable oils. Not all the reported catalyst systems are introduced below, but the ones showing greater potential. As we can see from Table 1.3, most studies were concentrated in the carbonation of epoxidized soybean oil, because of its readily availability and sufficient reserves, and in the carbonation of epoxidized linseed oil, because of its rich unsaturated fatty acid of linolenic acid (18:3) in linseed oil. Among the wide range of carbonation catalysts, TBABr has been widely applied for the synthesis of carbonated vegetable oils. The effort to discover new and more efficient catalysts is still going on (Alves et al., 2015; Jalilian et al., 2010; Li et al., 2008; Parzuchowski et al., 2006).

Figure 1.8 Synthesis of carbonated vegetable oil

In 2004, Tamami et al. (Tamami et al., 2004) firstly proposed the carbonation of epoxidized vegetable oils, and carbonation of soybean oil catalyzed by TBABr as homogeneous catalyst. The carbonated soybean oil was further proved to be a promising route for the non-isocyanate synthesis route for polyurethanes by Javni et al. (Javni et al., 2008).

In 2013, Langanke et al. (Langanke et al., 2013) studied the formation of methyl oleate carbonate by organic halides and polyoxometalates. During the kinetics study, a pseudo-first order reaction was used, because  $\text{CO}_2$  was present in large excess.

Also, during the past few years, the choices of cottonseed oil (Dinda et al., 2008) and vernonia oil (Mann et al., 2008) as raw materials seem to be interesting. Study of kinetic models including mass transfer parameters for the carbonation of epoxidized vegetable oils is relatively scarce. To the best of our knowledge, there is no kinetic model including mass transfer study for the carbonation of epoxidized vegetable oils.

Because of that, in this work, the gas-liquid mass transfer phenomena for the carbonation of epoxidized cottonseed oil with the homogeneous catalyst of TBABr was studied (Cai et al., 2017). The effects of different parameters, such as reaction temperature, pressure, catalyst loading and the stirring speed, on the kinetics were discussed. Based on the mass transfer

study, which was designed to predict the evolution of the volumetric mass transfer coefficients and Henry's constants with reaction advancement and temperature, a kinetic model was further proposed for the carbonation of epoxidized cottonseed oil catalyzed by TBABr.

### **1.6 Relationships of chemical structure and properties**

In case of vegetable oil, Yan et al. (Yan et al., 2018) proved that both the fatty acid components and function groups will affect physicochemical properties of the products and the corresponding reaction kinetics. Then, what is the specific nature of their constituting elements? What is the effect of their structures on their building-blocks? Is it possible to predict the reaction kinetics and mechanism through the establishment of a correlation between the chemical structure activity of these elements and their building-blocks? To reply such issues, the evaluation of chemical structure activity of the element and its corresponding compound is indispensable. However, researches concerning the relationships of chemical structure and properties are scarce.

For the chemical structure activity evaluation, two aspects are necessarily investigated: the physicochemical properties (density, viscosity, refractive index, heat capacity) and the reactivity: kinetic and thermodynamic constants of a chemical reaction.

#### **1.6.1 Chemical structure and physicochemical properties**

Numerous articles have reported the physicochemical properties of various triglycerides, fatty acids, and methyl esters.

Demirbas (Demirbas, 2008) has investigated physical properties of 22 kinds of vegetable oils and 14 kinds of methyl esters. It was reported the viscosity of vegetable oil can be highly decreased after being transesterified into methyl ester form.

Scala and Wool (Scala and Wool, 2005) pointed out that the chemical modification of triglycerides may change the interactions between molecules, thus resulting in a change in viscosity. For example, the viscosity of triglycerides increased as a result of slight polarity increase after being epoxidized.

Miloslavskiy et al. (Miloslavskiy et al., 2014) have pointed that during carbonation process, viscosity of epoxidized vegetable oils increase by ten times. Thus, the properties of raw materials play important roles during chemical structure modifications, such as epoxidation and carbonation reactions.

Yan et al. (Yan et al., 2018) have studied the role of fatty acid profiles on the epoxidation kinetics of three different vegetable oils (commodity soybean oil, high-oleic soybean oil and linseed oil). Also, physicochemical properties of the epoxidized products, such as the viscosity, X-ray diffraction data and differential calorimetry were measured. They pointed out that epoxidation process may increase the viscosity of oils during functionality, but with almost no effect on the melting temperature. Also, they mentioned that structural regularity can increase viscosity by improving molecular packing. Thus, with respect to triglycerides, when the double bonds increase, molecular packing will be reduced and viscosity will decrease.

Also, in our previous work (Cai et al., 2018), different physicochemical properties such as viscosity, density, refractive index, and specific heat capacity for the epoxidized and carbonated forms of vegetable oils (soybean oil, linseed oil and cottonseed oil) were investigated. The evolution of these properties with temperature and components in double bond, epoxide, and carbonated groups were studied. We have found that some correlations, for example, density and refractive index of these oils vary linearly with temperature and the ratio of specific heat capacity at a temperature to the specific heat capacity at a reference temperature follows a polynomial equation of second order with temperature, could be used to predict the evolutions of these physicochemical properties at different components and temperatures based on the property knowledge of the pure compounds.

#### 1.6.2 Chemical structure and reactivity

Quantitative structure-activity relationship (QSAR) (Chen et al., 2015; Cheng et al., 2018) and quantitative structure-property relationship (QSPR) techniques are used to link the chemical activities with the element and its building-blocks, while linear free-energy relationship (LFER) to predict the kinetic and thermodynamic constants (Leveneur, 2017). As to LFER description, two types of equations can be applied, i.e., the Hammett equation for aromatic systems, which takes into account the polar, steric and resonance effects, and the Taft equation for aliphatic systems, which takes into account polar, steric effects (Hancock, 1961; Lilja et al., 2002).

Several different research groups have tried to establish this kind of correlation for different reactions and pointed out that the correlation of intrinsic kinetic parameter between the constituting element and the building-blocks is important (Cheng et al., 2018; Leveneur, 2017).

In 1950, Bolland (Bolland, 1950) have investigated the influence of chemical structure on  $\alpha$ -methylene reactivity of olefins. He mentioned that the unsaturated group in the chemical structure of an olefin can determine the rate of its oxidation reaction.

Hita, et al. (Hita et al., 2018) have studied the relationships between chemical structure of lignin and reactivity during iron catalytic hydrogenation process. The observed structure relationships show that higher concentrations of methoxy groups appear to promote lignin gas formation during hydro treatment. Also, aliphatic compound with low oxygen content and higher content of lignin are not favorable for obtaining phenolic compounds.

Otto, et al. (Otto et al., 2018) have pointed out that all chemical reactions follow a pattern of associated activations, which are closely related to the steric effects in the chemical structure.

As a chemical platform, vegetable oil can be valorized through chemical modification into variety of products or intermediate materials, including polymers, composites, emulsions, coatings, binders in ink formulations, gels (Murawski and Quirino, 2018). The epoxidized vegetable oils are widely applied as the stabilizers and plasticizers for polyvinyl chloride and rubber compounds (Bueno-Ferrer et al., 2010; Chandrasekara et al., 2011). Based on the epoxidized vegetable oils, carbonated vegetable oils have attracted much interest that it is the reactant for non-isocyanate polyurethanes (NIPUs) product (Maisonneuve et al., 2015). However, literature recording the correlation between the chemical structure activity of fatty acid and vegetable oils is yet scarce.

Moreover, transesterification of vegetable oils (soybean oil, palm oil, cottonseed oil, sunflower oil, rapeseed oil, etc.) is the most common way to be used for biodiesel production (Fukuda et al., 2001; Leung et al., 2010). Several studies have proved that transesterification process helps to decrease the viscosity of vegetable oils, which is 9 to 17 times of fatty acid methyl esters and affects mass transfer and diffusion efficiency (Demirbas, 2008; Demirbaş, 2002; Rastogi et al., 2002).

In 2015, Huang et al. (Huang et al., 2015) have studied the epoxidation of different fatty acid methyl esters, and have demonstrated that the kinetics of epoxidation and ring-opening increases with the number of unsaturated groups.

In 2016, Omonov et al. (Omonov et al., 2016) have compared the kinetics of epoxidation of canola oil and its transesterified form. They have found that the kinetics of epoxidation of the transesterified form was faster, but they did not take into account the mass transfer, difference of viscosity and different side reactions.

To the best of our knowledge, no one has performed a fair comparison, i.e., measuring intrinsic kinetic constant, between the kinetics of vegetable oil and their corresponding fatty acid methyl ester.

### **1.7 Objective of the doctoral thesis**

As concerns this work, the thesis is made of seven chapters. Chapter II deals with a wide literature review of research advance on the methods for biomass and CO<sub>2</sub> valorization through epoxidation and carbonation of vegetable oils. Chapter III presents a short explanation of the materials, setup and analysis methods that we used to carry out all the experiments. From Chapter IV to Chapter VII, these four chapters expose all experiment results obtained, in which Chapter IV is focused on the influence of ring opening reactions on the kinetics of bio-based cottonseed oil epoxidation; Chapter V is focused on the Interaction between functional groups and physicochemical properties of vegetable oils and their epoxidized and carbonated derivatives; Chapter VI is focused on the carbonation of epoxidized vegetable oils; Chapter VII is focused on the comparison of chemical structure and reactivity between vegetable oils and fatty acid methyl ester. Chapter VIII provides a comprehensive summary of all the research content in this thesis.

The aim of this doctoral thesis focuses on the epoxidation and carbonation of vegetable oils. The objective of this work was divided into four parts:

- kinetics study of epoxidation and ring opening of vegetable oils by using acetic/peracetic acid in the presence of sulfuric acid;
- investigation on the physicochemical properties of vegetable oils (soybean oil, cottonseed oil and linseed oil) and their modified counterparts (epoxidized and carbonated);
- kinetics study of carbonation of epoxidized vegetable oils with homogeneous catalyst, namely Tetra-n-butylammonium bromide (TBABr);
- study of structure-reactivity relationship between vegetable oil and its fatty acid methyl ester for the carbonation reaction.

In the first part of work, kinetics studies of epoxidation and ring-opening were done to optimize the production of epoxidized cottonseed oil. Epoxidation of cottonseed oil by peracetic acid in a batch reactor was studied. The kinetic constants for the ring-opening reactions by water, hydrogen peroxide and acetic and peracetic acids were estimated. A suitable modeling strategy for ring opening was well developed.

For the second part, physicochemical properties (viscosity, density, refractive index, or specific heat capacity) were measured for three kinds of vegetable oils (soybean oil, cottonseed oil and linseed oil) and their modified forms. Solution of fresh vegetable oil, synthesized epoxidized vegetable oil and synthesized carbonated vegetable oil was made to investigate the effect of function groups. It was demonstrated that density and refractive index of these oils vary linearly with temperature. Viscosity of these oils, which were found to be Newtonian fluids, is an exponential function of temperature. In addition, these correlations could be used to predict the evolutions of these physicochemical properties at different components and temperatures based on the property knowledge of the pure compounds.

Then, the carbonation kinetics of epoxidized vegetable oils were investigated for the effects of different reaction parameters, like reaction pressure, reaction temperature and epoxide group concentration on. Furthermore, a kinetic model including mass transfer phenomena for the carbonation of epoxidized cottonseed oil was built.

At last, vegetable oil and its fatty acid methyl ester form were selected as research subject to investigate the relationship of chemical structure and reactivity via carbonation reactions. Relationship between the carbonation reaction kinetic constants of two substances was estimated by taking into account the physicochemical properties and mass transfer parameters.

### 2.1 Introduction

In this chapter, all the materials and setup that we used for the experiments are presented. Section 2.2 is about the materials; Sections 2.3-2.5 describes the setups and Section 2.6 is about the analytical methods. Section 2.7 describes the numerical methods used to solve out the ODEs.

### 2.2 Materials

For synthesis procedure, refined cottonseed oil, linseed oil was purchased from ThermoFisher Scientific GmbH (Schwerte, Germany). Soybean oil was purchased from Sigma Company (Sigma, USA). Sulphuric acid (purity> 98 wt.%), formic acid (purity> 99 wt.%), acetic acid (purity> 99 wt.%), hydrogen peroxide (33 wt.% in water) were obtained from VWR International SAS (Fontenay-sous-Bois, France). Tetra-n-butylammonium bromide (TBABr, purity>98wt.%) were purchased from Alfa Aesar (Alfa Aesar GmbH & Co., Ward Hill, MA, USA).

For analytical procedure, tetraethylammonium bromide (TEAB, 98 wt.%) and of perchloric acid standardized solution ( $0.1 \text{ mol.L}^{-1}$  in acetic acid) were obtained from Alfa Aesar (Alfa Aesar GmbH & Co., Ward Hill, MA, USA). Hanus standard solution, 2-propanol, and chloroform were obtained from VWR International SAS (Fontenay-sous-Bois, France). The iodine solution ( $0.1 \text{ mol.L}^{-1}$ ) was obtained from Chem-Lab NV (Chem-Lab, Belgium). Sodium thiosulfate solution ( $0.1 \text{ mol.L}^{-1}$ ) and ammonium cerium (IV) sulfate solution were purchased from Sigma-Aldrich (Sigma Aldrich Chemical Co, USA).

### **2.3 Apparatus and experimental procedures for physicochemical properties measurements**

#### 2.3.1 Refractive index measurement

Refractive index was measured by using the Abbemat 300 refractometer (Anton Paar, Austria) with an accuracy of 0.0001 nD according to the manufacturer. Densities were measured by using DMA 4100 M (Anton Paar, Austria) with an accuracy of temperature of  $\pm 0.02^\circ\text{C}$  and an accuracy of measurement of  $\pm 0.05 \text{ kg.m}^{-3}$  according to the manufacturer.

#### 2.3.2 Density measurement

Density was measured using a digital glass vibrating-tube densitometer (DMA5000, Anton Paar Ltd, Herts, UK) with an accuracy of  $\pm 0.001 \text{ kg.m}^{-3}$  and  $\pm 0.001 \text{ K}$  for the temperature according to the manufacturer.

#### 2.3.3 Viscosity measurement

The dynamic viscosity of vegetable oil and its epoxidized and carbonated derivatives were measured by the Brookfield CAP2000+ viscometer (Brookfield Engineering Laboratories, Inc., Stoughton, MA). It is equipped with a cone plate geometry system and precise temperature control system. CAP spindle 01 was used during the viscosity measurement. The rotational speed of the cone was fixed at 20 RPM under high torque model. The shear rate was selected as  $267 \text{ S}^{-1}$ . For each sample, the value of viscosity was obtained after 60 s of hold time for temperature stabilization and 60 s of recording time for criterion of stability. The accuracy of viscosity is  $\pm 2\%$  of full scale range (FSR), and  $\pm 2^\circ\text{C}$  for the temperature according to the manufacturer.

The dynamic viscosity of fatty acid methyl ester and its epoxidized and carbonated derivatives were measured in a digital rolling-ball viscometer (Lovis 2000 MME, Anton Paar, Graz, Austria) with an accuracy of  $\pm 0.5\%$  and  $\pm 0.002^\circ\text{C}$  for the temperature according to the manufacturer.

#### 2.3.4 Specific heat capacity measurement

The specific heat capacities for vegetable oils and their derivatives were measured by using a Tian-Calvet calorimeter C80 (Setaram Instrumentation, Caluire, France). The accuracy of temperature is  $\pm 0.1^{\circ}\text{C}$  and the accuracy of enthalpy is  $\pm 0.1\%$  according to the manufacturer. Successive heating of  $2^{\circ}\text{C}$  was applied to the samples in a stainless steel cell.

#### 2.4 Apparatus and experimental procedures for epoxidation and ring opening experiment

Epoxidation and ring opening experiments were performed in a 500 mL glass water-jacketed reactor (Figure 2.1) equipped with a pitched blade impeller (diameter 3.8 cm and 4 blades), a reflux condenser and different temperature probes to measure the temperatures of reaction mixture, inlet and outlet of the jacket. A heating circulator was installed to keep the jacket temperature constant. A dosing pump was applied for solution injection.

Figure 2.1. Experimental apparatus: (a) epoxidation and ring opening reactor  
(b) schematic view of epoxidation and ring opening setup

##### 2.4.1 Preparation of epoxidized vegetable oil

Epoxidized cottonseed oil (ECISO), epoxidized linseed oil (ELSO) and epoxidized soybean oil (ESBO) were produced by using the protocol developed by our group (Ait Aissa et al., 2016; Zheng et al., 2016). Briefly, in a 500 mL jacketed-reactor, a mixture of vegetable oil, hydrogen peroxide and distilled water was stabilized at  $60^{\circ}\text{C}$  under 650 rpm. When the reaction temperature was stable, formic acid was added with a volumetric flow rate of  $2.9\text{ mL}\cdot\text{min}^{-1}$  for

25 min. The reaction of epoxidation for CSO, LSO and SBO lasted for one hour under these operating conditions. The molar ratios of reactants were 2:4:1:3 (double bond of oil/water/formic acid/hydrogen peroxide). Then, the organic phase was washed with a 10% (in mass fraction) aqueous solution of Na<sub>2</sub>CO<sub>3</sub> to remove residual formic acid and then with distilled water for three times to remove the residual sodium carbonate. Furthermore, the purified organic phase was dried in a rotary evaporator and finally dried over anhydrous magnesium sulfate.

#### 2.4.2 Preparation of cottonseed oil fatty acid methyl ester

Transesterification of cottonseed oil was carried out as described by Campanella, *et al.* (Campanella et al., 2008), with slight modification. The reaction stoichiometry is 6.6:1 (methanol: cottonseed oil) in the presence of 1.0 wt.% of NaOH catalyst (cottonseed oil). The methanol-catalyst mixture was preheated before being fed and reacted with the cottonseed oil at 70 °C in the reactor. The transesterification reaction was done using 1 hour. After the reaction phase was stratified into two phases, the glycerol phase was removed. The methyl ester phase left in the reactor was washed with 600 mL of distilled water with one drop of phosphoric acid, then, washed three times with distilled water. The product was evaporated using an IKA RV10 control vacuum rotary evaporator (VWR, Darmstadt, Germany) at 60 °C and dried over magnesium sulfate. The resulting product was kept at 3 °C under an argon atmosphere.

