I would like to express my special appreciation and thanks to the director of my thesis Professor Philippe Dague. I am always surprised by how fast that you reply my emails, even when I was not your student. You are always very supportive and make sure that my thesis was on the right track. Besides, you are always there to help me when I had some administrative issues with the university and financial problems for attending conferences and academic visits. I have learned a lot from you, how to organize things and how you treat other people nicely. I am extremely lucky that I have such an amazing supervisor during my PhD.

I would especially like to thank Michel and Dirk. By working with you, I learned how to do serious research, how to write theoretical texts, how to do research on difficult topics, and what high-standard research is. I truly appreciate your generous efforts and help me better understand theory of logical difference. To be honest, at the beginning of our collaboration, I was complaining that how picky you are, but I understand you much better later: this work is so complicated that you have to be picky and extremely careful. Any tiny mistake will introduce a big error to the work.

I thank the jury members of my thesis: Professor Marie-Christine Rousset and Professor Thomas Schneider gave me a lot of useful comments for improving my thesis after dedicating to read my thesis carefully; Professor Marie-Laure Mugnier inspired me some idea for the future work in the defense; and Professor Anne Vilnat accepted to be the president of the jury and provided me useful documents timely for my visa application.

I would also like to thank all members in the team LaHDAK for your support. I thank Joe, Sanjay and Luis for the happy time we spent together. You made my life shining in Paris. I also thank Ismail, Patrick, Theo and Andreas for giving me very nice suggestion and useful information.

Special thanks to my boyfriend. Thank you so much for always being there when I am happy or sad, smiling or crying. It is a bit dramatic how we have been together and what we have been through. I am very grateful that we are together now and you care about me so much.
好的，现在开始中文部分。首先，当然要谢谢亲爱的可爱的跃姐。五年前，我们相识于德累斯顿。在遇到你之前，我脑子对女博士还是那种刻板的印象，觉得做科研是件很无聊和孤独的事儿。遇见你之后，看到你那时候在德国的状态，我改变了原来的想法。原来女博士也不是传说中的灭绝师太，原来跟大家一起做科研是一件多么有趣的事儿。然后呢，我就想开始读博啦，想继续做best excerpts，也想在社会中多个跟大家印象中不一样的女博士的例子:) 在这五年中，你是我的导师，我们一起在白板上讨论问题，写论文，赶deadline。你也是我的朋友，在生活中给我很多的帮助和鼓励。如果当时我们没有遇见，也就不会有这一篇博士论文了。

其次，我想谢谢在LRI认识的朋友，谢谢许钊，王战，张正(虽然你是Limsi的艹)，王伟，Lina Ye，史鹤欢，Kevin，还有其他中国朋友那姐，张曦予。因为有你们，就算在国外，我也不觉得孤单。

谢谢我硕士期间在吉大的导师刘磊教授。如果没有您当初的允许和支持，让我到德国进行交换学习，或许我今天也不会在欧洲读博了。谢谢张鹏师哥在我出国之前，在我犹豫迷茫时对我的指点。同时谢谢张睿师哥带我进入了语义网的大门，在硕士期间对我的帮助。

最后我要谢谢我最爱的爸爸妈妈，谢谢你们让我养成了独立自主的个性，谢谢你们总能让我无后顾之忧地做自己想做的事儿。你们永远是我最坚强的后盾！
Abstract

An increasing number of large ontologies are being developed and made available, e.g., in repositories such as the NCBO Bioportal. Ensuring access to the knowledge contained in ontologies that is most relevant to users has been identified as an important challenge. In this work, we tackle this challenge by proposing three different approaches to extracting knowledge from Description Logic ontologies: extracting minimal ontology modules (i.e., sub-ontologies that are minimal w.r.t. set inclusion while still preserving all entailments over a given vocabulary); computing best ontology excerpts (a certain, small number of axioms that best capture the knowledge about the vocabulary while allowing for a degree of semantic loss); and determining projection modules (sub-ontologies of a target ontology that entails subsumption, instance or conjunctive queries that follow from a reference ontology). For each of these approaches, we are interested in extracting not only one but all instances of the module notion. For computing minimal modules and best excerpts, we introduce the notion of subsumption justification as a generalisation of the notion of a justification (a minimal set of axioms needed to preserve a given logical consequence) to capture the subsumption knowledge over the vocabulary. Similarly, for computing projection modules, we introduce the notion of projection justifications that preserve the answers to one of three query types as given by a reference ontology.

We develop algorithms for computing subsumption (projection) justifications that collect all axioms that are relevant for answering the queries. The process of extracting minimal sub-ontologies is guided by specific simulation notions between ontologies. Different algorithms are required for computing subsumption justifications and projection justifications for the different query languages. The algorithm for computing subsumption justifications collects all minimal sub-ontologies that maintain the simulation in order to preserve the answers to subsumption queries. Similarly, the algorithm for computing projection justifications also employs the simulation notion, but it collects the relevant axioms in a target ontology that preserve the same answer to different types of queries in the reference ontology.

Finally, we evaluate our approaches using a prototype implementation of the algorithms on large ontologies.
Résumé

Un nombre croissant d’ontologies de grande taille sont en cours de développement et rendues disponibles, par exemple dans les référentiels tels que le bioportail de NCBO. Garantir l’accès aux connaissances contenues dans des ontologies qui sont les plus pertinentes pour les utilisateurs est un défi important. Dans ce travail, nous abordons ce défi en proposant trois approches différentes pour extraire des connaissances des ontologies en logique de description :

• Extraire les modules minimaux d’une ontologie (c’est-à-dire les sous-ontologies minimales pour l’inclusion ensembliste qui préservent toutes les implications sur un vocabulaire donné). Les modules peuvent aider à comprendre la structure interne d’une ontologie. Par conséquent, l’extraction des modules minimaux d’une ontologie peut être utile dans de nombreux cas. Par exemple, le raisonnement à base d’ontologies, la visualisation d’ontologies, la réutilisation d’ontologies, la structuration de connaissances.

• Calculer les meilleurs extraits d’une ontologie (un certain nombre, petit, d’axiomes qui capturent au mieux la connaissance du vocabulaire tout en permettant un certain degré de perte sémantique). Ceci afin de résoudre le problème de l’absence de contrôle du nombre d’axiomes contenus dans un module minimal. Même des modules minimaux pour de petites signatures peuvent être volumineux, ce qui rend la compréhension humaine difficile. Par contre, un meilleur extrait préserve autant de connaissances que possibles relativement à une taille donnée.

• Déterminer les modules de projection (sous-ontologies d’une ontologie cible qui impliquent des requêtes de souscription, d’instance ou conjonctives qui découlent d’une ontologie de référence). Différent des notions précédentes, le module de projection prend en compte une seconde ontologie comme la référence et le but est d’extraire une sous-ontologie de l’ontologie cible qui préserve les connaissances sur un vocabulaire donné impliquées par cette ontologie de référence.
Pour chacune de ces approches, nous souhaitons extraire non seulement une, mais toutes les instances de la notion correspondante de module. Pour le calcul des modules minimaux et des meilleurs extraits, nous introduisons la notion de justification de la subsomption en tant que généralisation de la notion de justification (un ensemble minimal d’axiomes nécessaires pour préserver une conséquence logique donnée) afin de capturer la connaissance déduite par subsomption sur le vocabulaire. De même, pour le calcul des modules de projection, nous introduisons la notion de justification de projection qui préserve les réponses à l’un des trois types de requête impliquées par une ontologie de référence.

Nous développons des algorithmes pour calculer les justifications de subsomption (resp. de projection) qui rassemblent tous les axiomes pertinents pour répondre aux requêtes. Le processus d’extraction de sous-ontologies minimales est guidé par des notions de simulation spécifiques entre ontologies. Différents algorithmes sont nécessaires pour calculer les justifications de subsomption et de projection pour les différents langages de requêtes. L’algorithme de calcul des justifications de subsomption recueille toutes les sous-ontologies minimales qui respectent les règles de simulation afin de conserver les réponses aux requêtes de subsomption. De même, l’algorithme de calcul des justifications de projection utilise également la notion de simulation, mais il recueille les axiomes pertinents dans une ontologie cible qui conservent la même réponse à différents types de requêtes dans l’ontologie de référence.

Nous évaluons nos approches à l’aide d’un prototype d’implémentation des algorithmes sur les grandes ontologies, y compris SNOMED CT et NCI. Les évaluations montrent qu’il est possible de calculer tous les modules minimaux, les meilleurs extraits, et les modules de projection d’ontologies à grande échelle. En plus, les modules minimaux et les meilleurs extraits peuvent être beaucoup plus petits que les ontologies originales, ce qui montre l’avantage de ces notions.

Bibliography 135
Artificial intelligence (AI), also known as machine intelligence, has received considerable attention in recent years. The current most popular areas include deep learning, speech recognition, natural language processing. Knowledge representation, as a traditional AI area, is still a core part of AI research since it was founded in 1956 as an academic discipline. Knowledge is represented in machine processable form and logic is used for automated reasoning. Description logics in particular appear to offer a good compromise between expressive power and computational complexity of reasoning. In computer science, ontologies are mainly used to represent terminological knowledge. An ontology consists of a TBox that defines the terminology of the application domain and an ABox that states facts about a specific world. Different formats for modelling information have been recommended by the World Wide Web Consortium (W3C), most notably the Resource Description Framework (RDF) and its extensions RDF Schema (RDFS) and the Web Ontology Language (OWL). In this thesis, we consider ontologies represented using description logics. Description logics are a family of knowledge representation formalisms and form the logical underpinning of OWL. As a mature field of research, description logics offer a wealth of theoretical results on expressivity and computational complexity as well as existing implementations of reasoning systems. Applications of description logics encompass several areas including ontology engineering, web-based information systems and database management, among others. Furthermore, in this thesis, we focus on methods for extracting knowledge from ontologies that are represented using description logics for human users. To satisfy different user requirements, we propose and investigate three different approaches to knowledge extraction: ontology modules, ontology excerpts and projection modules. A module of an ontology is a subset of the ontology that captures the knowledge about the terms of interest as specified by the user. Depending on the module notion, a module may have further desired properties and provide certain logical guarantees. A drawback of modules, however, is their
relatively large size. Modules may be as large as the original ontology in the worst case. Once the ontology and the terms of interest have been fixed, there is no way to control the module size other than by changing to different module notions altogether. The notion of ontology excerpts is designed to remedy this issue. An ontology excerpt is a size-bounded subset of an ontology that preserves the knowledge that is most relevant to users’ concerns.

However, due to the size restriction, ontology excerpts might be incomplete. Different to the notions of an ontology module and an ontology excerpt, projection modules preserve the answers to subsumption-instance/conjunctive queries as they follow from a reference ontology. Lastly, if users already know what they want and can express their interests as an ontology, they can use this ontology as a reference ontology and extract projection modules from the target ontology.

1.1 Ontology Modularity

Ontology modularity has investigated for over 10 years. This area has received considerable attention resulting in a formidable literature. A challenge that remains to date is the development of practical algorithms for computing modules that are minimal w.r.t. set inclusion. The difficulty is due to the inherently high computational complexity of this task. Depending on the underlying module notion, there may be exponentially many modules that are minimal.

A module is a subset of an ontology that can act as a substitute for the ontology in certain contexts. A basic requirement for modules is to be indistinguishable from the original ontology w.r.t. a relation of inseparability. We call such basic modules are also ‘plain’ modules. Further module properties such as self-containment and depletion (also called weak and strong in [25]) have been proposed in the literature [31, 27] that impose additional conditions on modules (regarding the knowledge that is contained in the module and that is left in the ontology without the module). These properties together with a range of different relations of inseparability give rise to a family of module notions. Several inseparability notions have been considered, e.g., model theoretic inseparability w.r.t. a signature [27], or inseparability w.r.t. answers to queries [35]. Popular query types are subsumption, instance and conjunctive queries. We call modules based on model theoretic inseparability semantic modules. This is a strong inseparability notion as in the case of $\mathcal{ELH}^r$-TBoxes, model theoretic inseparability w.r.t. a signature $\Sigma$ coincides with entailment of second-order logic sentences over $\Sigma$ (cf. Theorem 4 in [27]). In this thesis, however, we consider a weaker relation of inseparability that is based on subsumption queries between $\mathcal{EL}$-concepts over a given signature for an $\mathcal{ELH}^r$ terminology. We call the resulting modules $\mathcal{ELH}^r$-subsumption modules.
1.1 Ontology Modularity

An important requirement for modules is that they should be as small as possible, which is useful not only in the ontology re-use scenario [16] but also for other tasks including ontology classification, debugging, decomposition, matching and summarisation. As the smallest modules are not necessarily unique, we are interested in computing all basic $\mathcal{ELH}^\tau$-subsumption modules that are minimal w.r.t. set inclusion. Computing minimal basic semantic modules of $\mathcal{ELH}^\tau$-terminologies that are additionally self-contained and depleting has been investigated in [25, 27]. Algorithms for computing minimal modules of DL-Lite ontologies have been studied in [31]. However, to the best of our knowledge, no practical approach for computing one or all basic $\mathcal{ELH}^\tau$-subsumption modules of $\mathcal{ELH}^\tau$-terminologies has been developed so far.

Minimal modules can serve as explanations of the entire set of entailments over a signature, similar to the justifications for one consequence (i.e., minimal sets of axioms sufficient to entail the consequence) [20]. In this sense, minimal modules can improve our understanding of the internal structure of large and complex ontologies. Moreover, being able to compute all minimal modules allows us to select the smallest minimal module.

In general, extracting minimal modules is intractable, which is the reason why efficiently extractable approximations of the (union of all) minimal modules have been introduced. Among such approximations is the family of syntactic locality-based modules [16]. Such modules may contain more axioms than necessary to ensure the preservation of entailments over a signature. For instance, the size of the syntactic $\perp\top^+$-locality modules [42] of Snomed CT,\(^1\) the Systematized Nomenclature of Medicine – Clinical Terms, (Version Jan 2016) for 100 signatures consisting of 50 concept names selected at random together with all role names, ranges from 1 075 to 2 456 axioms. This is in contrast to the size of the minimal basic subsumption modules for these signatures that ranges from around 50 to 118 axioms. Hence, such minimal modules of Snomed CT may be more than 20 times smaller than the corresponding syntactic $\perp\top^+$-locality modules. Implementations for extracting locality-based modules are incorporated in the OWLAPI.\(^2\)

The system MEX\(^3\) has been introduced to compute minimal depleting semantic modules (which are unique for a given signature) from acyclic $\mathcal{EL}$-terminologies (possibly extended with inverse roles) such as Snomed CT [25]. The MEX-modules contain all minimal basic subsumption modules, which are generally smaller. The size of the MEX-modules of Snomed CT for the same signatures as above ranges from 401 to 720 axioms. However, the corresponding minimal basic subsumption modules are still at least 6 times smaller. Moreover, MEX cannot handle cyclic $\mathcal{EL}$-terminologies such as some recent versions of

\(^1\)https://www.snomed.org
\(^2\)https://github.com/owlcs/owlapi
\(^3\)https://cgi.csc.liv.ac.uk/~konev/software/
the National Cancer Institute’s Thesaurus (NCI). For instance, the size of the syntactic $\perp T^*$-locality modules of NCI (Version 14.01d) for 100 random signatures selected from NCIt (as before for Snomed CT just with 100 concept names) ranges from 679 to 3 895 axioms, whereas the size of the corresponding minimal basic $&L^*$-subsumption modules ranges from around 0 to 64 axioms. Clearly, the ratio of the size of the syntactic $\perp T^*$-locality based modules to that of the minimal basic subsumption modules is even more than 20 in this case. Another approach for extracting minimal depleting modules from DL-Lite ontologies is based on using QBF-solvers [31].

1.2 Ontology Excerpts

Knowledge about a complex system represented in ontologies yields a collection of axioms that is too large for human users to browse, let alone to comprehend or reason with. In Chapter 5 of this thesis, we propose a computational framework to zoom in on large ontologies by providing users with either the necessary axioms that act as explanations for sets of entailments, or fix-sized sub-ontologies containing the most relevant information over a vocabulary, that is signature, denoted by $\Sigma$.

Various approaches to extracting knowledge from ontologies have been suggested including ontology summarization [43, 51, 47], ontology modularization [16, 50, 48, 49, 27], ontology decomposition [11, 36], and consequence justifications [21]. Existing ontology summarization systems focus on producing an abridged version of RDF/S ontologies by identifying the most important nodes and their links under certain numeric measures, e.g., in/out degree centrality of a node [47]. Ontology modularization is also very helpful to extract knowledge from ontologies. However, computing minimal modules is known to be hard. Hence, existing systems are either restricted to tractable DLs [29, 25, 10] or they compute approximations of minimal modules [16, 11, 40].

However, different module notions and justifications share the property that the number of the axioms they contain is not bounded (besides the size of the entire ontology). Even minimal modules for small signatures may be large, rendering human understanding more difficult, which can be shown by the following experiment.

Figure 1.1 illustrates the dependency between signature size and module size in the case of SNOMED CT (Version Jan2014) consisting of 297090 axioms, 297079 concept names, and 62 role names. The coordinates of a point in Figure 1.1 are a pair $(n, m)$ of numbers, where $n$ corresponds to the number of terms in a signature $\Sigma$ and $m$ to the number of axioms in a subset $\mathcal{S}$ of the ontology $\mathcal{O}$. The curve connects over 30 data points, each

---

4https://ncit.nci.nih.gov/
of which represents the median value of the sizes of 500 $\bot \top^*$-local modules of SNOMED CT. Each module is extracted w.r.t. a signature consisting of $n$ concept names, for $n$ with $200 \leq n \leq 290000$, and 30 role names that are randomly selected from the signature of SNOMED CT. The special role name ‘RoleGroup’ is always selected. Note that we fixed the number of role names arbitrarily; similar results can be expected for different numbers of role names. The time needed to extract 500 modules ranges from about 30 min for small signatures (containing 200 concept names) to about 90 min for large signatures (containing 250000 concept names).\footnote{The experiments were conducted on a PC equipped with an Intel Xeon E5-2640 CPU running at 2.50GHz and with 100GB of RAM. We used Debian GNU/Linux 7.3 as operating system, Java version 1.7.0 51 and OWLAPI version 3.4.8.}

We can see from Figure 1.1 that the module sizes increase with the size of the input signature. For small signatures, the slope is steep, showing that the modules are relatively large compared to the signature size. However, with increasing signature sizes, the slope flattens. For different signatures of the same size, there are still variations in the sizes of the modules for these signatures. In this experiment, the module sizes vary from 2633 to 4086 for signatures up to 100000 concept names and 30 role names. For larger signatures the variation in module size reduces to 224 for signatures with 290000 concept names and 30 role names, and converges to 0 as signature is expanded to the whole signature of SNOMED CT.

Let us consider the coordinates of a point in the chart in Figure 1.1 as a pair $(n, m)$ of numbers, where $n$ corresponds to the size of a signature $\Sigma$ and $m$ to the size of a subset $\mathcal{S}$ of the ontology $\mathcal{O}$. Let $M_\Sigma(\mathcal{O})$ be the module of the ontology $\mathcal{O}$ w.r.t. the signature $\Sigma$ (under any module notion). Note that, for a signature $\Sigma'$ and a subset $\mathcal{S}' \subseteq \mathcal{O}$ that correspond to a point in the area above the curve for the ontology $\mathcal{O}$ in Figure 1.1, we may have that $M_{\Sigma'}(\mathcal{O}) \subset \mathcal{S}'$. In this case, $\mathcal{S}'$ likely contains axioms that do not contribute to the meaning of the symbols in $\Sigma'$. Therefore, we are mainly interested in the area below the curve for an ontology $\mathcal{O}$. Let $(n, m)$ be a point in that area, and let $\mathcal{S} \subseteq \mathcal{O}$ and $\Sigma$ be such that $|\Sigma| = n$ and
Introduction

Let \( |\mathcal{S}| = m \). We have that \( \mathcal{S} \) contains fewer axioms than the module \( \mathcal{M}_\Sigma(\mathcal{O}) \) (not considering the variation of module sizes), i.e., \( |\mathcal{S}| \leq |\mathcal{M}_\Sigma(\mathcal{O})| \). Therefore, \( \mathcal{S} \) is likely to be incomplete in capturing the meaning of the symbols in \( \Sigma \). The trade-off for obtaining full control over the size of \( \mathcal{S} \) is a certain degree of incompatibility of \( \mathcal{S} \). To this end, the notion of best excerpts is inspired as size-bounded subsets of ontologies that preserve as much knowledge about a given signature as possible.

The following real-world example illustrates possible benefits of best excerpts. The example axioms come from Snomed CT (FS for Finding_site, RG for Role_Group).

\[
\begin{align*}
\alpha_1 & := \text{Decreased\_blood\_volume} \sqsubseteq \text{Cardiovascular\_finding} \\
\alpha_2 & := \text{Cardiovascular\_shunt} \sqsubseteq \text{Cardiovascular\_finding} \\
\alpha_3 & := \text{Cardiac\_shunt} \sqsubseteq \text{Cardiovascular\_shunt} \sqcap \exists \text{RG}.(\exists \text{FS.Heart\_structure}) \\
\alpha_4 & := \text{Cardiovascular\_structure} \sqsubseteq \text{Body\_system\_structure}
\end{align*}
\]

Suppose a user is concerned with the cardiovascular disease defined in the Snomed CT ontology \( \mathcal{T} \) consisting of around 300000 axioms. The user then selects the terms \text{Cardiovascular\_finding}, \text{Decreased\_blood\_volume} and \text{Cardiac\_shunt} from \( \mathcal{T} \) as her signature \( \Sigma \) of interest. To help the user zoom in on \( \mathcal{T} \) for \( \Sigma \), we can extract, for instance, the \( \perp \top^* \)-module and obtain 51 axioms, or the smallest minimal modules, which yields a further reduction down to 15 axioms, among which are the axioms given above(\( \alpha_1-\alpha_4 \)). Arguably our user still feels overwhelmed by the amount of 15 axioms. This is where the notion of best \( k \)-excerpt steps in. By setting \( k = 3 \), the user can get a best 3-excerpt \( \mathcal{E}_1 \) consisting of the axioms 1–3 listed above. By zooming in further, say extracting one-sized excerpts, she obtains \( \mathcal{E}_2 \) consisting of the first axiom. As a best excerpt, \( \mathcal{E}_1 \) guarantees all logical entailments over the terms \text{Cardiac\_shunt} and \text{Decreased\_blood\_volume}. And the singleton \( \mathcal{E}_2 \) keeps the complete information over the term \text{Decreased\_blood\_volume}. Note that \( \mathcal{E}_2 \) is returned due to the fact that it needs more than two axioms to preserve the full information for any other concept in \( \Sigma \). Moreover, axiom 4 is missing in \( \mathcal{E}_1 \) and in \( \mathcal{E}_2 \). This is because the latter merely serve to provide background knowledge for reasoning over, thus not directly linked to, the user’s input terms \( \Sigma \), which are excluded from best excerpts due to the size restriction. In this way, the user is able to desired size that captures the most relevant information for her signature of interest, thus gains size control over a large ontology.

1.3 Projection Modules

Consider the scenario of the medical condition multiple myeloma, also known as bone marrow cancer (BMCancer). This is a cancer of plasma cells, an antibody producing type of white blood cell. The affected blood cells produce the protein albumin that can damage the kidneys. Damaged kidneys
may be detected in a urine test (Urinalysis) as the presence of increased amounts of albumin in the urine. Normal protein concentrations in urine should be low. Depending on the amounts of albumin, this finding is classified as microalbuminuria (MA). The cancerous cells activate certain bone cells (osteoclasts) to resorb bone tissue causing the release of calcium into the blood (leading to a possible Hypercalcemia). The disruption of red blood cell production in the bone marrow may cause anemia, and the breakdown of bone may eventually result in a broken back (Spinal_Fracture).

Suppose a medical terminology $T_1$ consisting of axioms $\alpha_1, \ldots, \alpha_6$ generally states that spinal fractures should be treated with orthopedic surgery and classifies multiple myeloma as bone marrow cancer. It also states that patients with multiple myeloma should be given cancer treatment. We can think of the information in $T_1$ as a basic classification and guideline that should be complemented with more specific domain knowledge on symptoms, diagnostic procedures and types of treatments where applicable.

We further suppose that domain experts together with ontology engineers in fact have, based on $T_1$, implemented a more specific terminology $T_2$ including the axioms $\alpha_2, \ldots, \alpha_6$ and $\beta_1, \ldots, \beta_5$, among many others. In the development of $T_2$, the axiom $\alpha_1$ has been extended to $\beta_1$ to include more information on prescribed treatments in the case of a spinal fracture. In particular, $\beta_1$ additionally states that a urinalysis should be performed to check for a possibly increased concentration of the protein albumin as well as medical imaging to detect any bone lesions. Each of these findings can be essential in diagnosing multiple myeloma, which may otherwise be undetected and, thus, have fatal consequences. The other axioms from $T_1$ have been preserved in $T_2$, whereas $\beta_2, \ldots, \beta_5$ are new axioms classifying treatments and describing symptoms of multiple myeloma.

\[
\begin{align*}
\alpha_1 & := \text{Spinal_Fracture} \sqsubseteq \text{Fracture} \\
\alpha_2 & := \text{Fracture} \sqcap \exists \text{prescribe}. \text{Orthopedic_Surgery} \\
\alpha_3 & := \text{Orthopedic_Surgery} \sqsubseteq \text{Treatment} \\
\alpha_4 & := \text{Multiple_Myeloma} \sqsubseteq \text{BMCancer} \\
\alpha_5 & := \text{BMCancer} \sqcap \exists \text{prescribe}. \text{Cancer_Treatment} \\
\alpha_6 & := \text{Cancer_Treatment} \sqsubseteq \text{Treatment} \\
\beta_1 & := \text{Spinal_Fracture} \sqsubseteq \text{Fracture} \sqcap \exists \text{prescribe}. \text{Urinalysis} \sqcap \exists \text{prescribe}. \text{Medical_Imaging} \\
\beta_2 & := \text{Multiple_Myeloma} \sqsubseteq \text{MA} \sqcap \text{Anemia} \sqcap \text{Hypercalcemia} \\
\beta_3 & := \text{MA} \equiv \exists \text{prescribe}. (\text{Urinalysis} \sqcap \exists \text{has_finding}. \text{Increased_Albumin}) \\
\beta_4 & := \text{Medical_Imaging} \sqsubseteq \text{Treatment} \\
\beta_5 & := \text{Urinalysis} \sqsubseteq \text{Treatment}
\end{align*}
\]
To promote quality and safety in the health care system, the integrity of $T_2$ needs to be verified. This means checking that $T_2$ correctly implements the knowledge regarding the terms, say, Spinal_Fracture, Treatment, Multiple_Myeloma, prescribe, and has_finding as used in $T_1$ (underlined). It also means checking that $T_2$ satisfies certain restrictions regarding the formulation of axioms as well as term usage. In an effort to ensure integrity of $T_2$ w.r.t. $T_1$ and compliance of $T_2$ with guidelines, the axioms from $T_2$ that capture $T_1$’s knowledge need to be inspected. Guidelines by health insurances may require hospitals to avoid unnecessary treatments so as to avoid medical waste. Additionally guidelines regarding the style or form of axioms may apply such as restrictions on term usage or the requirement to use certain design patterns.

A module of $T_2$ for the terms, however, preserves all knowledge of $T_2$ regarding these terms. The resulting axioms may be too numerous for it to be feasible to inspect them manually. In our illustrating example, a comprehensive module notion would, when applied to $T_2$ w.r.t. the terms, yield all axioms of $T_2$ as shown above. A module notion that is minimal (w.r.t. set inclusion) would yield the axioms $\beta_1, \ldots, \beta_5$. These axioms preserve $T_1$’s entailments Spinal_Fracture $\sqsubseteq \exists \text{prescribe.Treatment}$ and Multiple_Myeloma $\sqsubseteq \exists \text{prescribe.Treatment}$, but they also entail, e.g.,

$$\gamma := \text{Multiple_Myeloma} \sqsubseteq \exists \text{prescribe.has_finding.} \top,$$

which does not follow from $T_1$. On the other hand, the following subsets of $T_2$ that do preserve the entailments of $T_1$ are not minimal modules of $T_2$ as they do not entail $\gamma$: $\{\alpha_2, \ldots, \alpha_6, \beta_1\}$, $\{\alpha_4, \alpha_5, \alpha_6, \beta_1, \beta_4\}$, and $\{\alpha_4, \alpha_5, \alpha_6, \beta_1, \beta_5\}$. Each of these subsets needs to be inspected to ensure integrity and compliance of all relevant parts of $T_2$. For the inspection effort to be feasible, every such subset needs to be as small as possible.

To sum up, the task is to assist users to check how $T_1$’s knowledge is implemented in $T_2$. The solution is to extract only those subsets from $T_2$ that preserve the mere knowledge of $T_1$ and that are minimal w.r.t. set inclusion so as to enable processing by a human, which cannot be produced by existing module notions.

Best practices in engineering individual or networked systems of ontologies include the use of design patterns [37] and requirement specifications [45]. Design patterns are syntactic templates of axioms that are to be instantiated with terms. Requirements specifications help by facilitating the ontology development process including the application of design patterns as well as verification of the resulting ontologies.

Various approaches to comparing ontologies have been suggested, including ontology mapping, or ontology alignment [13], and logical difference [28, 30, 34]. Ontology matching is the process of determining correspondences, in particular the subsumption, equivalence, or disjointness relation between two concept or relation names from different ontologies. A good concept similarity [33, 1] is often helpful for ontology matching. In contrast, logical difference focuses on the comparison of entailed logical consequences from each ontology and returns difference witnesses if differences are present.
1.4 Structure of the Thesis

For latest results on inseparability (in particular inseparability w.r.t. conjunctive queries), see, e.g., [7, 8, 19], and for a survey on query inseparability, see, e.g., [6].

To compute projection modules, in this thesis, we generalize the notion of justification to *subsumption justification* as a minimal set of axioms that maintains a consequence. Currently, the approaches for computing all the justifications of an ontology w.r.t. a consequence can be classified into two categories: “glass-box” [5, 21, 2, 22] and “black-box” [21, 52, 46]. “Black-box” algorithms use existing reasoners to check whether a concept inclusion follows on from an ontology while searching for possible sub-ontology that can serve as justifications. Differently, “glass-box” approaches modify a pre-existing reasoner implementation in order to keep track of which axioms were used during the classification of an ontology. Since it is difficult to avoid generating duplicate inferences for the same consequence and there might exist exponentially many justifications for a given ontology and a concept inclusion in the worst case, computing all justifications in general is a difficult task. It is however possible to compute one justification in polynomial time.

1.4 Structure of the Thesis

The structure of the thesis is listed as follows:

Chapter 2 In this chapter, we introduce the relevant notions that are necessary for this thesis. We start by the foundations of Description Logics $\mathcal{EL}$ and then we review the theory of logical differences, relevant lemmas and theorems. In addition, some existing ontology module notions are recalled. Finally, we introduce the notion of ontology justification and partial Max-SAT problem.