#### 2.4.3 Preparation of epoxidized cottonseed oil fatty acid methyl ester (EFAME)

Epoxidized fatty acid methyl ester (EFAME) was prepared as follows: 100.0 g of cottonseed oil fatty acid methyl ester (FAME), 33.0 g of formic acid were loaded into the 500 mL glass-jacketed reactor at 40 °C. Then, hydrogen peroxide (33 wt. % in water) was introduced via a dosing pump at a volumetric flow rate of 5.1 mL.min<sup>-1</sup> for 60 min. The reaction time was 3 hours. After the reaction phase was stratified into two phases, the aqueous phase was removed. The organic phase left in the reactor was washed with distilled water for 3 times to remove the residual acid. The product was evaporated at 60 °C and dried over magnesium sulfate. The resulting epoxidized cottonseed oil fatty acid methyl ester was kept at 3 °C under an argon atmosphere.

## 2.5 Apparatus and experimental procedures for carbonation experiment

A high-pressure stainless-steel autoclave (Parr Instrument Company, Moline, 300 mL) was used as the carbonation reactor (Figure 2.2). In this reaction system, a gas feed system including a CO<sub>2</sub> bottle and a gas reservoir was connected to the reactor. A gas monitoring system equipped with temperature and pressure probes inside the gas reservoir was connected to a computer. A gas entrainment impeller (diameter 2.5 cm) with a hollow shaft was used. The uncertainty for the pressure probe was 0.01 bars and that for the temperature probe was 0.1 °C. The reactor was equipped with a temperature control system.

The carbonation of epoxidized vegetable oil or fatty acid methyl ester was carried out as follows: briefly, the epoxidized cottonseed oil and the catalyst TBABr were weighed out in the reactor at 100 °C. Then, the reactor was heated to the designed temperature. The gas feed system was adjusted to desired value via the pressure regulator and remained open. The atmosphere inside reactor was purged with CO<sub>2</sub> for two times via valve V<sub>3</sub> and then remained open. The value (pressure, temperature) inside the gas reservoir and the temperature inside the reactor were simultaneously recorded. After the pressure and temperature were stabilized, the agitation was started at 500 rpm. Samples were withdrawn in one hour intervals via a valve and the epoxide content was determined by titration.

Figure 2.2. Experimental apparatus: (a) carbonation reactor (b) Schematic view of carbonation setup

## 2.6 Analysis method

### 2.6.1 Determination of the fatty acid methyl ester components

#### (1) Gas chromatography

For determining the fatty acid methyl ester components, a Bruker Scion GC436 gas chromatography, equipped with a split injector and an elastic quartz capillary column (ZB-5, Phenomenex, 30 m × 0.32 mm i.d., 0.25 μm film thickness), was applied. Helium (99.99 %) was used as carrier gas at a constant flow rate of 1.0 mL.min<sup>-1</sup>. The temperature of the injector was 300 °C. The oven temperature was programmed as 40 °C for 2 min duration and then increased to 300 °C at 8.0 °C.min<sup>-1</sup> heating rate and maintained for 34.5 min. The injection volume was 1.0 μL and the split mode was 30:1. All data acquisition and analysis were performed using the Compass CDS software (Agilent Technologies, version 3.0).

The esterification of components in oil sample was performed as follows: 0.1 mL of the oil sample (4 mg.mL<sup>-1</sup> in methanol) was sampling into a 10 mL glass vial. Then, 2.5 mL of toluene-methanol mixture (volume fraction 20 %), 0.1 mL of C<sub>15</sub> internal standard solution (pentadecanoic ethyl ester, 1 mg.mL<sup>-1</sup> of in methanol) and 0.2 mL of acethyl chloride (purity > 98 %) were added to the vial. The mixture was pretreated at 80 °C for 1 hour before 4.0 mL of sodium carbonate solution (6 wt. % in water) and 2.0 mL of toluene were added. Finally, this mixture was vortexed for 5 minutes and further analyzed by GC.

#### (2) Fourier-transform infrared spectroscopy

<sup>1</sup>H NMR spectra were recorded on a Bruker 300 Fourier transform spectrometer at 300 MHz in CDCl<sub>3</sub> solutions using tetramethylsilane (TMS) as internal standard.

IR spectra were recorded on a FTIR spectrometer (Perkin-Elmer Spectrum 2000) equipped with a diamond ATR device (Attenuated Total Reflection). Spectra were obtained from 10 scans in the (4000–500) cm<sup>-1</sup> range. The enthalpies of reaction were measured using a Tian-Calvet heat flow calorimeter C80 (Setaram, France).

### 2.6.2 Concentration of epoxide content

Epoxide content was titrated by the method of Jay (Maerker, 1965). Briefly, 0.100 g of oil sample or organic phase (±0.001 g) was weighted out and dissolved in 10 mL of chloroform, followed by addition of 20 wt. % (in acetic acid) tetraethylammonium bromide (10 mL). Then, the mixture was titrated by 0.1 mol.L<sup>-1</sup> of perchloric acid (in acetic acid) standardized solution with a TIM-840 automatic titrator (Radiometer Analytical, France). The concentration of epoxide groups is calculated as

$$[\text{Ep}] = \frac{V_{\text{titration}} \times 0.1}{\left(\frac{m_{\text{sample}}}{\rho}\right)} \quad (2.1)$$

where, 0.1 is the concentration of perchloric acid standardized solution, mol.L<sup>-1</sup>; V<sub>titration</sub> is the titration volume of sample, L; m<sub>sample</sub> is the mass of measurement sample, g; ρ is the oil density of the sample, g.cm<sup>-3</sup>.

### 2.6.3 Concentration of double bonds

Double bonds were titrated as described in the Hanus iodine monobromide method (Paquot, 2013), with some modifications. Briefly, 0.200 g of oil sample or organic phase (± 0.001g) was dissolved in 10 mL of chloroform and 10 mL of HANUS (0.1 mol.L<sup>-1</sup>, iodine solution according HANUS), followed by being kept in dark place for 1 h of reaction. Then, 10 wt. % (in water) potassium iodide (10 mL) and 100 mL of water were added for titration with 0.1 mol.L<sup>-1</sup> sodium thiosulfate solution. The concentration of double bond is calculated as

$$[\text{DB}] = \frac{(V_{\text{blank}} - V_{\text{titration}}) \times 0.1}{\left(\frac{m_{\text{sample}}}{\rho} \times 2\right)} \quad (2.2)$$

where, 0.1 is the concentration of sodium thiosulfate solution, mol.L<sup>-1</sup>; V<sub>blank</sub> is the titration volume of blank, L; V<sub>titration</sub> is the titration volume of sample, L; m<sub>sample</sub> is the mass of measurement sample, g; ρ is the oil density of the sample, g.cm<sup>-3</sup>.

### 2.6.4 Concentration of hydrogen peroxide content

Hydrogen peroxide content was titrated by the method of Greenspan and Mackellar (Greenspan and Mackellar, 1948). Briefly, 0.130 g of aqueous phase (±0.001 g) was weighted out and dissolved in 50 mL of 5 wt. % sulfuric acid-water solution with two drops of Ferroin indicator. The mixture was then titrated with 0.1 mol.L<sup>-1</sup> of standard cerium (IV) sulfate solution to reach a pale blue endpoint. The concentration of hydrogen peroxide is calculated as

$$[\text{H}_2\text{O}_2] = \frac{(V_{\text{titration}} - V_{\text{blank}}) \times 0.1 \times 1.701}{\left(34 \times \frac{m_{\text{sample}}}{1.09}\right)} \quad (2.3)$$

where, 0.1 is the concentration of standard cerium (IV) sulfate solution, mol.L<sup>-1</sup>; V<sub>blank</sub> is the titration volume of blank, L; V<sub>titration</sub> is the titration volume of sample, L; 1.701 is the equivalent weight constant; 34 is the molar mass of hydrogen peroxide, g.mol<sup>-1</sup>; m<sub>sample</sub> is the mass of measurement sample, g; 1.09 is the density of the solution, g.cm<sup>-3</sup>.

### 2.6.5 Concentration of acid

This titration was performed to determine the concentration of acid in the aqueous and organic phases at the equilibrium. For the concentration in the aqueous phase, 0.300 g of aqueous phase was dissolved in 50 mL of distilled water, while, for the concentration in the organic phase 0.500 g of organic phase was dissolved in 50 mL of 2-propanol. Both samples

were titrated by 0.2 mol.L<sup>-1</sup> of sodium hydroxide solution with an automatic titrator (TIM-840) separately. The concentration of acid is calculated as

$$[H^+] = \frac{V_{\text{titration}} \times 0.2}{\left(\frac{m_{\text{sample}}}{\rho}\right)} \quad (2.4)$$

where, 0.2 is the concentration of sodium hydroxide solution, mol.L<sup>-1</sup>;  $V_{\text{sample}}$  is the titration volume of sample, L;  $m_{\text{sample}}$  is the mass of measurement sample, g;  $\rho$  is the density of the solution, g.cm<sup>-3</sup>.

## 2.7 Modeling section

During the kinetic modeling stage, the modeling was performed by using ModEst software, written in Fortran 90 (H. Haario, 2001). The system of ordinary differential Equations (ODEs) was solved out by the ODESSA algorithm, which is a package of Fortran routines based on backward difference method (Leis and Kramer, 1988).

The coefficient of determination  $R^2$  is one of the most common measure to evaluate the goodness of a data fitting and is defined as:

$$R^2 = 1 - \frac{(y_i - \hat{y}_i)^2}{(y_i - \bar{y})^2} \quad (2.5)$$

where,  $\hat{y}_i$  is the observable simulated by the model,  $\bar{y}$  is the mean value of the experimental observables and  $y_i$  is the experimental observable. The concentrations of double bond, epoxide group were used as observables. The standard error of the parameter estimated represents 95% of confidence interval.

The objective function  $\omega$  was

$$\omega = \sum_i (y_i - \hat{y}_i)^2 \quad (2.6)$$

The objective function was firstly minimized by the simplex algorithm (Spendley et al., 1962), using poor initial guess values when the knowledge of the initial guess values was not known. After that, the Levenberg-Marquardt algorithm (Marquardt, 1963) was used to improve the parameter estimation.

## **Chapter III Influence of ring opening reactions on the kinetics of bio-based cottonseed oil epoxidation**

Part of this chapter is adapted from the post print of the following article:

X. Cai, J.L. Zheng, A.F. Aguilera, L. Vernières-Hassimi, P. Tolvanen, T. Salmi, S. Leveneur. Influence of ring-opening reactions on the kinetics of cottonseed oil epoxidation. *International Journal of Chemical Kinetics*, 2018, 1-16.

### **3.1 Introduction**

In this chapter, epoxidation of cottonseed oil by peracetic acid in batch reactor was studied. By developing a suitable modeling strategy, the kinetic constants for the ring opening reactions by water, hydrogen peroxide, acetic and peracetic acids were estimated. The main goal of this part of work is to minimize the ring opening side reactions and to find the most suitable reactor configuration. This study provides a reference basis for the future optimization of epoxy processing technology. Section 3.2 gives details about the experimental procedure. Section 3.3 shows the experiment results and discussion. Section 3.4 gives the conclusion for this part of work.

### 3.2 Experimental section

Epoxidized cottonseed oil (ECSO) was prepared as described in the Section 2.4.1.

For the kinetic experiments, approximately 150 mL of epoxidized cottonseed oil was added into the reactor with specific amount of water to be fully mixed at the desired temperature. Then, depending on the type of ring opening reaction a designed amount of acetic acid (AA), sulfuric acid ( $\text{H}_2\text{SO}_4$ ) or hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) were preheated and added into the reactor to start the ring opening reaction. To follow the concentration of epoxide and double bond groups, 6 mL of sample was taken at regular intervals, followed by centrifugation (5000 rpm, 10 min) to separate the organic and aqueous phases. The two separated phases were then analyzed in the titration steps. Table 3.1 shows the ring opening experimental matrix.

For the kinetic modeling, only the concentrations of double bond and epoxide groups were determined at different reaction time. The initial concentrations of hydrogen peroxide and acetic acid in the aqueous phase were determined. Some experiments to determine the molar equilibrium distribution were performed, and the equilibrium concentration of acetic acid in the aqueous and organic phases was measured.

As shown in Table 3.1, the terms of Ep and DB represent the initial concentration of epoxide and double bond groups in the organic phase. Runs 1 to 6 are the set of experiments to study ring opening reaction by water. Runs 7 to 11 are the set of experiments to study the ring opening reactions by hydrogen peroxide. Runs 12 to 17 are the set of experiments to study the ring opening by acetic acid. Runs 18 to 25 represent the set of experiments to study the effect of peracetic acid on the ring opening reaction. Runs 26 to 29 are the set of experiments for the epoxidation reaction by PAA. At time zero, no peracetic acid (PAA) was present.

### 3.3 Results and discussion

For the sake of clarity, this chapter was divided into three sections: one describing the results of kinetic experiments of ring opening, the second one describing the kinetic model and the last one is a discussion on the distribution of ring-opening products.

#### 3.3.1 Kinetic study experiments

In this section, the effect of sulfuric acid, hydrogen peroxide, acetic acid and peracetic acid concentrations on the kinetics of ring opening reaction was investigated.

##### (1) Effect of sulfuric acid concentration

Figure 3.1. Effect of sulfuric acid concentration on the kinetics of ring opening reaction at 70 °C with  $[\text{ECSO}]_{\text{org, initial}}=3.28\text{-}3.87 \text{ mol.L}^{-1}$ ,  $[\text{AA}]_{\text{aq, initial}}=0.00 \text{ mol.L}^{-1}$ ,  $[\text{H}_2\text{O}_2]_{\text{aq, initial}}=0.00 \text{ mol.L}^{-1}$  and rotating speed of 650 rpm

Figure 3.1 shows the influence of sulfuric acid concentration on the ring opening of epoxide groups. The kinetics is faster when sulfuric acid concentration increases. This graph illustrates the catalytic effect of sulfuric acid on the kinetics of ring opening reaction.

(2) Influence of hydrogen peroxide

Figure 3.2. Effect of hydrogen peroxide concentration on the kinetics of ring opening reaction at 70 °C with  $[\text{ECSO}]_{\text{org, initial}}=3.19\text{-}3.54 \text{ mol L}^{-1}$ ,  $[\text{AA}]_{\text{aq}}=0.00 \text{ mol L}^{-1}$ ,  $[\text{H}_2\text{SO}_4]_{\text{aq}}=0.76\text{-}0.82 \text{ mol L}^{-1}$  and rotating speed of 650 rpm

Figure 3.2 shows the influence of hydrogen peroxide concentration on the ring opening of epoxide groups. As it is shown in this figure, the rate of ring opening slightly increases with hydrogen peroxide concentration.

Hydrogen peroxide could dissociate to provide protons as:  $\text{H}_2\text{O}_2 \rightleftharpoons \text{H}^+ + \text{HO}_2^-$

The pKa for this dissociation is of 11.75 at 20°C (Evans and Uri, 1949). Thus, hydrogen peroxide is a very weak acid compared to acetic acid, whose pKa is equal to 4.73 at 20°C (Evans and Uri, 1949; Sue et al., 2004), and compared to the second dissociation of sulfuric acid, whose pKa is equal to 1.88 at 20°C (Knopf et al., 2003). Thus, the enhancement of reaction rate with hydrogen peroxide cannot be linked to the acidity of hydrogen peroxide but maybe on its nucleophile activity.

### (3) Influence of acetic and peracetic acid

Figure 3.3. Effect of acetic acid concentration on the kinetics of ring opening reaction at 50 °C with  $[\text{ECSO}]_{\text{org, initial}}=3.79\text{-}3.86 \text{ mol L}^{-1}$ ,  $[\text{H}_2\text{O}_2]_{\text{aq, initial}}=5.95\text{-}6.07 \text{ mol L}^{-1}$ ,  $[\text{H}_2\text{SO}_4]_{\text{aq}}=0.26 \text{ mol L}^{-1}$  and rotating speed of 650 rpm

Figure 3.3 shows the influence of acetic acid concentration on the ring opening of epoxide group. The kinetic of ring opening accelerates when the concentration of acetic acid increases.

This rate enhancement with acetic acid can be explained by several factors:

- The nucleophile activity of acetic acid towards ring opening reaction,
- The increase of acetic acid concentration leads to the increase of peracetic acid production, who can open the epoxide group,
- The catalytic effect of acetic acid on the perhydrolysis and ring opening reactions.

For that reason, the kinetic model built in this study has taken into account these three factors. Kinetic results displayed in Figure 3.3 show the presence of an induction period. As the concentration of acetic acid increases, this induction period diminishes. Campanella and Baltanás (Campanella and Baltanás, 2005) have also observed this phenomenon for the ring opening of epoxidized soybean oil at medium pH value or low temperature. Based on their observation, this induction period seems to be linked to the polar effect of the aqueous phase.

To conclude, these experiments showed that the kinetic model should take into account the catalytic effect of sulfuric acid and acetic acid on the kinetics of perhydrolysis and ring opening reactions. The ring opening by water, hydrogen peroxide, acetic acid and peracetic acid should be included in the model.

### 3.3.2 Kinetic model

In this section, the description of the kinetic model is explained. This section is composed of four parts: determination of the distribution coefficients, kinetics of the different reactions, mass balance, and kinetic modeling and strategy.

#### (1) Determination of distribution coefficients

The distribution coefficient or equilibrium molar ratio of a compound  $j$  is defined as

$$K_j = \frac{[j]_{aq}^*}{[j]_{org}^*} \quad (3.1)$$

where,  $[j]^*$  is the concentration at the interface. This value can be obtained experimentally by letting the experiments run for a long period of time and reach the equilibrium. Based on the article of Wu et al. (Wu Zhenyu et al., 2016), this distribution coefficient is temperature independent. This coefficient depends on the concentration of epoxide, double bond and ring opening concentrations as:

$$K_{AA} = A \times [Ep]_{org}^2 + B \times [DB]_{org} + C \times [RO]_{org} \quad (3.2)$$

Table 3.2 presents the calculated distribution coefficient of acetic acid with different concentrations of double bond, epoxide groups and ring-opening products.

Table 3.2. Distribution coefficients of acetic acid  $K_{AA}$

T (°C)	Concentration [mol.L <sup>-1</sup> ]			Acetic acid [mol.L <sup>-1</sup> ]		$K_{AA}$
	[DB] <sub>org</sub>	[Ep] <sub>org</sub>	[RO] <sub>org</sub>	[AA] <sub>org</sub>	[AA] <sub>aq</sub>	
60	4.00	0.00	0.00	0.408	6.048	14.83
50	4.00	0.00	0.00	0.420	6.233	14.83
60	2.33	1.27	0.40	0.507	6.513	12.83
60	2.00	2.00	0.00	0.613	6.730	10.99

The determination of A, B and C was estimated by a quasi-newton method. By using this method, the values of A, B and C were estimated to be 0.8938, 3.7075 and 6.875, respectively.

According to Wu et al. (Wu Zhenyu et al., 2016), the solubility of performic acid was found to be three times higher than formic acid for the epoxidation of soybean oil. By analogy, the same logic was applied for acetic acid and peracetic acid in this study, thus,  $K_{PAA}=0.33\times K_{AA}$ .

## (2) Ring opening kinetics

Figure 3.4. Epoxidation and ring opening mechanism for vegetable oil by using acetic acid

Figure 3.4 presents the reaction scheme for the epoxidation of vegetable oil by peracetic acid. The perhydrolysis of acetic acid, i.e., step 1, produces peracetic acid. This reaction is reversible and occurs in the aqueous phase. The reaction rate can be demonstrated as:

$$R_{Perh} = k_{Perh} \times \left( [AA]_{aq} \times [H_2O_2]_{aq} - \frac{1}{K^C} \times [PAA]_{aq} \times [W]_{aq} \right) \quad (3.3)$$

$K^C$  is the equilibrium constant of the perhydrolysis reaction. In a former article of Leveneur et al. (Leveneur et al., 2009), they have demonstrated that this thermodynamic constant can be described by a van't Hoff law and the non-ideality is proportional to the concentration of sulfuric acid.

$$K^C(T_R) = \delta \times [H_2SO_4]_{aq} + K^T(T_R) \quad (3.4)$$

where,  $\delta$  is a parameter taking into account the non-ideality of the solution;  $K^T(T_R)$  is the true thermodynamic constant following the van't Hoff law and derived as

$$K^T(T_R) = K^T(T_{Ref}) \times \exp\left(\frac{-\Delta H_{R,Perhydrolysis}}{R} \times \left(\frac{1}{T_R} - \frac{1}{T_{Ref}}\right)\right) \quad (3.5)$$

Solubility of peracetic and acetic acids in the organic phase is higher than hydrogen peroxide (Campanella et al., 2008; Santacesaria et al., 2011; Wu Zhenyu et al., 2016). Thus, peracetic acid, produced in the aqueous phase, migrates in the organic phase to epoxidize the unsaturated groups on the triglyceride. The rate of epoxidation can be explained as:

$$R_{Ep} = k_{Ep} \times [PAA]_{org} \times [DB]_{org} \quad (3.6)$$

One can assume that mass transfer kinetics is faster than reaction kinetics. Thus, the distribution coefficient  $K_{PAA}$  was used to express the concentration of  $[PAA]_{org}$  as a function of  $[PAA]_{aq}$ .

Eq. (3.6) becomes

$$R_{Ep} = k_{Ep} \times \frac{[PAA]_{aq}}{K_{PAA}} \times [DB]_{org} \quad (3.7)$$

where,  $K_{PAA}$  is the molar equilibrium ratio for PAA.

Ring opening of epoxide group can be assumed to follow the mechanism illustrated in Figure 3.5.

Figure 3.5 Ring opening reaction by nucleophile NuH (water, hydrogen peroxide, acetic or peracetic acid)

The quasi steady state approximation (Zheng et al., 2016) was applied on reaction 1, i.e., protonation of the oxirane group. Thus, the concentration of protonated epoxide group can be indicated as

$$[E_P^+] = \frac{k_{+1} \times [Ep]_{org} \times [H_3O^+]_{org}}{k_{-1} \times [H_2O]_{org}} \quad (3.8)$$

The rate determining step is reaction 2, and thus the reaction rate for the ring opening reaction by a nucleophile can be evaluated as

$$\begin{aligned} R_{RO \text{ by NuH}} &= k_{RO \text{ by NuH}} \times [E_P^+]_{org} \times [NuH]_{org} \\ &= k_{RO \text{ by NuH}} \times \frac{k_{+1} \cdot [Ep]_{org} \cdot [H_3O^+]_{org}}{k_{-1} \cdot [H_2O]_{org}} \times [NuH]_{org} \end{aligned} \quad (3.9)$$

The kinetics of mass transfer was assumed to be faster. Then, the concentrations of hydroxonium and water in the organic phase can be expressed by using the coefficients of distribution  $K_{H_3O^+}$  and  $K_{H_2O}$ .

Eq. (3.9) becomes

$$\begin{aligned} R_{RO \text{ by NuH}} &= k_{RO \text{ by NuH}} \times [E_P^+]_{org} \times [NuH]_{org} \\ &= k'_{RO \text{ by NuH}} \times \frac{[Ep]_{org} \cdot [H_3O^+]_{aq}}{[H_2O]_{aq}} \times [NuH]_{org} \\ &= k'_{RO \text{ by NuH}} \times \frac{[Ep]_{org} \cdot [H_3O^+]_{aq}}{[H_2O]_{aq}} \times \frac{[NuH]_{aq}}{K_{NuH}} \end{aligned} \quad (3.10)$$

where,  $k'_{RO \text{ by NuH}}$  is a lump constant equal to  $\frac{K_{H_2O}}{K_{H_3O^+}}$ .

Hence, the rates of the ring opening reactions by different nucleophiles are

$$R_{RO \text{ by AA}} = k'_{RO \text{ by AA}} \times [Ep]_{org} \times \frac{[AA]_{aq}}{K_{AA}} \times \frac{[H_3O^+]_{aq}}{[H_2O]_{aq}} \quad (3.11)$$

$$R_{RO \text{ by PAA}} = k'_{RO \text{ by PAA}} \times [Ep]_{org} \times \frac{[PAA]_{aq}}{K_{PAA}} \times \frac{[H_3O^+]_{aq}}{[H_2O]_{aq}} \quad (3.12)$$

$$R_{RO \text{ by W}} = k'_{RO \text{ by W}} \times [Ep]_{org} \times [H_3O^+]_{aq} \quad (3.13)$$

$$R_{RO \text{ by HP}} = k'_{RO \text{ by HP}} \times [Ep]_{org} \cdot [H_2O_2]_{aq} \times \frac{[H_3O^+]_{aq}}{[H_2O]_{aq}} \quad (3.14)$$

where,  $k'_{RO \text{ by AA}}$ ,  $k'_{RO \text{ by PAA}}$ ,  $k'_{RO \text{ by W}}$  and  $k'_{RO \text{ by HP}}$  are equal to  $\frac{k_{+1}}{k_{-1}} \cdot \frac{K_{H_2O}}{K_{H_3O^+}}$ ,  $\frac{k_{+1}}{k_{-1}} \cdot \frac{K_{H_2O}}{K_{H_3O^+}}$ ,

$\frac{k_{+1}}{k_{-1}} \cdot \frac{K_{H_2O}}{K_{H_3O^+}} \cdot \frac{1}{K_W}$  and  $\frac{k_{+1}}{k_{-1}} \cdot \frac{K_{H_2O}}{K_{H_3O^+}} \cdot \frac{1}{K_{HP}}$ , respectively.

According to Leveneur et al. (Leveneur et al., 2008), the concentration of hydroxonium ion can be derived by taking into account the concentration of acetic and sulfuric acids as

$$[\text{H}_3\text{O}^+]_{\text{aq}} = \frac{1}{2} \times [\text{H}_2\text{SO}_4]_{\text{aq}} + \sqrt{\frac{[\text{H}_2\text{SO}_4]_{\text{aq}}^2}{4} + 2 \times K_{II}^C \times [\text{H}_2\text{SO}_4]_{\text{aq}} \times [\text{W}]_{\text{aq}} + K_{AA-diss.}^C \times [\text{AA}]_{\text{aq}} \times [\text{W}]_{\text{aq}}} \quad (3.15)$$

where,  $K_{II}^C$  is the second dissociation of sulfuric acid (Knopf et al., 2003) and  $K_{AA-diss.}^C$  is the dissociation of acetic acid (Sue et al., 2004).

One can notice that the estimation of the kinetic constants for epoxidation, ring opening by water, hydrogen peroxide, acetic and peracetic acids is cumbersome. Indeed, the number of kinetic constants to estimate is 10. Thus, one should define a proper strategy to estimate them.

### (3) Mass balance

Experiments were carried out in a batch reactor under isothermal mode.

By assuming fast mass transfer compared to chemical reaction, mass balance of compounds in the aqueous and organic phases can be simplified to (Leveneur et al., 2014),

$$\frac{dC_{j,\text{aq}}}{dt} = \left( \alpha + \frac{1-\alpha}{K_j} \right)^{-1} \times \left( \alpha \times \sum v_{ij} \times R_{\text{aq},i} + (1-\alpha) \times \sum v_{ij} \times R_{\text{org},i} \right) \quad (3.16)$$

$$\frac{dC_{j,\text{org}}}{dt} = (\alpha \times K_j + 1 - \alpha)^{-1} \times \left( \alpha \times \sum v_{ij} \times R_{\text{aq},i} + (1-\alpha) \times \sum v_{ij} \times R_{\text{org},i} \right) \quad (3.17)$$

Solubility of water, hydroxonium ions and hydrogen peroxide was assumed to be negligible in the organic phase. Solubility of CSO, ECSO and RO products in the aqueous phase was assumed to be negligible. Hence, the distribution coefficients for water, hydroxonium ion, hydrogen peroxide, CSO, ECSO and RO products can be written

$$K_W; K_{\text{H}_3\text{O}^+}; K_{\text{H}_2\text{O}_2} \rightarrow \infty \text{ and } K_{\text{CSO}}; K_{\text{ECSO}}; K_{\text{RO}} \rightarrow 0$$

Mass balances of acetic acid, hydrogen peroxide, peracetic acid and water in the aqueous phase can be derived as:

$$\frac{d[\text{AA}]_{\text{aq}}}{dt} = \left( \alpha + \frac{1-\alpha}{K_{\text{AA}}} \right)^{-1} \times \left( -\alpha \times R_{\text{Perh}} + (1-\alpha) \times (R_{\text{Ep}} - R_{\text{RO by AA}}) \right) \quad (3.18)$$

$$\frac{d[\text{HP}]_{\text{aq}}}{dt} = -R_{\text{Perh}} - \frac{(1-\alpha)}{\alpha} \times R_{\text{RO by HP}} \quad (3.19)$$

$$\frac{d[\text{PAA}]_{\text{aq}}}{dt} = \left( \alpha + \frac{1-\alpha}{K_{\text{PAA}}} \right)^{-1} \times \left( \alpha \times R_{\text{Perh}} + (1-\alpha) \times (-R_{\text{Ep}} - R_{\text{RO by PAA}}) \right) \quad (3.20)$$

$$\frac{d[\text{H}_2\text{O}]_{\text{aq}}}{dt} = R_{\text{Perh}} - \frac{(1-\alpha)}{\alpha} \times R_{\text{RO by H}_2\text{O}} \quad (3.21)$$

Mass balances of double bond, epoxide group and ring opening group in the organic phase can be derived as

$$\frac{d[\text{DB}]_{\text{org}}}{dt} = -R_{\text{Ep}} \quad (3.22)$$

$$\frac{d[\text{Ep}]_{\text{org}}}{dt} = R_{\text{Ep}} - R_{\text{RO by HP}} - R_{\text{RO by W}} - R_{\text{RO by AA}} - R_{\text{RO by PAA}} \quad (3.23)$$

$$\frac{d[\text{RO}]_{\text{org}}}{dt} = R_{\text{RO by HP}} + R_{\text{RO by W}} + R_{\text{RO by AA}} + R_{\text{RO by PAA}} \quad (3.24)$$

#### (4) Kinetic modeling and strategy

To estimate the 10 kinetic constants, the following methodology was used:

-Step 1: kinetic constants of ring opening by water ( $k'_{\text{RO by W}}$  &  $Ea'_{\text{RO by W}}$ ) were estimated by using Runs 1 to 6;

-Step 2: kinetic constants of ring opening by hydrogen peroxide ( $k'_{\text{RO by HP}}$  &  $Ea'_{\text{RO by HP}}$ ) were estimated by using Runs 7 to 11 and by using  $k'_{\text{RO by W}}$  &  $Ea'_{\text{RO by W}}$  from step 1;

-Step 2': this step was done in parallel than step 2, kinetic constants of ring opening by acetic acid ( $k'_{\text{RO by AA}}$  &  $Ea'_{\text{RO by AA}}$ ) were estimated by using Runs 12 to 17 and by using  $k'_{\text{RO by W}}$  &  $Ea'_{\text{RO by W}}$  from step 1;

-Step 3: kinetic constants of ring opening by peracetic acid ( $k'_{\text{RO by PAA}}$  &  $Ea'_{\text{RO by PAA}}$ ) were estimated by using Runs 18 to 25 and by using  $k'_{\text{RO by W}}$  &  $Ea'_{\text{RO by W}}$  from step 1,  $k'_{\text{RO by HP}}$  &  $Ea'_{\text{RO by HP}}$  from step 2 and  $k'_{\text{RO by AA}}$  &  $Ea'_{\text{RO by AA}}$  from step 2' ;

-Step 4: kinetic constants of epoxidation by peracetic acid ( $k'_{\text{Ep}}$  &  $Ea'_{\text{Ep}}$ ) were estimated by using Runs 26 to 29 and by using  $k'_{\text{RO by W}}$  &  $Ea'_{\text{RO by W}}$  from step 1,  $k'_{\text{RO by HP}}$  &  $Ea'_{\text{RO by HP}}$  from step 2,  $k'_{\text{RO by AA}}$  &  $Ea'_{\text{RO by AA}}$  from step 2' and  $k'_{\text{RO by PAA}}$  &  $Ea'_{\text{RO by PAA}}$  from step 3 ;

-Step 5: Re-estimation of all the kinetic constants by using as initial guess  $k'_{RO \text{ by } W}$  &  $Ea'_{RO \text{ by } W}$  from step 1,  $k'_{RO \text{ by } HP}$  &  $Ea'_{RO \text{ by } HP}$  from step 2,  $k'_{RO \text{ by } AA}$  &  $Ea'_{RO \text{ by } AA}$  from step 2',  $k'_{RO \text{ by } PAA}$  &  $Ea'_{RO \text{ by } PAA}$  from step 3 and  $k'_{Ep}$  &  $Ea'_{Ep}$  from step 4.

The last step is important to verify if this methodology is correct. Figure 3.6 illustrates the strategy of kinetic modeling.

Figure 3.6. Strategy of kinetic modeling

Based on the modeling method described in Section 2.7, Eqs (3.18) -(3.24) were solved out. The concentrations of double bond and epoxide group were used as observables.

The coefficient of determination  $R^2$  was higher than 95%.

Table 3.3 shows the estimated kinetic constants with their standard deviation. One should notice that all the standard errors are lower than 30% which means that the estimation is reliable. Ring opening by peracetic and acetic acid is faster than by water and hydrogen peroxide. One can notice that the activation energy for ring opening by hydrogen peroxide is

higher than the other ones. This high value of activation energy means that this reaction is less important than the other ring opening reactions.

Table 3.3. Estimated kinetic constants and statistical data at  $T_{ref} = 330$  K for epoxidation.

		Estimated parameters	Standard error (%)
$k'_{RO}$ by W	[L.mol <sup>-1</sup> .s <sup>-1</sup> ]	9.10E-06	19
$Ea'_{RO}$ by W	[kJ.mol <sup>-1</sup> ]	75200	19.9
$k'_{RO}$ by HP	[L.mol <sup>-1</sup> .s <sup>-1</sup> ]	1.10E-04	27.9
$Ea'_{RO}$ by HP	[kJ.mol <sup>-1</sup> ]	104000	22
$k'_{RO}$ by AA	[L.mol <sup>-1</sup> .s <sup>-1</sup> ]	3.69E-03	9
$Ea'_{RO}$ by AA	[kJ.mol <sup>-1</sup> ]	53400	20.6
$k'_{RO}$ by PAA	[L.mol <sup>-1</sup> .s <sup>-1</sup> ]	1.51E-02	11.4
$Ea'_{RO}$ by PAA	[kJ.mol <sup>-1</sup> ]	51400	26.2
$k'_{Ep}$	[L.mol <sup>-1</sup> .s <sup>-1</sup> ]	3.97E-03	10.2
$Ea'_{Ep}$	[kJ.mol <sup>-1</sup> ]	84200	7.9

Table 3.4 is the matrix of correlation for all the kinetic constants. In general, the correlations between the kinetic constants are negligible. Nevertheless, the correlations between the kinetic constants of ring opening by water and hydrogen peroxide ( $k'_{RO}$  by W &  $Ea'_{RO}$  by W and  $k'_{RO}$  by HP &  $Ea'_{RO}$  by HP) are high. This high correlation might mean that the kinetics of ring opening for these nucleophiles is more complex. In the model, we have assumed that mass transfer is fast which might not be the case for these two compounds.

Table 3.4. Matrix of correlation

	$k'_{RO}$ by W	$Ea'_{RO}$ by W	$k'_{RO}$ by HP	$Ea'_{RO}$ by HP	$k'_{RO}$ by AA	$Ea'_{RO}$ by AA	$k'_{RO}$ by PAA	$Ea'_{RO}$ by PAA	$k'_{Ep}$	$Ea'_{Ep}$

### 3.3.3 Influence of the configuration on ring opening products distribution

The goal of this section is to determine the best configuration to minimize the ring opening products. From the previous section, one can notice that it is not possible to avoid ring opening side reactions. The different configurations tested were:

- Batch reactor (Batch),
- Semi-batch reactor where hydrogen peroxide was added (SemiBatch HP),
- Semi-batch reactor where acetic acid was added (SemiBatch AA),
- Semi-batch reactor where acetic and sulfuric acid were added (SemiBatch AA SA),
- Semi-batch reactor where hydrogen peroxide and sulfuric acid were added (SemiBatch HP SA).

Based on the kinetic constants estimated during the modeling stage, the maximum concentration of epoxide group and its associated time ( $t_{max}$ ), and the ring opening product distribution at this time were determined for each configuration. Table 3.5 presents the experimental conditions for each configuration under isothermal conditions.