Chapter 3 We introduce the notion of *subsumption justification* to capture the subsumption knowledge concerning a term with respect to all primitive and complex concepts built from terms in a given vocabulary $\Sigma$. It extends the notion of classical justification that is a minimal set of axioms needed to preserve the entailment of a particular subsumption $C \sqsubseteq D$.

We provide two dedicated simulation notions to characterise the set of subsumers and the set of subsumees formulated over a target signature $\Sigma$ for a given signature term $X$ w.r.t. an $\mathcal{ELH}$- and $\mathcal{ELH}^r$-terminology $\mathcal{T}$. The simulation notions originate from the proof-theoretic approach from [34] developed for the problem of deciding the logical difference between ontologies [23]. Based on the simulation notions, we devise recursive algorithms for extracting the minimal subsets of axioms that preserve the entailments of all $\Sigma$-subsumers and all $\Sigma$-subsumees of $X$ w.r.t. $\mathcal{T}$. We show that the respective subsumer and subsumee justifications obtained in this way can then be combined to yield subsumption justifications.

Finally, we evaluate a prototype implementation for computing subsumption justifications over large biomedical terminologies. The results are encouraging as they show that computing subsumption justifications is indeed feasible in several important practical cases.
Chapter 4 In this chapter, we introduce a module notion, called basic $\mathcal{ELH}^r$-subsumption modules and present two different approaches to compute them. In section 4.2, we extend the black-box approach for finding one or all justifications in [20], which is based on Reiter’s hitting set algorithm [38]. Instead of ensuring that a given entailment is preserved, we introduce an oracle to determine the inseparability between the original ontology and the resulting module. As an oracle we use a variant of the system CEX, which is a tool for deciding whether two $\mathcal{ELH}^r$-terminologies are logically different w.r.t. a signature [28, 24, 34]. Additionally, several optimisations to speed up the computation of minimal modules are investigated.

We also present an experimental evaluation of our algorithms by applying them on the prominent and large medical ontologies Snomed CT and NCI. We note that our algorithms are applicable to ontologies formulated in any ontology language provided that a tool is available that can effectively decide the inseparability relation. As CEX works with variants of $\mathcal{ELH}^r$-terminologies, we restrict the presentation of our algorithms to $\mathcal{ELH}^r$-terminologies.

An alternative to the black-box approach for computing minimal modules is to directly select the relevant axioms from an ontology that preserve the desired entailments. Such a glass-box approach has been investigated for acyclic $\mathcal{ELH}$-terminologies (i.e., without domain and range restrictions of roles) in Section 4.3. This technique is based on subsumption justification that we introduced in Chapter 3. In addition, in this thesis we introduce a technique for computing even smaller (but possibly incomplete) modules called ontology excerpts.

Chapter 5 A best $k$-excerpt of a TBox is a sub-ontology that contains at most $k$ axioms that best capture the knowledge about users’ interests in terms of weighted signature. In Chapter 5, we encode the problem of selecting the right subsumption modules w.r.t. a signature as a partial Max-SAT problem based on subsumption justifications that we introduced in Chapter 3. Overall we obtain an algorithm for computing best $k$-excerpts w.r.t. a signature. Then we introduce weighted signature and update the encoding method as a weighted partial Max-SAT problem to computing best excerpts for weighted signature. We also propose a method to rank axioms in excerpts when presenting users a best excerpt. Finally, we evaluate our algorithm by using it with the prominent bio-medical ontologies Snomed CT. We demonstrate that computing best $k$-excerpts is a viable approach for the task of summarizing large ontologies with a controllable small number of axioms that are most relevant for a given set of terms.

Chapter 6 We introduce a novel module notion called projection module that entails the queries that follow on from a reference ontology. We consider subsumption, instance and conjunctive queries to represent the knowledge to be preserved. We develop algorithms for computing all minimal projection modules of $\mathcal{ELH}^r$-terminologies, inspired by the simulation notions developed for deciding the logical difference problem [34]. Our preliminary evaluation on real world biomedical ontologies shows that the projection module notion creates a new dimension to understand relations among multiple ontologies.
1.4 Structure of the Thesis

**Chapter 7**  In Chapter 7 we summarize the results and indicate some possible future work based on this thesis.
Chapter 2

Preliminaries

In this chapter we review the theoretical foundation that the following chapters are based on. We start by explaining the basic notions of the Description Logic $\mathcal{EL}$ and some of its extensions. We focus on these light-weight Description Logics as we deal in this thesis with the knowledge that is represented in such formalisms. Then we review the theory of logical difference, which plays an important role in the remainder of this thesis. In Section 2.3, we have a close look at existing ontology module notions. We follow by introducing the notion of justification, which we will use in Chapter 3. Finally, we introduce the foundation of the partial Max-SAT problem, which will be used in Chapter 5.

2.1 Description Logic $\mathcal{EL}$ and its Extensions

In this section, we are introducing the family of Description Logics $\mathcal{EL}$. We start by briefly reviewing the Description Logic $\mathcal{EL}$ and several of its extensions with range restrictions and conjunction of roles and the universal role as well as concept subsumptions based on these extensions. For a more detailed introduction to description logics, we refer to [3].

In the remainder of the thesis, we denote the sets of concept and role names by $N_C$ and $N_R$, respectively. We assume these sets to be mutually disjoint and countably infinite. Capital letters such as $A$, $B$, $X$, $Y$, $Z$ will denote concept names from $N_C$, whereas lower-case letters $r, s, t$ will denote role names from $N_R$.

**Definition 1 (Syntax of $\mathcal{EL}$-Family Concepts)** The sets of $\mathcal{EL}$-concepts $C$, $\mathcal{EL}^{\text{ran}}$-concepts $D$, $\mathcal{EL}^{\ominus}$-concepts $E$, and $\mathcal{EL}^{\ominus,u}$-concepts $F$ are built according to the grammar rules:

- $C ::= \top \mid A \mid C \sqcap C \mid \exists r.C \mid \text{dom}(r)$
- $D ::= \top \mid A \mid D \sqcap D \mid \exists r.D \mid \text{dom}(r) \mid \text{ran}(r)$
- $E ::= \top \mid A \mid E \sqcap E \mid \exists R.E$
- $F ::= \top \mid A \mid F \sqcap F \mid \exists R.F \mid \exists u.F$
where \( A \in \mathbb{N}_C \), \( r \in \mathbb{N}_R \), \( u \) is a fresh logical symbol (the universal role) and \( R = r_1 \sqcap \ldots \sqcap r_n \) with \( r_1, \ldots, r_n \in \mathbb{N}_R \), for \( n \geq 1 \).

**Definition 2 (Semantics of \( \mathcal{EL} \) Concepts)** An interpretation \( \mathcal{I} = (\Delta^\mathcal{I}, \cdot^\mathcal{I}) \) consists of a non-empty set, the domain \( \Delta^\mathcal{I} \), and an interpretation function \( \cdot^\mathcal{I} \) that maps each concept name \( A \) to a subset \( A^\mathcal{I} \) of \( \Delta^\mathcal{I} \), every role name \( r \) to a binary relation \( r^\mathcal{I} \) over \( \Delta^\mathcal{I} \) and the universal role \( u \) to \( u^\mathcal{I} = \Delta^\mathcal{I} \times \Delta^\mathcal{I} \).

The extension \( C^\mathcal{I} \) of an \( \mathcal{EL} \)-concept \( C \) is defined inductively as follows:

- \( \top^\mathcal{I} := \Delta^\mathcal{I} \),
- \( (C \sqcap D)^\mathcal{I} := C^\mathcal{I} \cap D^\mathcal{I} \),
- \( (\exists r).C^\mathcal{I} := \{ x \in \Delta^\mathcal{I} | \exists y \in C^\mathcal{I} : (x, y) \in r^\mathcal{I} \} \),
- \( (\text{dom}(r))^\mathcal{I} := \{ x \in \Delta^\mathcal{I} | \exists y : (x, y) \in r^\mathcal{I} \} \) and
- \( (r_1 \sqcap \ldots \sqcap r_n)^\mathcal{I} := r_1^\mathcal{I} \cap \ldots \cap r_n^\mathcal{I} \).

**Example 3** To illustrate concept descriptions, consider an example from the biomedical domain. We assume that \( \text{Finding_or_region_of_thorax} \) and \( \text{Mediastinal_Structure} \) are concept names, and \( \text{finding_site} \) is a role name. We can specify the concept of \( \text{Finding_or_region_of_thorax} \) that can be found in the \( \text{Mediastinal_Structure} \) by using the following concept:

\[
\text{Finding_or_region_of_thorax} \sqcap \exists \text{finding_site}. \text{Mediastinal_Structure}.
\]

**Definition 4 (Concept and Role Inclusions, and TBoxes)** Let \( C \) be an \( \mathcal{EL} \)-concept, \( D \) an \( \mathcal{EL}^{\text{ran}} \)-concept, \( F \) an \( \mathcal{EL}^{\sqcap,\text{u}} \)-concept and \( r, s \in \mathbb{N}_R \). The sets of \( \mathcal{EL} \)-inclusions \( \alpha \), \( \mathcal{EL}^{\sigma} \)-inclusions \( \beta \), \( \mathcal{EL}^{\text{ran}} \)-inclusions \( \gamma \) and \( \mathcal{EL}^{\text{ran},\sqcap,\text{u}} \)-inclusions \( \delta \) are built according to the grammar rules:

\[
\begin{align*}
\alpha & ::= C \sqsubseteq C \mid C \equiv C \mid r \subseteq s \\
\beta & ::= C \sqsubseteq C \mid r \sqsubseteq s \\
\gamma & ::= D \sqsubseteq C \mid r \sqsubseteq s \\
\delta & ::= D \sqsubseteq F \mid r \sqsubseteq s
\end{align*}
\]

An \( \mathcal{L} \)-TBox is a finite set of \( \mathcal{L} \)-inclusions, where \( \mathcal{L} \) ranges over the set of \( \mathcal{EL} \), \( \mathcal{EL}^{\sigma} \), \( \mathcal{EL}^{\text{ran}} \) and \( \mathcal{EL}^{\text{ran},\sqcap,\text{u}} \).

We refer to inclusions also as axioms.

**Definition 5 (Instance Assertions and ABoxes)** Let \( \mathbb{N}_I \) be a set of individuals names and let \( a, b \in \mathbb{N}_I \). Additionally, let \( C \) be an \( \mathcal{L} \)-concept and \( r \in \mathbb{N}_R \), where \( \mathcal{L} \) ranges over the set of \( \mathcal{EL} \), \( \mathcal{EL}^{\text{ran}} \), \( \mathcal{EL}^{\sqcap} \), and\( \mathcal{EL}^{\sqcap,\text{u}} \). A \( \mathcal{L} \)-instance assertion is an expression of the form:

\[
C(a) \quad \text{or} \quad r(a, b).
\]
An \( \mathcal{L} \)-ABox is a finite set of \( \mathcal{L} \)-instance assertions.

**Definition 6 (Semantics of Concepts, Inclusions, Assertions, TBoxes and ABoxes)** An interpretation \( \mathcal{I} \) satisfies a concept \( C \), an axiom \( C \sqsubseteq D \), \( C \equiv D \) or \( r \sqsubseteq s \), and an \( \mathcal{L} \)-instance assertion \( C(a) \) or \( r(a,b) \) iff, respectively:

- \( C^\mathcal{I} \neq \emptyset \),
- \( C^\mathcal{I} \subseteq D^\mathcal{I} \),
- \( C^\mathcal{I} = D^\mathcal{I} \),
- \( r^\mathcal{I} \subseteq s^\mathcal{I} \),
- \( a^\mathcal{I} \in C^\mathcal{I} \), or
- \( (a^\mathcal{I}, b^\mathcal{I}) \in r^\mathcal{I} \).

We write \( \mathcal{I} \models \varphi \) iff the interpretation \( \mathcal{I} \) satisfies the axiom or instance assertion \( \varphi \). An interpretation \( \mathcal{I} \) satisfies a TBox \( \mathcal{T} \) (or an ABox \( \mathcal{A} \)), written \( \mathcal{I} \models \mathcal{T} \) (\( \mathcal{I} \models \mathcal{A} \)), iff for every axiom \( \varphi \in \mathcal{T} \), it holds that \( \mathcal{I} \models \varphi \) (for every instance assertion \( \lambda \in \mathcal{A} \), \( \mathcal{I} \models \lambda \)). A TBox \( \mathcal{T} \) entails an axiom \( \varphi \) or, equivalently, \( \varphi \) follows from \( \mathcal{T} \), written \( \mathcal{T} \models \varphi \), iff for all interpretations \( \mathcal{I} \), \( \mathcal{I} \models \mathcal{T} \) implies \( \mathcal{I} \models \varphi \). A TBox \( \mathcal{T} \) and an ABox \( \mathcal{A} \) together entail an instance assertion \( \lambda \) or, equivalently, \( \lambda \) follows from \( \mathcal{T} \) and \( \mathcal{A} \), written \( (\mathcal{T}, \mathcal{A}) \models \lambda \), iff for all interpretations \( \mathcal{I} \), \( \mathcal{I} \models \mathcal{T} \) and \( \mathcal{I} \models \mathcal{A} \) implies \( \mathcal{I} \models \lambda \).

Note that each of the concepts introduced above is satisfiable.

**Example 7** Considering the following concept and role inclusions in the biomedical domain:

\[
\begin{align*}
\alpha_1 &::= \text{Color} \sqsubseteq \text{Clinical\_finding(finding)} \equiv \text{Clinical\_finding(finding)} \sqcap \exists \text{interprets(attribute)}.\text{Color} \\
\alpha_2 &::= \text{Disease(disorder)} \sqsubseteq \text{Clinical\_finding(finding)} \\
\alpha_3 &::= \exists \text{interprets(attribute)} \sqsubseteq \text{concept\_module\_object\_attribute(attribute)}
\end{align*}
\]

Axiom \( \alpha_1 \) defines the concept name \( \text{Color\_finding(finding)} \) in terms of the concept names \( \text{Clinical\_finding(finding)} \) and \( \text{Color} \) as well as the role name \( \text{interprets(attribute)} \) by stating that color findings are exactly the clinical findings that interpret colors. Axiom \( \alpha_2 \) specifies the concept name \( \text{Disease(disorder)} \) in terms of \( \text{Clinical\_finding(finding)} \) by stating that a disease is a clinical finding. Finally, Axiom \( \alpha_3 \) defines \( \exists \text{interprets(attribute)} \) in terms of the role name \( \text{concept\_module\_object\_attribute(attribute)} \) by stating that every relationship among the property ‘interprets’ also belongs to the property ‘concept module object attribute’.

**Definition 8 (\( \mathcal{ELH} \)-terminology)** An \( \mathcal{ELH} \)-terminology \( \mathcal{T} \) is an \( \mathcal{ELH} \)-TBox consisting of axioms \( \alpha \) of the following form:
• $A \sqsubseteq C$,
• $A \equiv C$,
• $r \sqsubseteq s$, or
• $\text{dom}(r) \sqsubseteq C$,

where $A \in \mathbb{N}_C$, $r, s \in \mathbb{N}_R$, $C$ is an $\mathcal{EL}$-concept and no concept name occurs more than once on the left-hand side of an axiom.\footnote{A concept equation $A \equiv C$ stands for the inclusions $A \sqsubseteq C$ and $C \sqsubseteq A$.}

Compared to $\mathcal{ELH}$-terminologies, an $\mathcal{ELH}^r$-terminology additionally allows for range restrictions.

**Definition 9 ($\mathcal{ELH}^r$-terminology)** An $\mathcal{ELH}^r$-terminology $\mathcal{T}$ is an $\mathcal{ELH}^r$-TBox consisting of axioms $\alpha$ of the following form:

• $A \sqsubseteq C$,
• $A \equiv C$,
• $r \sqsubseteq s$,
• $\text{dom}(r) \sqsubseteq C$ or
• $\text{ran}(r) \sqsubseteq C$,

where $A \in \mathbb{N}_C$, $r, s \in \mathbb{N}_R$, $C$ is an $\mathcal{EL}$-concept and no concept name occurs more than once on the left-hand side of an axiom.

**Example 10 (Ex. 7 contd.)** We complement axioms $\alpha_1$–$\alpha_3$ with four more axioms $\alpha_4$–$\alpha_7$ from the biomedical domain:

$\alpha_4 := \text{Normal\_color}(\text{finding}) \sqsubseteq \text{Color\_finding}(\text{finding})$

$\alpha_5 := \text{Normal\_color}(\text{finding}) \sqsubseteq \exists \text{interprets}(\text{attribute}).\text{Color}(	ext{observable\_entity})$

$\alpha_6 := \text{ran}(\text{finding\_sites}) \sqsubseteq \text{Body\_Structure}(\text{body\_structure})$

$\alpha_7 := \text{Color\_finding}(\text{finding}) \equiv \text{Diagnostic\_result}(\text{finding}) \sqcap \exists \text{has\_finding}(\text{attribute}).\text{Color}$

Axioms $\alpha_4$ and $\alpha_5$ both specify the concept name $\text{Normal\_color}(\text{finding})$, the former in terms of the concept name $\text{Color\_finding}(\text{finding})$ and the latter in terms of the role name $\text{interprets}(\text{attribute})$ and the concept name $\text{Color}(\text{observable\_entity})$. Then, Axiom $\alpha_4$ states that a normal color is a color...
finding, and \( \alpha_5 \) states that a normal color can be interpreted as an observable color. Next, Axiom \( \alpha_6 \) specifies the role name finding sites in terms of the concept name Body_Structure(body_structure) by restricting the range of the property 'finding sites' to refer to body structures. Finally, Axiom \( \alpha_7 \) provides an alternative definition of Color_finding(finding) in terms of the role name has_finding(attribute) and the concept names Diagnostic_result(finding) and Color by stating that color findings are exactly the diagnostic results that have a finding which is a color.

We have that \( T = \{ \alpha_1, \alpha_2, \alpha_3, \alpha_4 \} \) is an ELH-terminology and \( T \cup \{ \alpha_6 \} \) is an ELH-terminology. The set \( T' = \{ \alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5 \} \) is an ELH-TBox, but, according to Definition 9, it is not an ELH-terminology as the concept name Normal_color(finding) occurs on the left-hand side of two axioms, i.e. \( \alpha_4 \) and \( \alpha_5 \). Let \( T'' \) be a TBox obtained from \( T' \) by replacing \( \alpha_4 \) and \( \alpha_5 \) with Axiom \( \alpha_8 \).

\[
\alpha_8 := \text{Normal_color(finding)} \sqsubseteq \text{Color_finding(finding)} \sqcap \exists \text{interprets(attribute)}.\text{Color(observable_entity)}
\]

\( T'' \) is an ELH-terminology, and, moreover, \( T'' \) is semantically equivalent to \( T' \) (i.e. all axioms from \( T' \) are entailed by \( T'' \), and vice versa). Similarly, according to Definition 8, the set \( T \cup \{ \alpha_7 \} \) is not an ELH-terminology due to the concept name Color_finding(finding) occurring on the left-hand sides of axioms \( \alpha_1 \) and \( \alpha_7 \). In this case, however, we cannot simply replace \( \alpha_1 \) and \( \alpha_7 \) with a fresh axiom that combines the two.

To simplify the presentation, we assume that terminologies do not contain axioms of the form \( A \equiv B \) or \( A \equiv \top \) (after having removed multiple \( \top \)-conjuncts) for concept names \( A \) and \( B \).

**Definition 11 (Signature)** A signature \( \Sigma \) is a finite set of symbols from \( \mathbb{N}_C \) and \( \mathbb{N}_R \). We write \( \text{sig}(\chi) \) for the signature of \( \chi \) as the set of concept and role names occurring in \( \chi \), where \( \chi \) ranges over any syntactic object. Additionally, we define that \( \text{sig}^V(\chi) := \text{sig}(\chi) \cap V \), where \( V \) is a set.

The symbol \( \Sigma \) is used as a subscript (or a prefix) to a set of concepts or inclusions to denote that the elements only use symbols from \( \Sigma \), e.g., \( \mathcal{EL}_\Sigma, \mathcal{EL}^\text{ran}_\Sigma, \mathcal{EL}^\text{r}_\Sigma, \mathcal{EL}^\text{u}_\Sigma, \mathcal{ELH}_\Sigma, \Sigma\text{-ABox} \) or \( \Sigma\text{-query} \) etc.

**Definition 12 (Acyclic and Cyclic Terminology)** Let \( T \) be a terminology and \( \prec_T \) be the binary relation over \( \mathbb{N}_C \) defined by \( A \prec_T B \) iff there is an axiom of the form \( A \sqsubseteq C \) or \( A \equiv C \) in \( T \) such that \( B \in \text{sig}(C) \). A terminology \( T \) is acyclic if the transitive closure \( \prec_T^+ \) of \( \prec_T \) is irreflexive; otherwise \( T \) is cyclic.

**Definition 13 (Conjunctive Concept Name)** A concept name \( A \) is called conjunctive in \( T \) iff there exists an axiom of the form \( A \equiv B_1 \sqcap \ldots \sqcap B_n \), \( n \geq 2 \) in \( T \); otherwise \( A \) is said to be non-conjunctive in \( T \). We denote by \( B_i \in \text{non-conj}_T(A) \) and \( 1 \leq i \leq n \).
Definition 14 (Normalised $\mathcal{ELH}^r$-Terminology) Let $\varphi \in \{A, \text{dom}(s), \text{ran}(s)\}$, $A, B, B_i$ be concept names, and let $r, s$ be role names. Additionally, let each conjunct $B_i$ be non-conjunctive in $T$. An $\mathcal{ELH}^r$-terminology $T$ is normalised iff $T$ only contains axioms of the following forms:

- $r \sqsubseteq s$,
- $\varphi \sqsubseteq B_1 \sqcap \ldots \sqcap B_n$ with $n \geq 1$,
- $A \sqsubseteq \exists r.B$,
- $A \equiv \text{dom}(r)$,
- $A \equiv B_1 \sqcap \ldots \sqcap B_m$ with $m \geq 2$,
- $A \equiv \exists r.B$.

Every $\mathcal{ELH}^r$-terminology $T$ can be normalised in polynomial time such that the resulting terminology is a conservative extension of $T$ [23].

Example 15 (Ex. 7 contd.) The axiom $\alpha_1$ in Example 7 can be normalised resulting in, e.g., the following two new axioms:

- $\text{Color}_\text{finding}(\text{finding}) \equiv \text{Clinical}_\text{finding}(\text{finding}) \sqcap A$,
- $A \equiv \exists \text{interprets}(\text{attribute}).\text{Color}$,

where $A$ is a new concept name introduced by the normalization of $\alpha_1$.

Any $\mathcal{ELH}^r$-terminology can be normalised by appropriately replacing nested complex concepts $C$ by fresh concept names $X_C$ and adding concept equations $X_C \equiv C$ to the terminology that define the new symbols. It can readily be seen that this transformation is tractable and that it does not change the meaning of the original TBox. The following lemma from [23] makes this precise.

Lemma 16 For every $\mathcal{ELH}^r$-terminology $T$, there is a normalised $\mathcal{ELH}^r$-terminology $T'$ of polynomial size in the size of $T$ such that $T \equiv_{\Sigma} T'$ with $\Sigma = \text{sig}(T)$.

2.2 Logical Difference

In this section, we briefly recall basic notions related to logical difference between ontologies and some lemmas that we will use later in the thesis [23, 28].

Before we give the formal definitions of logical difference, first we recall the notions of instance and conjunctive queries. While instance queries are simply instance assertions (cf. Definition 5), conjunctive queries require their own definition.
Definition 17 (Conjunctive Query) Let $N_I$ and $N_V$ be disjoint sets of individual and variable names. A conjunctive query is a first-order formula built according to the following format:

$$\exists y_1 \ldots \exists y_n. \bigwedge_{i \in I_1} A_i(s_i) \land \bigwedge_{j \in I_2} r_j(t_j, t'_j),$$

where $y_1, \ldots, y_n \in N_V$ for $n \geq 1$ are variable names, $I_1, I_2$ are finite sets of indices, and for $i \in I_1$ and $j \in I_2$, $A_i$ ranges over concept names in $N_C$, $r_j$ ranges over role names in $N_R$, and $s_i, t_j, t'_j$ range over individual and variable names in $N_I \cup N_V$.

The notion of entailment of an instance query from a TBox and ABox generalises to conjunctive queries.

Example 18 We illustrate instance and conjunctive queries with the following example from the medical domain. Let $\mathcal{T}$ be a TBox and $\mathcal{A}$ an ABox, where

$$\mathcal{T}: \quad \text{Doctor} \equiv \text{Employee} \sqcap \exists \text{treat}\text{Disease}$$

$$\mathcal{A}: \quad \text{Employee(Ping)}$$

$$\text{Disease(Anemia)}$$

$$\text{treat(Ping, Anemia)}$$

Let $\lambda = (\text{Employee} \sqcap \exists \text{treat}\text{Disease})(\text{Ping})$ be an instance query and $q(x) = \exists y. \text{Employee}(x) \land \text{treats}(x, y)$ a conjunctive query. Note that $q(x)$ has one free variable, $x$. It can readily be verified that $(\mathcal{T}, \mathcal{A}) \models \lambda$ holds according to Definition 6. Moreover, it is not hard to see that $(\mathcal{T}, \mathcal{A}) \models q(x)$.

Definition 19 (Logical Difference) Let $\mathcal{T}_1$ and $\mathcal{T}_2$ be $\mathcal{EL}^\mathcal{R}$-TBoxes and let $\Sigma$ be a signature. Additionally, let $\mathcal{L} \in \{\mathcal{EL}^\mathcal{R}, \mathcal{EL}^\mathcal{ran}, \mathcal{EL}^{\mathcal{ran}, \mathcal{R}}\}$. The $\mathcal{L}$-subsumption query, instance query, and conjunctive query differences between $\mathcal{T}_1$ and $\mathcal{T}_2$ w.r.t. $\Sigma$ are the sets $\text{cDiff}_{\mathcal{L}}(\mathcal{T}_1, \mathcal{T}_2)$, $\text{iDiff}_{\mathcal{L}}(\mathcal{T}_1, \mathcal{T}_2)$ and $\text{qDiff}_{\mathcal{L}}(\mathcal{T}_1, \mathcal{T}_2)$, where

- $\varphi \in \text{cDiff}_{\mathcal{L}}(\mathcal{T}_1, \mathcal{T}_2)$ iff $\varphi$ is a $\mathcal{L}$-inclusion with $\text{sig}(\varphi) \subseteq \Sigma$, $\mathcal{T}_1 \models \varphi$ and $\mathcal{T}_2 \not\models \varphi$;

- $(\mathcal{A}, \lambda) \in \text{iDiff}_{\mathcal{L}}(\mathcal{T}_1, \mathcal{T}_2)$ iff $\mathcal{A}$ is an ABox with $\text{sig}(\mathcal{A}) \cap (N_C \cup N_R) \subseteq \Sigma$ and $\lambda$ a $\Sigma$-instance assertion, $(\mathcal{T}_1, \mathcal{A}) \models \lambda$ and $(\mathcal{T}_2, \mathcal{A}) \not\models \lambda$;

- $(\mathcal{A}, q(x)) \in \text{qDiff}_{\mathcal{L}}(\mathcal{T}_1, \mathcal{T}_2)$ iff $\mathcal{A}$ is an ABox with $\text{sig}(\mathcal{A}) \cap (N_C \cup N_R) \subseteq \Sigma$ and $q(x)$ a $\Sigma$-conjunctive query, $(\mathcal{T}_1, \mathcal{A}) \models q(x)$ and $(\mathcal{T}_2, \mathcal{A}) \not\models q(x)$.

The notion of subsumption, instance, and conjunctive query difference between $\mathcal{T}_1$ and $\mathcal{T}_2$ w.r.t. $\Sigma$ is not symmetric. In general, e.g., for subsumption query difference, it holds that $\text{cDiff}_{\mathcal{L}}(\mathcal{T}_1, \mathcal{T}_2) \neq \text{cDiff}_{\mathcal{L}}(\mathcal{T}_2, \mathcal{T}_1)$. Moreover, $\text{cDiff}_{\mathcal{L}}(\mathcal{T}_1, \mathcal{T}_2) = \emptyset$ does not imply $\text{cDiff}_{\mathcal{L}}(\mathcal{T}_2, \mathcal{T}_1) = \emptyset$, and vice versa. The same holds for instance and conjunctive query difference.
In remainder of the thesis, if \( \mathcal{L} \) is not specified in notions as in \( \text{cDiff}_\Sigma(\mathcal{T}_1, \mathcal{T}_2) \), then \( \mathcal{L} \) is taken to be the language in which \( \mathcal{T}_1 \) is formulated.

The following examples illustrate subsumption, instance, and conjunctive query differences.

**Example 20** Let \( \mathcal{T}_1 = \{ A \equiv \exists r B \cap X, r \subseteq s \} \), \( \mathcal{T}_2 = \{ A \equiv \exists s B \cap X, r \subseteq s \} \) and \( \Sigma = \{ A, B, r \} \). Then it holds that \( A \subseteq X \not\subseteq \text{cDiff}_\Sigma(\mathcal{T}_1, \mathcal{T}_2) \) as \( \mathcal{T}_1 \models A \subseteq X \) and \( \mathcal{T}_2 \models A \subseteq X \). We also have that \( \mathcal{T}_1 \models \exists r B \cap X \subseteq A \), but \( \mathcal{T}_2 \not\models \exists r B \cap X \subseteq A \). Therefore, \( \exists r B \cap X \not\subseteq \text{cDiff}_\Sigma(\mathcal{T}_1, \mathcal{T}_2) \).

**Example 21** Let \( \mathcal{T}_1 = \{ \text{ran}(r) \subseteq A, \text{ran}(s) \subseteq B, X \equiv A \cap B \} \), \( \mathcal{T}_2 = \emptyset \) and \( \Sigma = \{ X, s, r \} \). We have that the inclusion \( \phi = \text{ran}(r) \cap \text{ran}(s) \subseteq X \) uses only symbols from \( \Sigma \) and that \( \phi \) is entailed by \( \mathcal{T}_1 \) but not by \( \mathcal{T}_2 \). Note, however, that \( \phi \) is not an \( \mathcal{ELH}^\dagger \)-inclusion according to Definition 4. Moreover, \( \mathcal{ELH}^\dagger \)-inclusions such as \( \text{ran}(r) \subseteq A \) and \( \text{ran}(s) \subseteq B \) are not \( \mathcal{ELH}^\dagger \)-inclusions as \( \text{sig}(\text{ran}(r) \subseteq A) \not\subseteq \Sigma \) and \( \text{sig}(\text{ran}(s) \subseteq B) \not\subseteq \Sigma \). In fact, it holds that \( \text{cDiff}_\Sigma(\mathcal{T}_1, \mathcal{T}_2) = \emptyset \). Extending \( \Sigma \) to, say, the signature \( \Sigma' = \Sigma \cup \{ A \} \) yields \( \text{cDiff}_\Sigma(\mathcal{T}_1, \mathcal{T}_2) \neq \emptyset \) as \( \mathcal{T}_1 \models \text{ran}(r) \subseteq A \) and \( \mathcal{T}_2 \models \text{ran}(r) \subseteq A \). Additionally, let \( \mathcal{A} = \{ r(a, c), s(b, c) \} \) be an ABox. It can readily be verified that \( (\mathcal{T}_1, \mathcal{A}) \models X(c) \) and \( (\mathcal{T}_2, \mathcal{A}) \not\models X(c) \). So, we have that \( (\mathcal{A}, X(c)) \in \text{iDiff}_\Sigma(\mathcal{T}_1, \mathcal{T}_2) \).