Table 3.5. Initial experimental conditions for each configuration

		Units	Batch	SemiBatch HP	SemiBatch AA	SemiBatch HP SA	SemiBatch AA SA
INITIAL CONDITIONS	$(DB)_{org}$	mol.L <sup>-1</sup>	4.17	4.17	4.17	4.17	4.17
	$(Ep)_{org}$	mol.L <sup>-1</sup>	0	0	0	0	0
	$(RO\ by\ W)_{org}$	mol.L <sup>-1</sup>	0	0	0	0	0
	$(RO\ by\ AA)_{org}$	mol.L <sup>-1</sup>	0	0	0	0	0
	$(RO\ by\ PAA)_{org}$	mol.L <sup>-1</sup>	0	0	0	0	0
	$(RO\ by\ HP)_{org}$	mol.L <sup>-1</sup>	0	0	0	0	0
	$(AA)_{aq}$	mol.L <sup>-1</sup>	2.61	13.44	0	13.75	0.00
	$(H_2O_2)_{aq}$	mol.L <sup>-1</sup>	9.19	0.00	10.82	0.00	10.87
	$(PAA)_{aq}$	mol.L <sup>-1</sup>	0	0	0	0	0
	$(Water)_{aq}$	mol.L <sup>-1</sup>	35.24	11.30	41.48	11.55	41.69
	$(H_2SO_4)_{aq}$	mol.L <sup>-1</sup>	0.08	0.41	0.09	0.00	0.00
	$V_{org}$	L	0.16	0.16	0.16	0.16	0.16
	$V_{aq}$	L	0.13	0.02	0.11	0.02	0.11
	Temperature	°C	60	60	60	60	60
	Q	×10 <sup>-4</sup> L.min <sup>-1</sup>	0	8.93	9.52	8.93	9.52
	$t_{add}$	min	0	128.00	20.00	128.00	20.00
	$(AA)_{Feed}$	mol.L <sup>-1</sup>	0	0	17.49	0	17.00
	$(H_2O_2)_{Feed}$	mol.L <sup>-1</sup>	0	10.87	0	10.81	0
	$(H_2O)_{Feed}$	mol.L <sup>-1</sup>	0	41.69	0	41.47	0
$(H_2SO_4)_{Feed}$	mol.L <sup>-1</sup>	0	0	0	0.09	0.52	

The experimental conditions for these numerical experiments were designed to have the same number of moles of acetic acid, sulfuric acid, hydrogen peroxide or water at the end of the addition. The final concentration of sulfuric acid was fixed to ca. 0.08 mol.L<sup>-1</sup> to limit the ring opening reactions. The reaction temperature was set to 60°C for all of them. Figure 3.9 shows the distribution of the different compounds in the organic phase at the time  $t_{max}$ .

Figure 3.9. Distribution of compounds in the organic phase for the numerical experiments: Batch, SemiBatch HP, SemiBatch AA, SemiBatch HP SA and SemiBatch AA SA.

From Figure 3.9, one can notice that the optimal configuration to have the highest concentration of epoxide groups is the configuration of semi batch reactor where hydrogen peroxide and sulfuric acid solution is added. Furthermore, the time to reach this maximum is shorter than the other configuration, except the SemiBatch HP configuration.

The other benefit of the configuration SemiBatch HP SA is the thermal safety issue. Indeed, epoxidation of vegetable oils can lead to thermal runaway situation (Casson Moreno et al., 2017; Leveneur et al., 2015). Thus, by adding the oxidizing agent into the reaction mixture, it is easier to control this risk.

### 3.4 Conclusion

The influence of ring opening reactions during the epoxidation of cottonseed oil by peracetic acid was investigated. In the first part, a kinetic study shown that all the nucleophiles, *i.e.*, water, hydrogen peroxide, acetic and peracetic acids, can attack the epoxide groups. An induction period was observed to be present when the concentration of sulfuric acid was low.

Hence, a modeling strategy was developed to estimate the 10 kinetic constants of this system. A pseudohomogeneous model was used by taking into account the distribution coefficients of acetic and peracetic acids. These distribution coefficients were found to be dependent on the concentrations of epoxide groups, double bond and ring opening products. For that, the estimation of the ring opening reactions was done apart to get some reliable initial guess values during the last stage of the modeling. The correlation between the kinetic constants can be considered as negligible. It was found that ring opening by peracetic and acetic acid is faster than by water and hydrogen peroxide.

Based on this model, the semi batch reactor, where hydrogen peroxide and sulfuric acid were added continuously, was found to be the optimal configuration to maximize the concentration of epoxide group and minimize the concentration of ring opening products.

## Chapter IV Interaction between functional groups and physicochemical properties: application to vegetable oils and their epoxidized and carbonated derivatives

Part of this chapter is adapted from the post print of the following article:

Cai, X., Ait Aissa, K., Estel, L., & Leveneur, S. (2018). Investigation of the Physicochemical Properties for Vegetable Oils and Their Epoxidized and Carbonated Derivatives. *Journal of Chemical & Engineering Data*, 63(5), 1524-1533.

### 4.1 Introduction

The evolution of different physicochemical properties was investigated, such as refractive index, dynamic viscosity, density and specific heat capacity of vegetable oils, epoxidized vegetable oils and carbonated vegetable oils at different temperatures and concentrations of unsaturated, epoxide and carbonated groups. Three different types of vegetable oils were selected: cottonseed, linseed and soybean oils. We have chosen these vegetable oils because they are more representative since their components of unsaturated fatty acids and the iodine numbers are quite different (Table 4.1). The objective is to investigate the influence of the functional groups on the physicochemical properties, primarily because these functional groups change with the progress of the reaction. In order to predict the evolution of these properties at different concentrations of functional groups, we have measured the physicochemical properties of different mixtures of soybean oil and its derivatives. In this chapter, Section 4.2 gives detailed information about the experimental procedure. Section 4.3 shows the experiment results and discussion. Section 4.4 gives the conclusion for this part of the work.

Table 4.1. Components of vegetable oils in mass fraction

	Palmitic	Palmitoleic	Stearic	Oleic	Linoleic	Linolenic	Iodine number
	C16:0	C16:1	C18:0	C18:1	C18:2	C18:3	
Linseed oil	5.10	0.30	2.50	18.90	18.10	55.10	175.18
Soybean oil	10.60	-	4.80	22.50	52.30	8.20	132.16
Cottonseed oil	28.70	-	0.90	13.00	57.40	-	116.88

## 4.2 Experimental section

Epoxidized cottonseed oil (ECISO), epoxidized linseed oil (ELSO) and epoxidized soybean oil (ESBO) were prepared as described in the Section 2.4.1. Epoxidized fatty acid methyl ester-derived from cottonseed oil was prepared as described in Section 2.4.3.

Carbonated cottonseed oil (CCSO), carbonated linseed oil (CLSO) and carbonated soybean oil (CSBO) were produced by using the protocol as described in the Section 4.5. Briefly, epoxidized vegetable oil (ca. 0.09 kg) and the catalyst tetra-n-butylammonium bromide (TBABr, ca. 0.0039 kg) were introduced into a high-pressurized reactor. The reaction temperature was kept at 140 °C and the pressure of CO<sub>2</sub> was 50 bar. The reaction lasted for 50 hours.

In order to remove the TBABr catalyst, the carbonated product (CCSO, CLSO and CSBO) was diluted in ethyl acetate. Then, the mixture was washed four times with distilled water before being evaporated at 343.15 K. The residual water and solvent were removed through nitrogen-blowing.

Table 4.2 shows the molar fractions of double bonds ( $x_{DB}$ ), epoxide groups ( $x_{Ep}$ ), ring opening groups ( $x_{RO}$ ) and carbonated groups ( $x_{Carb}$ ) for the different species. These molar fractions were determined as:

$$x_i = \frac{n_i}{n_{DB \text{ in VO}}} \quad (4.1)$$

Where,  $n_i$  is the number of moles of groups (double bonds, epoxide groups) and  $n_{DB \text{ in VO}}$  is the number of double bonds in the fresh vegetable oils.

Table 4.2. Molar fractions:  $x_{DB}$ ,  $x_{Ep}$ ,  $x_{RO}$ ,  $x_{Carb}$  and iodine number for the different species

	$x_{DB}$	$x_{Ep}$	$x_{RO}$	$x_{Carb}$	Iodine value
CSO	1.00	0.00	0.00	0.00	116.88
SBO	1.00	0.00	0.00	0.00	132.16
LSO	1.00	0.00	0.00	0.00	175.18
ECISO	0.04	0.88	0.08	0.00	4.76
ESBO	0.01	0.99	0.00	0.00	3.41
ELSO	0.02	0.98	0.00	0.00	3.58
CCSO	0.04	0.00	0.08	0.88	0.00
CSBO	0.01	0.00	0.00	0.99	8.08
CLSO	0.02	0.00	0.00	0.98	8.71

One can notice that the molar fractions for epoxide and carbonated groups are similar for the different vegetable oils (Table 4.2). Due to the presence of the ring-opening side reactions, the molar fractions of epoxide and carbonated groups were lower than 100% (Table 4.2).

The physicochemical properties, as refractive index, density, dynamic viscosity, and the specific heat capacities for vegetable oils and their epoxidized and carbonated derivatives were measured as described in Section 2.3.

### 4.3. Results and discussion

#### 4.3.1 Refractive index

The use of refractive index for vegetable oil characterization is scarce. One can cite the work of Cho et al. (Cho et al., 2013), which has demonstrated that the refractive index is proportional to acid values of vegetable oil. Figure 4.1 shows the evolution of the refractive index (*RI*) for CSO, ECSO and CCSO. One can notice that the density is linear to the temperature, and this tendency was observed for the different vegetable oils and their corresponding epoxidized and carbonated forms. The coefficients of determination were higher than 95% for the different vegetable oils and their derivatives by using a linear correlation between refractive index and temperature. The variation of refractive index with temperature can be estimated as:

$$RI = a \times T + b \quad (4.1)$$

where, *a* and *b* are constants depending on the nature of the species; *T* is temperature, K.

This value was measured three times for each sample. The standard deviation of the mean ( $SV_{\text{mean}}\%$ ) for the refractive index measurement was 0.51%, showing the reliability of the measurement. Due to space limitation, only the results of cottonseed oil and its corresponding epoxidized and carbonated forms are presented in Figure 4.1, and the same tendency was observed for the other species (Appendix I). Refractive index linearly decreases when temperature increases. The refractive index for carbonated forms is higher than vegetable oils and epoxidized forms.

Table 4.3 presents the different values of *a* and *b* for the evolution of the refractive index of the different vegetable oils and their derivatives.

Figure 4.1. Measured refractive index versus temperature for cottonseed oil, epoxidized cottonseed oil and carbonated cottonseed oil. ◆, CSO; ●, ECSO; ○, CCSO

Table 4.3. Evolution of a and b for the refractive index.

	Refractive index $RI = a \times T + b$	
	a	b
CSO	-0.0004	1.6041
ECSO	-0.0003	1.5713
CCSO	-0.0003	1.5745
SBO	-0.0004	1.5815

CLSO	-0.0003	1.5570

The values of the refractive index depend on the concentrations of double bonds, epoxidized and carbonated groups. Indeed, the refractive index of linseed oil and its derivatives are higher than the two other vegetable oils and their derivatives. The concentrations of double bonds, epoxidized and carbonated groups are higher for linseed oil and its derivatives.

The differences of refractive index values between the fresh vegetable oils, epoxidized and carbonated forms show that this physical data can be used as an online analytical method.

#### 4.3.2 Density

The evolutions of density ( $\rho$ ) of CSO, ECSO and CCSO with temperature are displayed in Figure 4.2.

There is a linear relationship between the density value and the temperature, which can be explained as:

$$\rho = a' \times T + b' \quad (4.2)$$

where,  $a'$  and  $b'$  are two constants depending on the nature of vegetable oil,  $T$  is temperature expressed in kelvin.

This linear relationship is confirmed by the high values of determination coefficients, i.e., over than 99.9% for every vegetable oil and their derivatives. Table 4.4 shows the values of these constants for the different vegetable oils and their derivatives.

Table 4.4. Evolution of  $a'$  and  $b'$  for the density

	$a' / \text{g.cm}^{-3}.\text{K}^{-1}$	$b' / \text{g.cm}^{-3}$
CSO	-0.0007	0.93
ECSO	-0.0007	0.99
CCSO	-0.0007	1.05
SBO	-0.0007	0.94
ESBO	-0.0007	1.01
CSBO	-0.0007	1.09
LSO	-0.0007	0.95
ELSO	-0.0007	1.06
CLSO	-0.0008	1.11

Figure 4.2. Measured density versus temperature for cottonseed oil, epoxidized cottonseed oil and carbonated cottonseed oil. ◆, CSO; ●, ECSO; ○, CCSO

As the temperature increases, the value of density decreases. Density of vegetable oil is lower than its epoxidized form than its carbonated form.

Density was measured three times for each sample. The standard deviation of the mean ( $SV_{\text{mean}}\%$ ) for the measurement of density was 0.07%. The evolution of soybean oil density with temperature is similar to the ones found by Esteban et al (Esteban et al., 2012).

As the refractive index, density value is also sensitive to the concentrations of double bonds, epoxidized and carbonated groups. Density of LSO was found to be higher than CSO and SBO within the temperature range (283.15 to 353.15) K. This tendency was also observed for ELSO and CLSO (Appendix I).

### 4.3.3 Viscosity

Viscosity ( $\mu$ ) study of vegetable oils at different temperatures has been done by some research groups (Esteban et al., 2012; Fasina et al., 2006). However, such study is rare for epoxidized and carbonated vegetable oils and sometimes different (Bähr and Mülhaupt, 2012; Campanella et al., 2010; Ishimura and Yoshida, 2015; Parzuchowski et al., 2006; Poussard et al., 2016; Zhang et al., 2014). For instance, viscosity of ESBO at 313.15 K was measured of 0.3 Pa.s by Campanella et al. (Campanella et al., 2010), and of 0.036 Pa.s by Poussard et al. (Poussard et al., 2016).

Figures 4.3, I-3 and I-4 show the evolution of dynamic viscosity for cottonseed, linseed and soybean oils and their modified forms versus temperature. One can notice that the viscosity of linseed oil is higher than the other ones. Besides, as the number of carbonated groups increases, the viscosity values increase significantly.

Figure 4.3. Measured dynamic viscosity versus temperature for cottonseed oil, epoxidized cottonseed oil and carbonated cottonseed oil. ◆, CSO; ●, ECSO; ○, CCSO

From Figure 4.3, one can notice that the functional groups have a strong influence on the viscosity values. The evolution of dynamic viscosity is in the order of  $\mu(\text{VO}) < \mu(\text{EVO}) < \mu(\text{CVO})$ .

For instance, at 283.15 K, viscosity of LSO is of 80 mPa.s compared to 100 mPa.s and 120 mPa.s for SBO and CSO, respectively.

Viscosity measurement was done three times for each sample. The standard deviation of the mean ( $SV_{\text{mean}}\%$ ) for the measurement of viscosity was 1.56%.

Correlation between viscosity and temperature can be evaluated by an Arrhenius law

$$\mu = A \times e^{\frac{-E_a}{RT}} \quad (4.3)$$

Figure 4.4 illustrates this correlation, and due to space limitation, only the evolution of cottonseed oil and its derivatives are shown (Appendix I). The coefficients of determination were higher than 95% for the different vegetable oils showing the reliability of the exponential relationship between the viscosity and temperature.

Figure 4.4. Linear correlation between the logarithm of viscosity and  $1/RT$ .

◆, CSO; ●, ECSO; ○, CCSO

Table 4.5. Arrhenius data for Eq. (4.3)

	A / Pa.s	$E_a$ / J.mol <sup>-1</sup>
CSO	8.0E-06	-9402.9
ECSO	3.23E-04	-15979
CCSO	1.90E-05	-27129
SBO	2.96E-03	-8688.7
ESBO	5.20E-07	-21482
CSBO	1.70E-05	-28247
LSO	5.34E-03	-6617.7
ELSO	1.00E-04	-21986
CLSO	1.80E-05	-30371

Compared to the literature, the measured viscosities of the fresh vegetable oils are slightly higher. For example, the viscosity of SBO at 333.15 K was found to be 0.02 Pa.s by Campanella et al. (Campanella et al., 2010), Esteban et al. (Esteban et al., 2012), and Fasina et al. (Fasina et al., 2006), whereas we found 0.07 Pa.s.

Based on our experimental data and Eq. (4.3), the viscosity of ELSO was found to be similar to the one measured at 298.15 K by Ishimura et al. for the ESBO (Ishimura and Yoshida, 2015), the viscosity was found to be 0.2 Pa.s in this work which is the same with the one measured by Campanella et al. (Campanella et al., 2010) but higher than the one measured by Poussard et al. (Poussard et al., 2016), i.e., 0.036 Pa.s. The study made by Zhang et al. (Zhang et al., 2014) shows similar viscosity values for the ECSO compared to our work.

The viscosity data for carbonated vegetable oils in the literature varies. One can cite the following values: CSBO was found to be 2.5 Pa.s at 323.15 K (Bähr and Mülhaupt, 2012), 24.4 Pa.s at 313.15 K (Poussard et al., 2016), and 30.2 Pa.s at 293.15 K (Parzuchowski et al., 2006). Compared to these values, our data are lower. Nevertheless, for the CCSO we have found similar values to the ones measured by Zhang et al (Zhang et al., 2014).

#### 4.3.4 Specific heat capacity

The evolutions of specific heat capacity ( $C_p$ ) of vegetable oils with temperature are relatively rare in the literature (Fasina and Colley, 2008; Kowalski, 1988). The lack of this data is even more pronounced for the epoxidized and carbonated vegetable oils.

This thermal parameter was measured by using C80-Setaram calorimeter. It is a twin calorimeter where the measuring cell was filled with the oils (ca. 1.0 g  $\pm$  0.0001 g) and the reference cell was kept empty. The cells were kept under isothermal conditions at the desired temperature for 140 minutes. Then, a temperature ramp of 0.5°C.min<sup>-1</sup> was applied to increase the temperature by 2 °C. At that moment, the cells were again kept under isothermal conditions at this new temperature stage for 140 minutes. During the temperature increase, there was an endothermic phenomenon corresponding to the energy absorbed by the oils to increase its temperature by 2 °C.

To determine the  $C_p$  values, one needs to take into account the energy absorbed by the system, i.e., with no chemicals in the measuring and reference cells.

Hence, one can determine the values of the  $C_p$  at the certain temperature by using the following equation:

$$C_p(T) = \frac{Q_r(T) - Q_b(T)}{m \times \Delta T} \quad (4.4)$$

where,  $Q_r(T)$  is the heat absorbed by the oils at the desired temperature,  $Q_b(T)$  is the energy absorbed by the system in absence of oils,  $m$  is the mass of oils and  $\Delta T$  is the temperature difference, i.e., 2°C.

Figure 4.5 shows an example of measurement by C80-Setaram.

Figure 4.5. Illustration of  $C_p$  measurement with C80 for SBO

●, Temperature\_SBO; ▲, Temperature\_Blank; ○, Heat\_flow\_SBO; △, Heat\_flow\_Blank.

The standard deviation of the mean ( $SV_{\text{mean}}\%$ ) for the measurement of  $C_p$  was 1.06%. Figure 4.6 shows the evolutions of  $C_p$  for LSO, ELSO and CLSO with temperature. One can notice that the values of this parameter are similar for these three compounds within the temperature range (313.15 to 383.15) K. We have also observed this tendency for the other two vegetable oils (Appendix I).

Figure 4.6. Evolution of specific heat capacity of cottonseed oil and its derivatives with temperature. ◆, LSO; ●, ELSO; ○, CLSO.

The variation of  $C_p$  with temperature can be described by a polynomial equation of second order as: (Stoessel, 2008)

$$\frac{C_p(T)}{C_p(T_{ref})} = A \times T^2 + B \times T + C \quad (4.5)$$

where,  $T$  is the temperature and  $T_{ref}$  is a reference temperature in kelvin. The coefficient  $A$ ,  $B$  and  $C$  are constants. For this study, the reference temperature was fixed at 313.15 K.

Figure 4.7 shows the fitting of the experimental data, i.e.,  $\frac{C_p(T)}{C_p(T_{ref}=313.15\text{ K})}$  by using a polynomial equation for LSO, ELSO and CLSO. One can notice that the coefficient of determination was higher than 95% showing the reliability of this relationship. This observation was the same for CSO, SBO, ECSO, ESBO, CCSO and CSBO. Table 6 gives the values of the coefficients  $A$ ,  $B$  and  $C$  for the oils.

Figure 4.7. Polynomial fitting for  $C_p(T) / C_p(313.15 \text{ K})$  for cottonseed oil and its derivatives.  $\blacklozenge$ , CSO;  $\bullet$ , ECSO;  $\circ$ , CCSO.

Table 4.6. Evolution of the coefficients A, B and C of Eq. (4.5) for vegetable oils and their derivatives

$C_p(T) / C_p(T_{\text{ref}}=313.15 \text{ K})=AT^2 + BT + C$			
	A / K <sup>-2</sup> × 10 <sup>-6</sup>	B / K <sup>-1</sup>	C
CSO	-20.00	0.0149	-1.7740
ECSO	-10.00	0.0118	-1.3279
CCSO	-10.00	0.0093	-0.8714
SBO	-10.00	0.0086	-0.6907
ESBO	-3.00	0.0034	0.2521
CSBO	-8.00	0.0066	-0.2973
LSO	-5.00	0.0049	-0.0552
ELSO	-10.00	0.0091	-0.6965
CLSO	-4.00	0.0043	0.0688

#### 4.3.5 Effects of functional groups in the mixing

One can notice that the functional groups can have an important effect on refractive index, viscosity, density and specific heat capacity. Thus, can we predict the evolution of these parameters at different concentrations of double bonds, epoxide and carbonated groups?

For that, we have used the solution of fresh vegetable oils, synthesized epoxidized vegetable oils and synthesized carbonated vegetable oils (Table 4.2). From these solutions, we prepared different solutions at different weight percentage of SBO, ESBO and CSBO.

Table 4.7 shows the three different solutions used for these experiments.

Table 4.7. Solution components

Solution	Weight percentage w (% in mass fraction)		
	SBO	ESBO	CSBO
S1	49.80	50.20	0.00
S2	19.78	19.98	60.24
S3	39.12	31.41	29.47

The following correlations have been tested:

$$RI(SX) = w(SBO) \times RI(SBO) + w(ESBO) \times RI(ESBO) + w(CSBO) \times RI(CSBO) \quad (4.6)$$

$$\rho(SX) = w(SBO) \times \rho(SBO) + w(ESBO) \times \rho(ESBO) + w(CSBO) \times \rho(CSBO) \quad (4.7)$$

$$\ln\mu(SX) = w(SBO) \times \ln\mu(SBO) + w(ESBO) \times \ln\mu(ESBO) + w(CSBO) \times \ln\mu(CSBO) \quad (4.8)$$

$$Cp(SX) = w(SBO) \times Cp(SBO) + w(ESBO) \times Cp(ESBO) + w(CSBO) \times Cp(CSBO) \quad (4.9)$$

where, SX is the solution S1, S2 or S3.

Ramírez Verduzco (Ramírez Verduzco, 2013) has demonstrated that correlations Eqs (4.7) and (4.8) could be used for a mixture of vegetable oils and fatty acid methyl esters. For the specific heat capacity of a mixture, correlation (Eq. 4.9) is widely accepted (Stoessel, 2008).

Figures 4.8-4.11 show the fittings of the correlation between the experimental data and the model data for refractive index ( $RI$ ), density ( $\rho$ ),  $\ln\mu$  and specific heat capacity ( $Cp$ ) for the

different solutions S1, S2 and S3. Due to space limitation, the other fitting curves were put in Appendix I.

To evaluate the reliability of these correlations towards experimental data, the overall average relative deviation of determination (OARD) was introduced: (Freitas et al., 2013)

$$OARD(\%) = \frac{\sum_{i=0}^N \left| \frac{\theta_e - \hat{\theta}_e}{\theta_e} \right|}{N} \quad (4.10)$$

Where,  $\theta_e$  is the experimental value of the parameter,  $\hat{\theta}_e$  is the predicted value given by the correlation and  $N$  are experimental data points. The correlation results are shown in Table 4.8.

Table 4.8. OARD of refractive index, density,  $\ln\mu$  and specific heat capacity

	OARD / %
Refractive index	0.14
Density	0.33
$\ln\mu$	16.80
Specific heat capacity	2.37

Generally, one can notice that the experimental data (refractive index, density and specific heat capacity) can be successfully predicted with overall average relative deviation values less than 2.5 %. However, the overall average relative deviation value for  $\ln\mu$  is higher due to the fact that Eq. (4.8) does not take into account the interaction between the functional groups.

#### 4.4. Conclusion

This study proposed to investigate the influence of temperature on density, refractive index, viscosity and specific heat capacity for vegetable oils and their epoxidized and carbonated derivatives. Indeed, these data are missing in the literature.

It was demonstrated that refractive index value decreases linearly as the temperature increases. This parameter could be used as an analytical method to segregate vegetable oils and their derivatives. Density of these oils decreases linearly as temperature increases. It was found that the viscosity of vegetable oils is exponentially proportional to the temperature. The values for the specific heat capacity were found to be relatively constant with temperature and did not change significantly between fresh vegetable oils and their derivatives. Nevertheless, the ratio  $\frac{C_p(T)}{C_p(T_{ref})}$  follows a polynomial of second order with temperature allowing predicting the values of  $C_p$  for each oil. Hence, the functional groups have an effect on these parameters. The last part of this study demonstrated that it is possible to predict the values of these physicochemical parameters in case of mixture by knowing the evolutions of the pure compounds.

## Chapter V Carbonation of epoxidized vegetable oils

Part of this chapter is adapted from the post print of the following article:

X. Cai, J.L. Zheng, J. Wärnå, T. Salmi, B. Taouk, S. Leveneur. Influence of gas-liquid mass transfer on kinetic modeling: Carbonation of epoxidized vegetable oils. *Chemical Engineering Journal*, 313(2017) 1168-1183.

### 5.1 Introduction

In this chapter, a kinetic model for the carbonation of epoxidized cottonseed oil catalyzed by TBABr was proposed. For gas-liquid reaction system, one should take into account the kinetics of mass transfer.

In the first stage, a mass transfer model was built to predict the evolution of the volumetric mass transfer coefficients and Henry's constants with reaction advancement and temperature. Then, a kinetic model was built at different reaction temperature, catalyst and epoxide concentrations and CO<sub>2</sub> pressure.

Section 5.2 gives the information about the experimental procedure. Section 5.3 shows the experiment results and the discussion.

### 5.2 Experimental section

#### 5.2.1 Preparation of the epoxidized compound

Epoxidized cottonseed oil (ECSO) was prepared as described in the Section 2.4.1 and Appendix II.

#### 5.2.2 Kinetic study of carbonation reaction

Carbonation of epoxidized cottonseed (CCSO) oil was carried out by using the same protocol as described in the Section 2.5 according to the article of our group (Ait Aissa et al., 2016). Table 5.1 shows the experimental matrix for the different carbonation conditions.

The conversion rate (%) of epoxide was selected as a response value for the carbonation evaluation. It was calculated as Eq. (5.1).

$$\text{Conversion rate (\%)} = \left(1 - \frac{\text{Titrated epoxide content}}{\text{Initial epoxide content}}\right) \times 100 \quad (5.1)$$

Table 5.1 Experimental Matrix for carbonation reaction with an agitation velocity of 500rpm

Run	[Epoxidized group] (mol.L <sup>-1</sup> )	[TBAB] (mol.L <sup>-1</sup> )	[Double Bonds] (mol.L <sup>-1</sup> )	Pressure (bar)	Temperature (°C)

### 5.2.3 Mass transfer study for CO<sub>2</sub>

One of the goals of this section was to determine the gas-liquid mass transfer coefficients and the solubility of the CO<sub>2</sub> in the reaction mixture. It was also important to check the variation of these parameters as a function of the conversion.

During the mass transfer experiments, 90.0 g of oil sample (ECSO, CCSO or CSO) was weighted out and mixed in the reactor, then heated to a certain temperature. The atmosphere inside the reactor was purged with CO<sub>2</sub> for two times. The CO<sub>2</sub> pressure in the reactor was maintained constant by the pressure regulator. As the values had been stabilized, the agitation was started at 500 rpm. The values (temperature and pressure) inside the gas reservoir were simultaneously monitored. Table 5.2 shows the experimental matrix for the mass transfer study.

Table 5.2 Mass transfer experimental matrix

### 5.3 Results and discussion

#### 5.3.1 Preliminary kinetic experiments

In the previous article of our group (Zheng et al., 2015), it was shown that the formation rates of carbonated groups increase with temperature (110-130 °C), pressure (30-50 bar) and catalyst (0.05-0.36 mol.L<sup>-1</sup>). We have demonstrated that the optimum agitation rate was 500 rpm.

The goal of this section is to provide complementary data at lower CO<sub>2</sub> pressures, higher temperatures, lower catalyst concentrations and different initial concentrations of ECSO. The experiments were conducted under isobaric and isothermal conditions.

Figure 5.1. Effect of the CO<sub>2</sub> pressure on the kinetics of carbonation at 120 °C, [TBABr] = 0.13 mol.L<sup>-1</sup>, [ECSO]<sub>0</sub> = 3.4-3.5 mol.L<sup>-1</sup> and rotating speed of 500 rpm

Figure 5.1 shows the influence of CO<sub>2</sub> pressure on the conversion of epoxidized group at 120 °C. The presence of an induction period is observed when the pressure is less than 30 bar. This phenomenon has been previously observed by North and Pasquale (North and Pasquale, 2009) during the carbonation of styrene oxide by TBABr. However, they have observed this induction period at low concentrations of TBABr.

Figure 5.2 shows the influence of temperature on the kinetics of carbonation. As expected, the reaction rate increases with temperature.

Figure 5.2. Effect of temperature on the kinetics of carbonation at  $[TBABr] = 0.13 \text{ mol.L}^{-1}$ ,  $[ECSO]_0 = 3.4\text{-}3.5 \text{ mol.L}^{-1}$ , 50 bar and rotating speed of 500 rpm

Figure 5.3. Effect of initial concentration of ECSO on the kinetics of carbonation at  $[TBABr] = 0.13 \text{ mol.L}^{-1}$ , 110 °C and rotating speed of 500 rpm

Figure 5.3 reveals the influence of the ECSO concentration at 47 bar and 110 °C. To vary the concentration of ECSO, pure cottonseed oil with ECSO was mixed at different ratios. As the concentration of ECSO is within the range 2.47-3.40 mol.L<sup>-1</sup>, the kinetic behavior is similar. However, the kinetics of carbonation is faster when the concentration of ECSO is 1.72 mol.L<sup>-1</sup>. This effect might be linked to the viscosity of the reaction mixture which is higher at high concentration of ECSO (Figure 4.3) and could retard the mass transfer of CO<sub>2</sub>. Figure 4.3 shows that the viscosity increases in the order CCSO > ECSO > CSO.

Figure 5.4. Effect of catalyst concentration on the kinetics of carbonation at  $[ECSO]_0 = 3.2-3.4$  mol.L<sup>-1</sup>, 50 bar, 140 °C and agitation speed of 500 rpm

Figure 5.4 shows the effect of the catalyst concentration on the kinetics of carbonation at ca. 48 bar. As the catalyst concentration increases, the rate is enhanced. The association of the catalyst on the oxirane group can involve several steps affecting the reaction order. From Figure 5.4, it is possible to estimate the reaction order with respect to catalyst concentration by plotting the logarithm of the initial reaction rate ( $\ln(R_{\text{Carbonation},0})$ ) versus the logarithm of catalyst concentration (Figure 5.5).

Figure 5.5.  $\ln(R_{\text{Carbonation},0})$  versus  $\ln([TBABr])$  at  $[ECSO]_0 = 3.2\text{-}3.4 \text{ mol.L}^{-1}$ , 50 bar, 140 °C with agitation speed of 500 rpm

Figure 5.5 shows that the reaction order with respect to catalyst is probably equal to 0.5. The parameter  $n$  was estimated during the kinetic modeling stage to validate this observation. Based on the kinetic experiments, it can be noticed that the  $\text{CO}_2$  pressure, the epoxidized group and TBABr concentrations as well as reaction temperature play an important role on the reaction kinetics.

### 5.3.2 Kinetic model principles

According to related literatures (Lang, 2016; Langanke et al., 2013; North and Pasquale, 2009), mechanism illustrated by Figure 5.6 is proposed for the carbonation of the epoxidized groups of the vegetable oils.

Figure 5.6. Simplified mechanism of carbonation of epoxidized vegetable oils by TBABr

The overall reaction is:

The reaction rates of the different steps can be expressed as

$$R_1 = k_1 \times [\text{Ep}] \times [\text{TBABr}]^n - k_{-1} \times [\text{I}_1]$$

$$R_2 = k_2 \times [\text{I}_1] \times [\text{CO}_2]_{\text{liq}} - k_{-2} \times [\text{I}_2] \quad (5.2)$$

$$R_3 = k_3 \times [\text{I}_2] - k_{-3} \times [\text{Carb}] \times [\text{TBABr}]$$

with [Ep] is the concentration of epoxidized group, [I<sub>1</sub>] is the concentration of the intermediate 1, [I<sub>2</sub>] is the concentration of the intermediate 2, [Carb] is the concentration of carbonated group, *n* is the reaction order with respect to TBABr and [CO<sub>2</sub>]<sub>liq</sub> is the concentration of carbon dioxide dissolved in the liquid phase.

As demonstrated previously (Figure 5.5), the rate of carbonation is not first order with respect to TBABr concentration. For that reason, we have described the kinetics of reaction 1 as shown above.

Steady-state approximation was applied to  $I_1$  and  $I_2$ ,

$$r_{I_1} = R_1 - R_2 = 0 \quad (5.3)$$

$$r_{I_2} = R_2 - R_3 = 0 \quad (5.4)$$

where,  $r_{I_1}$  and  $r_{I_2}$  are the rates of formation and disappearance of intermediates 1 and 2, respectively.

We have assumed that the concentration of catalyst was constant during the reaction.

Reaction 2 was assumed to be the rate determining step, the carbonation reaction kinetic can be written as

$$R_{\text{Carbonation}} = R_2 = k_2 \times [I_1] \times [\text{CO}_2]_{\text{liq}} - k_{-2} \times [I_2] \quad (5.5)$$

Reaction 3 can be assumed to be irreversible, thus  $k_3 \rightarrow 0$ . By rearranging Eqs (5.3) and (5.4), one can find the following expression for the concentrations of  $I_1$  and  $I_2$ ,

$$[I_1] = \frac{(k_{-2} + k_3) \times k_1 \times [\text{Ep}] \times [\text{TBAB}]^n + k_{-2} \times k_3 \times [\text{Carb}] \times [\text{TBAB}]^n}{[k_{-1} \times k_{-2} + k_{-1} \times k_3 + k_2 \times k_3 \times [\text{CO}_2]_{\text{liq}}]} \quad (5.6)$$

$$[I_2] = \frac{(k_2 \times [\text{CO}_2]_{\text{liq}} \times [\text{TBAB}]^n) \times (k_1 \times [\text{Ep}] + k_{-2} \times k_3 \times [\text{Carb}])}{[k_{-1} \times k_{-2} + k_{-1} \times k_3 + k_2 \times k_3 \times [\text{CO}_2]_{\text{liq}}]} \quad (5.7)$$

By inserting Eqs (5.5) and (5.6) into Eq. (5.7), the kinetic for carbonation rate becomes

$$R_{\text{Carbonation}} = \frac{k_1 \times k_2 \times k_3 [\text{CO}_2]_{\text{liq}} \times [\text{TBAB}]^n \times \left( [\text{Ep}] + \frac{k_{-2}}{k_1} \times [\text{Carb}] - \frac{k_{-2}^2}{k_1} \times [\text{Carb}] \right)}{[k_{-1} \times k_{-2} + k_{-1} \times k_3 + k_2 \times k_3 \times [\text{CO}_2]_{\text{liq}}]} \quad (5.8)$$

The reverse reaction of reaction 2, i.e., the release of  $\text{CO}_2$  from intermediate  $I_2$ , can be assumed negligible in the temperature range 90-130°C. Then, the kinetic constant  $k_{-2}$  is low compare to kinetic constant  $k_1$ . The term  $\frac{k_{-2}^2}{k_1}$  can be assumed to tend to zero.

The following notations were introduced:  $k_{\text{Carbonation}} = k_1 \times k_2 \times k_3$ ,  $\alpha = k_{-1} \times k_{-2} + k_{-1} \times k_3$ ,  $\beta = k_2 \times k_3$  and

$\gamma = \frac{k_{-2}}{k_1}$ . Eq. (5.8) becomes

$$R_{\text{Carbonation}} = \frac{k_{\text{Carbonation}} \times [\text{CO}_2]_{\text{liq}} \times [\text{TBAB}]^n \times ([\text{Ep}] + \gamma \times [\text{Carb}])}{[\alpha + \beta \times [\text{CO}_2]_{\text{liq}}]} \quad (5.9)$$

These parameters were estimated during the modeling stage. The value of  $\beta$  was fixed to 1 L.mol<sup>-1</sup>.s<sup>-2</sup> because the statistical results were better.