**Example 22** Let \( \mathcal{T}_1 = \{ A \equiv \exists r. T, r \subseteq s, r \subseteq t \} \), \( \mathcal{T}_2 = \{ A \equiv \exists s. T \cap \exists r. T \} \) and \( \Sigma = \{ A, s, t \} \). We have that, e.g., \( A \equiv \exists s. T \) and \( A \equiv \exists r. T \) are each entailed by \( \mathcal{T}_1 \) and \( \mathcal{T}_2 \). This holds for all \( \mathcal{ELH}_\Sigma \)-inclusions. Note that \( r \subseteq s \) and \( r \subseteq t \) are not \( \mathcal{ELH}_\Sigma \)-inclusions as \( \text{sig}(r \subseteq s) \not\subseteq \Sigma \) and \( \text{sig}(r \subseteq t) \not\subseteq \Sigma \). In fact, we have that \( \text{cDiff}_\Sigma(\mathcal{T}_1, \mathcal{T}_2) = \emptyset \). Additionally, let \( \mathcal{A}_1 = \{ r(a, b) \} \) be an ABox and \( \lambda_1 = s(a, b) \) be an assertion. We have that \( \lambda_1 \) follows from \( (\mathcal{T}_1, \mathcal{A}_1) \) but not from \( (\mathcal{T}_2, \mathcal{A}_1) \). However, \( \mathcal{A}_1 \) is an ABox that is not of the required form as it contains a role name that is not in \( \Sigma \), i.e., \( \text{sig}(\mathcal{A}_1) \cap (\text{N}_C \cup \text{N}_R) \not\subseteq \Sigma \). In fact, for ABoxes \( \mathcal{A} \) satisfying \( \text{sig}(\mathcal{A}) \cap (\text{N}_C \cup \text{N}_R) \subseteq \Sigma \) and for \( \Sigma \)-instance queries \( \lambda \), it holds that \( (\mathcal{T}_1, \mathcal{A}) \models \lambda \) and \( (\mathcal{T}_2, \mathcal{A}) \not\models \lambda \). That is, \( \text{iDiff}_\Sigma(\mathcal{T}_1, \mathcal{T}_2) = \emptyset \). Finally, let \( \mathcal{A}_2 = \{ A(a) \} \) be an ABox and \( q(x) = \exists x. (s(a, x) \land t(a, x)) \) be a conjunctive query (with no free variables). We have that \( (\mathcal{T}_1, \mathcal{A}_2) \models q(x) \) but \( (\mathcal{T}_2, \mathcal{A}_2) \not\models q(x) \). So, \( (\mathcal{A}_2, q(x)) \in \text{qDiff}_\Sigma(\mathcal{T}_1, \mathcal{T}_2) \).

If the set \( \text{cDiff}_\Sigma(\mathcal{T}_1, \mathcal{T}_2) \) is not empty, then it typically contains infinitely many concept inclusions. We make use of the primitive witnesses theorems from [23], which state that if there is a concept inclusion difference in \( \text{cDiff}_\Sigma(\mathcal{T}_1, \mathcal{T}_2) \), then there exists an inclusion in \( \text{cDiff}_\Sigma(\mathcal{T}_1, \mathcal{T}_2) \) of one of the following five types \( \delta_1, \ldots, \delta_5 \), which are built according to the grammar rules below:

\[
\begin{align*}
\delta_1 &::= r \subseteq s \\
\delta_2 &::= C \subseteq A \mid \text{ran}(r) \cap C \subseteq A \\
\delta_3 &::= D \subseteq A \\
\delta_4 &::= A \subseteq C \mid \text{dom}(r) \subseteq C \mid \text{ran}(r) \subseteq C \\
\delta_5 &::= A \subseteq E \mid \text{dom}(r) \subseteq E \mid \text{ran}(r) \subseteq E
\end{align*}
\]

where \( \delta_1 \) ranges over role inclusions, \( \delta_2 \) and \( \delta_4 \) are \( \mathcal{L}^\dagger \)-inclusions, \( \delta_3 \) is an \( \mathcal{L}^\dagger \)-inclusion and \( \delta_5 \) is an \( \mathcal{L}^\dagger \)-inclusion. Note that each of these inclusions has either a simple left-hand or right-hand side.
The following table summarises results from [23], which identify the types of inclusions that are sufficient to represent the concept inclusion difference between $\mathcal{ELH}^r$-terminologies for the three query languages that we consider (and from now on simply refer to as ‘ran’, ‘Ran’ and ‘Ran$^\cap,u$’).\footnote{We refer to Theorems 40 and 61 in [23].}

Figure 2.1 The concept differences between $\mathcal{ELH}^r$-terminologies

In case two ontologies are logically different, the set $\text{cDiff}_{\Sigma}(\mathcal{T}_1, \mathcal{T}_2)$ consists of infinitely many concept inclusions. The primitive witnesses theorems from [23] allow us to consider only certain inclusions of a simpler syntactic form.

**Definition 23 (Subsumption Difference Witnesses)** Let $\mathcal{T}_1$ and $\mathcal{T}_2$ be $\mathcal{ELH}^r$-terminologies, $\Sigma$ be a signature and $\mathcal{L} \in \{\text{ran}, \text{Ran}, \text{Ran}^{\cap,u}\}$. The set of all $\mathcal{L}$-subsumption difference witnesses, denoted by $\text{Wtn}_{\Sigma}^\cap(\mathcal{T}_1, \mathcal{T}_2)$, is the set of $\phi \in \{A, \text{dom}(r), \text{ran}(r), r | A \in \Sigma \cap \mathcal{N}_C, r \in \Sigma \cap \mathcal{N}_R\}$ such that $\phi$ occurs either on the left-hand side or right-hand side of $\mathcal{L}$-concept inclusions $\alpha$ where $\mathcal{T}_1 \models \alpha$, but $\mathcal{T}_2 \not\models \alpha$.

We use $\text{lhs}(\alpha)$ (resp. $\text{rhs}(\alpha)$) to represent the left-hand side (resp. right-hand side) of an inclusion $\alpha$.

**Theorem 24** Let $\mathcal{T}_1$ and $\mathcal{T}_2$ be $\mathcal{ELH}^r$-terminologies, $\Sigma$ be a signature and $\mathcal{L} \in \{\text{ran}, \text{Ran}, \text{Ran}^{\cap,u}\}$. The set of all $\mathcal{L}$-subsumption difference witnesses is given by

$$
\text{Wtn}_{\Sigma}^\cap(\mathcal{T}_1, \mathcal{T}_2) = \text{roleWtn}_{\Sigma}(\mathcal{T}_1, \mathcal{T}_2) \cup \text{lhsWtn}_{\Sigma}^\cap(\mathcal{T}_1, \mathcal{T}_2) \cup \text{rhsWtn}_{\Sigma}^\cap(\mathcal{T}_1, \mathcal{T}_2),
$$

where the set $\text{roleWtn}_{\Sigma}^\cap(\mathcal{T}_1, \mathcal{T}_2) = \{r \in \Sigma \cap \mathcal{N}_R | r \subseteq s$ or $s \subseteq r \text{ in the set } \text{cDiff}_{\Sigma}^\cap(\mathcal{T}_1, \mathcal{T}_2)\}$, the set $\text{lhsWtn}_{\Sigma}^\cap(\mathcal{T}_1, \mathcal{T}_2) = \{\phi \in (\Sigma \cap \mathcal{N}_C) \cup \Sigma^{\text{dom}} \cup \Sigma^{\text{ran}} | \phi \subseteq \text{rhs}(\alpha)$ and $\alpha$ is a type-$\delta_4$ or type-$\delta_5$ inclusions in the set $\text{cDiff}_{\Sigma}^\cap(\mathcal{T}_1, \mathcal{T}_2)\}$ and the set $\text{rhsWtn}_{\Sigma}^\cap(\mathcal{T}_1, \mathcal{T}_2) = \{A \in \Sigma \cap \mathcal{N}_C | \text{lhs}(\alpha) \subseteq A$ and $\alpha$ is a type-$\delta_2$ or type-$\delta_3$ inclusions in the set $\text{cDiff}_{\Sigma}^\cap(\mathcal{T}_1, \mathcal{T}_2)\}$ respectively, depending on the query language $\mathcal{L}$ (cf. Fig. 2.1). The set $\text{Wtn}_{\Sigma}^\cap(\mathcal{T}_1, \mathcal{T}_2)$ can be seen as a finite representation of the set $\text{cDiff}_{\Sigma}^\cap(\mathcal{T}_1, \mathcal{T}_2)$, which is typically infinite when it is not empty.

As a corollary of the primitive witnesses theorems in [23], we have that the representation is complete in the following sense: $\text{cDiff}_{\Sigma}^\cap(\mathcal{T}_1, \mathcal{T}_2) = \emptyset$ iff $\text{roleWtn}_{\Sigma}(\mathcal{T}_1, \mathcal{T}_2) = \text{lhsWtn}_{\Sigma}^\cap(\mathcal{T}_1, \mathcal{T}_2) =$
rhsWtn^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2) = \emptyset. Thus, for deciding the existence of concept inclusion differences, it is equivalent to decide non-emptiness of one of the three witnesses sets.

Observe that the set \( Wtn^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2) \) is finite as \( \Sigma \) is finite. Consequently, it can be seen as a succinct representation of the set \( cDiff^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2) \) in the sense that:

\[
cDiff^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2) = \emptyset \iff Wtn^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2) = \emptyset \quad [23].
\]

**Example 25** Let \( \mathcal{T} \) consist of the following four axioms:

\[
\begin{align*}
\alpha_1 : & \quad A \sqsubseteq B \land \exists X \in B \\
\alpha_2 : & \quad B \sqsubseteq A \\
\alpha_3 : & \quad X \equiv A \sqcap B \\
\alpha_4 : & \quad Y \equiv B \sqcap \exists (X \sqcap \exists sA)
\end{align*}
\]

For \( \Sigma = \{A, B\} \), it holds that \( Wtn^\varnothing_2(\mathcal{T}, \{\alpha_1, \alpha_2\}) = cDiff^\varnothing_2(\mathcal{T}, \{\alpha_1, \alpha_2\}) = \emptyset \) and \( Wtn^\varnothing_2(\mathcal{T}, \emptyset) = \Sigma \) as \( A \sqsubseteq B, B \sqsubseteq A \in cDiff^\varnothing_2(\mathcal{T}, \emptyset) \). If \( \Sigma = \{A, r\} \), we have that \( Wtn^\varnothing_2(\mathcal{T}, \emptyset, \{\alpha_1\}) = \{A\} \) as \( A \sqsubseteq \exists r. \top \in cDiff^\varnothing_2(\mathcal{T}, \emptyset, \{\alpha_1\}) \).

As we can see from Definition 23, the set \( Wtn^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2) \) can be seen as a finite representation of the set \( cDiff^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2) \) [23], which is typically infinite.

The following theorem states that \( \mathcal{EL}^{\text{ran}} \)-subsumption and \( \mathcal{EL}^{\text{ran.\cap.\cup}} \)-subsumption queries are sufficient to capture the absence of instance query and conjunctive query differences.

**Theorem 26** Let \( \mathcal{T}_1 \) and \( \mathcal{T}_2 \) be \( \mathcal{EL}^{\mathcal{T}} \)-TBoxes and let \( \Sigma \) be a signature. Then:

- \( \text{rhsWtn}^{\mathcal{EL}^{\text{ran}}}_2(\mathcal{T}_1, \mathcal{T}_2) \neq \text{rhsWtn}^{\mathcal{EL}^{\text{ran}}}_2(\mathcal{T}_1, \mathcal{T}_2) \)
- \( \text{rhsWtn}^{\mathcal{EL}^{\text{ran}}}_2(\mathcal{T}_1, \mathcal{T}_2) = \text{rhsWtn}^{\mathcal{EL}^{\text{ran.\cap.\cup}}}_2(\mathcal{T}_1, \mathcal{T}_2) \)
- \( \text{lhsWtn}^{\mathcal{EL}^{\text{ran}}}_2(\mathcal{T}_1, \mathcal{T}_2) = \text{lhsWtn}^{\mathcal{EL}^{\text{ran}}}_2(\mathcal{T}_1, \mathcal{T}_2) \)
- \( \text{lhsWtn}^{\mathcal{EL}^{\text{ran.\cap.\cup}}}_2(\mathcal{T}_1, \mathcal{T}_2) \neq \text{lhsWtn}^{\mathcal{EL}^{\text{ran.\cap.\cup}}}_2(\mathcal{T}_1, \mathcal{T}_2) \)

This theorem follows from Lemmas 62 and 63 in [23]. The following lemma shows that logical difference has the property of monotonicity.

**Lemma 27 (Monotonicity of Logical Difference)** Let \( \mathcal{T}_1, \mathcal{T}_2 \) be two \( \mathcal{EL}^{\mathcal{T}} \)-terminologies, and \( \mathcal{T}_2 \subseteq \mathcal{T}_2 \). Additionally, let \( \Sigma \) be a signature. The following statements hold:

- \( cDiff^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2) \subseteq cDiff^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2') \)
- \( iDiff^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2) \subseteq iDiff^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2') \)
- \( qDiff^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2) \subseteq qDiff^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2') \)
- \( Wtn^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2) \subseteq Wtn^\varnothing_2(\mathcal{T}_1, \mathcal{T}_2') \)
2.2 Logical Difference between Ontologies

Algorithms for computing the witnesses sets, and hence for deciding whether a logical difference w.r.t. a signature exists, have been implemented in the CEX2.5 tool.\textsuperscript{3} Given two acyclic $\mathcal{ELH}^r$-terminologies $\mathcal{T}_1$ and $\mathcal{T}_2$ and a signature $\Sigma$ as input, CEX2.5 can compute and output the set $\text{Wtn}_\Sigma(\mathcal{T}_1, \mathcal{T}_2)$ in a fully automatic way.

We still note that a new approach for computing logical differences that can also handle large cyclic terminologies has recently been introduced \cite{12, 34}.

2.2.1 Proof system for $\mathcal{ELH}^r$

A concept name $A$ is called pseudo-primitive in a normalised terminology $\mathcal{T}$ if it does not occur on the left-hand side of an inclusion of the form $A \equiv C$ in $\mathcal{T}$. Note that concept names that do not occur in $\mathcal{T}$ are pseudo-primitive in $\mathcal{T}$. A concept name $A$ is said to be non-conjunctive in $\mathcal{T}$ if it is pseudo-primitive in $\mathcal{T}$ or there exists a concept of the form $\exists r.C$ such that $A \equiv \exists r.C \in \mathcal{T}$. Otherwise, $A$ is called conjunctive in $\mathcal{T}$. Thus, $A$ is conjunctive in $\mathcal{T}$ iff there exist concept names $B_1, \ldots, B_n$, $n \geq 2$ such that $A \equiv B_1 \sqcap \ldots \sqcap B_n \in \mathcal{T}$.

We can now categorise a concept name $A$ w.r.t. a normalised terminology $\mathcal{T}$ as one of the following holds:

- $A$ is pseudo-primitive in $\mathcal{T}$,
- $A$ is conjunctive in $\mathcal{T}$, or
- there exists exactly one axiom of the form $A \equiv \exists r.B$ in $\mathcal{T}$.

**Definition 28** Let $C$ be an $\mathcal{EL}$-concept. We define the set $\text{sub}(C) \subseteq \mathcal{EL}$ inductively as follows:

- $\text{sub}(\top) = \{\top\}$;
- $\text{sub}(A) = \{A\}$;
- $\text{sub}(\exists r.C) = \{\exists r.C\} \cup \text{sub}(C)$;
- $\text{sub}(C_1 \sqcap C_2) = \{C_1 \sqcap C_2\} \cup \text{sub}(C_1) \cup \text{sub}(C_2)$.

Moreover, we define the set $\text{sub}_0(C) \subseteq \mathcal{EL}$ inductively as follows:

- $\text{sub}_0(\top) = \{\top\}$;
- $\text{sub}_0(A) = \{A\}$;
- $\text{sub}_0(\exists r.C) = \{\exists r.C\}$;
- $\text{sub}_0(C_1 \sqcap C_2) = \text{sub}_0(C_1) \cup \text{sub}_0(C_2)$.
Preliminaries

Figure 2.2 Gentzen-style proof system for normalised $\mathcal{ELH}$-terminologies

Figure 2.2 depicts the Gentzen-style proof system for $\mathcal{ELH}$-terminologies from [17] extended with a number of inference rules to deal with the top-concept, and concept inclusions of the form $A \sqsubseteq C$, domain- and range restrictions, and role inclusions [23]. For a normalised $\mathcal{ELH}$-terminology $\mathcal{T}$ and concepts $C, D$, we write $C \triangleright \mathcal{T} \sqsubseteq D$ iff there exists a proof tree of $C \sqsubseteq D$ using the inference rules of the calculus shown in Figure 2.2. We use this to characterise which concept inclusions are logically entailed by a normalised terminology $\mathcal{T}$.

**Example 29** Let $\mathcal{T} = \{A \equiv B_1 \cap X, X \equiv \exists r.B_2\}$. Then a proof tree for $\mathcal{T} \models B_1 \cap \exists r.B_2 \sqsubseteq A$ looks as follows.

The deduction system is sound and complete w.r.t. the model theoretic semantics.

**Theorem 30 (see [17, 23])** Let $\mathcal{T}$ be a normalised $\mathcal{ELH}$-terminology and let $C, D$ be $\mathcal{EL}^{\text{ran}}$-concepts. Then: $\mathcal{T} \models C \sqsubseteq D$ iff $C \triangleright \mathcal{T} \sqsubseteq D$.

It follows from Theorem 30 that $\mathcal{T} \not\models \top \sqsubseteq A$ holds for every concept name $A$ and for every normalised $\mathcal{ELH}$-terminology $\mathcal{T}$.

2.2.2 Properties Regarding Logical Differences

The following lemma allows us to characterise an entailment of the form $\mathcal{T} \models C \sqsubseteq A$ in terms of the conjuncts that occur in $C$.

Lemma 31 Let $\mathcal{T}$ be a normalised $\mathcal{ELH}$-terminology, $r$ a role name, $A$ a concept name and $D$ an $\mathcal{EL}$-concept.

1. Assume $\mathcal{T} \models C \sqsubseteq A$, where

   $$C = \bigcap_{1 \leq i \leq n} A_i \bigcap \bigcap_{1 \leq j \leq m} \exists r_j.C_j,$$

   $A$ is pseudo-primitive in $\mathcal{T}$, $A_i$ are concept names for $1 \leq i \leq n$, $C_j$ are $\mathcal{EL}$-concepts for $1 \leq j \leq m$, and $m, n \geq 0$. Then there exists $A_i$, $1 \leq i \leq n$, such that $\mathcal{T} \models A_i \sqsubseteq A$.

2. Assume now $\mathcal{T} \models C \sqsubseteq \exists r.D$, where

   $$C = \bigcap_{1 \leq i \leq n} A_i \bigcap \bigcap_{1 \leq j \leq m} \exists r_j.C_j,$$

   $A_i$ are concept names for $1 \leq i \leq n$, $C_j$ are $\mathcal{EL}$-concepts for $1 \leq j \leq m$, and $m, n \geq 0$. Then either

   - there exists $A_i$, $1 \leq i \leq n$, such that $\mathcal{T} \models A_i \sqsubseteq \exists r.D$, or
   - there exists $r_j$, $1 \leq j \leq m$, such that $r_j = r$ and $\mathcal{T} \models C_j \sqsubseteq D$.

Lemma 31 is an extension of Lemma 15 in [23] additionally allowing for role inclusions in the terminology. The proof of Lemma 31 uses Theorem 30, which states soundness and completeness of the Gentzen-style proof system for $\mathcal{ELH}$-terminologies in Figure 2.2. The proof proceeds by induction on the length of the left-hand side of a subsumption (cf. Item 1 and 2 of Lemma 31) that follows from the terminology. The idea is to analyse possible derivations for the subsumption (determining which inference rules could have been used last) and show that a derivation for a simpler subsumption can be found. Role inclusion axioms are accounted for by the inference rule (SUB) in Figure 2.2. Since neither $\mathcal{ELH}$-terminologies nor the subsumptions considered in Lemma 31 contain range concepts, the inference rules (EXRAN), (RAN) and (RANSUB) do not apply.

Lemma 32 Let $\mathcal{T}$ be a normalised $\mathcal{ELH}$-terminology, let $X$ be a concept name, let $\exists r.D$ be an $\mathcal{ELH}$-concept such that $\mathcal{T} \models X \sqsubseteq \exists r.D$. Then there exists an axiom $Y \sqsupseteq \exists X.Z \in \mathcal{T}$ ($\sqsupseteq \in \{\sqsubseteq, \equiv\}$) such that $\mathcal{T} \models X \sqsubseteq Y$, $\mathcal{T} \models s \sqsubseteq r$ and $\mathcal{T} \models Z \sqsubseteq D$.

Proof Let $\Delta$ be the derivation of the inclusion $X \sqsubseteq \exists r.D$ w.r.t. $\mathcal{T}$. We assume now towards a contradiction that there does not exist an application of the (DEFL), (PDEFL) or (SUB) rule w.r.t. an axiom $Y \sqsupseteq \exists X.Z \in \mathcal{T}$ in $\Delta$. It is then easy to see that no concept of the form $\exists r.E$ occurs on the
left-hand side of any inclusion in $\Delta$. We can infer that no concept of the form $\exists r. E$ occurs on the right-hand side of any inclusion in $\Delta$ as well, i.e. $\Delta$ is not a derivation of the inclusion $A \sqsubseteq \exists r. D$, which contradicts our assumption. □

**Definition 33 (Concept Witness [23])** Let $T_1$ and $T_2$ be normalised $\mathcal{EL}$-terminologies, and let $\Sigma$ be a signature. The set $cWtn_\Sigma(T_1, T_2)$ consists of concept names $A$ from $\Sigma$ such that there exists an $\mathcal{EL}_\Sigma$-concept inclusion $\alpha$ of the form $A \sqsubseteq D$ or $C \sqsubseteq A$ satisfying $T_1 |= \alpha$ but $T_2 \not|= \alpha$.

**Lemma 34 (see [23])** Let $\mathcal{T}$ be an $\mathcal{ELH}\mathcal{r}$-terminology, $A_j$ concept names and $\exists r. D$ an $\mathcal{EL}$-concept. Assume

$$T |= \bigcap_{1 \leq i \leq l} \text{ran}(s_i) \sqcap \bigcap_{1 \leq j \leq n} A_j \sqcap \bigcap_{1 \leq k \leq m} \exists r_k. C_k \sqsubseteq \exists r. D,$$

where $C_k$, $1 \leq k \leq m$, are $\mathcal{EL}^{\text{ran}, \ominus}$-concepts and $l, m, n \geq 0$. Then at least one of the following conditions holds:

(e1) there exists $r_k$, $1 \leq k \leq m$, such that $T |= r_k \sqsubseteq r$ and $T |= C_k \sqcap \text{ran}(r_k) \sqsubseteq D$;

(e2) there exists $A_j$, $1 \leq j \leq n$, such that $T |= A_j \sqsubseteq \exists r. D$;

(e3) there exists $r_k$, $1 \leq k \leq m$, such that $T |= \text{dom}(r_k) \sqsubseteq \exists r. D$;

(e4) there exists $s_i$, $1 \leq i \leq l$, such that $T |= \text{ran}(s_i) \sqsubseteq \exists r. D$.

Now assume that $A$ is pseudo-primitive and

$$T |= \bigcap_{1 \leq i \leq l} \text{ran}(s_i) \sqcap \bigcap_{1 \leq j \leq n} A_j \sqcap \bigcap_{1 \leq k \leq m} \exists r_k. C_k \sqsubseteq A,$$

where $C_k$, $1 \leq k \leq m$, are $\mathcal{EL}^{\text{ran}, \ominus}$-concepts and $l, m, n \geq 0$. Then at least one of the following conditions holds:

(a1) there exists $A_j$, $1 \leq j \leq n$ such that $T |= A_j \sqsubseteq A$;

(a2) there exists $r_k$, $1 \leq k \leq m$ such that $T |= \text{dom}(r_k) \sqsubseteq A$;

(a3) there exists $s_i$, $1 \leq i \leq l$ such that $T |= \text{ran}(s_i) \sqsubseteq A$.

The set of $\mathcal{EL}^{\text{ran}, \ominus}$-concepts is defined as the set of all $\mathcal{EL}^{\text{ran}, \ominus, u}$-concepts without the universal role.

**Lemma 35 (see [23])** Let $\mathcal{T}$ be an $\mathcal{ELH}$-terminology and $\exists R. D$ a $\mathcal{EL}^{\text{ran}, \ominus}$-concept with $R = t_1 \sqcap \cdots \sqcap t_q$ a conjunction of role names. Assume

$$\mathcal{T} |= \bigcap_{1 \leq i \leq l} \text{ran}(s_i) \sqcap \bigcap_{1 \leq j \leq n} A_j \sqcap \bigcap_{1 \leq k \leq m} \exists r_k. C_k \sqsubseteq \exists R. D,$$
where $C_k, 1 \leq k \leq m$, are $\mathcal{E}L_{\text{ran}}$-concepts and $l, m, n \geq 0$. Then at least one of the following conditions holds:

(e1) there exists $r_k, 1 \leq k \leq m$, such that $r_k \subseteq \mathcal{F} t_1, \ldots, r_k \subseteq \mathcal{F} t_q$, and $\mathcal{T} \models C_k \cap \text{ran}(r_k) \subseteq D$;

(e2) there exists $A_j, 1 \leq j \leq n$, such that $\mathcal{T} \models A_j \subseteq \exists R. D$;

(e3) there exists $r_k, 1 \leq k \leq m$, such that $\mathcal{T} \models \text{dom}(r_k) \subseteq \exists R. D$;

(e4) there exists $s_i, 1 \leq i \leq l$, such that $\mathcal{T} \models \text{ran}(s_i) \subseteq \exists R. D$.

If $u$ is the universal role and $\mathcal{T} \models C \subseteq \exists u. D$, where $C$ is a $\mathcal{E}L_{\text{ran}}$-concept and $D$ is a $\mathcal{E}L_{\text{ran}, \sqcap}$-concept, then at least one of the following holds:

(e1) there exists a subconcept $\exists r. C'$ of $C$ such that $\mathcal{T} \models C' \cap \text{ran}(r) \subseteq D$;

(e2) there exists a concept name $A$ in $C$ such that $\mathcal{T} \models A \subseteq \exists u. D$;

(e3) there exists a role name $r$ in $C$ such that $\mathcal{T} \models \text{dom}(r) \subseteq \exists u. D$;

(e4) there exists a role name $r$ in $C$ such that $\mathcal{T} \models \text{ran}(r) \subseteq \exists u. D$;

(e5) $\mathcal{T} \models C \subseteq D$;

(e6) there exists a subconcept $(\text{ran}(r) \cap C')$ of $C$ such that $\mathcal{T} \models \exists r. C' \subseteq D$.

### 2.3 Ontology Modules

A module is a subset of an ontology that captures the knowledge that the ontology describes about a signature. In general, there are two different kinds of ontology modules. One is semantic modules that are based on model-theoretic inseparability [27] and the other one is locality based modules that are based on syntactic check [42].

#### 2.3.1 Inseparability and Semantic Modules

In this section, we review some notions about inseparability and relative properties, which are introduced in [27, 40].

**Definition 36 (Σ-Reduct)** Let $\mathcal{I}$ be an interpretation and $\Sigma$ a signature. The $\Sigma$-reduct $\mathcal{I}|_{\Sigma}$ of $\mathcal{I}$ is the interpretation obtained from $\mathcal{I}$ by the following rules:

- $\Delta^{\mathcal{I}|_{\Sigma}} := \Delta^{\mathcal{I}}$;
- $\sigma^{\mathcal{I}|_{\Sigma}} := \sigma^{\mathcal{I}}$, for all $\sigma \in \Sigma$;
- $\sigma^{\mathcal{I}|_{\Sigma}} := \emptyset$, for all $\sigma \in (N_C \cup N_R) \setminus \Sigma$. 

Definition 37 (Sigma-Inseparability) Let $T_1$ and $T_2$ be general TBoxes and $\Sigma$ a signature. Then $T_1$ and $T_2$ are $\Sigma$-inseparable, denoted as $T_1 \equiv_\Sigma T_2$, iff $\{ I | I \models T_1 \} = \{ I | I \models T_2 \}$.

Example 38 Considering the following terminologies $T_1$, $T_2$ and $T_3$. $T_1$ consists of the following axiom ($FS$ is short for finding_site(attribute)):

$$\text{Disorder_of_Body_Cavity}(\text{disorder}) \equiv \text{Disorder_of_Body_Site}(\text{disorder}) \sqcap \exists FS.\text{Trunk_Structure}(\text{Body_Structure}),$$

$T_2$ consists of the following axioms:

$$\text{Disorder_of_Body_Cavity}(\text{disorder}) \sqsubseteq \text{Disorder_of_trunk}(\text{disorder})$$

$$\text{Disorder_of_trunk}(\text{disorder}) \sqsubseteq \text{Disorder_of_Body_Site}(\text{disorder}) \sqcap \exists FS.\text{Trunk_Structure}(\text{Body_Structure}),$$

and $T_3$ consists of the following axiom:

$$\text{Disorder_of_Body_Cavity}(\text{disorder}) \sqsubseteq \text{Disorder_of_Body_Site}(\text{disorder}).$$

We have that $T_1 \not\equiv T_2 \not\equiv T_3$. But for

$$\Sigma = \{ \text{Disorder_of_Body_Cavity}(\text{disorder}), \text{Disorder_of_Body_Site}(\text{disorder}) \}$$

we have that $T_1 \equiv_\Sigma T_2 \equiv_\Sigma T_3$.

The following lemma shows that inseparability has the monotonicity property.

Lemma 39 Let $T_1$ and $T_2$ be two general TBoxes. Additionally, let $\Sigma_1$ and $\Sigma_2$ be two signatures and $\Sigma_1 \subseteq \Sigma_2$. Then $T_1 \equiv_{\Sigma_2} T_2$ implies $T_1 \equiv_{\Sigma_1} T_2$.

We then introduce some notions of semantic modules.

Definition 40 (Sigma-Modules) Let $T$ be a general TBox and $\Sigma$ a signature. Then $M \subseteq T$ is a:

- plain $\Sigma$-module of $T$ w.r.t. $\Sigma$ iff $M \equiv_\Sigma T$;
- self-contained $\Sigma$-module of $T$ w.r.t. $\Sigma$ iff $M \equiv_{\Sigma, \text{sig}(M)} T$;
- depleting $\Sigma$-module of $T$ w.r.t. $\Sigma$ iff $T \setminus M \equiv_{\Sigma, \text{isig}(M)} \emptyset$.