The mass balances of the components can be described by the following system under isothermal and isobaric conditions,

$$\begin{aligned}\frac{d[Ep]}{dt} &= -R_{\text{Carbonation}} \\ \frac{d[Carb]}{dt} &= +R_{\text{Carbonation}} \\ \frac{d[CO_2]_{\text{liq}}}{dt} &= -R_{\text{Carbonation}} + N_{CO_2} \cdot a\end{aligned}\quad (5.10)$$

where,  $N_{CO_2} \cdot a$  represents the gas-liquid transfer of CO<sub>2</sub>.

$N_{CO_2}$  is the interfacial component flux and can be explained by the law of Fick:

$$N_{CO_2} = k_L \cdot \left( [CO_2]_{\text{Liq}}^* - [CO_2]_{\text{Liq}} \right),$$

where  $k_L$  is the mass transfer coefficient of CO<sub>2</sub> in the liquid phase and the asterisk represents the equilibrium concentration between the two phases. The term  $a$  is the mass transfer area-to-volume ratio  $\left( \frac{A}{V_{\text{liq}}} \right)$ , with  $A$  the gas-liquid surface area and

$V_{\text{liq}}$  the volume of the liquid phase.

### 5.3.3 Mass transfer experiments

During the mass transfer experiments, the amount of substance (in moles) absorbed in the reaction mixture was assumed to be the same as the number of moles disappearing from the reservoir.

The Peng-Robinson equation of state was used to determine the number of moles (Zheng et al., 2015). The carbonation reaction was not present or can be assumed negligible, i.e.,  $R_{\text{carbonation}} \sim 0$  mol.L<sup>-1</sup>.s<sup>-1</sup>. Consequently, the mass balance in the liquid phase can be written as

$$\begin{aligned}\frac{d[Ep]}{dt} &= 0 \\ \frac{d[Carb]}{dt} &= 0 \\ \frac{d[CO_2]_{\text{Liq}}}{dt} &= \frac{k_L \cdot a}{V_{\text{liq}}} \cdot \left( n_{CO_2, \text{Liq}}^* - n_{CO_2, \text{Liq}} \right) \Leftrightarrow \frac{dn_{CO_2, \text{Liq}}}{dt} = k_L \cdot a \cdot \left( n_{CO_2, \text{Liq}}^* - n_{CO_2, \text{Liq}} \right)\end{aligned}\quad (5.11)$$

where,  $k_L \cdot a$  represents the gas-liquid volumetric mass transfer coefficient and  $n_{CO_2, \text{Liq}}^*$  is the number of moles of CO<sub>2</sub> at the interface from the liquid side.

The Whitman model or two-film theory was used to describe the mass transfer phenomenon (Charpentier, 1981). The resistance from the gas side was neglected. At time zero (before starting the stirring), the concentration of CO<sub>2</sub> in the liquid phase can be assumed to be zero. Figure 5.6-5.8 present mass transfer experimental results for the effects of CO<sub>2</sub> pressure, temperature and the components on the kinetics of CO<sub>2</sub> absorption.

Figure 5.7. Effect of CO<sub>2</sub> pressure on the kinetics of CO<sub>2</sub> absorption in the ECSO solution at 130 °C and rotating speed of 500 rpm

Figure 5.7 presents the evolution of the number of moles of CO<sub>2</sub> in the liquid phase at 130 °C. One can notice that as the CO<sub>2</sub> pressure increases, the kinetics of carbonation becomes faster.

Figure 5.8. Effect of temperature on the kinetics of CO<sub>2</sub> absorption in the epoxidized cottonseed oil solution at 20 bar and rotating speed of 500 rpm

As the liquid temperature increases, the CO<sub>2</sub> absorption is faster but the number of moles absorbed is lower (Figure 5.8).

During the carbonation, the mass transfer is affected by the variation of liquid viscosity due to the increase of CCSO concentration (Figure 5.9). To measure this effect experimentally, a series of absorption experiments was performed with CSO, ECSO, CCSO and a mixture of 78 wt.% of ECSO and 22 wt.% of CCSO solutions.

Figure 5.9. Effect of the components on the kinetics of CO<sub>2</sub> absorption in the liquid phase at 20 bar, 120 °C and rotating speed of 500 rpm

Figure 5.9 reveals that the kinetic of CO<sub>2</sub> absorption increases in the following order: CSO>ECSO>Mixture (78 wt.% ECSO + 23 wt.% CCSO)>CCSO. It can be observed that the number of CO<sub>2</sub> moles absorbed in the equilibrium increases in the following order: CSO>CCSO>Mixture>ECSO.

The solubility of CO<sub>2</sub> concentration  $[\text{CO}_2]_{\text{liq}}^*$  in the liquid phase can be linked to the pressure of CO<sub>2</sub> in the gas phase by the Henry's constant ( $He$ ). This coefficient depends on the properties of the liquid phase and temperature, and it can be described as

$$\begin{aligned}
 [\text{CO}_2]_{\text{liq}}^* &= He_{\text{ECSO}} \cdot P_{\text{CO}_2} \\
 [\text{CO}_2]_{\text{liq}}^* &= He_{\text{CCSO}} \cdot P_{\text{CO}_2} \\
 [\text{CO}_2]_{\text{liq}}^* &= He_{\text{CSO}} \cdot P_{\text{CO}_2}
 \end{aligned} \tag{5.12}$$

where,  $He_{\text{ECSO}}$ ,  $He_{\text{CCSO}}$  and  $He_{\text{CSO}}$  represent the Henry's constants for epoxidized cottonseed oil, carbonated cottonseed oil and pure cottonseed oil solution separately.

Figure 5.10. Evolution of the Henry's constant at different temperatures for ECSO

Figure 5.11. Evolution of the Henry's constant at different temperatures for CCSO

Figure 5.12. Evolution of the Henry's constant at different temperature for CSO

Figures 5.10-5.12 show the evolution of the concentration of CO<sub>2</sub> in the liquid phase follows a Henry's law at different temperatures.

Figure 5.13. Evolution of the Henry's constant versus temperature

Figure 5.13 shows that the solubility of CO<sub>2</sub> is higher in CSO solution than CCSO or ECSO solution within the temperature range 110-120°C. However, at higher temperature than 130 °C, the solubility of CO<sub>2</sub> increases in the following order: CCSO>CSO≥ECSO.

To describe the evolution of the Henry's constant with the temperature, van't Hoff law can be used as

$$\begin{aligned} \frac{He_{ECSO}(T)}{He_{ECSO}(T_{ref})} &= \exp\left(\frac{-\Delta H_{sol,ECSO}}{R} \cdot \left(\frac{1}{T} - \frac{1}{T_{ref}}\right)\right) \\ \frac{He_{CCSO}(T)}{He_{CCSO}(T_{ref})} &= \exp\left(\frac{-\Delta H_{sol,CCSO}}{R} \cdot \left(\frac{1}{T} - \frac{1}{T_{ref}}\right)\right) \\ \frac{He_{CSO}(T)}{He_{CSO}(T_{ref})} &= \exp\left(\frac{-\Delta H_{sol,CSO}}{R} \cdot \left(\frac{1}{T} - \frac{1}{T_{ref}}\right)\right) \end{aligned} \quad (5.13)$$

where,  $\Delta H_{sol,ECSO}$ ,  $\Delta H_{sol,CCSO}$  and  $\Delta H_{sol,CSO}$  are the dissolution enthalpies for the epoxidized, carbonated and pure cottonseed oil solutions separately. By plotting

$\ln\left(\frac{He_{CCSO}(T)}{He_{CCSO}(T_{ref})}\right)$  versus  $\left(\frac{1}{R} \cdot \left(\frac{1}{T} - \frac{1}{T_{ref}}\right)\right)$ , it was verified that this hypothesis is correct within

the experimentally temperature interval.

Figure 5.14. Van't Hoff curve for Henry's constants for cottonseed oil (CSO), epoxidized cottonseed oil (ECSO) and carbonated cottonseed oil (CCSO)

Figure 5.14 shows that the dissolution of CO<sub>2</sub> is more exothermic in the CSO solution ( $\Delta H = -40.406 \text{ kJ.mol}^{-1}$ ) than in the ECSO solution ( $\Delta H = -29.03 \text{ kJ.mol}^{-1}$ ) than in the CCSO solution ( $\Delta H = -11.52 \text{ kJ.mol}^{-1}$ ).

The different values of dissolution enthalpies were used in the modeling. To take into account the change of the solubility during the carbonation reaction, an average Henry's constant was used:

$$He_{Mixing}(T) = x_{ECSO} \times He_{ECSO}(T) + x_{CCSO} \times He_{CCSO}(T) + x_{CSO} \times He_{CSO}(T) \quad (5.14)$$

The evolution of the solubility of CO<sub>2</sub> with temperature and reaction components can be determined by using Eqs (5.13) and (5.14). In Eq. (5.11), it is important to find a way to calculate the volumetric mass transfer coefficient  $k_{L,a}$  as a function of the carbonation reaction advancement and temperature. Figure 5.8 shows clearly that these two mass transfer properties are affected by the components of the reaction mixture.

According to Kawase and Moo-Young (Kawas, 1988), the volumetric mass transfer coefficient can be estimated as

$$k_{L,a} = \frac{2}{\sqrt{\pi}} \times \sqrt{D_{\text{CO}_2/\text{liq}}} \times \left( \frac{\xi \times \rho_{\text{liq}}}{\mu_{\text{liq}}} \right)^{0.25} \quad (5.15)$$

where,  $\xi$  is the energy dissipation rate per unit mass,  $\rho_{\text{Liq}}$  is the liquid density,  $\mu_{\text{Liq}}$  is the liquid viscosity and  $D_{\text{CO}_2/\text{Liq}}$  is the diffusion coefficient of  $\text{CO}_2$  in the liquid phase.

The diffusion coefficient can be explained by the Wilke-Chang equation (Wilke and Chang, 1955),

$$D_{\text{CO}_2, \text{liq}} = \frac{\text{Constant} \times T_{\text{liq}} \times (\varphi \times M_{\text{liq}})^{1/2}}{\mu_{\text{liq}} \times V_{\text{CO}_2}^{0.6}} \quad (5.16)$$

where,  $\varphi$  is the association factor,  $M_{\text{liq}}$  and  $\mu_{\text{liq}}$  are the molar mass and viscosity of the liquid phase and  $V_{\text{CO}_2}^{0.6}$  is the molar volume of  $\text{CO}_2$ . The constant value was found to be  $7.4 \times 10^{-8} \text{ cm}^2 \cdot \text{C} \cdot \text{K}^{-1} \cdot \text{s}^{-1} \cdot (\text{cm}^3 \cdot \text{mol}^{-1})^{0.6} \cdot (\text{g} \cdot \text{mol}^{-1})^{-0.5}$  by Wilke and Chang (Wilke and Chang, 1955).

By combining Eqs (5.15) and (5.16), the mass transfer coefficient can be derived as

$$k_L \cdot a = (k_L \cdot a)' \times \left( \frac{T_{\text{liq}}}{\mu_{\text{liq}}} \right)^{0.5} \left( \frac{\rho_{\text{liq}}}{\mu_{\text{liq}}} \right)^{0.25} \quad (5.17)$$

$$\text{with } (k_L \cdot a)' = \frac{2}{\sqrt{\pi}} \cdot \sqrt{\frac{\text{Constant} \cdot (\varphi \cdot M_{\text{liq}})^{0.5}}{V_{\text{CO}_2}^{0.6}}} (\xi)^{0.25} .$$

By using Eq. (5.17), it is possible to determine the variation of  $k_L \cdot a$  with the reaction temperature. The term  $(k_L \cdot a)'$  can be assumed constant for the absorption of  $\text{CO}_2$  in pure solution of ECSO or in pure solution of CCSO or in pure solution of CSO. Thus, this parameter was estimated for ECSO, CCSO and CSO during the modeling of mass transfer by solving the ODEs system.

During the carbonation reaction, the mass density and viscosity of the mixture vary with the reaction advancement. The densities and viscosities of ECSO, CCSO and CSO were shown in Figure 4.2 and Figure 4.3. In case of mixture, densities and viscosities can be evaluated as (Vahteristo et al., 2008)

$$\rho_{\text{mixing}} = w_{\text{ECSO}} \times \rho_{\text{ECSO}} + w_{\text{CSO}} \times \rho_{\text{CSO}} + w_{\text{CCSO}} \times \rho_{\text{CCSO}} \quad (5.18)$$

$$\ln \mu_{\text{mixing}} = w_{\text{ECSO}} \times \ln \mu_{\text{ECSO}} + w_{\text{CSO}} \times \ln \mu_{\text{CSO}} + w_{\text{CCSO}} \times \ln \mu_{\text{CCSO}} \quad (5.19)$$

To take into account the variation of the mass transfer coefficient with the reaction advancement, the modified mass transfer coefficient for the reaction mixture,  $(k_L \cdot a)_{\text{mixing}}'$ , was expressed as

$$(k_L \cdot a)_{\text{mixing}}' = w_{\text{CSO}} \times (k_L \cdot a)'_{\text{CSO}} + w_{\text{ECSO}} \times (k_L \cdot a)'_{\text{ECSO}} + w_{\text{CCSO}} \times (k_L \cdot a)'_{\text{CCSO}} \quad (5.20)$$

We have assumed that  $(k_L.a)_{mixing}'$  can be expressed by using the values of the modified mass transfer coefficients for pure solution of CSO, ECSO and CCSO. Then, the volumetric mass transfer coefficient can be derived as

$$(k_L.a) = (k_L.a)_{mixing}' \times \left( \frac{T_{liq}}{\mu_{mixing}} \right)^{0.5} \times \left( \frac{\rho_{mixing}}{\mu_{mixing}} \right)^{0.25} \quad (5.21)$$

The derivation of Eq. (5.21) was similar to Eq. (5.17), but Eq. (5.21) takes into account the contribution of CSO, ECSO and CCSO for the determination of the volumetric mass transfer coefficient.

#### 5.3.4 Mass transfer model

During the mass transfer modeling stage, the number of moles of CO<sub>2</sub> absorbed was used as observable. The modified mass transfer coefficients  $(k_L.a)'$  for CSO, ECSO and CCSO were estimated by regression analysis by using Eqs (5.20) and (5.21). Eq. (5.14) was used to determine the solubility of carbon dioxide in the liquid phase.

Figures 5.15 A-D show some selected modeling results.

Figure 5.15. A Fit of the model to the mass transfer experimental observation for Run 25

Figure 5.15. B Fit of the model to the mass transfer experimental observation for Run 38

Figure 5.15. C Fit of the model to the mass transfer experimental observation for Run 49

Figure 5.15. D Fit of the model to the mass transfer experimental observation for Run 53

The fit of the proposed model to the experimental data is in general satisfactory. The explanation coefficient exceeds 90%. The model fits well the experimental data for the absorption of CO<sub>2</sub> in 100% of pure cottonseed oil (Runs 17-28), epoxidized cottonseed oil (Runs 29-39) and carbonated cottonseed oil (Runs 51-64).

Table 5.3 gives the estimated values for modified mass transfer coefficients ( $k_L \cdot a$ ). The standard errors for the estimated parameters are lower than 2% (Table 5.3), which shows the reliability of the model. The matrix correlation shows no correlation between the estimated parameters (Table 5.4). The contour plots shown in the Figure 1-3 (Appendix II), proved that the parameters were well estimated.

Table 5.3 Estimated and statistical data for modified mass transfer coefficients

	Unit	Estimated value	Standard error	Standard error %
$(k_L \cdot a)'$ <sub>CCSO</sub>	$\left(\frac{K}{\text{Pa} \cdot \text{s}}\right)^{-0.5} \cdot \left(\frac{\text{kg} \cdot \text{m}^{-3}}{\text{Pa} \cdot \text{s}}\right)^{-0.25} \text{s}^{-1}$	3.03E-06	4.78E-08	1.6
$(k_L \cdot a)'$ <sub>ECSO</sub>	$\left(\frac{K}{\text{Pa} \cdot \text{s}}\right)^{-0.5} \cdot \left(\frac{\text{kg} \cdot \text{m}^{-3}}{\text{Pa} \cdot \text{s}}\right)^{-0.25} \text{s}^{-1}$	1.23E-05	2.30E-07	1.9
$(k_L \cdot a)'$ <sub>CSO</sub>	$\left(\frac{K}{\text{Pa} \cdot \text{s}}\right)^{-0.5} \cdot \left(\frac{\text{kg} \cdot \text{m}^{-3}}{\text{Pa} \cdot \text{s}}\right)^{-0.25} \text{s}^{-1}$	2.57E-05	4.22E-07	1.6

Table 5.4 Correlation matrix

	$(k_L \cdot a)'$ <sub>CCSO</sub>	$(k_L \cdot a)'$ <sub>ECSO</sub>	$(k_L \cdot a)'$ <sub>CSO</sub>
$(k_L \cdot a)'$ <sub>CCSO</sub>	1		
$(k_L \cdot a)'$ <sub>ECSO</sub>	-0.007	1	
$(k_L \cdot a)'$ <sub>CSO</sub>	0	0	1

Some deviations were observed for the absorption of CO<sub>2</sub> in the reaction mixture (Runs 40-50). This deviation can be explained by the fact that the interaction between the epoxidized and carbonated groups is not well taken into account by Eqs (5.14) and (5.21).

The calculation of  $(k_L \cdot a)'$  takes into account the molar mass, association factor and the energy dissipation rate. The mass transfer coefficients for CSO and ECSO are similar, but the one for CCSO is lower. This observation cannot be linked to the difference of molar mass because as the molar mass increases, as  $(k_L \cdot a)'$  increases (Eq. 5.17). The difference is linked to the association factor or the energy dissipation rate which might be lower for the absorption of CO<sub>2</sub> in CCSO.

Compare to our previous study on mass transfer (Zheng et al., 2015), we have found that Henry's constant follows a van't Hoff law and we have developed a model to predict the value of Henry's constants and volumetric mass transfer coefficient.

During the mass transfer study, we did not observe an induction period when the pressure was lower than 30 bar as discussed for Figure 5.1. Thus, the induction period is linked to the chemical reaction and not to the mass transfer phenomena.

### 5.3.5 Kinetic model

During the kinetic modeling stage, the concentration of epoxidized group was used as observable. The estimated modified mass transfer coefficients determined in the Section 5.3.3 and 5.3.4 were implemented in this model. The estimated kinetic constants were rate constant  $k_{\text{carbonation}}$ , activation energy for carbonation  $E_{a_{\text{Carbonation}}}$ , reaction order  $n$  with catalyst. A modified Arrhenius equation was used to diminish the correlation between the rate constant and the energy of activation:

$$k = k_{\text{ave}} \exp\left(\frac{-E_a}{R} \left(\frac{1}{T} - \frac{1}{T_{\text{ave}}}\right)\right) \quad (5.22)$$

where,  $T_{\text{ave}}$  is the average temperature of the set of experiments.

Figures 5.15 A-F show the fit of the model to the experimental data and the evolution of the concentrations of carbonated group and  $\text{CO}_2$  in the liquid phase. Due to space limitation, the rest modeling results are presented in the Appendix II.

Figure 5.16. A Fit of the model to the experiments and simulation of  $[\text{CO}_2]_{\text{liq}}$  for Run 1

Figure 5.16. B Fit of the model to the experiments and simulation of  $[CO_2]_{liq}$  for Run 3

Figure 5.16. C Fit of the model to the experiments and simulation of  $[CO_2]_{liq}$  for Run 4

Generally, it can be noticed that the model fits the experimental data reasonably well. The explanation coefficient exceeded 95%.

However, this model has some difficulties to take into account the induction period at low pressure (Figure 5.16 B). This is due to the fact that steady-state approximation cannot be applied during induction period.

The model fits the experimental data at temperature exceeding 130°C (Figures 5.16 B, C). The fact that the model fits the experimental data at 140°C tends to prove that the decomposition components of TBABr can be assumed neglected.

The model fits the experimental data even when the initial concentration of epoxidized group is different with 3.5 mol.L<sup>-1</sup> (Figure 5.16 C). This proves that the difference of conversion observed in Figure 5.3 was linked to mass transfer.

Table 5.5 presents the estimated kinetic data for the carbonation of cottonseed oil. The standard errors for the rate constant, activation energy and reaction order are lower than 20%. The standard errors for the kinetic parameters  $\gamma$  and  $\alpha$  are relatively high. This might be due to the fact that these parameters are temperature-dependent.

Table 5.5. Estimated and statistical data at  $T_{ref} = 403$  K for carbonation

	Estimated	Standard error	Standard error %
$k_{Carbonation}$ [L <sup>2</sup> .mol <sup>-2</sup> .s <sup>-1</sup> ]	1.85E-04	2.94E-05	15.9
$E_{aCarbonation}$ [J.mol <sup>-1</sup> ]	5.16E+04	3.05E+03	5.9
$n$	5.83E-01	5.19E-02	8.9
$\alpha$ [s <sup>-2</sup> ]	3.26E-01	9.56E-02	29.3
$\gamma$ [mol.L <sup>-1</sup> ]	8.12E-02	5.02E-02	61.8

Table 5.5 shows the correlation matrix for the kinetic parameters. One can notice that the correlations between the different kinetic parameters are medium. This is due to the different assumptions done.

Table 5.6 Correlation matrix

	$k_{\text{Carbonation}}$	$Ea_{\text{Carbonation}}$	$n$	$\alpha$	$\gamma$
$k_{\text{Carbonation}}$	1				
$Ea_{\text{Carbonation}}$	0.56	1			
$n$	0.734	0.196	1		
$\alpha$	0.67	0.603	0.021	1	
$\gamma$	-0.639	-0.561	-0.444	-0.314	1

The parameter sensitivity analysis (Figure 5.17) with the Markov Chain Monte Carlo method (Vahteristo et al., 2008) shows that the estimated parameters have well-defined optimal values.

Figure 5.17. Plots of the parameter sensitivity analysis (MCMC)

Also, the variation of the mass transfer coefficients during the reaction advancement at different operating conditions was illustrated in Figures 5.18 A-C (Runs 1, 4, 12). One can observe that when the concentration of carbonate increases, as the mass transfer coefficient decreases. Based on the model, the variation of  $k_L a$  cannot be assumed constant.

Figure 5.18. A Evolution of mass transfer coefficient for Run 1

Figure 5.18. B Evolution of mass transfer coefficient for Run 4

Figure 5.18. C Evolution of mass transfer coefficient for Run 12

## 5.4 Conclusions

The kinetics of the carbonation of epoxidized cottonseed oil in an autoclave was studied in the presence of TBABr, as a homogeneous catalyst. The conversion of epoxidized groups to carbonated groups leads to an increase of the viscosity, which has a strong influence on the gas-liquid mass transfer.

The parameters influencing the mass transfer effects were investigated in the first stage. Modified volumetric mass transfer coefficients were used to represent the mass transfer of CSO, ECSO and CCSO. The benefit of these coefficients is that they are temperature, viscosity and density independent. By using these coefficients, it is possible to determine the value of the volumetric mass transfer as a function of the reaction advancement. It was demonstrated that Henry's constants for CSO, ECSO and CCSO follow van't Hoff law. The exothermicity of the CO<sub>2</sub> dissolution increases in the following order  $|\Delta H_{CO_2/CSO}| > |\Delta H_{CO_2/ECSO}| > |\Delta H_{CO_2/CCSO}|$ . The proposed approach to take into account mass transfer phenomena is an empirical approach by assuming that the effects of double bond, epoxidized and carbonated groups are addable. Some further investigation should be performed by determining local mass transfer coefficient by using CFD calculation.

In the last stage, a kinetic model was developed. It was assumed that the reaction between the epoxidized group and TBABr producing an intermediate was in quasi-equilibrium (steady state), while the rate-determining step was the reaction between this intermediate and dissolved CO<sub>2</sub>. Thus, the rate of carbonation was expressed with the concentration of TBABr, epoxidized group and dissolved CO<sub>2</sub>. By including the mass transfer parameters estimated in the previous stage, the rate constant at the reference temperature of 403 K was estimated to be  $2.07 \times 10^{-4} \text{ L}^2 \cdot \text{mol}^{-2} \cdot \text{s}^{-1}$  and activation energy was estimated to  $50060 \text{ J} \cdot \text{mol}^{-1}$ . The reliability of the kinetic parameters was verified by using Markov chain Monte Carlo method.

## Chapter VI Structure-reactivity: comparison between vegetable oils and fatty acid methyl ester

Part of this chapter is adapted from the post print of the following article:

X. Cai, M. Matos, S. Leveneur. Structure-reactivity: comparison between the carbonation of epoxidized vegetable oils and the corresponding epoxidized fatty acid methyl ester. *Industrial & Engineering Chemistry Research*, 2019.

### 6.1 Introduction

Several studies have shown that one should transesterify vegetable oils to decrease their viscosity. It is true that viscosity plays an important role, but steric hindrance due to the conformation of the chemical structure of vegetable oils changes the chemical reactivity.

The objective of this study is to measure the effect of steric hindrance on the kinetics of carbonation of epoxidized vegetable oils where the reactive centers are located on the fatty acid moieties. For that, a comparison between the reactivity of a cottonseed oil and its fatty acid methyl ester counterpart will be done. To carry out such study, it is compulsory to take into account the mass transfer phenomena of carbon dioxide from gas to liquid phase. This phenomenon is interfered by the physicochemical properties of the solvent. Carbonation reaction performed by using homogeneous catalyst of tetra-n-butylammonium bromide (TBABr) was studied.

In this chapter, Section 6.2 gives the detail information about the experimental procedure. Section 6.3 shows the experiment results and discussion. Section 6.4 gives the conclusion for this part of work.

### 6.2 Experimental section

Epoxidized cottonseed oil (ECSO) was prepared as described in Section 2.4.1. Fatty acid methyl ester derived from cottonseed oil was prepared as described in Section 2.4.2. Epoxidized fatty acid methyl ester derived from cottonseed oil was prepared as described in Section 2.4.3.

Apparatus and experimental procedures for carbonation experiment were introduced in Section 2.5.

### 6.2.1 Measurement of CO<sub>2</sub> Solubility

The solubility measurement of CO<sub>2</sub> was conducted in the high-pressure autoclave. During the mass transfer experiments, 90.0 g of oil sample (FAME, EFAME or CFAME) was weighted out and mixed in the reactor, then heated to a certain temperature. The atmosphere inside the reactor was purged with CO<sub>2</sub> for two times. The CO<sub>2</sub> pressure in the reactor was maintained constant by the pressure regulator. As the values had been stabilized, the agitation was started at 500 rpm. The values (temperature and pressure) inside the gas reservoir were simultaneously monitored. Table 6.1 shows the experimental matrix for the mass transfer study.

Table 6.1 Mass transfer experimental matrix

### 6.2.2 Carbonation kinetics

Carbonation of ECSO and EFAME were carried out as follows (Cai et al., 2017; Zheng et al., 2015): epoxidized cottonseed oil (or epoxidized fatty acid methyl ester) and the catalyst TBABr

were weighted out in the reactor. The reactor was purged with N<sub>2</sub> for two times, followed by heating up to the designed temperature. Then, the atmosphere inside reactor was purged with CO<sub>2</sub> for two times and kept under the desired pressure. After the pressure and temperature were stabilized, the agitation started at 500 rpm. Sample was withdrawn in 1 hour intervals via the sampling port. The conversion of epoxide group was selected as a response value for different carbonation conditions (as shown in Table 6.2).

### 6.2.3 Analytical methods

In a first stage, physicochemical properties (density and viscosity) measurement of cottonseed oil, fatty acid methyl ester, and the epoxidized, carbonated derivatives are reported. The apparatus and experimental procedures for physicochemical properties measurements were introduced in Section 2.3. Each oil sample was measured three times.

The determination of epoxide content and double bond was described in Section 2.6.

## 6.3 Results and discussion

### 6.3.1 Comparison of physicochemical properties

The evolutions of density and viscosity of the different compounds with temperature are displayed in Appendix III Figures 1-2. The values for cottonseed oil and its epoxidized, carbonated derivatives come from Chapter III. Figure 1 in Appendix III shows that as functional groups are larger, density is higher, i.e., as  $\rho_{\text{Carb}} > \rho_{\text{Ep}} > \rho_{\text{VO}}$ .

#### 6.3.1.1 Density comparison

Figure 6.1 Ratio of  $\frac{\rho_{\text{CSO}}}{\rho_{\text{FAME}}}$ ,  $\frac{\rho_{\text{ECSO}}}{\rho_{\text{EFAME}}}$  and  $\frac{\rho_{\text{CCSO}}}{\rho_{\text{CFAME}}}$  versus temperature

Figure 6.1 shows the evolution of density ratios:  $\frac{\rho_{\text{CSO}}}{\rho_{\text{FAME}}}$ ,  $\frac{\rho_{\text{ECSO}}}{\rho_{\text{EFAME}}}$  and  $\frac{\rho_{\text{CCSO}}}{\rho_{\text{CFAME}}}$  versus

temperature. One can notice that the ratios of  $\frac{\rho_{\text{CSO}}}{\rho_{\text{FAME}}}$  and  $\frac{\rho_{\text{ECSO}}}{\rho_{\text{EFAME}}}$  are similar and equal to

ca. 1.05, whereas the ratio of  $\frac{\rho_{\text{CCSO}}}{\rho_{\text{CFAME}}}$  is smaller and equal to 1.02 in the temperature range

100-150°C. Thus, when the functional group is bigger, the difference of density between the vegetable oil and the methyl ester forms is lower.

Thus, the density is not a main parameter explaining the difference of kinetics on mass transfer between CSO and FAME.

### 6.3.1.2 Viscosity comparison

Figure 6.2 Ratio of  $\frac{\mu_{\text{CSO}}}{\mu_{\text{FAME}}}$ ,  $\frac{\mu_{\text{ECSO}}}{\mu_{\text{EFAME}}}$  and  $\frac{\mu_{\text{CCSO}}}{\mu_{\text{CFAME}}}$  versus temperature

Figure 6.2 shows the evolution of viscosity ratios:  $\frac{\mu_{CSO}}{\mu_{FAME}}$ ,  $\frac{\mu_{ECSO}}{\mu_{EFAME}}$  and  $\frac{\mu_{CCSO}}{\mu_{CFAME}}$  versus

temperature. Unlike density behavior, the viscosity difference between vegetable oil and methyl ester derivatives is more pronounced. We clearly notice that viscosity of vegetable oil and its derivatives can be 20 to 40 times higher than the corresponding methyl ester and its derivatives. This difference illustrated the benefit of using fatty acid methyl ester instead of vegetable oil from a mixing viewpoint.

In case of mixture, the following correlations were used to determine the viscosity and density (Cai et al., 2017):

$$\rho_{\text{mixing}} = w_{\text{FAME}} \times \rho_{\text{FAME}} + w_{\text{EFAME}} \times \rho_{\text{EFAME}} + w_{\text{CFAME}} \times \rho_{\text{CFAME}} \quad (6.1)$$

$$\ln \mu_{\text{mixing}} = w_{\text{FAME}} \times \ln \mu_{\text{FAME}} + w_{\text{EFAME}} \times \ln \mu_{\text{EFAME}} + w_{\text{CFAME}} \times \ln \mu_{\text{CFAME}} \quad (6.2)$$

where,  $w_j$  is the weight percentage of the compound in mass fraction, wt.%;

### 6.3.2 Mass transfer comparison

As described in Chapter V, this stage is designed to measure the solubility of CO<sub>2</sub> in the reaction mixture. For that, two mass transfer parameters should be evaluated with the variation of functional groups, CO<sub>2</sub> pressure and temperature: Henry's constant and global mass transfer coefficient from the liquid side.

During the experiments, the pressure inside the reactor was maintained constant by using a pressure regulator, and the decrease of pressure inside the reservoir was monitored. The same treatment described in the previous Chapter V was applied in this mass transfer study. The Whitman model was used to describe the mass transfer phenomenon (Charpentier, 1981). Experiments were performed in absence of catalyst to avoid any chemical reaction. The amount of CO<sub>2</sub> absorbed in the reaction mixture was assumed to be the same as the ones disappeared from the gas reservoir. Peng-Robinson equation of state was applied to determine the number of moles of CO<sub>2</sub> in the gas phase.

The mass balance of the components in the liquid phase can be described as

$$\frac{d[\text{Ep}]}{dt} = 0 \quad (6.3)$$

$$\frac{d[\text{Carb}]}{dt} = 0 \quad (6.4)$$

$$\frac{d[\text{CO}_2]_{\text{Liq}}}{dt} = \frac{k_L \cdot a}{V_{\text{Liq}}} \times (n_{\text{CO}_2, \text{Liq}}^* - n_{\text{CO}_2, \text{Liq}}) \quad (6.5)$$

where, [Ep] is the concentration of epoxidized group, mol.L<sup>-1</sup>; [Carb] is the concentration of carbonated group, mol.L<sup>-1</sup>; [CO<sub>2</sub>]<sub>Liq</sub> is the concentration of CO<sub>2</sub> in the liquid phase, mol.L<sup>-1</sup>; V<sub>Liq</sub> is the volume of the liquid phase, m<sup>3</sup>; a is mass transfer ratio of the gas-liquid surface area to the volume of the liquid phase, m<sup>-1</sup>. n<sub>CO<sub>2</sub>,Liq</sub><sup>\*</sup> is the equilibrium mole of CO<sub>2</sub> between the gas and liquid phase, mol; n<sub>CO<sub>2</sub>,Liq</sub> is the real-time mole of CO<sub>2</sub> in the liquid phase, mol.

Here, Eq. (6.5) can be modified as

$$\frac{dn_{\text{CO}_2, \text{Liq}}}{dt} = k_L \times a \times (n_{\text{CO}_2, \text{Liq}}^* - n_{\text{CO}_2, \text{Liq}}) \quad (6.6)$$

where, k<sub>L</sub>×a is the gas-liquid volumetric mass transfer coefficient, s<sup>-1</sup>.

The mass transfer parameters for CSO, ECSO and CCSO are estimated in Chapter V.

Figure 6.3. Effect of CO<sub>2</sub> pressure on the kinetics of CO<sub>2</sub> absorption in the EFAME solution at 130 °C and rotating speed of 500 rpm

Figure 6.3 shows the influence of CO<sub>2</sub> pressure on the kinetics of CO<sub>2</sub> absorption in the EFAME solution at 130 °C. It indicated that when the reaction pressure increases, the mass transfer of CO<sub>2</sub> goes faster, and the dissolution of CO<sub>2</sub> in the liquid phase becomes larger. This tendency is the same than for the absorption of CO<sub>2</sub> in ECSO.

Figure 6.4. Effect of temperature on the kinetics of CO<sub>2</sub> absorption in the EFAME solution at 20 bar and rotating speed of 500 rpm

Figure 6.4 shows the influence of temperature on the kinetics of CO<sub>2</sub> absorption in the EFAME solution at 20 bar. It can be noticed that when the reaction temperature increases, the kinetics of CO<sub>2</sub> absorption does not change significantly. The dissolution of CO<sub>2</sub> in the liquid phase decreases when the temperature increases. The similar situation was noticed for adsorption of CO<sub>2</sub> in CFAME solution (Appendix III).

Figure 6.5. Effect of the components on the kinetics of CO<sub>2</sub> absorption in the EFAME solution at 20 bar, 120°C and rotating speed of 500 rpm

Figure 6.5 reveals that the kinetics of CO<sub>2</sub> absorption in the three solutions of different compounds are similar. Nevertheless, the equilibrium is more sensitive to the chemical components of the solution. Based on our previous research (Zheng et al., 2015) and Chapter V, it was noticed that the kinetics of CO<sub>2</sub> absorption and the solubility of CO<sub>2</sub> in CSO, ECSO or CCSO were more pronounced.

Henry's law was used to describe the relationship between the solubility of CO<sub>2</sub> in the liquid phase and the pressure of CO<sub>2</sub> in the gas phase (Eq. 6.7).

$$[\text{CO}_2]_{\text{Liq}}^* = He \times P_{\text{CO}_2} \quad (6.7)$$

where, *He* is the Henry's constant for FAME, EFAME or CFAME.  $P_{\text{CO}_2}$  is the pressure of CO<sub>2</sub> in the gas phase.