We say a plain (self-contained, depleting) $\Sigma$-module of $T$ w.r.t. $\Sigma$ is minimal iff there does not exist an $M' \subset M$ such that $M'$ is a plain (resp. self-contained, depleting) $\Sigma$-module of $T$ w.r.t. $\Sigma$.

The following proposition states the relations among these module notions [27].
Proposition 41 Let $T$ be a general TBox and $\Sigma$ a signature. If $M$ is a self-contained $\Sigma$-module of $T$, then it is a plain $\Sigma$-module. Additionally, if $M$ is a depleting $\Sigma$-module of $T$, then it is a self-contained $\Sigma$-module.

An algorithm for computing a unique minimal depleting module of an acyclic $\mathcal{ELI}$-terminology, an $\mathcal{EL}$-terminology additionally allowing for inverse roles, has been implemented in the tool MEX.\(^4\) Recently, new algorithms to compute depleting module for DL-Lite TBox [31] and $\mathcal{ALCQI}$ TBox [15] have been developed.

### 2.3.2 Locality-Based Modules

Extracting semantic modules (as presented in the last subsection) from real-world ontologies is computationally difficult. This is why more practical approaches to module extraction have been investigated resulting, most notably, in the module notions that are based on syntactic locality. Syntactic locality modules are approximating semantic module notions from above, i.e., they contain semantic modules but they cannot guarantee minimality w.r.t. set inclusion. Actually syntactic locality-based modules are usually larger than minimal semantic modules. On the other hand, the algorithm for extracting syntactic locality-based modules is rather efficient.

We consider the syntactic locality-based notions of $\bot$-locality and $\top$-locality. Intuitively, an axiom $\alpha$ is $\bot$-local or $\top$-local w.r.t. a signature $\Sigma$ if $\alpha$ becomes a tautology after all symbols that are not in $\Sigma$ have either been replaced with $\bot$ or $\top$. We now give the formal definition of $\bot$-locality and $\top$-locality for an $\mathcal{ELH}^r$-ontology.

**Definition 42 ($\bot$-locality)** Let $C$ be an $\mathcal{EL}$ concept, $r \in \mathbb{N}_R$, $A \notin \Sigma \in \mathbb{N} \setminus \Sigma$ and $s \notin \Sigma \in \mathbb{N} \setminus \Sigma$. Additionally, let $C_\bot$ and $C_\top$ be defined recursively by the following rules:

$$
\begin{align*}
C_\bot &::= A \notin \Sigma \mid \bot \mid C \sqcap C_\bot \mid C_\bot \sqcap C \mid \exists s \notin \Sigma . C \mid \exists r . C_\bot \mid \text{dom}(s \notin \Sigma) \mid \text{ran}(s \notin \Sigma) \\
C_\top &::= \top \mid C_\top \sqcap C_\top
\end{align*}
$$

An axiom $\alpha$ is $\bot$-local w.r.t. a signature $\Sigma$ if $\alpha$ is of one of the following forms:

$$
C_\bot \sqsubseteq \alpha \quad \text{or} \quad \alpha \sqsubseteq C_\bot \quad \text{or} \quad C_\top \equiv \alpha \quad \text{or} \quad \alpha \equiv C_\top.
$$

**Definition 43 ($\top$-locality)** Let $C$ be an $\mathcal{EL}$ concept, $r \in \mathbb{N}_R$, $A \notin \Sigma \in \mathbb{N} \setminus \Sigma$ and $s \notin \Sigma \in \mathbb{N} \setminus \Sigma$. Additionally, let $C_\bot$ and $C_\top$ be defined recursively by the following rules:

$$
\begin{align*}
C_\bot &::= \bot \mid C \sqcap C_\bot \mid C_\bot \sqcap C \mid \exists r . C_\bot \\
C_\top &::= A \notin \Sigma \mid C_\top \sqcap C_\top \mid C_\top \sqcap C \mid \exists s \notin \Sigma . C \mid \text{dom}(s \notin \Sigma) \mid \text{ran}(s \notin \Sigma)
\end{align*}
$$

\(^4\)The tool is available under an open-source license from https://cgi.csc.liv.ac.uk/~konev/software/
An axiom \( \alpha \) is \( \top \)-local w.r.t. a signature \( \Sigma \) if \( \alpha \) is of one of the following forms:

\[
C \perp \sqsubseteq \ C \quad \text{or} \quad C \sqsubseteq \ C^\top \quad \text{or} \quad C^\top \equiv \ C^\top \quad \text{or} \quad C \perp \equiv \ C \perp.
\]

**Definition 44** An \( \mathcal{EL} \mathcal{H} \mathcal{R} \)-terminology \( \mathcal{T} \) is \( \perp \)-local (resp. \( \top \)-local) w.r.t. \( \Sigma \) iff for every axiom \( \alpha \in \mathcal{T} \), \( \alpha \) is \( \perp \)-local (resp. \( \top \)-local) w.r.t. \( \Sigma \). Generally, we say that \( \mathcal{T} \) is local w.r.t. \( \Sigma \) iff \( \mathcal{T} \) is either \( \top \)-local or \( \perp \)-local w.r.t. \( \Sigma \).

**Definition 45 (Locality-based Module)** Let \( \mathcal{T} \) be an \( \mathcal{EL} \mathcal{H} \mathcal{R} \)-terminology and \( \Sigma \) be a signature. A \( \perp \)-local (resp. \( \top \)-local) module of \( \mathcal{T} \) w.r.t. \( \Sigma \), denoted by \( \mathcal{M} \perp \) (resp. \( \mathcal{M} \top \)), is the minimal \( \mathcal{M} \subseteq \mathcal{T} \) such that \( \mathcal{T} \setminus \mathcal{M} \) is \( \perp \)-local (resp. \( \top \)-local) w.r.t. \( \Sigma \cup \text{sig}(\mathcal{M}) \).

Algorithm 1 [16] shows how to compute \( \perp \)-local (resp. \( \top \)-local) module of a \( \mathcal{T} \) w.r.t. \( \Sigma \).

**Algorithm 1: Computing a Locality-Based Module for a Signature**

\[
\begin{align*}
\text{function} & \quad \text{LOCALITY-BASED-MODULE} \quad (\mathcal{T}, \Sigma, x) \\
\text{2} & \quad \mathcal{M} := \emptyset, \mathcal{T}' := \mathcal{T} \\
\text{3} & \quad \text{repeat} \\
\text{4} & \quad \text{\quad \mathcal{M}' := \mathcal{M}} \\
\text{5} & \quad \text{\quad for every } \alpha \in \mathcal{T}' \text{ do} \\
\text{6} & \quad \text{\quad \quad if } \alpha \text{ is not } x\text{-local w.r.t. } \Sigma \cup \text{sig}(\mathcal{M}) \text{ then} \\
\text{7} & \quad \text{\quad \quad \quad \quad } \mathcal{M} := \mathcal{M} \cup \{\alpha\} \\
\text{8} & \quad \text{\quad \quad \quad \quad } \mathcal{T}' := \mathcal{T}' \setminus \{\alpha\} \\
\text{9} & \quad \text{\quad end} \\
\text{10} & \quad \text{end} \\
\text{11} & \quad \text{until } \mathcal{M} = \mathcal{M}'; \\
\text{12} & \quad \text{return } \mathcal{M}.
\end{align*}
\]

**Proposition 46** If \( \mathcal{M} \) is a \( \top \)-local or \( \perp \)-local module, then \( \mathcal{M} \) is also a plain, self-contained and depleting \( \Sigma \)-module.

As extracting locality-based modules is rather efficient, when computing semantic modules we extract locality-based module first.

### 2.4 Ontology Justification

In this section, we review the notion of ontology justification.
2.5 Partial Max-SAT Problem

Definition 47 (Ontology Justification [5]) Let $\mathcal{T}$ be an $\mathcal{ELH}^\ell$-TBox and let $\alpha$ be an $\mathcal{ELH}$-concept inclusion. A subset $M \subseteq \mathcal{T}$ is called a justification for $\alpha$ from $\mathcal{T}$ iff $M \models \alpha$ and $M' \not\models \alpha$ for every $M' \subsetneq M$.

We denote the set of all justifications for an $\mathcal{ELH}$-concept inclusion $\alpha$ from an $\mathcal{ELH}$-terminology $\mathcal{T}$ with $\text{Just}_\mathcal{T}(\alpha)$.

Example 48 Let $\mathcal{T} = \{ A \sqsubseteq X_1 \sqcap X_2, X_1 \sqsubseteq Y, X_2 \sqsubseteq Y \}$. Then the set $\text{Just}_\mathcal{T}(A \sqsubseteq Y)$ consists of the two sets $\{ A \sqsubseteq X_1 \sqcap X_2, X_1 \sqsubseteq Y \}$ and $\{ A \sqsubseteq X_1 \sqcap X_2, X_2 \sqsubseteq Y \}$.

Note that $\text{Just}_\mathcal{T}(\alpha)$ may contain exponentially many justifications in the number of axioms in $\mathcal{T}$. Therefore, it is not possible to compute all justifications in polynomial time w.r.t. the size of TBox in every case. But theoretically, it is possible to compute just one justification in polynomial time [5].

2.5 Partial Max-SAT Problem

Maximum Satisfiability (Max-SAT) problem has shown successfully to have many applications in various domains in computer science. In this section, we review relevant knowledge about the Max-SAT problem and its extension, the partial Max-SAT problem.

Let $\Pi$ be a countably infinite set of propositional variables which we denote with $p, q$, etc. The set $\Phi$ of propositional logic formulas $\phi$ is built according to the following grammar rule:

$$
\phi ::= p \mid \neg \phi \mid \phi \land \psi \mid \phi \lor \psi \mid \phi \rightarrow \psi \mid \phi \leftrightarrow \psi
$$

where $\phi, \psi \in \Phi$. A propositional valuation $v: \Pi \rightarrow \{0, 1\}$ is a function mapping each propositional variable $p \in \Pi$ to a truth value $v(p) \in \{0, 1\}$. The valuation $v$ is extended to propositional formulas as follows:

$$
v(\neg \phi) := 1 - v(\phi) \\
v(\phi \land \psi) := \min\{v(\phi), v(\psi)\} \\
v(\phi \lor \psi) := \max\{v(\phi), v(\psi)\} \\
v(\phi \rightarrow \psi) := \max\{1 - v(\phi), v(\psi)\} \\
v(\phi \leftrightarrow \psi) := \max\{\min\{v(\phi), v(\psi)\}, \min\{1 - v(\phi), 1 - v(\psi)\}\}
$$

where $\phi, \psi \in \Phi$. A propositional formula $\phi \in \Phi$ is satisfied in $v$ iff $v(\phi) = 1$. We say that $\phi$ is satisfiable iff there exists a valuation $v$ such that $v(\phi) = 1$.

A literal $\ell$ is a propositional variable $p$ or a negated propositional variable $\neg p$, and a clause is a disjunction $\ell_1 \lor \ldots \lor \ell_n$ of literals $\ell_i \ (0 \leq i \leq n)$. For a propositional formula $\phi \in \Phi$, we denote with $\text{Clauses}(\phi)$ the transformation of $\phi$ into an equi-satisfiable clause set, i.e., $\text{Clauses}(\phi)$ is a finite set of propositional clauses such that $\phi$ is satisfiable iff the formula $\bigwedge_{\psi \in \Phi} \psi$ is satisfiable,
where $\Psi = \text{Clauses}(\varphi)$. It is known that every propositional formula $\varphi \in \Phi$ can be transformed in polynomial time (in the size of $\varphi$) into an equi-satisfiable set of clauses. Note that the clauses in Clauses($\varphi$) may contain propositional variables that are not present in $\varphi$.

The Boolean Satisfiability Problem (SAT), also known as Propositional Satisfiability Problem, is the problem of deciding whether there exists a valuation that satisfies a given propositional formula $\varphi$, or alternatively, all the clauses contained in a set of clauses $\Psi = \text{Clauses}(\varphi)$. As an extension, the set $\Psi$ is split into two sets $H$ and $S$, called hard and soft clause sets. The problem of finding a valuation that satisfies all the clauses in $H$ and a maximal number of clauses in $S$ is called the partial Max-SAT problem.

**Definition 49 (Partial Max-SAT Problem [14])** Let $H$ and $S$ be finite sets of propositional clauses. We say that $\mathcal{P} = (H, S)$ is an instance of a partial Max-SAT problem. A valuation $v$ is a solution of $\mathcal{P}$ iff the following conditions are satisfied:

(i) $\sum_{\varphi \in H} v(\varphi) = |H|$, and

(ii) for every propositional valuation $v'$ with $\sum_{\varphi \in H} v'(\varphi) = |H|$ it holds that

$$\sum_{\psi \in S} v'(\psi) \leq \sum_{\psi \in S} v(\psi).$$

In other words, the objective of a partial Max-SAT problem is to find a propositional valuation that satisfies all the hard clauses in $H$ and that satisfies a maximal number of the clauses in $S$. Note that a partial Max-SAT problem may have several solutions.

**Example 50** Let $\mathcal{P} = (H, S)$ be a partial Max-SAT problem, where $H = \{\neg p_1, p_2 \lor p_3\}$ and $S = \{p_1 \lor \neg p_2, \neg p_3\}$. We have the following two solutions of $\mathcal{P}$: $v_1(p_1) = 0$, $v_1(p_2) = 0$, $v_1(p_3) = 1$ and $v_2(p_1) = 0$, $v_2(p_2) = 1$, $v_2(p_3) = 0$.

A weighted clause is a pair $(\psi, w_{\psi})$, where $\psi$ is a clause and $w_{\psi}$ is a natural number or infinity meaning the cost for falsifying the clause $\psi$. If a clause $\psi \in H$, then $w_{\psi}$ is infinite. Given a valuation $v$ and a set of weighted clauses $\Phi$, the cost of valuation $v$ on $\Phi$ is the sum of the weights of the clauses falsified by $v$. The Weighted Partial Max-SAT problem for weighted clauses is the problem of finding an optimal valuation for the variables of $\Phi$, i.e., a valuation of minimal cost.

**Definition 51 (Weighted Partial Max-SAT Problem [14])** Let $H$ and $S$ be finite sets of weighted propositional clauses of the form $(\psi, w_{\psi})$, where $\psi$ is a clause and $w_{\psi}$ is a natural number or infinity meaning the cost for falsifying the clause $\psi$. We say that $\mathcal{P} = (H, S)$ is an instance of a weighted partial Max-SAT problem. A valuation $v$ is a solution of $\mathcal{P}$ iff the following conditions are satisfied:

(i) $\sum_{\varphi \in H} v(\varphi) = |H|$, and
(ii) for every propositional valuation \( v' \) with \( \sum_{\varphi \in H} v'(\varphi) = |H| \) it holds that
\[
\sum_{\psi \in S} v'(\psi) \times w_\psi \leq \sum_{\psi \in S} v(\psi) \times w_\psi.
\]

**Example 52** Let \( \mathcal{P}' = (H, S) \) be a weighted partial Max-SAT problem, where \( H = \{(-p_1, \infty), (p_2 \lor p_3, \infty)\} \) and \( S = \{(p_1 \lor -p_2, 4), (-p_3, 1)\} \). We have the following solution of \( \mathcal{P}' \): \( v_1(p_1) = 0, v_1(p_2) = 0, v_1(p_3) = 1 \). The possible solution of \( \mathcal{P} \) in Example 50: \( v_2(p_1) = 0, v_2(p_2) = 1, v_2(p_3) = 0 \) is not a solution of \( \mathcal{P}' \), as the cost of valuation \( v_2 \) is 4, which is higher than the cost of \( v_1 \).
Chapter 3

Extraction of Ontology Subsumption Justifications

In this chapter, we propose a notion called subsumption justification to capture the subsumption knowledge about a term with respect to all primitive and complex concepts built from terms in a given vocabulary \( \Sigma \).

We proceed by first defining the notions of subsumer/subsumee module and subsumer/subsumee justification and then present algorithms to compute subsumption justifications in \( \mathcal{ELH} \) and \( \mathcal{ELH}^r \)-terminologies. We prove the correctness of algorithms and finally evaluate the algorithms on large biomedical terminologies.

In the rest, we use the operator \( \otimes \) to combine sets of axioms as follows. Given a set \( S \) and \( S_1, S_2 \subseteq 2^S \), \( S_1 \otimes S_2 := \{ S_1 \cup S_2 \mid S_1 \in S_1, S_2 \in S_2 \} \). For instance, if \( S_1 = \{ \{ \alpha_1, \alpha_2 \}, \{ \alpha_3 \} \} \) and \( S_2 = \{ \{ \alpha_1, \alpha_3 \}, \{ \alpha_4, \alpha_5 \} \} \), then \( S_1 \otimes S_2 = \{ \{ \alpha_1, \alpha_2, \alpha_3 \}, \{ \alpha_1, \alpha_2, \alpha_4, \alpha_5 \}, \{ \alpha_3, \alpha_4, \alpha_5 \}, \{ \alpha_1, \alpha_3 \} \} \).

For a set \( M \) of sets, we define a function Minimise \( \subseteq (M) \) as follows: \( M \in \text{Minimise} \subseteq (M) \) iff \( M \in M \) and there does not exist a set \( M' \in M \) such that \( M' \subseteq M \). Continuing the previous example, \( \text{Minimise} \subseteq (S_1 \otimes S_2) = \{ \{ \alpha_1, \alpha_3 \}, \{ \alpha_1, \alpha_2, \alpha_4, \alpha_5 \}, \{ \alpha_3, \alpha_4, \alpha_5 \} \} \). Note that \( M \otimes \{ \emptyset \} = M \), but \( M \otimes \emptyset = \emptyset \). We use \( \otimes \) and \( \text{Minimise} \subseteq (\cdot) \) to combine sets of subsumer/subsumee/role subsumption modules, whose correctness is guaranteed by Proposition 59.

3.1 Subsumption Justifications of \( \mathcal{ELH} \)-Terminologies

In this section we first introduce the definition of (role) subsumption justification based on the notion of (role) subsumption module for an \( \mathcal{ELH} \)-terminology and a given signature.

Definition 53 (Subsumption Justification for \( \mathcal{ELH} \)-terminology) Let \( T \) be a normalised \( \mathcal{ELH} \)-terminology, let \( \Sigma \) be a signature, and let \( X \in \mathbb{N}_C \) and \( r \in \mathbb{N}_R \). We say that
Finally, the set 
\[ \{ M \subseteq T \mid \text{for every } C \in \mathcal{L}_\Sigma, T \models C \subseteq X \} \]

is called an \langle X, \Sigma \rangle-subsumee module of \mathcal{T} iff for every \( C \subseteq X \) implies 
\( M \models C \subseteq X \);

\[ \{ M \subseteq T \mid \text{for every } D \in \mathcal{L}_\Sigma, T \models D \subseteq X \} \]

is called an \langle X, \Sigma \rangle-subsumer module \( M \) of \mathcal{T} iff for every \( \Sigma \subseteq D \subseteq X \) implies 
\( M \models \Sigma \subseteq D \);

\[ \{ M \subseteq T \mid \text{for every } s \in \Sigma, T \models r \subseteq s \} \]

is called an \langle r, \Sigma \rangle-role subsumption module of \mathcal{T} iff for every \( r \subseteq s \) implies 
\( M \models r \subseteq s \).

Additionally, a set \( M \) is called an \langle X, \Sigma \rangle-subsumee module of \mathcal{T} iff \( M \) is an \langle X, \Sigma \rangle-subsumee and \langle \Sigma, \Sigma \rangle-subsumer module of \mathcal{T}. An \langle X, \Sigma \rangle-subsumee (resp. subsumer, subsumption) justification is an \langle X, \Sigma \rangle-subsumee (resp. subsumer, subsumption) module of \mathcal{T} that is minimal w.r.t. \( \subseteq \). Similarly, an \langle r, \Sigma \rangle-role subsumption justification is an \langle r, \Sigma \rangle-role subsumption module of \mathcal{T} that is minimal w.r.t. \( \subseteq \).

We denote an \langle X, \Sigma \rangle-subsumee (resp. subsumer, subsumption) justification as \( \mathcal{J}_{\mathcal{T}}^\Sigma \langle X, \Sigma \rangle \) (resp. \( \mathcal{J}_{\mathcal{T}} \langle X, \Sigma \rangle \)). Note that there may exist multiple \langle X, \Sigma \rangle-(subsumer, subsumee) subsumption justifications. So we denote the set of all \langle X, \Sigma \rangle-subsumee (resp. subsumer, subsumption) justifications as \( \mathcal{J}_{\mathcal{T}}^\Sigma \langle X, \Sigma \rangle \) (resp. \( \mathcal{J}_{\mathcal{T}} \langle X, \Sigma \rangle \)). Similarly, we denote a \langle r, \Sigma \rangle-role subsumption justification of \( \mathcal{T} \) as \( \mathcal{J}_{\mathcal{T}}(r, \Sigma) \) and the set of all \langle r, \Sigma \rangle-role subsumption justifications of \( \mathcal{T} \) as \( \mathcal{J}_{\mathcal{T}}^r (r, \Sigma) \).

According to the Definition 53, it is easy to compute subsumption justifications.

**Theorem 54** Let \( \mathcal{T} \) be a normalised \( \mathcal{ELH} \)-terminology, let \( \Sigma \) be a signature, and let \( X \in \mathbb{N}_C \) and \( r \in \mathbb{N}_R \). Additionally, let \( \mathcal{J}_{\mathcal{T}}^\Sigma \langle X, \Sigma \rangle \) (resp. \( \mathcal{J}_{\mathcal{T}} \langle X, \Sigma \rangle \)) be the set of all \langle X, \Sigma \rangle-subsumee justifications (resp. subsumer justification, subsumption justification). We have that

\[ \mathcal{J}_{\mathcal{T}} \langle X, \Sigma \rangle := \text{Minimise}_\Sigma (\mathcal{J}_{\mathcal{T}}^\Sigma \langle X, \Sigma \rangle \cup \mathcal{J}_{\mathcal{T}} \langle X, \Sigma \rangle). \]

**Example 55** Let \( \Sigma = \{ A_1, A_2, B \} \) and \( \mathcal{T} = \{ \alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5 \} \), where \( \alpha_1 := X \equiv Y \sqcap Z, \alpha_2 := Y \sqsubseteq B, \alpha_3 := Z = Z_1 \sqcap Z_2, \alpha_4 := A_1 \sqsubseteq Y \), and \( \alpha_5 := A_2 \sqsubseteq Z \sqcap Z_1 \sqcap Z_2 \). Then the sets \( \mathcal{M}_1 = \{ \alpha_1, \alpha_4, \alpha_5 \}, \mathcal{M}_2 = \{ \alpha_1, \alpha_3, \alpha_4, \alpha_5 \} \), and \( \mathcal{T} \) are all \langle X, \Sigma \rangle-subsumee modules of \( \mathcal{T} \), whereas only \( \mathcal{M}_1 \) is an \langle X, \Sigma \rangle-subsumer module of \( \mathcal{T} \). The set \( \mathcal{M}_1 = \{ \alpha_1, \alpha_2 \} \) is an \langle X, \Sigma \rangle-subsumee justification of \( \mathcal{T} \). Finally, the set \( \{ \alpha_1, \alpha_2, \alpha_3 \} \) is an \langle X, \Sigma \rangle-subsumer justification of \( \mathcal{T} \).

**Example 56** Let \( \Sigma = \{ r, t \} \) and let \( \mathcal{T} = \{ \alpha_1, \alpha_2 \} \), where \( \alpha_1 := r \sqsubseteq s, \alpha_2 := s \sqsubseteq t \). Then the set \( \mathcal{M}_1 = \{ \alpha_1, \alpha_2 \} \) is an \langle r, \Sigma \rangle-role subsumption justification of \( \mathcal{T} \).

It is not difficult to get the following proposition from the *primitive witnesses theorems* 24 and

**Proposition 57** Let \( \mathcal{T} \) be an \( \mathcal{ELH} \)-terminology, \( \Sigma \) be a signature, \( X \in \Sigma \sqcap \mathbb{N}_C \) and \( r \in \Sigma \sqcap \mathbb{N}_R \). Then the following statements hold:
3.1 Subsumption Justifications of $\mathcal{ELH}$-Terminologies

- $\mathcal{M}$ is an $\langle X, \Sigma \rangle$-subsumer module of $\mathcal{T}$ iff $X \not\in \text{lhsWtn}_\Sigma(\mathcal{T}, \mathcal{M})$;
- $\mathcal{M}$ is an $\langle X, \Sigma \rangle$-subsumee module of $\mathcal{T}$ iff $X \not\in \text{rhsWtn}_\Sigma(\mathcal{T}, \mathcal{M})$;
- $\mathcal{M}$ is a $\langle r, \Sigma \rangle$-role subsumption module of $\mathcal{T}$ iff $r \not\in \text{roleWtn}_\Sigma(\mathcal{T}, \mathcal{M})$.

In the following subsections, we present algorithms for computing subsumer and subsumee justifications. The algorithms use the following notion of a cover of a set of sets.

**Definition 58 (Cover)** For a finite set $S$ and a set $T \subseteq 2^S$, we say that a set $M \subseteq 2^S$ is a cover of $T$ iff $M \subseteq T$ and, for every $M \in T$, there exists $M' \in M$ such that $M' \subseteq M$.

In other words, a cover is a subset of $T$ containing all sets from $T$ that are minimal w.r.t. $\subseteq$. Therefore, a cover of the set of all subsumption modules also contains all subsumption justifications. We will use covers to characterise the output of our algorithms to ensure that all justifications have been computed.

### 3.1.1 Computing Role Subsumption Justifications

Algorithm 2 shows how to collect relevant $\Sigma$-role inclusions by its definition.

**Algorithm 2:** Computing the set of all Role Subsumption Justifications for Role Inclusions

```plaintext
function COVER$^R$ ($\mathcal{T}, \Sigma, r$)

1. $M_r = \{\emptyset\}$
2. for every $s \in \Sigma \cap N_R$ such that $\mathcal{T} \models r \subseteq s$
   1. $M_r := M_r \otimes \text{Just}_\mathcal{T}(r \subseteq s)$
3. end
4. for every $t \in \Sigma \cap N_R$ such that $\mathcal{T} \models t \subseteq r$
   1. $M_r := M_r \otimes \text{Just}_\mathcal{T}(t \subseteq r)$
5. end
6. return $\text{Minimise}_\subseteq(M_r)$
```

It is easy to see that Algorithm 2 indeed computes all $\langle r, \Sigma \rangle$-role subsumption justifications of $\mathcal{T}$ w.r.t. $\Sigma$ for $r \in N_R$.

**Proposition 59** Let $\mathcal{T}$ be a normalized $\mathcal{ELH}$-terminology, $\Sigma$ be a signature and $r \in N_R$. Additionally, let $M := \text{COVER}^R(\mathcal{T}, \Sigma, r)$ be computed by Algorithm 2. Then $M$ is the set of all $\langle r, \Sigma \rangle$-role subsumption justifications.

### 3.1.2 Computing Subsumer Justifications

The algorithm for computing subsumer justifications relies on the notion of a subsumer simulation between terminologies, which is similar to the simulation notion between ontology hypergraphs introduced in [12, 34].
Lemma 61 (Subsumer Simulation for \(\mathcal{ELH}\)-terminology) Let \(\mathcal{T}_1\) and \(\mathcal{T}_2\) be two normalised \(\mathcal{ELH}\)-terminologies and \(\Sigma\) a signature. A relation \(S \subseteq \text{sig}^N(\mathcal{T}_1) \times \text{sig}^N(\mathcal{T}_2)\) is called a \(\Sigma\)-subsumer simulation from \(\mathcal{T}_1\) to \(\mathcal{T}_2\) iff the following conditions hold:

\[
\begin{align*}
(S_{N_1}^+) & \text{ if } (X_1, X_2) \in S, \text{ then for every } B \in \Sigma \text{ with } \mathcal{T}_1 \models X_1 \sqsubseteq B \text{ it holds that } \mathcal{T}_2 \models X_2 \sqsubseteq B; \text{ and } \\
(S_{N_2}^+) & \text{ if } (X_1, X_2) \in S, \text{ then for every } Y_1 \ni r Z_1 \in \mathcal{T}_1 \text{ with } \mathcal{T}_1 \models X_1 \sqsubseteq Y_1, \mathcal{T}_1 \models r \sqsubseteq s, s \in \Sigma, r_1 \in \{\subseteq, =\}, \text{ there exists } Y_2 \ni r', Z_2 \in \mathcal{T}_2 \text{ with } \mathcal{T}_2 \models X_2 \sqsubseteq Y_2, r_2 \in \{\subseteq, =\}, \mathcal{T}_2 \models r' \sqsubseteq s, \text{ and } (Z_1, Z_2) \in S.
\end{align*}
\]

We write \((\mathcal{T}_1, X_1) \sim_{\mathcal{ELH}} (\mathcal{T}_2, X_2)\) iff there is a \(\Sigma\)-subsumer simulation \(S\) from \(\mathcal{T}_1\) to \(\mathcal{T}_2\) with \((X_1, X_2) \in S\). In particular, we write \(\text{sim}_{\mathcal{ELH}}(X_1, X_2)\) when \(\mathcal{T}_1 = \mathcal{T}_2 = \mathcal{T}\).

A subsumer simulation conveniently captures the set of subsumers in the following sense: if a \(\Sigma\)-subsumer simulation from \(\mathcal{T}_1\) to \(\mathcal{T}_2\) contains the pair \((X_1, X_2)\), then \(X_2\) entails \(\mathcal{T}_2\) all subsumers of \(X_1\) w.r.t. \(\mathcal{T}_1\) that are formulated in the signature \(\Sigma\). Formally, we obtain the following lemma.

Lemma 61 Let \(\mathcal{T}_1\) and \(\mathcal{T}_2\) be normalised \(\mathcal{ELH}\)-terminologies, and let \(\Sigma\) be a signature. If \((\mathcal{T}_1, X_1) \sim_{\mathcal{ELH}} (\mathcal{T}_2, X_2)\), then, for every \(D \in \mathcal{ELH}\) with \(\mathcal{T}_1 \models X_1 \sqsubseteq D\), it holds that \(\mathcal{T}_2 \models X_2 \sqsubseteq D\).

**Algorithm 3:** Computing the set of all Subsumer Justifications for an \(\mathcal{ELH}\)-terminology

1. function \(\text{COVER}_{\rightarrow} (\mathcal{T}, X, \Sigma)\)
2. \hspace{1em} \(M_X^\rightarrow = \{\emptyset\}\)
3. \hspace{1em} for every \(B \in \Sigma \cap N_C\) such that \(\mathcal{T} \models X \sqsubseteq B\)
4. \hspace{2em} \(M_X^\rightarrow := M_X^\rightarrow \otimes \text{Just}_{\mathcal{T}}(X \sqsubseteq B)\)
5. end
6. for every \(Y \ni r Z \in \mathcal{T}\) \((\ni \in \{\subseteq, =\})\) and \(s \in \Sigma \cap N_R\) such that \(\mathcal{T} \models X \sqsubseteq Y\) and \(\mathcal{T} \models r \sqsubseteq s\)
7. \hspace{1em} \(M_{\Sigma, Z}^\rightarrow := \emptyset\)
8. \hspace{1em} for every \(Y' \ni r' Z' \in \mathcal{T}\) \((\ni \in \{\subseteq, =\})\) such that \(\mathcal{T} \models X \sqsubseteq Y', \mathcal{T} \models r' \sqsubseteq s, \text{ sim}_{\mathcal{T}}(Z, Z')\)
9. \hspace{2em} \(M_{Z'}^\rightarrow := \text{COVER}_{\rightarrow}(\mathcal{T}, Z', \Sigma)\)
10. \hspace{2em} \(M_{\Sigma, Z}^\rightarrow := M_{\Sigma, Z}^\rightarrow \sqcup \{ \{Y' \ni r' Z'\} \otimes M_{Z'}^\rightarrow \otimes \text{Just}_{\mathcal{T}}(X \sqsubseteq Y') \otimes \text{Just}_{\mathcal{T}}(r' \sqsubseteq s) \}\)
11. end
12. end
13. \(M_X^\rightarrow := \bigotimes M_X^\rightarrow \otimes M_{\Sigma, Z}^\rightarrow\)
14. return Minimise\(\subset X^\rightarrow\)

Guided by the subsumer simulation notion, we can devise our algorithm for computing subsumer justifications. Algorithm 3 computes the subsumer justifications for an acyclic normalised \(\mathcal{ELH}\)-terminology \(\mathcal{T}\), a signature \(\Sigma\), and a concept name \(X\). Lines 3–13 of the algorithm compute all \((X, \Sigma)\)-subsumption modules of \(\mathcal{T}\). To ensure that the returned modules are minimal w.r.t. \(\subseteq\), the
algorithm calls the function Minimise$_C(M_X^\neg)$ in Line 14, which removes any set in $M_X^\neg$ that is not minimal.

We illustrate Algorithm 3 with the following two examples. First example, let $\mathcal{T} = \{X \sqsubseteq B, X \sqsubseteq Y, Y \sqsubseteq B\}$ and $\Sigma = \{B\}$. Consider the execution of $\text{Cover}_\rightarrow(\mathcal{T}, X, \Sigma)$. In Line 4, $M_X^\neg$ is set to $\text{Just}_{\mathcal{T}}(X \sqsubseteq B)$, where $\text{Just}_{\mathcal{T}}(X \sqsubseteq B) = \{\{X \sqsubseteq B\}, \{X \sqsubseteq Y, Y \sqsubseteq B\}\}$. Since there are no axioms of the form $Y \sqsubseteq \exists rZ \in \mathcal{T}$ or $Y \equiv \exists rZ \in \mathcal{T}$, the lines 6–14 have no effect. Finally, the algorithm returns $M_X^\neg$ in Line 14.

For the second example, let $\mathcal{T} = \{\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5\}$ and $\Sigma = \{A, B, s\}$, where $\alpha_1 = X \sqsubseteq \exists rA$, $\alpha_2 = X \sqsubseteq \exists rB$, $\alpha_3 = X \sqsubseteq \exists rY$, $\alpha_4 = Y \equiv A \cap B$, and $\alpha_5 = r \sqsubseteq s$. We consider again the execution of $\text{Cover}_\rightarrow(\mathcal{T}, X, \Sigma)$. We proceed to Line 5 as there are no concept names in $\Sigma$ entailed by $X$ w.r.t. $\mathcal{T}$. However, the concepts $\exists rA$, $\exists rB$ and $\exists rY$ are entailed by $X$ w.r.t. $\mathcal{T}$. It holds that $\text{sim}_{\mathcal{T}, \Sigma}(Z, Z')$ for every $(Z, Z') \in \{(A, A), (B, B), (Y, Y), (A, Y), (B, Y)\}$, whereas $\text{sim}_{\mathcal{T}, \Sigma}(Z, Z')$ does not hold for any $(Z, Z') \in \{(A, B), (A, A), (Y, A), (Y, B)\}$. Therefore, for every $Z \in \{A, B, Y\}$ the recursive call $\text{Cover}_\rightarrow(\mathcal{T}, Z, \Sigma)$ is made in Line 9. The following sets are computed in lines 6–12: $M_A^\neg = \emptyset$, $M_B^\neg = \{\emptyset\}$, and $M_Y^\neg = \{\{\alpha_4\}\}$ as well as

\[
M_{34}^\neg_A = (\{\alpha_1, \alpha_5\} \otimes M_A^\neg) \cup (\{\alpha_3, \alpha_3\} \otimes M_Y^\neg) = \{\{\alpha_1, \alpha_5\}, \{\alpha_3, \alpha_4, \alpha_5\}\}
\]

\[
M_{34}^\neg_B = (\{\alpha_2, \alpha_5\} \otimes M_B^\neg) \cup (\{\alpha_3, \alpha_3\} \otimes M_Y^\neg) = \{\{\alpha_2, \alpha_5\}, \{\alpha_3, \alpha_4, \alpha_5\}\}
\]

\[
M_{34}^\neg_Y = \{\alpha_3, \alpha_5\} \otimes M_Y^\neg = \{\{\alpha_3, \alpha_4, \alpha_5\}\}
\]

Minimise$_C(M_X^\neg) = \text{Minimise}_C(M_{34}^\neg_A \otimes M_{34}^\neg_B \otimes M_{34}^\neg_Y) = \{\{\alpha_3, \alpha_4, \alpha_5\}\}.$

Finally, $\text{Cover}_\rightarrow(\mathcal{T}, X, \Sigma)$ returns $\text{Minimise}_C(M_X^\neg) = \{\{\alpha_3, \alpha_4, \alpha_5\}\}$ in Line 14.

The following theorem shows that Algorithm 3 indeed computes the set of subsumer modules, thus producing a cover of subsumer justifications.

**Theorem 62** Let $\mathcal{T}$ be an acyclic, normalised $\mathcal{ELH}$-terminology, and let $\Sigma$ be a signature. Let $X \in \text{NC}_C$, and let $M_X^\neg := \text{Cover}_\rightarrow(\mathcal{T}, X, \Sigma)$ computed by Algorithm 3. Then $M_X^\neg$ is the set of all $(X, \Sigma)$-subsumer justifications of $\mathcal{T}$.

Observe that $\text{Cover}_\rightarrow(\mathcal{T}, X, \Sigma)$ may be called several times during the execution of Algorithm 3. The algorithm can be optimised by caching the return value of the first execution, and retrieving it from memory for subsequent calls.

### 3.1.3 Computing Subsume Justifications

Similar with the algorithm for computing subsumer justifications, algorithm for computing subsume justifications relies on the notion of subsume simulation between terminologies, which we introduce below. Before that, we first introduce the notion of $\Sigma$-entailment.
Definition 63 (Σ-Entailment for ELH-terminology) Let Σ be a signature and \( \mathcal{T} \) a normalised ELH-terminology. We say that \( X \in \text{N}_C \) is Σ-entailed w.r.t. \( \mathcal{T} \) if there exists \( C \in \mathcal{E}\mathcal{L}_\Sigma \) with \( \mathcal{T} \models C \sqsubseteq X \); and \( r \in \text{N}_R \) is Σ-entailed w.r.t. \( \mathcal{T} \) if there exists \( s \in \Sigma \cap \text{N}_R \) with \( \mathcal{T} \models s \sqsubseteq r \).

Example 64 Let \( \mathcal{T} = \{ X \equiv X_1 \cap X_2, B_1 \sqsubseteq X_1, X_2 \equiv \exists r.Z, B_2 \sqsubseteq Z, s \sqsubseteq r \} \). We have that

\[ \text{non-conj}_\mathcal{T}(X) = \{ \langle X_1, X_2 \rangle \}. \]

Then \( r \) is Σ-entailed w.r.t. \( \mathcal{T} \); \( X \) is complex Σ-entailed w.r.t. \( \mathcal{T} \) for \( \Sigma = \{ B_1, B_2, s \} \); but \( X \) is not complex Σ'-entailed w.r.t. \( \mathcal{T} \), where \( \Sigma' \) ranges over \( \{ B_1, B_2 \}, \{ B_1, s \}, \{ B_2, s \} \). Additionally, \( X \) is not complex Σ-entailed w.r.t. \( \mathcal{T} \cup \{ B_1 \subseteq X \} \).

Definition 65 (Subsumee Simulation for ELH-terminology) Let \( \mathcal{T}_1, \mathcal{T}_2 \) be normalised ELH-terminologies, and let \( \Sigma \) be a signature. A relation \( S \subseteq \text{sig}^{\text{NC}}(\mathcal{T}_1) \times \text{sig}^{\text{NC}}(\mathcal{T}_2) \) is a Σ-subsumee simulation from \( \mathcal{T}_1 \) to \( \mathcal{T}_2 \) iff the following conditions are satisfied:

\( S^+ \): if \( (X_1, X_2) \in S \), then for every \( B \in \Sigma \) with \( \mathcal{T}_1 \models B \sqsubseteq X_1 \), it holds that \( \mathcal{T}_2 \models B \sqsubseteq X_2 \);

\( S^- \): if \( (X_1, X_2) \in S \), \( X_1 \equiv \exists r.Y_1 \in \mathcal{T}_1 \) and \( \mathcal{T}_1 \models s \sqsubseteq r \), \( s \in \Sigma \) and \( Y_1 \) is Σ-entailed w.r.t. \( \mathcal{T}_1 \), then for every \( X'_1 \in \text{non-conj}_{\mathcal{T}_1}(X_2) \), there exists \( X'_2 \equiv \exists r'Y_2 \in \mathcal{T}_2 \) such that \( \mathcal{T}_2 \models s \sqsubseteq r' \) and \( (Y_1, Y_2) \in S \);

\( S^{\bot} \): if \( (X_1, X_2) \in S \) and \( X_1 \equiv Y_1 \sqcap \ldots \sqcap Y_n \in \mathcal{T}_1 \), then for every \( X'_1 \in \text{non-conj}_{\mathcal{T}_1}(X_2) \), there exists \( X'_1 \in \text{non-conj}_{\mathcal{T}_1}(X_1) \) with \( (X'_1, X'_2) \in S \).

We write \( \langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, ELH} \langle \mathcal{T}_2, X_2 \rangle \) iff there exists a Σ-subsumee simulation \( S \) from \( \mathcal{T}_1 \) to \( \mathcal{T}_2 \) with \( (X_1, X_2) \in S \).

In Line 6 of Algorithm 4, the definition of complex Σ-entailment is given as follows.

Definition 66 (Complex Σ-Entailment) Let \( \mathcal{T} \) be a normalised ELH-terminology, \( \Sigma \) be a signature, and let \( X \in \text{N}_C \) and \( r \in \text{N}_R \).

We say that \( X \) is complex Σ-entailed w.r.t. \( \mathcal{T} \) iff for every \( Y \in \text{non-conj}_{\mathcal{T}}(X) \) at least one of the following conditions holds:

- there exists \( B \in \Sigma \) such that \( \mathcal{T} \models B \sqsubseteq Y \) and \( \mathcal{T} \notmodels B \sqsubseteq X \);
- there exists \( Y \equiv \exists r.Z \in \mathcal{T} \) and \( r \) and \( Z \) are each Σ-entailed in \( \mathcal{T} \).

Otherwise, \( X \) is said to be simply Σ-entailed.

Analogously to subsumer simulations, a subsumee simulation captures the set of subsumees as it is made precise in the following lemma.

Lemma 67 Let \( \mathcal{T}_1 \) and \( \mathcal{T}_2 \) be two normalised ELH-terminologies, and let \( \Sigma \) be a signature. If \( \langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, ELH} \langle \mathcal{T}_2, X_2 \rangle \), then \( \mathcal{T}_2 \models D \sqsubseteq X_2 \) holds for every \( D \in \mathcal{E}\mathcal{L}_\Sigma \) with \( \mathcal{T}_1 \models D \sqsubseteq X_1 \).
3.1 Subsumption Justifications of $\mathcal{ELH}$-Terminologies

Now we present some auxiliary notions for handling conjunctions on the left-hand side of subsumptions.

We define for each concept name $X$ a so-called *definitorial forest* consisting of sets of axioms of the form $Y \equiv Y_1 \sqcap \ldots \sqcap Y_n$, which can be thought of as forming trees. Any $\langle X, \Sigma \rangle$-subsumee justification contains the axioms of a selection of these trees, i.e., one tree for every conjunction formulated over $\Sigma$ that entails $X$ w.r.t. $\mathcal{T}$. Formally, we define DefForest$_{\mathcal{T}}(X) \subseteq 2^{\mathcal{T}}$ to be the smallest set closed under the following conditions:

- $\emptyset \in \text{DefForest}_{\mathcal{T}}(X)$;
- $\{ \alpha \} \in \text{DefForest}_{\mathcal{T}}(X)$ for $\alpha := X \equiv X_1 \sqcap \ldots \sqcap X_n \in \mathcal{T}$; and
- $\Gamma \cup \{ \alpha \} \in \text{DefForest}_{\mathcal{T}}(X)$ for $\Gamma \in \text{DefForest}_{\mathcal{T}}(X)$ with $Z \equiv Z_1 \sqcap \ldots \sqcap Z_k \in \Gamma$ and $\alpha := Z_i \equiv Z_i^1 \sqcap \ldots \sqcap Z_i^n \in \mathcal{T}$.

Given $\Gamma \in \text{DefForest}_{\mathcal{T}}(X)$, we set $\text{leaves}(\Gamma) := \text{sig}(\Gamma) \setminus \{ X \in \text{sig}(C) \mid X \equiv C \in \Gamma \}$ if $\Gamma \neq \emptyset$; and $\{ X \}$ otherwise. We denote the maximal element of DefForest$_{\mathcal{T}}(X)$ w.r.t. $\subseteq$ with max-tree$_{\mathcal{T}}(X)$. Finally, we set non-conj$_{\mathcal{T}}(X) := \text{leaves}(\text{max-tree}_{\mathcal{T}}(X))$.

**Example 68** Let $\mathcal{T} = \{ \alpha_1, \alpha_2, \alpha_3 \}$, where $\alpha_1 := X \equiv Y \sqcap Z$, $\alpha_2 := Y \equiv Y_1 \sqcap Y_2$, and $\alpha_3 := Z \equiv Z_1 \sqcap Z_2$. Then DefForest$_{\mathcal{T}}(X) = \{ \emptyset, \{ \alpha_1 \}, \{ \alpha_1, \alpha_2 \}, \{ \alpha_1, \alpha_3 \}, \{ \alpha_1, \alpha_2, \alpha_3 \} \}$. We have that leaves($\{ \alpha_1, \alpha_3 \}$) = $\{ Y, Z_1, Z_2 \}$, max-tree$_{\mathcal{T}}(X) = \{ \alpha_1, \alpha_2, \alpha_3 \}$, and non-conj$_{\mathcal{T}}(X) = \{ Y_1, Y_2, Z_1, Z_2 \}$.

We define definitorial forest in order to enumerate all possible situations and find all possible sub-trees such that Case($S_3^{\mathcal{T}, \Sigma}$) can be satisfied.

Using the notion of a subsumee simulation, we can device Algorithm 4 for computing a cover of the subsume justifications for a given normalized $\mathcal{ELH}$-terminology $\mathcal{T}$, a concept name $X$, and a signature $\Sigma$. The function for obtaining the $\langle X, \Sigma \rangle$-subsume justifications of $\mathcal{T}$ is $\text{COVER}_{\Sigma}^E(\mathcal{T}, X, \Sigma, \mathcal{T}, X)$. Note that Algorithm 5, Algorithm 6, and Algorithm 7 are called as subroutines in Line 5, 10 and 13 in Algorithm 4. The five different parameters for Algorithm 4 are needed due to the recursive calls in Algorithm 7 (Line 11) and Algorithm 6 (Line 9).

The existence of axiom $\alpha_{X_1} := X_1 \equiv \exists r.Y_1 \in \mathcal{T}_1$ in Line 2 of Algorithm 6 is guaranteed by Line 9 of Algorithm 4. The axiom $\alpha_{X_2} := X_2 \equiv \exists r'.Y_2 \in \mathcal{T}_2$ in Line 8 of Algorithm 6 exists as we assume that $\langle \mathcal{T}_2, X_2 \rangle$ subsume-simulates $\langle \mathcal{T}_1, X_1 \rangle$. Moreover, there is at most one axiom $\alpha_{X_1} \in \mathcal{T}_1$ and at most one $\alpha_{X_2} \in \mathcal{T}_2$ as $\mathcal{T}_1$ and $\mathcal{T}_2$ are terminologies. The concept name $X_2$ may be defined as a conjunction in $\mathcal{T}_2$ whose conjuncts in turn may also be defined as a conjunction in $\mathcal{T}_2$ and so forth. In Line 3 of Algorithm 6 all axioms forming the maximal resulting definitorial conjunctive tree are collected.

For Algorithm 7, we define

$$\text{def}_{\mathcal{T}} := \{ X \in \text{sig}^N(\mathcal{T}) \mid X \equiv Y_1 \sqcap \ldots \sqcap Y_n \in \mathcal{T} \}$$
Algorithm 4: Computing the set of all Subsumee Justifications for an $\mathcal{ELH}$-terminology

```plaintext
1 function COVER$_\prec$($\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2$)
2     if $X_1$ is not $\Sigma$-entailed w.r.t. $\mathcal{T}_1$ then
3         return \{\emptyset\}
4     end
5     $M^\prec_{(X_1,X_2)} :=$ COVER$_\prec$($\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2$)
6     if $X_1$ is not complex $\Sigma$-entailed in $\mathcal{T}_1$ then
7         return Minimise$_\prec$($M^\prec_{(X_1,X_2)}$)
8     end
9     if $X_1 \equiv \exists r. Y \in \mathcal{T}_1$, and $r, Y$ are $\Sigma$-entailed w.r.t. $\mathcal{T}_1$ then
10        $M^\prec_{(X_1,X_2)} := M^\prec_{(X_1,X_2)} \otimes$ COVER$_\prec$($\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2$)
11     end
12     else if $X_1 \equiv Y_1 \cap \ldots \cap Y_m \in \mathcal{T}_1$ then
13        $M^\prec_{(X_1,X_2)} := M^\prec_{(X_1,X_2)} \otimes$ COVER$_\prec$($\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2$)
14     end
15     return Minimise$_\prec$($M^\prec_{(X_1,X_2)}$)
```

Algorithm 5: Computing the set of all Subsumee Justifications for an $\mathcal{ELH}$-terminology – Local Case

```plaintext
1 function COVER$_\prec$$_\text{NC}$($\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2$)
2     $M^\prec_{(X_1,X_2)} = \{\emptyset\}$
3     for every $B \in \Sigma \cap N_\Sigma$ such that $\mathcal{T}_1 \models B \subseteq X_1$ do
4         $M^\prec_{(X_1,X_2)} := M^\prec_{(X_1,X_2)} \otimes$ Just$\mathcal{T}_1$($B \subseteq X_2$)
5     end
6     return Minimise$_\prec$($M^\prec_{(X_1,X_2)}$)
```

We illustrate Algorithm 4 with the following example.

**Example 69** Let $\mathcal{T} = \{X \equiv \exists r. Y, Y \equiv \exists s. Z, Z \equiv A \cap Z', A \subseteq B, B \subseteq Z', Z' \subseteq A\}$ be an $\mathcal{ELH}$-terminology, and let $\Sigma = \{A, B, r, s\}$ be a signature. It can readily be verified that $\mathcal{T}$ is normalised.
3.1 Subsumption Justifications of $\mathcal{ELH}$-Terminologies

Algorithm 6: Computing the set of all Subsumee Justifications for an $\mathcal{ELH}$-terminology – Existential Case

1. function $\text{COVER}^3_{\Sigma}(\mathcal{T}, X, \Sigma, \mathcal{T})$
2. \hspace{1em} let $\alpha_X := X_1 \equiv \exists r Y_1 \in \mathcal{T}$
3. \hspace{1em} $M^{\alpha_X}_{(X,X)} := \{\text{max-tree}^\oplus_\Sigma(X_2)\}$
4. \hspace{1em} for every $s \in \Sigma \cap N_R$ such that $\mathcal{T} \models s \subseteq r$
5. \hspace{2em} for every $X'_2 \in \text{non-conj}_{\Sigma}(X_2)$ do
6. \hspace{3em} let $\alpha_{X'_2} := X'_2 \equiv \exists r' Y'_2 \in \mathcal{T}$ such that $\mathcal{T} \models s \subseteq r'$
7. \hspace{3em} $M^{\alpha_{X'_2}}_{(X'_2,X'_2)} := \text{COVER}(\mathcal{T}_1, Y_1, \Sigma, \mathcal{T}_2, Y'_2)$
8. \hspace{3em} $M^{\alpha_X}_{(X,X)} := M^{\alpha_X}_{(X,X)} \sqcup \{\alpha_{X'_2}\} \sqcup \text{Just}_{\mathcal{T}}(s \subseteq r') \cap M^{\alpha_{X'_2}}_{(X'_2,X'_2)}$
9. end
10. end
11. return $\text{Minimise}_\Sigma(M^{\alpha_X}_{(X,X)})$

To determine the $(X, \Sigma)$-subsumee justifications of $\mathcal{T}$, we need to execute Algorithm 4 computing $\text{COVER}^3_{\Sigma}(\mathcal{T}, X, \Sigma, \mathcal{T})$. As $X$ is (complex) $\Sigma$-entailed, Lines 2–4 and Lines 6–8 are omitted. In Line 5, $\text{COVER}^3_{\Sigma}(\mathcal{T}, X, \Sigma, \mathcal{T})$ is called which is implemented in Algorithm 4.

The for-loop in Lines 3–5 of Algorithm 5 does not apply as $\mathcal{T} \not\models A \subseteq X$ and $\mathcal{T} \not\models B \subseteq X$. We obtain $\text{COVER}^3_{\Sigma}(\mathcal{T}, X, \Sigma, \mathcal{T}) = \{\emptyset\}$, and then backtrack to Line 5 of Algorithm 4. The if-statement in Line 9 applies as $\mathcal{T}$ contains an axiom of the form $X \equiv \exists r Y$ and both, $X$ and $r$, are $\Sigma$-entailed w.r.t. $\mathcal{T}$. We proceed in Line 10 with calling $\text{COVER}^3_{\Sigma}(\mathcal{T}, X, \Sigma, \mathcal{T}, X)$, which is implemented in Algorithm 6.

We obtain $M^{\alpha_X}_{(X,X)} := \{\text{max-tree}^\oplus_\Sigma(X)\} = \{\emptyset\}$ in Line 3 of Algorithm 6. The for-loop from Line 4 to 10 is executed for $r \in \Sigma$ as $\mathcal{T} \models r \subseteq r$. The nested for-loop in Lines 5–9 is executed for $X$ as non-conj $\mathcal{T}(X) = \{X\}$. In Line 6 $\alpha_{X'_2}$ is set to $X \equiv \exists r Y$ and, in Line 8, the recursive call $\text{COVER}^3_{\Sigma}(\mathcal{T}, Y, \Sigma, \mathcal{T}, Y)$ is made, which is computed in Algorithm 4.

Then, in Line 10 of Algorithm 4, $\text{COVER}^3_{\Sigma}(\mathcal{T}, Y, \Sigma, \mathcal{T}, Y)$ is called as $Y$ is complex $\Sigma$-entailed w.r.t. $\mathcal{T}$, $Y \equiv \exists s Z \in \mathcal{T}$, and $s, Z$ are each $\Sigma$-entailed w.r.t. $\mathcal{T}$. Similar to $\text{COVER}^3_{\Sigma}(\mathcal{T}, X, \Sigma, \mathcal{T}, X)$, the execution of $\text{COVER}^3_{\Sigma}(\mathcal{T}, Y, \Sigma, \mathcal{T}, Y)$ causes another recursive call $\text{COVER}^3_{\Sigma}(\mathcal{T}, Z, \Sigma, \mathcal{T}, Z)$ from Line 7 of Algorithm 6.

As $Z$ is $\Sigma$-entailed w.r.t. $\mathcal{T}$, we have that $\text{COVER}^3_{\Sigma}(\mathcal{T}, Z, \Sigma, \mathcal{T}, Z)$ is executed. The for-loop starting in Line 3 of Algorithm 5 applies as $\mathcal{T} \models A \subseteq Z$ and $\mathcal{T} \models B \subseteq Z$. We obtain $M^\alpha_Z := \text{Just}_{\mathcal{T}}(A \subseteq Z) \odot \text{Just}_{\mathcal{T}}(B \subseteq Z)$, where $\text{Just}_{\mathcal{T}}(A \subseteq Z) = \text{Just}_{\mathcal{T}}(B \subseteq Z) = \{Z \equiv A \cap Z', A \subseteq B, B \subseteq Z', Z' \subseteq A\}$. This finishes the call $\text{COVER}^3_{\Sigma}(\mathcal{T}, Z, \Sigma, \mathcal{T}, Z)$, and we backtrack to Line 4 of $\text{COVER}^3_{\Sigma}(\mathcal{T}, Z, \Sigma, \mathcal{T}, Z)$. As $Z$ is not complex $\Sigma$-entailed, this finishes the call $\text{COVER}^3_{\Sigma}(\mathcal{T}, Z, \Sigma, \mathcal{T}, Z)$ with $M^\alpha_Z = \{Z \equiv A \cap Z', A \subseteq B, B \subseteq Z', Z' \subseteq A\}$.

We backtrack to Line 10 of $\text{COVER}^3_{\Sigma}(\mathcal{T}, Y, \Sigma, \mathcal{T}, Y)$ and set $M^\alpha_Y := M^\alpha_Y \odot \{\{Y \equiv \exists s Z\}\} \odot M^\alpha_Z$ which yields $M^\alpha_Y = \{\{Y \equiv \exists s Z, Z \equiv A \cap Z', A \subseteq B, B \subseteq Z', Z' \subseteq A\}\}$. This finishes the call.
Additionally, let

\[ M_{(X_1, X_2)} := \emptyset \]

for \( \Gamma \in \text{DefForest}^T(T_2) \) do

\[ \text{Let } \delta_T := \{ \text{def}_T^2(\mathcal{X}') \mid \mathcal{X}' \in \text{leaves}(\Gamma) \} \]

\[ M_{\Gamma}^\leftarrow := \{ \Gamma \} \]

for \( X'_1 \in \text{leaves}(\Gamma) \) do

\[ M_{X'_2}^\leftarrow := \emptyset \]

for every \( X'_1 \in \text{non-conj}_{T_1}(X_1) \) do

\[ \text{if } \langle T_1, X'_1 \rangle \sim_{\Sigma, T} (T_2 \setminus \delta_T, X'_2) \text{ then} \]

\[ M_{X'_2}^\leftarrow := M_{X'_2}^\leftarrow \cup \text{COVER}_\leftarrow(T_1, X'_1, \Sigma, T_2 \setminus \delta_T, X'_2) \]

end

end

\[ M_{\Gamma}^\leftarrow := M_{\Gamma}^\leftarrow \otimes M_{X'_2}^\leftarrow \]

end

end

return Minimise_\subseteq(M_{(X_1, X_2)}^\leftarrow)

\[ \text{COVER}_\leftarrow^3(T, Y, \Sigma, T, Y) \text{ and it backtracks to Line 9 and ends the call } \text{COVER}_\leftarrow(T, T, \Sigma, T, Y). \text{ We set } M_{\Gamma}^\leftarrow := M_{\Gamma}^\leftarrow \otimes \{ \{ \mathcal{X} \equiv \exists \mathcal{Y} \} \} \otimes M_{T}^\leftarrow \text{ in Line 8 of Algorithm 6 for } \text{COVER}_\leftarrow^3(T, X, \Sigma, T, X). \text{ Thus } \text{COVER}_\leftarrow^3(T, X, \Sigma, T, X) \text{ returns } M_{\Gamma}^\leftarrow = \{ \{ \mathcal{X} \equiv \exists \mathcal{Y}, \mathcal{Y} \equiv \exists \mathcal{Z}, \mathcal{Z} \equiv \exists \mathcal{A}, \mathcal{A} \subseteq B, B \subseteq \mathcal{Z}', \mathcal{Z}' \subseteq \mathcal{A} \} \} \text{ and we backtrack to Line 10 of Algorithm 4. Finally, all sets that are not minimal w.r.t. } \subseteq \text{ are removed from } M_{\Gamma}^\leftarrow \text{ in Line 15, which ends the execution of } \text{COVER}_\leftarrow(T, X, \Sigma, T, X). \]

The following theorem shows that Algorithm 4 indeed computes a cover of the set of subsumee modules, which are all subsumee justifications after the function Minimise_\subseteq.

**Theorem 70** Let \( T \) be an acyclic, normalised \( \mathcal{L} \mathcal{H} \)-terminology, \( X \in \mathcal{N}_\mathcal{C} \) and \( \Sigma \) be a signature. Additionally, let \( M_{X}^\leftarrow := \text{COVER}_\leftarrow(T, X, \Sigma, T, X) \) computed by Algorithm 4. Then \( M_{X}^\leftarrow \) is the set of all \( \langle X, \Sigma \rangle \)-subsumee justifications of \( T \).

The number of subsumption (subsumer, subsumee) justifications depends on \( T \) and \( \Sigma \). Clearly, it can be exponential many in the size of the terminology. Note that the simulation checks can be performed in polynomial time [12, 34]. Therefore, our algorithm for computing subsumption (subsumer, subsumee) justifications runs in exponential time w.r.t. the size of input terminology in the worst case.
As we can see from the algorithms given in this section, the reason that there might exist exponential many subsumption justifications is caused by the fact that there can be exponential many justifications w.r.t. an inclusion \( \alpha \) in the worst case. However, it is obvious that if the number of justifications w.r.t. an inclusion \( \alpha \) is bounded by a constant number, which happens often in real world ontologies, the number of subsumption justifications is also bounded. In this case, our algorithm for subsumer justifications becomes polynomial, but the algorithm for subsume and subsumption justifications are still exponential in the worst case.

**Proposition 71** Let \( \mathcal{T} \) be a normalised \( \mathcal{ELH} \)-terminology, let \( \Sigma \) be a signature and \( X \in \Sigma \). The algorithm of computing all \( \langle X, \Sigma \rangle \)-subsumption justifications runs in \( \text{EXPTIME} \).

### 3.1.4 Proofs

#### Proofs about \( \otimes \)

**Lemma 61** Let \( \mathcal{T}_1 \) and \( \mathcal{T}_2 \) be normalised \( \mathcal{ELH} \)-terminologies, and let \( \Sigma \) be a signature. If \( \langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \otimes} \langle \mathcal{T}_2, X_2 \rangle \), then, for every \( D \in \mathcal{EL} \Sigma \) with \( \mathcal{T}_1 \models X_1 \subseteq D \), it holds that \( \mathcal{T}_2 \models X_2 \subseteq D \).

**Proof** We prove by induction on the structure of \( D \) that for every \( X_1, X_2 \in N_C \cup \{ \top \} \) with \( \mathcal{T}_1 \models X_1 \subseteq D \) and \( \langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \otimes} \langle \mathcal{T}_2, X_2 \rangle \), it holds that \( \mathcal{T}_2 \models X_2 \subseteq D \).

Let \( D \in \mathcal{EL} \Sigma \) and let \( X_1, X_2 \in N_C \) such that \( \langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \otimes} \langle \mathcal{T}_2, X_2 \rangle \) and \( \mathcal{T}_1 \models X_1 \subseteq D \). We now distinguish between the following cases.

- \( D = \top \): then we are done, since \( \mathcal{T}_2 \models X_2 \subseteq \top \) always holds.
We first prove that $T \in \text{Theorem 62} \, X \subset N$ is acyclic. The proof now proceeds by induction on $\mathcal{N}$.

Let $X \in \mathcal{N}$, and let $\mathcal{M}^{\mathcal{X}} := \text{COVER}_{\rightarrow} (\mathcal{T}, X, \Sigma)$ computed by Algorithm 3. Then $\mathcal{M}^{\mathcal{X}}$ is the set of all $(X, \Sigma)$-subsumer justifications of $\mathcal{T}$.

**Proof** We first prove that $\mathcal{M}^{\mathcal{X}}$ is a cover of the set of all $(X, \Sigma)$-subsumer module of $\mathcal{T}$ by Definition 58. (i) We show that every $\mathcal{M} \in \mathcal{M}^{\mathcal{X}}$ is an $(X, \Sigma)$-subsumer module of $\mathcal{T}$.

First, we define the relation $\triangleright_{\mathcal{T}} \subseteq \mathcal{N} \times \mathcal{N}$ as follows: for $X, Y \in \mathcal{N}$ we set $X \triangleright_{\mathcal{T}} Y$ iff there exists $X' \triangleright \exists x. Y \in \mathcal{T}$ with $\mathcal{T} \models X \sqsupseteq X'$, $\mathcal{T} \models s \sqsubseteq r$ and $\exists x \in \{\subseteq, \equiv\}$. Note that $\triangleright_{\mathcal{T}}$ is well-founded as $\mathcal{T}$ is acyclic. The proof now proceeds by induction on $\triangleright_{\mathcal{T}}$.

Let $X \in \mathcal{N}$ and let $\mathcal{M} \in \mathcal{M}^{\mathcal{X}}$. We now distinguish between the following cases.

- If there does not exist $Y \in \mathcal{N}$ with $X \triangleright_{\mathcal{T}} Y$, let $D \in \mathcal{E}\mathcal{L}_{\Sigma}$ such that $\mathcal{T} \models X \sqsubseteq D$. The proof now continues by induction on the structure of $D$. For $D = \top$ or $D = X$, it immediately follows that $\mathcal{M} \models X \sqsubseteq D$. For $D = B \in \mathcal{N}$ and $B \neq X$, there exists $\mathcal{J} \in \text{Just}_{\mathcal{T}} (X \sqsubseteq B)$ with $\mathcal{J} \subseteq \mathcal{M}$ (Line 4), i.e., $\mathcal{M} \models X \sqsubseteq D$ holds. For $D = D_1 \sqcap D_2$ we obtain $\mathcal{M} \models X \sqsubseteq D_1$ and $\mathcal{M} \models X \sqsubseteq D_2$ by applying the induction hypothesis on $D_1$ and $D_2$. Consequently, it holds that $\mathcal{M} \models X \sqsubseteq D$. Note that $D$ cannot be of the form $\exists r. E$ by Lemma 32.

- Otherwise, let $D \in \mathcal{E}\mathcal{L}_{\Sigma}$ such that $\mathcal{T} \models X \sqsubseteq D$. The proof now continues by induction on the structure of $D$. The cases of $D = \top$, $D = A \in \mathcal{N}$, and $D = D_1 \sqcap D_2$ can be proved as above. For $D = \exists r. E$, there exists $Y \triangleright \exists r. Z \in \mathcal{T}$ such that $\mathcal{T} \models X \sqsupseteq Y$ and $\mathcal{T} \models Z \sqsubseteq E$ by Lemma 32. Consequently, there exists $\alpha = Y' \triangleright \exists Z' \in \mathcal{T}$ such that $\mathcal{T} \models X \sqsupseteq Y'$, $\mathcal{T} \models s \sqsubseteq r$, $(\mathcal{T}, Z) \sim_{\mathcal{E}\mathcal{L}_{\Sigma}} (\mathcal{T}, Z')$ and $\alpha \in \mathcal{M}$. Note that $(\mathcal{T}, Z) \sim_{\mathcal{E}\mathcal{L}_{\Sigma}} (\mathcal{T}, Z')$ holds. Furthermore, there exists $\mathcal{J} \in \text{Just}_{\mathcal{T}} (X \sqsubseteq Y')$ such that $\mathcal{J} \subseteq \mathcal{M}$ and there exists $\mathcal{M}_Z \in \text{COVER}_{\rightarrow} (\mathcal{T}, \Sigma, Z')$ such that $\mathcal{M}_Z \subseteq \mathcal{M}$. As $X \triangleright Z'$, it follows from the induction hypothesis $\mathcal{M}_Z$ is a $(Z', \Sigma)$-subsumer module of $\mathcal{T}$, i.e., $\mathcal{M}_Z \models Z' \sqsubseteq E$ Additionally, it holds that $\mathcal{T} \models Z' \sqsubseteq E$ by $(\mathcal{T}, Z) \sim_{\mathcal{E}\mathcal{L}_{\Sigma}} (\mathcal{T}, Z')$ and Lemma 61, which implies that $\mathcal{M}_Z \models Z' \sqsubseteq E$. Overall, we hence obtain $\mathcal{M} \models X \sqsubseteq \exists r. E$.
3.1 Subsumption Justifications of $\mathcal{E}\mathcal{L}\mathcal{H}$-Terminologies

(ii) We show that for every $\langle X, \Sigma \rangle$-subsumer module $\mathcal{M}$ of $T$ there exists $\mathcal{M'} \subseteq \mathcal{M}$.

The proof now proceeds by induction on $\triangleright$. Let $X \in \mathbb{N}_\Sigma$ and let $\mathcal{M}$ be a $\langle X, \Sigma \rangle$-subsumer module of $T$. We now distinguish between the following cases.

- If there does not exist $Y \in \mathbb{N}_\Sigma$ with $X \triangleright Y$, let $B \in \Sigma$. As $\mathcal{M}$ is a $\langle X, \Sigma \rangle$-subsumer module, there exists $S_B \in \text{Just}_T(X \sqsubseteq B)$ with $S_B \subseteq \mathcal{M}$. Consequently, it is easy to see that there exists $\mathcal{M'} \in \mathbb{M}_X^\triangleright$ with $\mathcal{M'} = \bigcup_{B \in \Sigma} S_B$ as there does not exist $X' \triangleright \exists s Y \in T$ with $T \models X \sqsubseteq X'$ and $T \models s \sqsubseteq r$.

- Otherwise, let $S$ be a $\Sigma$-subsumer simulation from $T$ to $\mathcal{M}$ with $(X, X) \in S$. Similarly to the previous case, for every $B \in \Sigma$ there exists $S_B \in \text{Just}_T(X \sqsubseteq B)$ with $S_B \subseteq \mathcal{M}$.

Now let $\{ Y \triangleright \exists r Z \in T \mid r \in \Sigma, T \models X \sqsubseteq Y \text{ and } T \models s \sqsubseteq r \} = \{ Y_1 \triangleright \exists r_1 Z_1, \ldots, Y_n \triangleright \exists r_n Z_n \}$ and let $1 \leq i \leq n$. Thus, by definition of $S$ there exists $Y'_i \triangleright \exists s_i Z'_i \in \mathcal{M}$ such that $T \models X \sqsubseteq Y'_i$ and $\mathcal{M} \models s_i \sqsubseteq r_i$ with $(Z, Z'_i) \in S$, i.e. $(T, Z) \sim_{\Sigma, \xi, \mathcal{M}} (T, Z'_i)$ holds. Consequently, there exists $S_{Y'_i} \in \text{Just}_T(X \sqsubseteq Y'_i)$ with $S_{Y'_i} \subseteq \mathcal{M}$ and $S_{r_i} \in \text{Just}_T(s_i \sqsubseteq r_i)$ with $S_{r_i} \subseteq \mathcal{M}$. Moreover, as $(Z, Z'_i) \in S$, we have that $\mathcal{M}$ is a $\langle Z'_i, \Sigma \rangle$-subsumer module of $T$. It follows from the induction hypothesis that there exists $\mathcal{M}'_{Z'_i} \in \mathbb{M}_{Z'}^{\triangleright} := \text{COVER}_{\triangleright} (T, \Sigma, Z'_i)$ with $\mathcal{M}'_{Z'_i} \subseteq \mathcal{M}$. Let

$$\mathcal{M} := \bigcup_{B \in \Sigma} S_B \cup \bigcup_{i=1}^n \{ S_{Y'_i} \cup S_{r_i} \cup \{ Y'_i \triangleright \exists s_i Z'_i \} \cup \mathcal{M}'_{Z'_i} \}.$$ 

It is easy to see that $\mathcal{M} \in \mathbb{M}_X^\triangleright$ and $\mathcal{M}' \subseteq \mathcal{M}$.

Then we have that $\mathbb{M}_X^\triangleright$ is the set of all $\langle X, \Sigma \rangle$-subsumer justifications of $T$. Let $\mathcal{M} \in \mathbb{M}_X^\triangleright$. We prove by assuming towards a contradiction. We assume that there exist an $\mathcal{M}' \not\subseteq \mathcal{M}$ such that $\mathcal{M}'$ is a $\langle X, \Sigma \rangle$-subsumer module of $T$. As $\mathbb{M}_X^\triangleright$ is initialed as $\{ \emptyset \}$, we enumerate all possible situations that $\mathcal{M}$ is generated in the algorithms but $\alpha \notin \mathcal{M}$, we have that the absence of $\alpha$ in any situation will lead to the failure of the subsumer simulation. So $\mathcal{M}'$ could not be a $\langle X, \Sigma \rangle$-subsumer module of $T$, which contradicts to our assumption.

$\blacksquare$

**Proofs about Computing Subsumee Justifications**

**Lemma 73** Let $T$ be a normalised and acyclic $\mathcal{E}\mathcal{L}\mathcal{H}$-terminology, let $\Sigma$ be a signature, and let $X \in \mathbb{N}_\Sigma$ be pseudo-primitive in $T$.

Then $X$ is not complex $\Sigma$-entailed w.r.t. $T$.

**Proof** As $X$ is pseudo-primitive in $T$, we have non-conj$_T(X) = \{ X \}$. We can infer that there cannot exist $B \in \Sigma$ with $T \models B \sqsubseteq Y$ and $T \not\models B \sqsubseteq X$. Additionally, we observe that no axiom of the form $X \equiv \exists r Y$ is contained in $T$, which implies that $X$ is not complex $\Sigma$-entailed w.r.t. $T$. $\blacksquare$
Lemma 74  Let $\mathcal{T}$ be a normalised and acyclic $\mathcal{ELH}$-terminology and let $X \in N_C$ that is not complex $\Sigma$-entailed w.r.t. $\mathcal{T}$.

Then for every $C \in \mathcal{EL}_{\Sigma}$ it holds that: $\mathcal{T} \models C \sqsubseteq X$ iff there exists $B \in \text{sub}_0(C)$ such that $\mathcal{T} \models B \sqsubseteq X$.

Proof  Let $C \in \mathcal{EL}_{\Sigma}$.

First we prove that for every $C \in \mathcal{EL}_{\Sigma}$ it holds that: $\mathcal{T} \models C \sqsubseteq X$ only if there exists $B \in \text{sub}_0(C)$ such that $\mathcal{T} \models B \sqsubseteq X$. We assume that $\mathcal{T} \models C \sqsubseteq X$. Note that $\mathcal{T} \not\models \top \sqsubseteq C$ as $\mathcal{T}$ is a normalised terminology, which implies that $\top \not\in \text{sub}(\mathcal{T})$. Then, as $X$ is not complex $\Sigma$-entailed w.r.t. $\mathcal{T}$, it follows that there exists $Y \in \text{non-conj}_\mathcal{T}(X)$ such that

(i) for every $B \in \Sigma$ with $\mathcal{T} \models B \sqsubseteq Y$ it holds that $\mathcal{T} \models B \sqsubseteq X$, and

(ii) for every $Y \equiv \exists r.Z \in \mathcal{T}$, $r$ is $\Sigma$-entailed, it holds that $Z$ is not $\Sigma$-entailed in $\mathcal{T}$.

Note that $\mathcal{T} \models C \sqsubseteq Y$ since $\mathcal{T} \models X \sqsubseteq Y$. We now distinguish between the following cases. If $Y$ is pseudo-primitive in $\mathcal{T}$, then it follows from Lemma 31 that there exists $B \in \text{sub}_0(C)$ with $\mathcal{T} \models B \sqsubseteq Y$, which implies that $\mathcal{T} \models B \sqsubseteq X$ by (i).

Otherwise, there exists an axiom $Y \equiv \exists x.Y' \in \mathcal{T}$ and it holds that $\mathcal{T} \models C \sqsubseteq \exists x.Y'$. If follows from Lemma 31 that either (a) there exists $B \in \text{sub}_0(C)$ with $\mathcal{T} \models B \sqsubseteq Y$, or (b) there exists $\exists x.C' \in \text{sub}_0(C)$ with $\mathcal{T} \models C' \sqsubseteq Y'$. For (a), we have $\mathcal{T} \models B \sqsubseteq Y$, and thus, $\mathcal{T} \models B \sqsubseteq X$ by (i). We note that (b) cannot hold as $s$ is $\Sigma$-entailed, $\mathcal{T} \models C' \sqsubseteq Y'$, and $\text{sig}(C') \subseteq \Sigma$, which implies that $Y'$ would be $\Sigma$-entailed in $\mathcal{T}$.

“if” Then we prove that for every $C \in \mathcal{EL}_{\Sigma}$ it holds that: $\mathcal{T} \models C \sqsubseteq X$ if there exists $B \in \text{sub}_0(C)$ such that $\mathcal{T} \models B \sqsubseteq X$.

Let $B \in \text{sub}_0(C)$ such that $\mathcal{T} \models B \sqsubseteq X$. Since $\mathcal{T} \models C \sqsubseteq B$, it follows that $\mathcal{T} \models C \sqsubseteq X$. \hfill $\square$

Lemma 75  Let $\mathcal{T}$ be a normalised and acyclic $\mathcal{ELH}$-terminology and let $X \in N_C$ be complex $\Sigma$-entailed w.r.t. $\mathcal{T}$.

Then there exists $C \in \mathcal{EL}_{\Sigma}$ such that $\mathcal{T} \models C \sqsubseteq X$ and $\mathcal{T} \models \alpha \not\models C \sqsubseteq X$ for $\alpha = X \equiv D \in \mathcal{T}$.

Proof  Let $\text{non-conj}_\mathcal{T}(X) = \{Y_1, \ldots, Y_n\}$. As $X \in N_C$ is complex $\Sigma$-entailed w.r.t. $\mathcal{T}$ it holds that for every $1 \leq i \leq n$ one of the following conditions holds:

1. there exists $B_i \in \Sigma$ such that $\mathcal{T} \models B_i \sqsubseteq Y_i$ and $\mathcal{T} \not\models B_i \sqsubseteq X$, or
2. there exists $Y_i \equiv \exists r_i.Z_i \in \mathcal{T}$ such that $r_i.Z_i$ is $\Sigma$-entailed in $\mathcal{T}$.

For every $1 \leq i \leq n$, we define

$$D_i := \begin{cases} B_i & \text{if } B_i \in \Sigma \text{ with } \mathcal{T} \models B_i \sqsubseteq Y_i \text{, and } \mathcal{T} \not\models B_i \sqsubseteq X \\ \exists r_i.C_z & \text{otherwise, where } C_z \in \mathcal{EL}_{\Sigma} \text{, with } \mathcal{T} \models C_z \sqsubseteq Z_i \end{cases}$$
Finally, let $C := \prod_{i=1}^{n} D_i$. It is easy to see that $\mathcal{T} \models C \subseteq X$. Note that there exists at most one axiom of the form $\alpha = X \equiv E \in \mathcal{T}$ as $\mathcal{T}$ is a terminology, and that $X$ is primitive in $\mathcal{T} \setminus \{\alpha\}$.

If we assume towards a contradiction that $\mathcal{T} \setminus \{\alpha\} \models C \subseteq X$, it would follow from Lemma 31 that there exists $1 \leq j \leq n$ such that $\mathcal{T} \setminus \{\alpha\} \models B_j \subseteq X$ and hence, $\mathcal{T} \models B_j \subseteq X$; contradicting the assumptions.

**Definition 76** Let $\mathcal{T}_1$ and $\mathcal{T}_2$ be normalised and acyclic $\mathcal{ELH}$-terminologies, and $\Sigma$ be a signature. Additionally, let $X_1, X_2 \in NC$ such that $\langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \mathcal{EL}} \langle \mathcal{T}_2, X_2 \rangle$. Then $\mathcal{M} \subseteq \mathcal{T}_2$ is a $\langle \mathcal{T}_1, X_1, \Sigma \rangle$-subsume module of $\mathcal{T}_2$ w.r.t. $X_2$ if $\mathcal{M} \models C \subseteq X_2$ holds for every $C \in \mathcal{EL}_\Sigma$ such that $\mathcal{T}_1 \models C \subseteq X_1$.

**Lemma 67** Let $\mathcal{T}_1$ and $\mathcal{T}_2$ be two normalised $\mathcal{ELH}$-terminologies, and let $\Sigma$ be a signature. If $\langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \mathcal{EL}} \langle \mathcal{T}_2, X_2 \rangle$, then $\mathcal{T}_2 \models D \subseteq X_2$ holds for every $D \in \mathcal{EL}_\Sigma$ with $\mathcal{T}_1 \models D \subseteq X_1$.

**Proof** We prove that for every $\mathcal{EL}_\Sigma$-concept $C$ and for every $(A_1, A_2) \in S$ with $\mathcal{T}_1 \models C \subseteq A_1$ that $\mathcal{T}_2 \models C \subseteq A_2$ holds by induction on the structure of $C$.

Let now $C$ be an $\mathcal{EL}_\Sigma$-concept and let $\langle \mathcal{T}_1, A_1 \rangle \sim_{\Sigma, \mathcal{EL}} \langle \mathcal{T}_2, A_2 \rangle$ such that $\mathcal{T}_1 \models C \subseteq A_1$. We distinguish between the following cases:

- $C = \top$: this case cannot occur since $\mathcal{T}_1 \not\models C \subseteq A_1$.
- $C = B \in NC$: as $B \in \Sigma$, we have $\mathcal{T}_2 \models C \subseteq A_2$ by the definition 65.
- $C = \exists x D$ for an $\mathcal{EL}_\Sigma$-concept $D$: we can infer that $\mathcal{T}_1 \models \exists x D \subseteq A_{1,i}$ for every $A_{1,i} \in \text{non-}\mathcal{T}_1(A_1) = \{A_{1,1}, \ldots, A_{1,n}\}$. Moreover, we can infer from Lemma 31 that every $A_{1,i} \in \text{non-}\mathcal{T}_1(A_1)$ is not pseudo-primitive in $\mathcal{T}_1$, i.e. for every $A_{1,i} \in \text{non-}\mathcal{T}_1(A_1)$ we have $A_{1,i} \equiv \exists x D_{1,i} \in \mathcal{T}_1$ with $\mathcal{T}_1 \models D_{1,i} \subseteq D_{1,i}$ and $r$ is $\Sigma$-entailed. In particular, for every $A_{1,i} \in \text{non-}\mathcal{T}_1(A_1)$, $D_{1,i}$ is $\Sigma$-entailed.

Let now non-\mathcal{T}_1(A_2) = \{A_{2,1}, \ldots, A_{2,m}\}. It then follows from the definition 65 for every $1 \leq j \leq m$ that $A_{2,j} \equiv \exists x D_{2,j} \in \mathcal{T}_2$ and that there exists $1 \leq i \leq n$ with $\langle \mathcal{T}_1, D_{1,i} \rangle \sim_{\Sigma, \mathcal{EL}} \langle \mathcal{T}_2, D_{2,j} \rangle$, i.e. we obtain $\mathcal{T}_2 \models D \subseteq D_{2,j}$ for every $1 \leq j \leq m$ by applying the induction hypothesis, and thus $\mathcal{T}_2 \models C \subseteq A_2$.

- $C = C_1 \sqcap \ldots \sqcap C_n$: we can infer that $\mathcal{T} \models C \subseteq A_1'$ for every $A_1' \in \text{non-}\mathcal{T}_1(A_1)$, i.e. every $A_1' \in \text{non-}\mathcal{T}_1(A_1)$ Now, let $A_2' \in \text{non-}\mathcal{T}_2(A_2)$, and let $A_1' \in \text{non-}\mathcal{T}_1(A_1)$ with $\langle \mathcal{T}_1, A_1' \rangle \sim_{\Sigma, \mathcal{EL}} \langle \mathcal{T}_2, A_2' \rangle$, which exists by the definition 65. It then follows from Lemma 31 that there exists $1 \leq j \leq n$ and a conjunct $Y$ of $C_j$ such that $Y \in NC$ or $Y = \exists x D$ (for an $\mathcal{ELH}_\Sigma$-concept $D$), and $\mathcal{T}_1 \models Y \subseteq A_1'$, i.e. $\mathcal{T}_1 \models C_j \subseteq A_1'$. By applying the induction hypothesis we can infer that $\mathcal{T}_2 \models C_j \subseteq A_2'$ holds, and thus $\mathcal{T}_2 \models C \subseteq A_2'$. Hence, we have $\mathcal{T}_2 \models C \subseteq A_2$ for every $A_1' \in \text{non-}\mathcal{T}_1(A_2)$, i.e. $\mathcal{T}_2 \models C \subseteq A_2$.
Lemma 77  Let $\mathcal{R}_1$ and $\mathcal{R}_2$ be normalised and acyclic $\mathcal{EL}$-terminologies, and $\Sigma$ be a signature. Additionally, let $X_1, X_2 \in N_C$ such that $(\mathcal{R}_1, X_1) \sim_{\Sigma, \mathcal{EL}} (\mathcal{R}_2, X_2)$, and let

$$M_{(X_1, X_2)} := \text{COVER}_{\mathcal{L}}(\mathcal{R}_1, \mathcal{R}_2, \Sigma, X_1, X_2)$$

computed by Algorithm 4. Then for every $\mathcal{M} \in M_{(X_1, X_2)}$, we have that for every $\mathcal{EL}_\Sigma C$, $\mathcal{R}_1 \models C \subseteq X_1$ implies that $\mathcal{M} \models C \subseteq X_2$.

Proof  First, we define the relation $\triangleright_{\mathcal{R}_1} \subseteq N_C \times N_C$ as follows: for $X, Y \in N_C$ we set $X \triangleright Y$ iff either there exists $X \equiv \exists r Y \in \mathcal{R}_1$ or there exists $X \equiv Y_1 \cap \ldots \cap Y_n \in \mathcal{R}_1$ such that $Y_i = Y$ for some $1 \leq i \leq n$. Note that $\triangleright_{\mathcal{R}_1}$ is well-founded as $\mathcal{R}_1$ is acyclic. The proof now proceeds by induction on $\triangleright_{\mathcal{R}_1}$.

Let $X_1, X_2 \in N_C$ such that $(\mathcal{R}_1, X_1) \sim_{\Sigma, \mathcal{EL}} (\mathcal{R}_2, X_2)$ and let $\mathcal{M} \in M_{(X_1, X_2)}$. We now distinguish between the following cases.

If $X_1$ is not $\Sigma$-entailed w.r.t. $\mathcal{R}_1$, then $\mathcal{M} = \emptyset$ and there does not exist $C \in \mathcal{EL}_\Sigma$ with $\mathcal{R}_1 \models C \subseteq X_1$. Hence, it trivially holds for every $C \in \mathcal{EL}_\Sigma$ with $\mathcal{R}_1 \models C \subseteq X_1$ that $\mathcal{M} \models C \subseteq X_2$.

Otherwise, $X_1$ is $\Sigma$-entailed w.r.t. $\mathcal{R}_1$. We further distinguish between the following cases. If $X_1$ is not complex $\Sigma$-entailed w.r.t. $\mathcal{R}_1$, then let $C \in \mathcal{EL}_\Sigma$ such that $\mathcal{R}_1 \models C \subseteq X_1$. Then by Lemma 74 there exists $B \in \text{sub}_0(C)$ such that $\mathcal{R}_1 \models B \subseteq X_1$. As $(\mathcal{R}_1, X_1) \sim_{\Sigma, \mathcal{EL}} (\mathcal{R}_2, X_2)$ there exists $J \in \text{Just}_{\mathcal{R}_2}(B \subseteq X_2)$ with $J \subseteq \mathcal{M}$, which implies that $\mathcal{M} \models C \subseteq X_2$.

Otherwise, $X_1$ is complex $\Sigma$-entailed w.r.t. $\mathcal{R}_1$. We distinguish between the following cases. If $X_1 \equiv \exists r Y_1 \in \mathcal{R}_1$ such that $r$ or $Y_1$ is not $\Sigma$-entailed w.r.t. $\mathcal{R}_1$, then let $C \in \mathcal{EL}_\Sigma$ such that $\mathcal{R}_1 \models C \subseteq X_1$, and therefore $\mathcal{R}_1 \models C \subseteq \exists r Y_1$. By Lemma 31 we can infer that there exists $B \in \text{sub}_0(C)$ with $\mathcal{R}_1 \models B \subseteq \exists r Y_1$. We can then show that $\mathcal{M} \models C \subseteq X_2$ as above.

If $X_1 \equiv \exists r Y_1 \in \mathcal{R}_1$ such that $\mathcal{R}_1 \models s \subseteq r, s \in \Sigma$ and $Y_1$ is $\Sigma$-entailed w.r.t. $\mathcal{R}_1$, then let $C \in \mathcal{EL}_\Sigma$ such that $\mathcal{R}_1 \models C \subseteq X_1$, and therefore $\mathcal{R}_1 \models C \subseteq \exists r Y_1$. By Lemma 31 either (a) there exists $B \in \text{sub}_0(C)$ with $\mathcal{R}_1 \models B \subseteq \exists r Y_1$, or (b) there exists $\exists r' C \in \text{sub}_0(C)$ with $\mathcal{R}_1 \models C' \subseteq Y_1$ and $\mathcal{R}_1 \models r' \subseteq s$. For (a), we can show that $\mathcal{M} \models C \subseteq X_2$ as above.

For (b), we can infer that for every $X'_2 \in \text{non-} rdf\mathcal{R}_2 X_2$ there exists $X' \equiv \exists r' Y_2 \in \mathcal{R}_2$ such that $\mathcal{R}_2 \models r' \subseteq s$ and $(\mathcal{R}_1, Y_1) \sim_{\Sigma, \mathcal{EL}} (\mathcal{R}_2, Y_2)$ as $(\mathcal{R}_1, X_1) \sim_{\Sigma, \mathcal{EL}} (\mathcal{R}_2, X_2)$. Moreover, for every $X'_2 \in \text{non-} rdf\mathcal{R}_2 X_2$ there exists $\mathcal{M}'_{X'_2} \in M_{(Y_1, Y_2)}$ (Line 8 in Algorithm 6) such that $\mathcal{M}'_{X'_2} \cup \{X'_2 \equiv \exists r Y'_2\} \subseteq \mathcal{M}$ (Line 10 in Algorithm 6).

By applying the induction hypothesis we have that for every $\mathcal{EL}$ concept $D$, $\mathcal{R}_1 \models D \subseteq Y'_2$ implies that $\mathcal{M}'_{X'_2} \models D \subseteq Y'_2$ for every $X'_2 \in \text{non-} rdf\mathcal{R}_2 X_2$. Consequently, we have that $\mathcal{M} \models C' \subseteq X'_2$ for every $X'_2 \in \text{non-} rdf\mathcal{R}_2 X_2$. Finally, as max-tree $\mathcal{F}(X'_2) \subseteq \mathcal{M}$ (Line 3 in Algorithm 6), we have

$\mathcal{M} \models C \subseteq X_2$.

If $X_1 \equiv Y_1 \cap \ldots \cap Y_m \in \mathcal{R}_1$, then let $C \in \mathcal{EL}_\Sigma$ such that $\mathcal{R}_1 \models C \subseteq X_1$, i.e. $\mathcal{R}_1 \models C \subseteq X'_1$ for every $X'_1 \in \text{non-} rdf\mathcal{R}_1 X_1$. As $M_{(X_1, X_2)} \neq \emptyset$, we can infer that there exists $\Gamma \in \text{DefForest}_{\mathcal{R}_1}(X_2)$ such that for every $X'_2 \in \text{leaves}(\Gamma)$ there exists $\xi(X'_2) \in \text{non-} rdf\mathcal{R}_1 X_1$ with $(\mathcal{R}_1, X'_2) \sim_{\Sigma, \mathcal{EL}} (\mathcal{R}_2 \setminus \delta_\Gamma, X'_2)$ and there exists $\mathcal{M}'_{X'_2} \in \text{COVER}_{\mathcal{L}}(\mathcal{R}_1, \mathcal{R}_2 \setminus \delta_\Gamma, \Sigma, \xi(X'_2), X'_2)$ with $\mathcal{M}'_{X'_2} \subseteq \mathcal{M}$ (Lines 4 to 17 in Algorithm 7).
3.1 Subsumption Justifications of $\mathcal{ELH}$-Terminologies

By applying the induction hypothesis we have for every $X'_2 \in \text{leaves}(\Gamma)$ that $\mathcal{M}_{X'_2}$ is a $(\mathcal{T}_1, \xi(X'_2), \Sigma)$-subsume module of $\mathcal{T}_2 \setminus \delta_{\Gamma}$ w.r.t. $X'_2$, i.e. $\mathcal{M}_{X'_2} \models C \sqsubseteq X'_2$ and $\mathcal{M} \models C \sqsubseteq X'_2$ hold as $\mathcal{T}_1 \models C \sqsubseteq \xi(X'_2)$. Consequently, we have $\mathcal{M} \models C \sqsubseteq X_2$ as $\Gamma \subseteq \mathcal{M}$ (Line 16 in Algorithm 7).

□

Lemma 78 Let $\mathcal{T}_1$ and $\mathcal{T}_2$ be normalised and acyclic $\mathcal{ELH}$-terminologies, and $\Sigma$ be a signature. Additionally, let $X_1, X_2 \in \mathbb{N}_C$ such that $(\mathcal{T}_1, X_1) \sim_{\Sigma, \delta, \Sigma} (\mathcal{T}_2, X_2)$, and let

$$
\mathcal{M}_{(X_1, X_2)}^= := \text{Cover}(\mathcal{T}_1, \mathcal{T}_2, \Sigma, X_1, X_2)
$$

computed by Algorithm 4. Moreover, let $\mathcal{M} \subseteq \mathcal{T}_2$. If $\mathcal{T}_1 \models C \subseteq X_1$ implies $\mathcal{M} \models C \subseteq X_2$ for every $\mathcal{EL}$ concept $C$. Then we have that there exists $\mathcal{M}' \in \mathcal{M}_{(X_1, X_2)}^=$ such that $\mathcal{M}' \subseteq \mathcal{M}$.

Proof First, we define the relation $\triangleright \mathcal{T}_1 \subseteq \mathbb{N}_C \times \mathbb{N}_C$ as follows: for $X, Y \in \mathbb{N}_C$ we set $X \triangleright Y$ iff either there exists $X \equiv \exists r Y \in \mathcal{T}_1$ or there exists $X \equiv Y \sqcap \ldots \sqcap Y_n \in \mathcal{T}_1$ such that $Y_i = Y$ for some $1 \leq i \leq n$. Note that $\triangleright$ is well-founded as $\mathcal{T}_1$ is acyclic.

The proof now proceeds by induction on $\triangleright$. Let $X_1, X_2 \in \mathbb{N}_C$ with $(\mathcal{T}_1, X_1) \sim_{\Sigma, \delta, \Sigma} (\mathcal{T}_2, X_2)$ and let $\mathcal{M}$ be a $(\mathcal{T}_1, X_1, \Sigma)$-subsume module of $\mathcal{T}_2$ w.r.t. $X_2$. Additionally, let $S$ be a $\Sigma$-subsume simulation from $\mathcal{T}_1$ to $\mathcal{M}$ with $(X_1, X_2) \in S$.

First, we observe that for every $B \in \Sigma$ with $\mathcal{T}_1 \models B \subseteq X_1$, there exists $J_{B \subseteq X_1}^\mathcal{M} \in \text{Just}_{\mathcal{T}_1}(B \subseteq X_2)$ with $J_{B \subseteq X_1}^\mathcal{M} \subseteq \mathcal{M}$.

We now distinguish between the following cases. If $X_1$ is not $\Sigma$-entailed w.r.t. $\mathcal{T}_1$, we set $\mathcal{M}' := \emptyset$. Then it holds that $\mathcal{M}' \in \mathcal{M}_{(X_1, X_2)}^=$ (Line 3 in Algorithm 4) and $\mathcal{M}' \subseteq \mathcal{M}$.

Otherwise, $X_1$ is $\Sigma$-entailed w.r.t. $\mathcal{T}_1$, and we proceed as follows. If $X_1$ is not complex $\Sigma$-entailed w.r.t. $\mathcal{T}_1$, we set $\mathcal{M} := \bigcup_{B \in \Sigma} J_{B \subseteq X_1}^\mathcal{M}$. Then it holds that $\mathcal{M}' \in \mathcal{M}_{(X_1, X_2)}^=$ (Line 5 in Algorithm 4 and Algorithm 5) and $\mathcal{M}' \subseteq \mathcal{M}$.

Otherwise, $X_1$ is complex $\Sigma$-entailed w.r.t. $\mathcal{T}_1$, which implies that $X_1$ is not pseudo-primitive in $\mathcal{T}_1$ by Lemma 73. We now distinguish between the following two cases.

If $X_1 \equiv \exists r Y_1 \in \mathcal{T}_1$, we analyse the following subcases.

If $r \not\in \Sigma$ or $Y_1$ is not $\Sigma$-entailed w.r.t. $\mathcal{T}_1$, then for $\mathcal{M}' := \bigcup_{B \in \Sigma} J_{B \subseteq X_1}^\mathcal{M}$ it holds that $\mathcal{M}' \in \mathcal{M}_{(X_1, X_2)}^=$ (Line 5 in Algorithm 4 and Algorithm 5) and $\mathcal{M}' \subseteq \mathcal{M}$.

Otherwise, we assume that $Y_1$ and $r$ is $\Sigma$-entailed w.r.t. $\mathcal{T}_1$, $\mathcal{T}_1 \models s \sqsubseteq r$ and $s \in \Sigma$. By Condition (S$^\mathcal{T}_1$) we have that for every $X'_2 \in \text{non-conj}_\mathcal{M}(\mathcal{T}_2)$ there exists $Y'_2 \equiv \exists r Y'_2 \in \mathcal{M}$ such that $(Y_1, X'_2) \in S$.

Now we show that max-tree $\xi_\mathcal{T}_2(X_2) \subseteq \mathcal{M}$ by showing that max-tree $\xi_\mathcal{T}_2(X_2) = \text{max-tree}_\mathcal{M}(X_2)$. It immediately holds that max-tree $\xi_\mathcal{T}_2(X_2) \subseteq \text{max-tree}_\mathcal{M}(X_2)$ as $\mathcal{M} \subseteq \mathcal{T}_2$. Let $\alpha \in \text{max-tree}_\mathcal{M}(X_2)$. If we assume towards a contradiction that $\alpha \notin \text{max-tree}_\mathcal{T}_2(X_2)$, then there exists $\xi \in \text{leaves}(\text{max-tree}_\mathcal{T}_2(X_2))$ such that $\xi \in \text{def}_\mathcal{T}_2$ and $\xi \equiv \exists r Y \in \mathcal{M} \subseteq \mathcal{T}_2$. We have derived a contradiction.
Let \( X'_1 \in \text{non-conj}_\mathcal{H}(X_2) \). By Condition \((S^\rightarrow)\) there exists \( \mathcal{A}_{X'_1}^\mathcal{H} := X'_1 \equiv \exists Y'. Y' \in \mathcal{M} \) with \( \mathcal{R}_2 \models s \subseteq r', \ s \in \Sigma \) and \( \langle \mathcal{R}_1, Y_1 \rangle \sim_{\sum, \mathcal{H}} \langle \mathcal{R}_2, Y'_2 \rangle \). Consequently, it holds that for every \( \mathcal{F}_T \) concept \( C \), \( \mathcal{R}_1 \models C \subseteq Y_1 \) implies \( \mathcal{M} \models C \subseteq Y'_2 \). By applying the induction hypothesis there exists \( \mathcal{M}^\mathcal{H}_{X'_1} \in \mathcal{M}^\mathcal{H}_{(Y_1, Y'_2)} \) such that \( \mathcal{M}^\mathcal{H}_{X'_1} \subseteq \mathcal{M} \).

We set
\[
\mathcal{M}' := \bigcup_{B \subseteq X_1} J_B^\mathcal{M} \cup \{ \text{max-tree}^\mathcal{M}_{B}(X_2) \} \cup \text{Just}_{\mathcal{R}_1}(s \subseteq r') \cup \bigcup_{X'_1 \in \text{non-conj}_\mathcal{H}(X_1)} \mathcal{M}^\mathcal{H}_{X'_1} \cup \{ \mathcal{A}_{X'_1}^\mathcal{H} \}.
\]

Then it holds that \( \mathcal{M}' \in \mathcal{M}^\mathcal{H}_{(X_1, X_2)} \) (Line 10 in Algorithm 4 and Algorithm 6) and \( \mathcal{M}' \subseteq \mathcal{M} \).

If \( X_1 \equiv Y_1 \cap \ldots \cap Y_m \in \mathcal{R}_1 \), then for every \( X'_2 \in \text{non-conj}_\mathcal{H}(X_2) \) there exists \( \xi(X'_2) \in \text{non-conj}_\mathcal{R}_1(X_1) \) such that \( \langle \xi(X'_2), X'_2 \rangle \in \Sigma \) by Condition \((S^\rightarrow)\). Hence, for \( \Gamma := \text{max-tree}^\mathcal{M}_{\mathcal{H}}(X_2) \) it holds that \( \Gamma \in \text{DefForest}_{\mathcal{R}_1}(X_2) \) and \( \Gamma \subseteq \mathcal{M} \).

Moreover, for every \( X'_2 \in \text{non-conj}_\mathcal{H}(X_2) \) it holds that for every \( \mathcal{F}_T \Sigma \) concept \( C \), \( \mathcal{R}_1 \models C \subseteq \xi(X'_2) \) implies \( \mathcal{M} \models C \subseteq X'_2 \).

By applying the induction hypothesis for every
\[
X'_2 \in \text{non-conj}_\mathcal{H}(X_2),
\]

there exists \( \mathcal{M}^\mathcal{H}_{X'_2} \in \mathcal{M}^\mathcal{H}_{(\xi(X'_2), X'_2)} \) such that \( \mathcal{M}^\mathcal{H}_{X'_2} \subseteq \mathcal{M} \). We set
\[
\mathcal{M}' := \bigcup_{B \subseteq X_1} J_B^\mathcal{M} \cup \bigcup_{X'_2 \in \text{non-conj}_\mathcal{H}(X_2)} \mathcal{M}^\mathcal{H}_{X'_2}.
\]

Note that for every \( X'_2 \in \text{non-conj}_\mathcal{H}(X_2) \), \( \langle \mathcal{R}_1, \xi(X'_2) \rangle \sim_{\sum, \mathcal{H}} \langle \mathcal{R}_2 \setminus \delta, X'_2 \rangle \) holds as \( \langle \xi(X'_2), X'_2 \rangle \in \Sigma \) and \( \mathcal{M} \subseteq \mathcal{R}_2 \setminus \delta \).

Then it holds that \( \mathcal{M}' \in \mathcal{M}^\mathcal{H}_{(X_1, X_2)} \) and therefore, \( \mathcal{M}' \in \mathcal{M}^\mathcal{H}_{(X_1, X_2)} \) (Algorithm 7 and Line 13 in Algorithm 4) and \( \mathcal{M}' \subseteq \mathcal{M} \).

\[\square\]

**Theorem 70** Let \( \mathcal{T} \) be an acyclic, normalised \( \mathcal{E}_\Sigma \mathcal{H} \)-terminology, \( X \in \mathcal{N}_X \) and \( \Sigma \) be a signature. Additionally, let \( \mathcal{M}^\mathcal{H}_{X} := \text{COVER}_\mathcal{H}(\mathcal{F}, X, \Sigma, \mathcal{T}, X) \) computed by Algorithm 4. Then \( \mathcal{M}^\mathcal{H}_{X} \) is the set of all \( \langle X, \Sigma \rangle \)-subsumejustifications of \( \mathcal{T} \).

**Proof** By Lemma 77, Lemma 78 and Definition 58, we have that \( \mathcal{M}^\mathcal{H}_{X} \) is a cover of of the set of \( \langle X, \Sigma \rangle \)-subsume modules of \( \mathcal{T} \). Let \( \mathcal{M} \in \mathcal{M}^\mathcal{H}_{X} \).

Then we have that \( \mathcal{M} \) is a cover of the set of \( \langle X, \Sigma \rangle \)-submure modules of \( \mathcal{T} \). Let \( \mathcal{M} \in \mathcal{M}^\mathcal{H}_{X} \).

We prove by assuming towards a contradiction. We assume that there exist an \( \mathcal{M}' \subseteq \mathcal{M} \) such that \( \mathcal{M}' \) is a \( \langle X, \Sigma \rangle \)-subsume module of \( \mathcal{T} \). As \( \mathcal{M}^\mathcal{H}_{X} \) is initialized as \( \{ \emptyset \} \), we enumerate all possible situations

\[\square\]
3.2 Subsumption Justifications of $\mathcal{ELH}^\nu$-Terminologies

In this section, we extend the notion of subsumption justification to $\mathcal{ELH}^\nu$ language. For a signature $\Sigma$, let $\Sigma^{\text{dom}} = \{ \text{dom}(i) \mid i \in N_R \cap \Sigma \}$ and $\Sigma^{\text{ran}} = \{ \text{ran}(i) \mid i \in N_R \cap \Sigma \}$ be the sets consisting of concepts of the form $\text{dom}(i)$ and $\text{ran}(i)$ for every role name $i$ in $\Sigma$, respectively. Similar to Definition 53, we can define subsumption justifications for $\mathcal{ELH}^\nu$-terminology as follows.

**Definition 79 (Subsumption Justification for $\mathcal{ELH}^\nu$-terminology)** Let $\Sigma$ be a signature, $\mathcal{T}$ a normalised $\mathcal{ELH}^\nu$-terminology, and let $r \in N_R$, $s \in N_R \cap \Sigma$ and $X \in N_C \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in N_R \}$. We say that

- $\mathcal{M} \subseteq \mathcal{T}$ is an $\langle X, \Sigma \rangle$-subsumee module of $\mathcal{T}$ iff for every $D \in \mathcal{ELH}^{\text{ran}}$ such that $\mathcal{T} \models D \subseteq X$, $\mathcal{M} \models D \subseteq X$.

- $\mathcal{M} \subseteq \mathcal{T}$ is an $\langle X, \Sigma \rangle$-subsumer module $\mathcal{M}$ of $\mathcal{T}$ iff for every $C \in \mathcal{ELH}$ such that $\mathcal{T} \models X \subseteq C$, $\mathcal{M} \models X \subseteq C$;

- $\mathcal{M} \subseteq \mathcal{T}$ is an $\langle r, \Sigma \rangle$-role subsumption module of $\mathcal{T}$ iff for every $s \in \Sigma$ such that $\mathcal{T} \models \alpha$ where $\alpha$ is of the form either $r \subseteq s$ or $s \subseteq r$, $\mathcal{M} \models \alpha$.

Additionally, a set $\mathcal{M}$ is called an $\langle X, \Sigma \rangle$-subsumption module of $\mathcal{T}$ iff $\mathcal{M}$ is an $\langle X, \Sigma \rangle$-subsumee and $\langle X, \Sigma \rangle$-subsumer module of $\mathcal{T}$. An $\langle X, \Sigma \rangle$-subsumee (resp. subsumer, subsumption) justification is an $\langle X, \Sigma \rangle$-subsumee (resp. subsumer, subsumption) module of $\mathcal{T}$ that is minimal w.r.t. $\subseteq$. Similarly, a $\langle r, \Sigma \rangle$-role subsumption justification of $\mathcal{T}$ is an $\langle r, \Sigma \rangle$-role subsumption module of $\mathcal{T}$ that is minimal w.r.t. $\subseteq$.

We denote a $\langle X, \Sigma \rangle$-subsumee (resp. subsumer, subsumption) justification as $\mathcal{J}_{\mathcal{T}}(X, \Sigma)$ (resp. $\mathcal{J}_{\mathcal{T}}^\nu(X, \Sigma)$, $\mathcal{J}_{\mathcal{T}}(X, \Sigma)$). Note that there may exist multiple $\langle X, \Sigma \rangle$-(subsumer, subsumee) subsumption justifications. So we denote the set of all $\langle X, \Sigma \rangle$-subsumee (resp. subsumer, subsumption) justifications as $\mathcal{J}_{\mathcal{T}}^\nu(X, \Sigma)$ (resp. $\mathcal{J}_{\mathcal{T}}(X, \Sigma)$, $\mathcal{J}_{\mathcal{T}}(X, \Sigma)$). Similarly, we denote a $\langle r, \Sigma \rangle$-role subsumption justification of $\mathcal{T}$ as $\mathcal{J}_{\mathcal{T}}(r, \Sigma)$ and the set of all $\langle r, \Sigma \rangle$-role subsumption justification of $\mathcal{T}$ as $\mathcal{J}_{\mathcal{T}}(r, \Sigma)$. The donations are the same as subsumption justification on $\mathcal{ELH}^\nu$-terminology.

According to the Definition 79, it is easy to compute subsumption justifications.

**Theorem 80** Let $\mathcal{T}$ be a normalised $\mathcal{ELH}^\nu$-terminology, let $\Sigma$ be a signature, and let $X \in N_C$. Additionally, let $\mathcal{J}_{\mathcal{T}}^\nu(X, \Sigma)$ (resp. $\mathcal{J}_{\mathcal{T}}(X, \Sigma)$, $\mathcal{J}_{\mathcal{T}}(X, \Sigma)$) be the set of all $\langle X, \Sigma \rangle$-subsumee justifications (resp. subsumer justification, subsumption justification). We have that

$$\mathcal{J}_{\mathcal{T}}^\nu(X, \Sigma) := \text{Minimise}_{\subseteq} (\mathcal{J}_{\mathcal{T}}^\nu(X, \Sigma) \otimes \mathcal{J}_{\mathcal{T}}(X, \Sigma)).$$
Example 81 Let $\Sigma = \{X, Y, r\}$ and let $T = \{\alpha_1, \alpha_2, \alpha_3\}$, where $\alpha_1 := \text{ran}(r) \subseteq X$, $\alpha_2 := Y \subseteq X$, $\alpha_3 := X \equiv \exists r.Z$. Then both sets, $M = \{\alpha_1, \alpha_3\}$ and $T$ itself, are $(X, \Sigma)$-subsume modules of $T$. Moreover, $M$ is a $(X, \Sigma)$-subsume justification of $T$.

We obtain the following propositions from together with Definition 79. Recall that we use ‘ran’ as an abbreviation for the query language $\mathcal{ELH}^r$.

Proposition 82 Let $T$ be a normalised $\mathcal{ELH}^r$-terminology, $\Sigma$ be a signature, $X \in N_C \cup \Sigma_{\text{dom}} \cup \Sigma_{\text{ran}}$ and $r \in \Sigma \cap N_R$. Then the following statements hold:

- $M$ is an $(X, \Sigma)$-subsumer module of $T$ iff $X \not\in \text{lhsWtn}^\text{ran}_T(M, T)$;
- $M$ is an $(X, \Sigma)$-subsume module of $T$ iff $X \not\in \text{rhsWtn}^\text{ran}_T(M, T)$;
- $M$ is an $(r, \Sigma)$-role subsumption module of $T$ iff $r \not\in \text{roleWtn}_T(M, T)$.

The algorithm for computing role subsumption justifications for $\mathcal{ELH}^r$-terminologies coincides with the algorithm for $\mathcal{EL}^r$-terminologies, cf. Section 3.1.1. Now we present the algorithms for computing subsumer and subsume justifications for $\mathcal{ELH}^r$-terminologies.

3.2.1 Computing Subsumer Justifications

Similar to the algorithm introduced in Section 3.1.2, we use a specific notion of a subsumer simulation to guide us when collecting the relevant axioms for subsumer justifications. First, we extend the definition of a subsumer simulation to $\mathcal{ELH}^r$-terminologies.

Definition 83 (Subsumer Simulation for $\mathcal{ELH}^r$-terminology) Let $T_1$ and $T_2$ be two normalised $\mathcal{ELH}^r$-terminologies, and let $\Sigma$ be a signature. Moreover, let $N(T_1, \Sigma) = \{X, \text{dom}(r), \text{ran}(r) \mid X, r \in (\text{sig}(T) \cup \Sigma), X \in N_C, r \in N_R\}$, where $T$ ranges over terminologies. A relation $S \subseteq N(T_1, \Sigma) \times N(T_2, \Sigma)$ is a $\Sigma$-subsumer simulation from $T_1$ to $T_2$ iff the following conditions $(S_{N_C}^\Sigma)$ and $(S_{\Sigma}^\Sigma)$ are both satisfied:

$(S_{N_C}^\Sigma)$ if $(X_1, X_2) \in S$, then for every $\varphi \in \Sigma \cup \Sigma_{\text{dom}}$ with $T_1 \models X_1 \subseteq \varphi$, it holds that $T_2 \models X_2 \subseteq \varphi$;

$(S_{\Sigma}^\Sigma)$ if $(X_1, X_2) \in S$, $X_1' \models \exists r Y_1 \in T_1$ with $\models r \in \{\subseteq, \equiv\}$ and $T_1 \models X_1 \subseteq X_1'$, then for every $s \in \Sigma$ with $T_1 \models s \subseteq s$ and $X_1' \models \exists r Y_2 \subseteq Y_2$ with $\models r \in \{\subseteq, \equiv\}$ such that $T_2 \models X_2 \subseteq X_2'$, $T_2 \models r' \subseteq s$ and $(Y_1, Y_2) \in S$.

We write $T_1 \sim_{\Sigma, \text{ran}} T_2$ iff there exists a $\Sigma$-subsumer simulation $S$ from $T_1$ to $T_2$ such that for every $\varphi \in (\Sigma \cap N_C) \cup \Sigma_{\text{dom}} \cup \Sigma_{\text{ran}}$; $(\varphi, \varphi) \in S$.

For $X_1, X_2 \in (\Sigma \cap N_C) \cup \Sigma_{\text{dom}} \cup \Sigma_{\text{ran}}$, we write $(T_1, X_1) \sim_{\Sigma, \text{ran}} (T_2, X_2)$ iff there exists a $\Sigma$-subsumer simulation $S$ from $T_1$ to $T_2$ with $(X_1, X_2) \in S$ for which $T_1 \sim_{\Sigma, \text{ran}} T_2$. 

A subsumer simulation captures the set of subsumers in the following way: If a \( \Sigma \)-subsumer simulation from \( \mathcal{T}_1 \) to \( \mathcal{T}_2 \) contains the pair \( (X_1, X_2) \), then \( X_2 \) entails w.r.t. \( \mathcal{T}_2 \) all subsumers of \( X_1 \) w.r.t. \( \mathcal{T}_1 \) that are formulated in the signature \( \Sigma \). Formally, we obtain the following theorem. Note that the right-hand side of an \( \mathcal{ELH}^{\tau} \)-inclusion ranges over \( \mathcal{EL} \)-concepts (cf. Definition 4).

**Lemma 84** Let \( \mathcal{T}_1 \) and \( \mathcal{T}_2 \) be normalised \( \mathcal{ELH}^{\tau} \)-terminologies, \( \Sigma \) a signature and \( X_1 \in N_C \cup \Sigma_{\text{dom}} \cup \Sigma_{\text{ran}} \). Additionally, let \( \langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma_{\text{ran}}} \langle \mathcal{T}_2, X_2 \rangle \). Then, for every \( D \in \mathcal{EL}_{\Sigma} \): \( \mathcal{T}_1 \models X_1 \subseteq D \) implies \( \mathcal{T}_2 \models X_2 \subseteq D \).

We can update Algorithm 3 according to the new subsumer simulation and get an algorithm to compute subsumer justifications for \( \mathcal{ELH}^{\tau} \)-terminology, which is shown in Algorithm 8. Compared with Algorithm 3, additionally, we need to collect the justifications of the inclusion of the form \( X \subseteq \text{dom}(r) \) that follows from \( \mathcal{T} \). Moreover, the condition of for-loop in Algorithm 3 changes according to the new subsumer simulation definition.

**Algorithm 8:** Computing the set of all Subsumer Justifications

```
function COVER\rightarrow (\mathcal{T}, X, \Sigma)
M_{X} := \{\emptyset\}
for every \( \phi \in (\Sigma \cap N_C) \cup \{\text{dom}(r) \mid r \in \Sigma\} \) such that \( \mathcal{T} \models X \subseteq \phi \)
M_{X} := M_{X} \otimes \text{Just}_{\mathcal{T}}(X \subseteq \phi)
end
for every \( Y \; \triangleright_{1} \exists r. Z \in \mathcal{T} \; (\triangleright_{1} \in \{\subseteq, \equiv\}) \) and \( s \in \Sigma \cap N_R \) such that \( \mathcal{T} \models X \subseteq Y \) and \( \mathcal{T} \models r \subseteq s \)
M_{Y,Z} := \{\emptyset\}
for every \( s \in \{s' \in \Sigma \cap N_R \mid \mathcal{T} \models r \subseteq s'\} \)
for every \( Y' \; \triangleright_{2} \exists r'. Z' \in \mathcal{T} \; (\triangleright_{2} \in \{\subseteq, \equiv\}) \) such that \( \mathcal{T} \models X \subseteq Y' \), \( \mathcal{T} \models r' \subseteq s \), and \( \langle \mathcal{T}, Z \rangle \sim_{\Sigma_{\text{ran}}} \langle \mathcal{T}, Z' \rangle \)
M_{Y,Z} := M_{Y,Z} \otimes \text{Just}_{\mathcal{T}}(X \subseteq Y') \otimes \text{Just}_{\mathcal{T}}(r' \subseteq s)
end
end
M_{X} := M_{X} \otimes M_{Y,Z}
return \text{Minimise}_{\subseteq}(M_{X})
```

**Theorem 85** Let \( \mathcal{T} \) be an acyclic, normalised \( \mathcal{ELH}^{\tau} \)-terminology, and let \( \Sigma \) be a signature. Additionally, let \( X \in N_C \cup \Sigma_{\text{dom}} \cup \Sigma_{\text{ran}} \), and let \( M_{X} \triangleq \text{COVER}_{\rightarrow}(\mathcal{T}, X, \Sigma) \) computed by Algorithm 8. Then \( M_{X} \) is the set of \( (X, \Sigma) \)-subsumer justifications of \( \mathcal{T} \).
3.2.2 Computing Subsume Simulation Justifications

Similar to the algorithm for computing subsume justifications that presented in Section 3.1.3, we update the definition of \( \Sigma \)-entailment and \( \Sigma \)-subsume simulation to deal with range restrictions.

The axioms of the form \( \text{ran}(r) \subseteq X \) might cause non-trivial entailments. For example, let \( \mathcal{R}_1 = \{ X \equiv \exists Y. Y \equiv A_1 \cap A_2 \}, \mathcal{R}_2 = \mathcal{R}_1 \cup \{ \text{ran}(r) \subseteq A_1 \}, \Sigma = \{ X, A_1, A_2, r \}. \) Then we have \( \mathcal{R}_1 \models \exists r. (A_1 \cap A_2), \) however, as the axiom \( \text{ran}(r) \subseteq A_1 \in \mathcal{R}_2, \) the conjunct \( A_1 \) of \( Y \) is already covered by \( \alpha. \) Hence, when we define the notion of \( \Sigma \)-reachability, an additional parameter \( \zeta \in \{ \varepsilon \} \cup (\text{N}_R \cap \Sigma) \) is used. We call this additional parameter the context of a role, i.e. an expression of the form \( \text{ran}(\zeta). \)

We treat \( \varepsilon \) as a special role name and set \( \text{ran}(\varepsilon) = \top. \) The set of all role contexts, in symbols \( C^\Sigma, \) is defined as \( C^\Sigma = \{ \varepsilon \} \cup (\text{N}_R \cap \Sigma). \)

In the following, we extend the notions of \( \Sigma \)-entailment (Definition 63) and complex \( \Sigma \)-entailment (Definition 66) to \( \mathcal{ELH}^c \)-terminologies in order to deal with range restrictions.

**Definition 86 (\( \Sigma \)-Entailment for \( \mathcal{ELH}^c \)-subsumption)** Let \( \mathcal{T} \) be a normalised \( \mathcal{ELH}^c \)-terminology and \( \Sigma \) be a signature. For \( \zeta \in \text{N}_R \cup \{ \varepsilon \}, A \in \text{N}_C \) and \( s \in \text{N}_R, \) we say that:

(i) \( A \in \text{N}_C \) is (\( \Sigma, \text{ran}, \zeta \))-entailed in \( \mathcal{T} \) iff there is an \( \mathcal{ELH}^c \)-concept \( C \) such that \( \mathcal{T} \models \text{ran}(\zeta) \cap C \subseteq A; \)

(ii) \( s \in \text{N}_R \) is \( \Sigma \)-entailed in \( \mathcal{T} \) iff there exists \( s' \in \text{N}_R \cap \Sigma \) such that \( \mathcal{T} \models s' \subseteq s. \)

We now define the notion of a subsume simulation from \( \mathcal{R}_1 \) to \( \mathcal{R}_2 \) as a subset of \( \text{sig}^{\text{Nc}}(\mathcal{R}_1) \times \text{sig}^{\text{Nc}}(\mathcal{R}_2) \times C^\Sigma_{\mathcal{R}_1}, \) where \( C^\Sigma_{\mathcal{R}_1} := \{ \varepsilon \} \cup (\text{N}_R \cap (\Sigma \cup \text{sig}(\mathcal{R}_1))) \) is the range of role contexts.

**Definition 87 (Complex \( \Sigma \)-Entailment for \( \mathcal{ELH}^c \)-terminology)** Let \( \Sigma \) be a signature, \( \mathcal{T} \) a normalised and acyclic \( \mathcal{ELH}^c \)-terminology, and \( X \in \text{N}_C \cup \Sigma^{\text{dom}} \cup \Sigma^{\text{ran}}. \)

We say that \( X \) is complex (\( \Sigma, \text{ran}, \zeta \))-entailed w.r.t. \( \mathcal{T} \) iff for every \( Y \in \text{non-conj} \mathcal{T}(X) \) one of the following conditions hold:

(i) there exists \( B \in \mathcal{T}(\text{ran}, \zeta) \) such that \( \mathcal{T} \models B \subseteq Y \) and \( \mathcal{T} \not\models B \subseteq X; \)

(ii) there exists \( Y \equiv \exists r. Z \in \mathcal{T} \) and \( r \) and \( Z \) are each (\( \Sigma, \text{ran}, \zeta \))-entailed in \( \mathcal{T}. \)

Otherwise, \( X \) is said to be simply (\( \Sigma, \text{ran}, \zeta \))-entailed.

The concept name \( X \) being complex \( \Sigma \)-entailed w.r.t. \( \mathcal{T} \) states that every conjunct of \( X \) is either defined as a \( \Sigma \)-entailed existential restriction (Condition (ii)) or it is entailed by a \( \Sigma \)-concept name, dom- or ran-concept by which \( X \) is not entailed.

**Definition 88 (Subsume Simulation for \( \mathcal{ELH}^c \)-terminology)** Let \( \mathcal{R}_1 \) and \( \mathcal{R}_2 \) be two normalised \( \mathcal{ELH}^c \)-terminologies, and let \( \Sigma \) be a signature. A relation \( \mathcal{S} \subseteq \text{sig}^{\text{Nc}}(\mathcal{R}_1) \times \text{sig}^{\text{Nc}}(\mathcal{R}_2) \times C^\Sigma_{\mathcal{R}_1} \) is a \( \Sigma \)-subsume simulation from \( \mathcal{R}_1 \) to \( \mathcal{R}_2 \) iff the following conditions hold:
3.2 Subsumption Justifications of \( \mathcal{E} \mathcal{L} \mathcal{H}^r \)-Terminologies

\((S_{\text{rc}-\text{ran}})\) if \((X_1, X_2, \zeta) \in S\), then for each \(\phi \in \Sigma \cup \Sigma^\text{dom} \cup \{\text{ran}(\zeta) \mid \zeta \neq \epsilon\}\) and for each \(X'_2 \in \text{non-conj}_T(X_2)\) with \(T \not\models \text{ran}(\zeta) \subseteq X'_2\), \(T \models \phi \subseteq X_1\) implies \(T \models \phi \subseteq X'_2\):

\((S_{\text{r}-\text{ran}})\) if \((X_1, X_2, \zeta) \in S\) and \(X_1 \equiv \exists r Y_1 \in T\) such that \(T \models s \subseteq r\) for \(s \in \Sigma\) and \(Y_1\) is \((\Sigma, s)\)-entailed in \(T\), then for every \(X'_2 \in \text{non-conj}_T(X_2)\) not entailed by \(\text{dom}(s)\) or \(\text{ran}(\zeta)\) w.r.t. \(T\), there exists \(X'_2 \equiv \exists r Y_2 \in T\) such that \(T \models s \subseteq r'\) and \((Y_1, Y_2, s) \in S\);

\((S_{\text{ran}})\) if \((X_1, X_2, \zeta) \in S\) and \(X_1 \equiv Y_1 \cap \ldots \cap Y_n \in T\), then for every \(Y_2 \in \text{non-conj}_T(X_2)\) not entailed by \(\text{ran}(\zeta)\) w.r.t. \(T\), there exists \(Y_1 \in \text{non-conj}_T(X_1)\) not entailed by \(\text{ran}(\zeta)\) w.r.t. \(T\) with \((Y_1, Y_2, \epsilon) \in S\).

We write \(T_1 \sim_{\Sigma, \text{ran}} T_2\) iff there is a \(\Sigma\)-subsumee simulation \(S\) from \(T_1\) to \(T_2\) such that for every \(A, r \in \Sigma\), \((A, A, r) \in S\) and \((A, A, r) \in S\).

For \(\zeta \in \Sigma \cap N_R\), we write \((T_1, X_1) \sim_{\Sigma, \zeta, \text{ran}} (T_2, X_2)\) iff there is a \(\Sigma\)-subsumee simulation \(S\) from \(T_1\) to \(T_2\) with \((X_1, X_2, \zeta) \in S\) for which \(T_1 \sim_{\Sigma, \zeta, \text{ran}} T_2\).

**Lemma 89** Let \(T_1\) and \(T_2\) be normalised and acyclic \(\mathcal{E} \mathcal{L} \mathcal{H}^r\)-terminologies, and let \(\Sigma\) be a signature. Then: \(T_1 \sim_{\Sigma, \text{ran}} T_2\) iff \(\text{rhsWtn}^{\text{ran}}_\Sigma(T_1, T_2) = \emptyset\).

**Lemma 90** Let \(T_1\) and \(T_2\) be two normalised and acyclic \(\mathcal{E} \mathcal{L} \mathcal{H}^r\)-terminologies, and let \(\Sigma\) be a signature. It holds that \((T_1, X_1) \sim_{\Sigma, \zeta, \text{ran}} (T_2, X_2)\) iff for every \(C \in \mathcal{E} \mathcal{L} \Sigma:\ T_1 \models \text{ran}(\zeta) \cap C \subseteq X_1\) implies \(T_2 \models \text{ran}(\zeta) \cap C \subseteq X_2\).

Next we devise the following algorithms for computing subsumee justifications for \(\mathcal{E} \mathcal{L} \mathcal{H}^r\)-terminologies. The notions that we use in the algorithm are the same as the same notions we introduced in Section 3.1.3 unless we revised them in this section.

Based on the notion of a subsumee simulation, we present Algorithm 9 for Computing the set of the subsumee justifications for a given \(\mathcal{E} \mathcal{L} \mathcal{H}^r\)-terminology \(T\), a concept \(X \in N_C\) and a signature \(\Sigma\). The function call for obtaining the \((X, \Sigma)\)-subsumee justifications of \(T\) is \(\text{COVER}_\Sigma(T, X, \Sigma, T, X, \epsilon)\).

The following theorem states that Algorithm 9 can be used to compute a cover of the set of subsumee modules, which outputs all subsumee justifications via the operator \(\text{Minimise}_\Sigma(\cdot)\).

**Theorem 91** Let \(T\) be an acyclic, normalised \(\mathcal{E} \mathcal{L} \mathcal{H}^r\)-terminology, \(X \in N_C \cup \Sigma^\text{dom} \cup \Sigma^\text{ran}\) and \(\Sigma\) be a signature. Additionally, let

\[
\mathcal{M} := \text{Minimise}_\Sigma(\text{COVER}_\Sigma(T, X, \Sigma, T, X, \epsilon) \otimes \bigotimes_{r \in \Sigma \cap N_R} \text{COVER}_\Sigma(T, X, \Sigma, T, X, r))
\]

computed recursively by Algorithm 9. Then \(\mathcal{M}\) is the set of all \((X, \Sigma)\)-subsumee justifications of \(T\).
The difference is that we use Lemma 34 instead of Lemma 31 to take care of role restrictions in all ⟨...⟩-terminology.

Algorithm 9: Computing the set of all Subsumee Justifications for an $\mathcal{ELH}^\ast$-terminology

1. function $\text{COVER}_\ast(T_1, X_1, \Sigma, T_2, X_2, \zeta)$
2.   if $X_1$ is not $\langle \Sigma, \text{ran, } \zeta \rangle$-entailed w.r.t. $T_1$ then
3.     return $\emptyset$
4.   end
5.   $M^+_\ast(X_1, X_2) := \text{COVER}_\ast(T_1, X_1, \Sigma, T_2, X_2, \zeta)$
6.   if $X_1$ is not complex $\langle \Sigma, \text{ran, } \zeta \rangle$-entailed in $T_1$ then
7.     return $\text{Minimise}_\subseteq(M^+_\ast(X_1, X_2))$
8.   end
9.   if $X_1 \equiv \exists r \in T_1$, and $r$ is $\Sigma$-entailed and $Y$ is $\langle \Sigma, \text{ran, } \zeta \rangle$-entailed w.r.t. $T_1$ then
10.     $M^+_\ast(X_1, X_2) := M^+_\ast(X_1, X_2) \otimes \text{COVER}_\ast(T_1, X_1, \Sigma, T_2, X_2, \zeta)$
11.   end
12. else if $X_1 \equiv Y_1 \cap \ldots \cap Y_m \in T_1$ then
13.     $M^+_\ast(X_1, X_2) := M^+_\ast(X_1, X_2) \otimes \text{COVER}_\ast(T_1, X_1, \Sigma, T_2, X_2, \zeta)$
14. end
15. return $\text{Minimise}_\subseteq(M^+_\ast(X_1, X_2))$

Similar to $\mathcal{ELH}$-terminology $T$, our algorithm for computing subsumption justifications in $\mathcal{ELH}^\ast$-terminology runs in time exponential in the size of $T$ and signature.

The idea of the proof of the lemmas and theorems in this section is similar with Section 3.1.4. The difference is that we use Lemma 34 instead of Lemma 31 to take care of role restrictions in $\mathcal{ELH}^\ast$-terminology.

Proposition 92 Let $T$ be a normalised $\mathcal{ELH}^\ast$-terminology, $\Sigma$ a signature, $X \in N_C$, and $\varphi \in N_C \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in N_R \}$. The algorithm for computing all $\langle \varphi, \Sigma \rangle$-subsumer justifications and all $\langle X, \Sigma \rangle$-subsumer justifications runs in EXPTIME in the size of $T$.

Algorithm 10: Computing the set of all Subsumee Projection Justifications for an $\mathcal{ELH}^\ast$-terminology ($\mathcal{S}^\ast_{N_C \otimes}$)

1. function $\text{COVER}_{\ast_{N_C \otimes}}(T_1, X_1, \Sigma, T_2, X_2, \zeta)$
2.   $M^+_{\ast_{N_C \otimes}}(X_1, X_2) = \{\emptyset\}$
3.   for every $B \in \Sigma \cup \Sigma^{\text{dom}} \cup \{ \text{ran}(\zeta) \mid \zeta \neq \epsilon \}$ such that $T_1 \models B \subseteq X_1$
4.     for every $X_2 \in \text{non-conf}_{T_2}(X_1)$ such that $\zeta = \epsilon$ or $T_2 \models \text{ran}(\zeta) \subseteq X_2$
5.       $M^+_{\ast_{N_C \otimes}}(X_1, X_2) := M^+_{\ast_{N_C \otimes}}(X_1, X_2) \otimes \text{Just}_{\otimes}(B \subseteq X_2)$
6.   end
7. end
8. return $\text{Minimise}_\subseteq(M^+_{\ast_{N_C \otimes}}(X_1, X_2))$
3.3 Evaluation

We have implemented our algorithms for computing subsumption justifications and for computing all minimal modules for $\mathcal{ELH}$-terminology in Java. In the evaluation, we first show the feasibility of computing subsumption justifications; The tool we use to compute justifications is BEACON [2].

We have evaluated the performance of the implementation using two prominent biomedical ontologies: Snomed CT (version Jan 2016), an $\mathcal{ELH}$-terminology consisting of 317891 axioms, and NCI (version 16.03d), an $\mathcal{EL}$-terminology containing 165341 axioms. All the experiments were conducted on the machines equipped with Intel Xeon Core 4 Duo CPU running at 2.50GHz and with 64GiB RAM. An execution timeout is 10 minutes.

Moreover, Table 3.1 details how the computation time was spent on different sub-tasks which determined the bottleneck of our tool. Indeed, 94.6% of the computation time was spent by BEACON on computing all justifications for concept name inclusions. Therefore, a considerable boost in performance of our tool can be expected by precomputing such justifications.

Computation of all Subsumption Justifications

Table 3.2 shows the results obtained for computing all subsumption justifications. The first row indicates the ontology used in each experiment. The experiments are divided into four categories according to the numbers of concept and role names included in an input signature, as specified in the second row. For each category, we generated 1000 random signatures and computed the corresponding subsumption justifications for each concept name in the signature. Row 3 shows that multiple subsumption justifications can exist in real-world ontologies, e.g., there are 1328 subsumption justifications for a random signature consisting of 30 concept and 10 role names in Snomed CT. Meanwhile, Row 4 reports the cardinality of subsumption justifications, e.g., the largest one having 27 axioms for a signature of 30 concept and 10 role names from NCI. Row 5 shows that the subsumption justifications for more than 82.4% of random signatures

Algorithm 11: Computing the set of all Subsumption Projection Justifications for an $\mathcal{ELH}'$-terminology $(\mathcal{S}\mathcal{T}^-\mathcal{L})$

1. function $\text{COVER}^-\mathcal{T}$ $(\mathcal{T}, X_1, \Sigma, \mathcal{R}, X_2, \zeta)$
2. Let $\alpha_{X_1} := X_1 \equiv \exists r. Y_1 \in \mathcal{T}_1$
3. $\mathcal{M}^-_{(X_1,X_2)} := \{\text{max-tree } \mathcal{T}_2(X_2)\}$
4. for every $s \in \Sigma \cap \mathcal{N}_R$ such that $\mathcal{T}_1 \models s \sqsubseteq r$ do
5. for every $X'_2 \in \text{non-conj}_\mathcal{R}(X_2)$ such that $\zeta \neq \epsilon$ implies $\mathcal{R}_2 \not\models \text{ran}(\zeta) \sqsubseteq X'_2$ and $\mathcal{R}_2 \not\models \text{dom}(s) \sqsubseteq X'_2$ do
6. Let $\alpha_{X'_2} := X'_2 \equiv \exists r' Y'_2 \in \mathcal{R}_2 \mathcal{M}^-_{(Y'_2)} := \text{COVER}^-\mathcal{T}(\mathcal{T}_1, Y_1, \Sigma, \mathcal{R}_2, Y'_2, s)$
7. $\mathcal{M}^-_{(X_1,X_2)} := \mathcal{M}_{(X_1,X_2)} \otimes \{\{ \alpha_{X'_2} \}\} \otimes \text{Just}_{\mathcal{R}} (s \sqsubseteq r) \otimes \mathcal{M}^-_{Y'_2}$
8. end
9. end
10. return $\text{Minimise}_\subseteq (\mathcal{M}_{(X_1,X_2)})$
Algorithm 12: Computing the set of all Subsumee Justifications for an $\mathcal{ELH}$-terminology $(S_i^- 
rightarrow S_f^-)$

1 function $C_{\overline{\mathcal{H}}}^{-}(\mathcal{R}_1, X_1, \Sigma, \mathcal{R}_2, X_2, \zeta)$
2 let $\alpha_{\mathcal{R}_1} := X_1 \equiv Y_1 \cap \ldots \cap Y_m \in \mathcal{R}_1$
3 $M_{(X_1, X_2)} := \emptyset$
4 for every $\Gamma \in \text{DefForest}(\mathcal{R}_2)$ do
5   Let $\delta_\Gamma := \{ \text{def}_{\mathcal{R}_2}(X') \mid X' \in \text{leaves}(\Gamma) \cap \text{def}_{\mathcal{R}_2} \}$
6   $M_{\Gamma}^- := \{ \Gamma \}$
7   for every $X'_2 \in \text{leaves}(\Gamma)$ such that $\zeta = \varepsilon$ or $\mathcal{R}_2 \not\models \text{ran}(\zeta) \subseteq X'_2$ do
8     $M_{X'_2}^- := \emptyset$
9     for every $X'_1 \in \text{non-conj}_{\mathcal{R}_1}(X_1)$ such that $\zeta = \varepsilon$ or $\mathcal{R}_2 \not\models \text{ran}(\zeta) \subseteq X'_1$ do
10    if $(\mathcal{R}_1, X'_1) \sim_{\Sigma, \zeta} (\mathcal{R}_2 \setminus \delta_\Gamma, X'_2)$ then
11      $M_{X'_2}^- := M_{X'_2}^- \cup C_{\overline{\mathcal{H}}}^{-}(\mathcal{R}_1, X'_1, \Sigma, \mathcal{R}_2 \setminus \delta_\Gamma, X'_2, \varepsilon)$
12    end
13  end
14  $M_{\Gamma}^- := M_{\Gamma}^- \otimes M_{X'_2}^-$
15 end
16 $M_{(X_1, X_2)} := M_{(X_1, X_2)}^- \cup M_{\Gamma}^-$
17 end
18 return $\text{Minimise}_C(M_{(X_1, X_2)}^-)$

Table 3.3: Computation of numbers, size, and computation time of subsumer/subsumee justifications for Snomed CT and NCI for 1000 random signatures containing 10/30 concept names and 10 role names (minimal / maximal / median / standard deviation with timeout of 10 mins).
Chapter 4

Extraction of Ontology Subsumption Modules

In this section, we first introduce a notion of ontology module called basic subsumption module w.r.t. a given signature that preserves all $\mathcal{ELH}^r$-inclusions of a terminology over the signature. Note that this is a different notion from $\langle X, \Sigma \rangle$-subsumption modules that are w.r.t. a particular concept name $X$ and a signature.

We present two approaches to computing all minimal subsumption modules of an ontology for a signature: a black-box approach and a glass-box approach. We follow the black-box approach for finding one or all justifications by replacing the entailment tests with logical difference checks, obtaining modules that preserve not only a given consequence but all entailments over a signature. The glass-box algorithm computes all possible subsumption modules of an ontology w.r.t. the signature by combining all subsumption justifications of every concept name in signature, as discussed in the previous chapter. At the end, we evaluate both approaches by computing all subsumption modules on large biomedical ontologies. The experiment shows that either black-box algorithm or glass-box algorithm is practical to be used to compute basic subsumption modules in large ontologies when the signature is not relatively large. In general, glass-box algorithm is faster than black-box algorithm. However, glass-box algorithm can only deal with acyclic terminologies for the moment.

4.1 Definition of Subsumption Module

In general, a module is a subset of an ontology that can act as a substitute for the ontology w.r.t. a given signature. In this chapter, we consider the notion of basic modules from [10] for $\mathcal{ELH}$-terminologies. We now give a formal definition of the module notion.

**Definition 93 (Basic $\mathcal{ELH}^r$-Subsumption Module)** Let $\mathcal{T}$ be an $\mathcal{ELH}^r$-terminology and let $\Sigma$ be a signature. A subset $\mathcal{M} \subseteq \mathcal{T}$ is called a basic $\mathcal{ELH}^r$-subsumption module of $\mathcal{T}$ w.r.t. $\Sigma$ iff for
all $\mathcal{EL}^r$-inclusions $\alpha$ with $\text{sig}(\alpha) \subseteq \Sigma$ it holds that $\mathcal{I} \models \alpha$ iff $\mathcal{M} \models \alpha$. $\mathcal{M}$ is called a minimal basic $\mathcal{EL}^r$-subsumption module of $\mathcal{I}$ w.r.t. $\Sigma$ iff $\mathcal{M}$ is minimal w.r.t. $\subseteq$ with that property.

In the remainder, for simplicity’s sake, we refer to a (minimal) basic $\mathcal{EL}^r$-subsumption module of $\mathcal{I}$ w.r.t. $\Sigma$ as a (minimal) basic subsumption module.

**Lemma 94** Let $\mathcal{I}$ be an $\mathcal{EL}^r$-terminology, and let $\Sigma$ be a signature. Then $\mathcal{M} \subseteq \mathcal{I}$ is a basic $\mathcal{EL}^r$-subsumption module of $\mathcal{I}$ w.r.t. $\Sigma$ iff $c\text{Diff}_{\Sigma}^{T} (\mathcal{I}, \mathcal{M}) = \emptyset$, where $L = \mathcal{EL}^r$.

Every subset $\mathcal{M}$ of a terminology $\mathcal{I}$ that preserves the entailment of all $\mathcal{EL}^r$-subsumptions over a given signature $\Sigma$ is a basic $\mathcal{EL}^r$-subsumption module of $\mathcal{I}$ w.r.t. $\Sigma$. In particular, $\mathcal{I}$ itself is a basic $\mathcal{EL}^r$-subsumption module of $\mathcal{I}$ w.r.t. any signature. It can readily be seen that $\mathcal{M}$ is a basic $\mathcal{EL}^r$-subsumption module of $\mathcal{I}$ w.r.t. $\Sigma$ iff $c\text{Diff}_{\Sigma}^{T} (\mathcal{I}, \mathcal{M}) = \emptyset$, for the query language $L = \mathcal{EL}^r$ (cf. Definition 19). We have that $\mathcal{M}$ and $\mathcal{I}$ are inseparable w.r.t. $\mathcal{EL}^r$-inclusions over $\Sigma$. More precisely, as $\mathcal{M} \subseteq \mathcal{I}$, it holds that $\mathcal{I}$ is a conservative extension of $\mathcal{M}$ w.r.t. $\mathcal{EL}^r$-inclusions over $\Sigma$ [35].

The following propositions show the relation between the basic $\mathcal{EL}^r$-subsumption module notion and other module notions.

A relation between basic $\mathcal{EL}^r$-subsumption modules and depleting modules is given below:

**Proposition 95** Let $\mathcal{I}$ be an $\mathcal{EL}^r$-TBox and $\Sigma$ a signature. Let $\mathcal{M}^\dagger$ be a depleting module of $\mathcal{I}$ w.r.t. $\Sigma$. Then $\mathcal{M}^\dagger$ is a basic subsumption module of $\mathcal{I}$ w.r.t. $\Sigma$.

**Proof** By Property 41, we have that a depleting $\Sigma$-module $\mathcal{M}^\dagger$ of $\mathcal{I}$, is also a plain $\Sigma$-module of $\mathcal{I}$. As model-theoretic inseparability is strictly stronger than inseparability w.r.t. first-order logic queries (see, e.g., [26] and references therein), $\mathcal{M}^\dagger$ is a basic subsumption module w.r.t. $\Sigma$. □

There may be exponentially many (in the size of $\mathcal{I}$) basic subsumption modules (see Example 99). For the use-case of ontology re-use, however, we are most interested in modules that are as small as possible [16]. Note that smallest modules (regarding the number of axioms) are also minimal w.r.t. $\subseteq$, whereas the converse does not hold in general, i.e., there may be minimal modules w.r.t. $\subseteq$ that contain more axioms than other minimal modules w.r.t. $\subseteq$.

**Example 96** Let $\mathcal{I} = \{A \sqcap X \sqcap Y, X \sqsubseteq B, Y \sqsubseteq Z, Z \sqsubseteq B\}$ be an $\mathcal{EL}^r$-terminology and $\Sigma = \{A, B\}$ be a signature. It holds that both sets, $\mathcal{M}_1 = \{A \sqcap X \sqcap Y, X \sqsubseteq B\}$ and $\mathcal{M}_2 = \{A \sqcap X \sqcap Y, Y \sqsubseteq Z, Z \sqsubseteq B\}$, are minimal basic $\mathcal{EL}^r$-subsumption modules of $\mathcal{I}$ w.r.t. $\Sigma$, whereas $\mathcal{M}_1$ is the smallest minimal basic $\mathcal{EL}^r$-subsumption module of $\mathcal{I}$ w.r.t. $\Sigma$ as $|\mathcal{M}_1| < |\mathcal{M}_2|$. The notion of a justification for a concept inclusion $\alpha$ has been introduced as a minimal subset of a TBox that entails a given concept inclusion [4]. We can understand a minimal module as a more general notion of justification: a minimal basic $\mathcal{EL}^r$-subsumption module of $\mathcal{I}$ w.r.t. $\Sigma$ is a justification for all the concept inclusions over $\Sigma$ entailed by $\mathcal{I}$. 

64 Extraction of Ontology Subsumption Modules
4.1 Definition of Subsumption Module

Semantic modules of $\mathcal{L}\mathcal{H}^\tau$-terminologies that are self-contained or depleting (in fact, such modules have both properties [27]) can be strictly larger than basic $\mathcal{L}\mathcal{H}^\tau$-subsumption modules as illustrated by the following example.

**Example 97** Let $\mathcal{T} = \{A \sqsubseteq \exists r.B\}$ be an $\mathcal{L}\mathcal{H}^\tau$-terminology, and $\Sigma = \{A, B\}$ be a signature. It is easy to verify that $\mathcal{T}$ itself is a basic, self-contained, and depleting semantic module of $\mathcal{T}$ w.r.t. $\Sigma$ [25, 27], whereas the empty set is the minimal basic $\mathcal{L}\mathcal{H}^\tau$-subsumption module of $\mathcal{T}$ w.r.t. $\Sigma$.

The following example extends Example 96 to show that the modules computed by the system MEX [25] as well as the modules based on syntactic locality can be strictly larger than minimal basic $\mathcal{L}\mathcal{H}^\tau$-subsumption modules as introduced in Definition 93. Note that MEX-modules are semantic modules that are self-contained as well as depleting [27] (equivalently, weak and strong [25]).

**Example 98** Consider an $\mathcal{L}\mathcal{H}^\tau$-terminology $\mathcal{T} = \{A \sqsubseteq X \sqcap Y \sqcap U, X \sqsubseteq B, Y \sqsubseteq Z, Z \sqsubseteq B, U \equiv V \sqcap W\}$ and a signature and $\Sigma = \{A, B\}$. It holds that both sets, $\mathcal{M}_1 = \{A \sqsubseteq X \sqcap Y, X \sqsubseteq B\}$ and $\mathcal{M}_2 = \{A \sqsubseteq X \sqcap Y, Y \sqsubseteq Z, Z \sqsubseteq B\}$, are minimal basic $\mathcal{L}\mathcal{H}^\tau$-subsumption modules of $\mathcal{T}$ w.r.t. $\Sigma$. Moreover, MEX outputs $\mathcal{M}_3 = \mathcal{M}_1 \cup \mathcal{M}_2 = \{A \sqsubseteq X \sqcap Y \sqcap U, X \sqsubseteq B, Y \sqsubseteq Z, Z \sqsubseteq B\}$ as module of $\mathcal{T}$ w.r.t. $\Sigma$. Finally, $\mathcal{T}$ itself is the $\sqsubseteq_{\mathcal{T}^*}$-local module of $\mathcal{T}$ w.r.t. $\Sigma$.

In general, there can be several minimal basic $\mathcal{L}\mathcal{H}^\tau$-subsumption modules of an acyclic $\mathcal{L}\mathcal{H}^\tau$-terminology for a signature, and even the smallest of such modules are not necessarily unique. The next example shows a sequence of acyclic $\mathcal{L}\mathcal{H}^\tau$-terminologies whose number of minimal basic $\mathcal{L}\mathcal{H}^\tau$-subsumption modules for a given signature is exponentially increasing.

**Example 99** Let $\mathcal{T}_n = \{A \sqsubseteq X_0 \} \cup \{X_{i-1} \sqsubseteq Y_i \sqcap Z_i \mid 1 \leq i \leq n\} \cup \{Y_i \sqsubseteq X_i, Z_i \sqsubseteq X_i \mid 1 \leq i \leq n\} \cup \{X_n \sqsubseteq B\}$ with $n \geq 0$ be $\mathcal{L}\mathcal{H}^\tau$-terminologies, and let $\Sigma = \{A, B\}$ be a signature.

It holds that the set $\{A \sqsubseteq X_0, X_0 \sqsubseteq B\}$ is the minimal basic $\mathcal{L}\mathcal{H}^\tau$-subsumption module of $\mathcal{T}_0$ w.r.t. $\Sigma$. The sets $\{A \sqsubseteq X_0, X_0 \sqsubseteq Y_1 \sqcap Z_1, Y_1 \sqsubseteq X_1, X_1 \sqsubseteq B\}$ and $\{A \sqsubseteq X_0, X_0 \sqsubseteq Y_1 \sqcap Z_1, Z_1 \sqsubseteq X_1, X_1 \sqsubseteq B\}$ are the two minimal basic $\mathcal{L}\mathcal{H}^\tau$-subsumption modules of $\mathcal{T}_1$. Moreover, the four sets $\{A \sqsubseteq X_0, X_0 \sqsubseteq Y_1 \sqcap Z_1, Y_1 \sqsubseteq X_1, X_1 \sqsubseteq Y_2 \sqcap Z_2, Y_2 \sqsubseteq X_2, X_2 \sqsubseteq B\}$ and $\{A \sqsubseteq X_0, X_0 \sqsubseteq Y_1 \sqcap Z_1, Y_1 \sqsubseteq X_1, X_1 \sqsubseteq Y_2 \sqcap Z_2, Z_2 \sqsubseteq X_2, X_2 \sqsubseteq B\}$ as well as $\{A \sqsubseteq X_0, X_0 \sqsubseteq Y_1 \sqcap Z_1, Z_1 \sqsubseteq X_1, X_1 \sqsubseteq Y_2 \sqcap Z_2, Y_2 \sqsubseteq X_2, X_2 \sqsubseteq B\}$ and $\{A \sqsubseteq X_0, X_0 \sqsubseteq Y_1 \sqcap Z_1, Z_1 \sqsubseteq X_1, X_1 \sqsubseteq Y_2 \sqcap Z_2, Z_2 \sqsubseteq X_2, X_2 \sqsubseteq B\}$ are the minimal basic $\mathcal{L}\mathcal{H}^\tau$-subsumption modules of $\mathcal{T}_2$, etc. In general, it can readily be verified that $\mathcal{T}_n$ has $2^n$ many distinct minimal basic $\mathcal{L}\mathcal{H}^\tau$-subsumption modules w.r.t. $\Sigma$.

In the remainder of this section, we present two different approaches for computing minimal basic $\mathcal{L}\mathcal{H}^\tau$-subsumption modules. We will simply write module instead of ‘basic $\mathcal{L}\mathcal{H}^\tau$-subsumption module’ in the remainder of this chapter.
4.2 Black-Box Algorithm

In this section, we extend the black-box approach for finding one or all justifications in [20], which is based on Reiter’s hitting set algorithm [38]. Instead of ensuring that a given entailment is preserved, we introduce an oracle to determine the inseparability between the original ontology and the resulting module. As an oracle we use a variant of the system CEX, which is a tool for deciding whether two ELH\(_r\)-terminologies are logically different w.r.t. a signature [28, 24, 34]. Additionally, several optimisations to speed up the computation of minimal modules are investigated. We present an experimental evaluation of our algorithms by applying them on the prominent and large medical ontologies Smomed CT and NCI. We note that our algorithms are applicable to ontologies formulated in any ontology language provided that a tool is available that can effectively decide the inseparability relation. As CEX works with variants of ELH\(_r\)-terminologies, we restrict the presentation of our algorithms to ELH\(_r\)-terminologies.

4.2.1 Computing a Single Minimal Module

A first straightforward procedure `SINGLE-MINIMAL-MODULE` for computing a minimal module of an ELH\(_r\)-terminology \( T \) w.r.t. a signature \( \Sigma \) is given in Algorithm 13.\(^1\) The procedure operates as follows. First, the variable \( \mathcal{M} \) is initialised with \( T \). Subsequently, the procedure iterates over every axiom \( \alpha \in T \) and checks whether \( cDiff(T, M \setminus \{ \alpha \}) = \emptyset \), in which case the axiom \( \alpha \) is removed from \( \mathcal{M} \). During the execution of the while-loop the set \( \mathcal{M} \) is hence shrunk by removing axioms that do not lead to a logical difference until a minimal module of \( T \) for \( \Sigma \) remains.

\[\text{Algorithm 13: Computing a Single Minimal Module w.r.t. a Signature}\]

\[
\begin{align*}
1 & \quad \text{function} \quad \text{SINGLE-MINIMAL-MODULE} \quad (T, \Sigma) \\
2 & \quad \mathcal{M} := T \\
3 & \quad \text{for every axiom} \ \alpha \in T \ \text{do} \\
4 & \quad \quad \text{if} \ cDiff(T, \mathcal{M} \setminus \{ \alpha \}) = \emptyset \ \text{then} \\
5 & \quad \quad \quad \mathcal{M} := \mathcal{M} \setminus \{ \alpha \} \\
6 & \quad \quad \text{end} \\
7 & \quad \text{end} \\
8 & \quad \text{return} \ \mathcal{M}
\end{align*}
\]

Note that the minimal module that is extracted by Algorithm 13 depends on the order in which axioms were chosen during the iteration (Line 3), i.e. by iterating over the axioms in a different order one can potentially obtain a different minimal module. Moreover, one can show that all minimal modules can be computed by using all possible orderings on the axioms \( \alpha \in T \) in the for-loop in Line 3.

\(^1\)A similar algorithm for DL-Lite ontologies has already been described in Theorem 67 of [31].
It is easy to see that Algorithm 13 always terminates and that it runs in polynomial time in the size of $\mathcal{I}$ and $\Sigma$ since deciding the existence of a logical difference between $\mathcal{ELH}'$-terminologies can be performed in polynomial time in the size of $\mathcal{I}$ and $\Sigma$.

Regarding correctness, if we assume towards a contradiction that a set $\mathcal{M}_{\text{min}} \subseteq \mathcal{I}$ computed by Algorithm 13 applied on $\mathcal{I}$ and $\Sigma$ is not a minimal module of $\mathcal{I}$ w.r.t. $\Sigma$, then there would exist an axiom $\alpha \in \mathcal{M}$ such that $\text{cDiff}(\mathcal{I}, \mathcal{M}_{\text{min}} \setminus \{\alpha\}) = 0$. However, when $\alpha$ was analysed in the for-loop in Line 3, $\text{cDiff}(\mathcal{I}, \mathcal{M}' \setminus \{\alpha\})$ must have been empty as well by monotonicity of $\models$, where $\mathcal{M}'$ with $\mathcal{M}_{\text{min}} \subseteq \mathcal{M}'$ represents the value of the variable $\mathcal{M}$ in Algorithm 13 at the time $\alpha$ was inspected. Consequently, it would hold that $\alpha \not\in \mathcal{M}_{\text{min}}$ and we have derived a contradiction. We hence obtain the following result.

**Theorem 100** Let $\mathcal{I}$