Figure 6.6 shows the evolution of the solubility of CO<sub>2</sub> in the liquid phase with the variation of CO<sub>2</sub> pressure. One can notice that, the solubility of CO<sub>2</sub> increases when the pressure increases.

Also, the concentration of CO<sub>2</sub> follows the Henry's law at different temperature. The similar phenomenon was noticed for the FAME and CFAME (Appendix III Figures 3 and 4).

Figure 6.6 Evolution of the solubility of CO<sub>2</sub> at different CO<sub>2</sub> pressure for EFAME

Figure 6.7 shows the evolution of Henry's constant ratios:  $\frac{He_{CSO}}{He_{FAME}}$ ,  $\frac{He_{ECSO}}{He_{EFAME}}$  and  $\frac{He_{CCSO}}{He_{CFAME}}$  versus

temperature. Figure 6.7 shows that Henry's constant is sensible to the use of CSO/ECSO/CCSO or FAME/EFAME/CFAME. From a thermodynamic viewpoint, solubility of CO<sub>2</sub> in FAME-derivatives is higher than CSO-derivatives, which is a benefit for the kinetics.

The evolution of the Henry's constants with temperature is shown in Appendix III Figure 5. One can notice that Henry's constants for CSO, ECSO and CCSO are lower than for their methyl ester counterparts. This fact is more pronounced for ECSO and CCSO. It indicates that the solubility of CO<sub>2</sub> follows the order of CFAME > EFAME > FAME when the temperature is higher than 120 °C. However, the solubility of CO<sub>2</sub> in the CFAME solution is lower than EFAME within the temperature of 110-120 °C. For CSO and its derivatives, it was observed that solubility of carbon dioxide increases in the following order CCSO > CSO ≥ ECSO when temperature is higher than 130 °C, but when temperature is within the range 110-120 °C the solubility is higher in CSO than CCSO or ECSO solution. From a thermodynamic viewpoint, solubility of CO<sub>2</sub> in FAME-derivatives is higher than CSO-derivatives, which is a benefit for the kinetics.

Figure 6.7. Ratio of  $\frac{He_{CSO}}{He_{FAME}}$ ,  $\frac{He_{ECSO}}{He_{EFAME}}$  and  $\frac{He_{CCSO}}{He_{CFAME}}$  versus temperature

A van't Hoff law was used to describe the evolution of the Henry's constant with the temperature (Eq. 6.8).

$$\frac{He(T)}{He(T_{ref})} = \exp\left(\frac{-\Delta H_{sol,i}}{R} \times \left(\frac{1}{T} - \frac{1}{T_{ref}}\right)\right) \quad (6.8)$$

where,  $\Delta H_{sol,i}$  is the dissolution enthalpy of CO<sub>2</sub> in the solution *i*.  $T_{ref}$  is the reference temperature. In the study, 383.15K was used as the reference temperature.

Figure 6.8 Van't Hoff curve for Henry's constants

Based on the van't Hoff curve shown in Figure 6.8, it suggests that the dissolution of CO<sub>2</sub> in FAME, EFAME and CFAME is an exothermic phenomenon:  $\Delta H_{sol,FAME} = -11.83 \text{ kJ} \cdot \text{mol}^{-1}$ ,  $\Delta H_{sol,EFAME} = -17.31 \text{ kJ} \cdot \text{mol}^{-1}$  and  $\Delta H_{sol,CFAME} = -11.85 \text{ kJ} \cdot \text{mol}^{-1}$ . However, the enthalpies of dissolution of CO<sub>2</sub> in fatty methyl ester and its epoxidized derivatives are lower compared to cottonseed oil ( $\Delta H_{sol,CSO} = -40.41 \text{ kJ} \cdot \text{mol}^{-1}$ ) and its epoxidized forms ( $\Delta H_{ECSO} = -29.03 \text{ kJ} \cdot \text{mol}^{-1}$ ), respectively. However, the enthalpy of carbonated fatty acid methyl ester is similar to the one for carbonated cottonseed oil ( $\Delta H_{CCSO} = -11.52 \text{ kJ} \cdot \text{mol}^{-1}$ ).

As described in the previous work shown in Chapter V, the global mass transfer coefficient depends on temperature, dynamic viscosity ( $\mu_{Liq}$ ) and density ( $\rho_{Liq}$ ) (Eq. 6.9).

$$k_L \cdot a = (k_L \cdot a)' \times \left(\frac{T_{Liq}}{\mu_{Liq}}\right)^{0.5} \times \left(\frac{\rho_{Liq}}{\mu_{Liq}}\right)^{0.25} \quad (6.9)$$

To take into account the chemical components and temperature, a modified mass transfer coefficient ( $k_L \cdot a$ )' was proposed as:

$$(k_{L,a})' = \frac{2}{\sqrt{\pi}} \times \sqrt{\frac{7.4 \times 10^{-8} \times (\phi \times M_{Liq})}{V_{CO_2}^{0.6}}} \times (\xi)^{0.25} \quad (6.10)$$

where, the term of  $(k_{L,a})'$  is assumed to be constant;  $\rho_{Liq}$  is the density and  $\mu_{Liq}$  is viscosity of the liquid phase;  $M_{Liq}$  is the molar mass of the liquid phase;  $V_{CO_2}$  is the molar volume of the gas phase;  $\phi$  is the association factor and  $\xi$  is the energy dissipation rate per unit mass.

To estimate  $(k_{L,a})'$ , the number of moles of  $CO_2$  absorbed in the liquid phase was used as observable. The ordinary differential equation (Eq. 6.5) was solved out by using the solver ODESSA. The objective function  $\omega$  (Eq. 6.11) was minimized by using simplex and Levenberg-Marquardt algorithms.

$$\omega = \sum (n_{CO_2,Liq} - \hat{n}_{CO_2,Liq})^2 \quad (6.11)$$

where,  $n_{CO_2,Liq}$  is the number of moles of  $CO_2$  absorbed in the liquid phase obtained experimentally and  $\hat{n}_{CO_2,Liq}$  is the ones obtained by simulation.

Figure 6.9 shows an example of fitting. One can notice that the model fits correctly the experimental data. The other model fittings are shown in Appendix III. The coefficient of determination was found to be 92% showing the good reliability of the model.

Figure 6.9. Fitting of the model to the experimental observation for  $CO_2$  absorption in the FAME solution at 20 bar, 110 °C and rotating speed of 500 rpm for Run 9

The estimated values and their standard errors are shown in Table 6.5. For the sake of comparison, the data for CSO, CCSO and ECSO were included in Table 6.5.

From Table 6.5, one can see that the standard errors are low. The modified mass transfer parameters are almost the same for CFAME and CCSO, but the ones of EFAME and FAME are ca. 100 times lower than ECSO and CSO.

To recap, solubility of CO<sub>2</sub> in methyl ester and its derivatives is slightly higher than for CSO and its derivatives. The modified mass transfer coefficients  $(k_L \cdot a)'$  for methyl ester and epoxidized derivatives are lower than for CSO and ECSO.

Similarly to the previous study, in case of mixture, the parameters  $(k_L \cdot a)'$  and the Henry's constant were estimated as shown in Chapter V:

$$(k_L \cdot a)'_{\text{mixing}} = w_{\text{FAME}} \times (k_L \cdot a)'_{\text{FAME}} + w_{\text{EFAME}} \times (k_L \cdot a)'_{\text{EFAME}} + w_{\text{CFAME}} \times (k_L \cdot a)'_{\text{CFAME}} \quad (6.12)$$

$$\text{He}_{\text{mixing}}(T) = x_{\text{FAME}} \times \text{He}_{\text{FAME}}(T) + x_{\text{EFAME}} \times \text{He}_{\text{EFAME}}(T) + x_{\text{CFAME}} \times \text{He}_{\text{CFAME}}(T) \quad (6.13)$$

where,  $w$  is the weight fraction of the compound, wt.%;  $x$  is the molar fraction of the functional group (double bond, epoxide group, carbonated group), %.

Table 6.5 Estimated and statistical data for modified mass transfer coefficients

	Unit	Estimated value ( $\times 10^{-6}$ )	Standard error ( $\times 10^{-8}$ )	Standard error / %

### 6.3.3 Kinetics comparison

The kinetic model of carbonation reaction for the EFAME was firstly proposed on the basis of kinetic model for cottonseed oil as described in Chapter V, which is evaluated as

$$R_{\text{Carbonation}} = \frac{k_{\text{Carbonation}} \times [\text{CO}_2]_{\text{Liq}} \times [\text{TBABr}]^n \times ([\text{Ep}] + \gamma \times [\text{Carb}])}{\alpha + [\text{CO}_2]_{\text{Liq}}} \quad (6.14)$$

where,  $R_{\text{Carbonation}}$  is carbonation reaction rate,  $\text{mol.L}^{-1}.\text{s}^{-1}$ ;  $k_{\text{Carbonation}}$  is the reaction constant,  $\text{L}^2.\text{mol}^{-2}.\text{s}^{-1}$ ;  $[\text{TBABr}]$  is the concentration of the catalyst TBABr,  $\text{mol.L}^{-1}$ ;  $[\text{Carb}]$  is the concentration of carbonated group,  $\text{mol.L}^{-1}$ ;  $n$  is the reaction order with respect to the catalyst;  $\alpha$  and  $\gamma$  are the terms associated with the reaction constant. The same value of  $n$ ,  $\alpha$  and  $\gamma$  from the kinetic model for the carbonation of ECSO was used for the carbonation of EFAME, because the reaction mechanism should be the same (Table 6.6).

Thus, during the kinetic modeling stage, we have estimated the carbonation reaction rate constant  $k_{\text{carbonation}}$  and the activation energy  $E_{\text{carbonation}}$  for FAME. The concentration of epoxidized group was selected as the observable.

Figures 6.10-6.11 show a comparison between the carbonation kinetic model fitting of ECSO and EFAME. One can notice that the kinetic model fits for the experimental data very well. Both of the explanation coefficients for the kinetic of carbonation are over 95%. One could also notice that the experimental data appear a double slope within the reaction time. This could be explained by a different reaction mechanism, for example, a different mass transfer rate of  $\text{CO}_2$  initially leads to different carbonation rate equation.

Figure 6.10. The carbonation kinetic model fitting of ECSO and EFAME at 110°C, 30bar,  $[TBABr]_0 = 0.13 \text{ mol.L}^{-1}$  and rotating speed of 500 rpm for Runs 53 and 61

Figure 6.11. The carbonation kinetic model fitting of ECSO and EFAME at 130°C, 30bar,  $[TBABr]_0 = 0.13 \text{ mol.L}^{-1}$  and rotating speed of 500 rpm for Runs 52 and 63

Table 6.6 Estimated and statistical data at  $T_{ref} = 403$  K for the carbonation of EFAME

	Estimated	Standard error	Standard error %
$(k_{Carbonation})_{EFAME} [L^2 \cdot mol^{-2} \cdot s^{-1}]$	$2.57 \times 10^{-4}$	$5.15 \times 10^{-6}$	2.4
$(Ea_{Carbonation})_{EFAME} [J \cdot mol^{-1}]$	47200	2580	6.4
$(k_{Carbonation})_{ECSO} [L^2 \cdot mol^{-2} \cdot s^{-1}]$	$2.07 \times 10^{-4}$	$3.35 \times 10^{-5}$	16.2
$(Ea_{Carbonation})_{ECSO} [J \cdot mol^{-1}]$	50700	2930	5.8
n	0.584	0.0518	8.9
$\alpha [s^{-2}]$	0.318	0.0924	29
$\gamma [mol \cdot L^{-1}]$	0.078	0.0502	64.3

Table 6.6 shows the estimated kinetic data for the carbonation of EFAME. One can notice that the kinetics of carbonation of EFAME and ECSO are in the same order of magnitude.

Figure 6.12. The variation of  $\frac{(k_{\text{carbonation}})_{\text{ECISO}}}{(k_{\text{carbonation}})_{\text{EFAME}}}$  with different reaction temperature

Figure 6.12 shows the variation of reaction rate constant ratio of the carbonation of EFAME to ECSO at different reaction temperatures. One can notice that there is a linear relationship between the ratio of  $\frac{(k_{\text{carbonation}})_{\text{ECISO}}}{(k_{\text{carbonation}})_{\text{EFAME}}}$  and temperature. At low temperature, the rate of carbonation of EFAME is ca. 1.4 times higher than the rate of ECSO, while this difference is lower when temperature increases. Thus, it suggests that it is possible to find a way to predict the reaction kinetics of vegetable oil if the reaction kinetics of fatty acid methyl ester forms are known. This result shows that steric hindrance plays also a role during the carbonation of vegetable oils. It is possible to find a linear correlation between the reaction rate ratio and temperature.

## 6.4 Conclusion

In this chapter, a comparison between the intrinsic carbonation kinetics of epoxidized cottonseed oil and the corresponding fatty acid methyl ester was performed by using homogeneous catalyst. In this part of work, the mass transfer parameters, like the Henry's constant and global mass transfer coefficient were determined for epoxidized fatty acid methyl ester systems. Also, physicochemical properties of density and viscosity were measured. We have found that density for the two systems were similar. The difference of viscosity was proved to be important, for instance, at 140 °C, the density ratios are observed as follow:  $\frac{\mu_{CSO}}{\mu_{FAME}} \approx 50$ ,  $\frac{\mu_{ECSO}}{\mu_{EFAME}} \approx 40$  and  $\frac{\mu_{CCSO}}{\mu_{CFAME}} \approx 20$ .

Besides, the dissolution of CO<sub>2</sub> was higher in FAME-derivatives than in CSO-derivatives, and the carbonation rate constant of EFAME is higher than ECSO in the temperature range 100-150 °C. Furthermore, there exists a linear relationship between the reaction rate constant ratios of the carbonation of ECSO and EFAME. It suggested that it is possible to find a way to predict the reaction kinetics of vegetable oil based on the reaction kinetics of fatty acid methyl ester forms.

A continuation of this work could be to study more vegetable oils to see if the ratio of  $\frac{(k_{\text{carbonation}})_{\text{EVOs}}}{(k_{\text{carbonation}})_{\text{EFAME}}}$  is always similar.

## CONCLUSIONS

This research has studied four aspects for the valorization of vegetable oils:

Firstly, kinetics of epoxidation of vegetable oil and ring opening of epoxidized vegetable oil was studied in batch reactor. By developing a suitable modeling strategy, the kinetic constants for the ring opening reactions by water, hydrogen peroxide, acetic and peracetic acids were estimated. As conclusion, it shows that ring opening by peracetic and acetic acid is faster than by water and hydrogen peroxide. The semibatch reactor, where hydrogen peroxide and sulfuric acid were added continuously, was found to be the optimal configuration to maximize the concentration of epoxide group and minimize the concentration of ring opening products.

Secondly, interactions between functional groups (double bond, epoxide group and carbonated group) and physicochemical properties were investigated for vegetable oils and their epoxidized and carbonated derivatives. The influence of temperature on the physicochemical properties like density, refractive index, viscosity and specific heat capacity were discussed. As conclusion, refractive index value and density decreases linearly as temperature increases. Viscosity of these oils is exponentially proportional to temperature. Specific heat capacity was found to be relatively constant with temperature. The conversion of epoxidized groups to carbonated groups leads to an increase of the viscosity, suggesting that the oil components affect the physicochemical parameters, which will influence the gas-liquid mass transfer during the carbonation reactions. Thus, based on the evolutions of the corresponding pure compounds, the physicochemical properties of density, refractive index, viscosity and specific heat capacity of vegetable oils could be predicted.

Then, a kinetic model for the carbonation of epoxidized cottonseed oil using a homogeneous catalyst of tetra-n-butylammonium bromide (TBABr) was developed. During the kinetic study, mass transfer phenomenon of carbon dioxide was taken into consideration, and the evolution of mass transfer parameters with temperature and components were estimated during the mass transfer modeling stage. A kinetic expression for the carbonation of epoxidized cottonseed oil was derived by assuming the reaction in a steady state. The mass transfer results show that the dissolution of CO<sub>2</sub> in the oil phase is exothermic.

At last stage, a comparison between the intrinsic carbonation kinetics of epoxidized cottonseed oil and the corresponding fatty acid methyl ester was performed by using homogeneous catalyst tetra-n-butylammonium bromide (TBABr). From the comparisons of the physicochemical properties, we have observed a strong influence of the functional groups

(double bond, epoxide group and carbonated group) on the viscosity value, which is probably associated with steric hindrance. The mass transfer comparison results showed that the solubility of CO<sub>2</sub> was higher in FAME-derivatives than in CSO-derivatives, indicating that epoxide groups of epoxidized FAME is more accessible than the ones of epoxidized vegetable oils. A linear relationship was found between the reaction rate constant of the carbonation of epoxidized cottonseed oil and epoxidized fatty acid methyl ester. It suggested a possible way to predict the reaction kinetics of vegetable oil base on the reaction kinetics of fatty acid methyl ester forms.

Continuations of this doctoral thesis could be: 1) for the epoxidation process, a fundamental approach need to be found to estimate the evolution of the induction period before the start of epoxidation and ring opening reaction; 2) oil solutions with different conversion rates, which are obtained from the epoxidation and carbonation reactions, could be used instead of the mixed solutions to study the interaction between function groups and physicochemical properties; 3) for the carbonation process, more vegetable oils need to be tested to see if the

ratio of  $\frac{(k_{\text{carbonation}})_{\text{EVOs}}}{(k_{\text{carbonation}})_{\text{EFAME}}}$  is always similar.

## Appendix II Carbonation of epoxidized vegetable oils

### II.1 Preparation of the epoxidized intermediate

180.0 g of cottonseed oil, 180.0 g of hydrogen peroxide and 50.0 g of distilled water were loaded into a 500 mL glass-jacketed reactor at 60 °C. Then, formic acid was introduced via a dosing pump at a volumetric flow rate of 2.9 mL.min<sup>-1</sup> for 25 min. The reaction time was 1 hour. After the reaction phase was stratified into two phases, the aqueous phase was removed. The organic phase left in the reactor was washed with 300 mL of Na<sub>2</sub>CO<sub>3</sub> (10 wt.% in water), then, washed three times with distilled water to remove the residual sodium salt. The product was evaporated using an IKA RV10 control vacuum rotary evaporator (VWR, Darmstadt, Germany) at 60 °C and dried over magnesium sulfate. The resulting epoxidized cottonseed oil was kept at 3 °C under an argon atmosphere. This product had a conversion exceeding 97% and a selectivity exceeding 81%.
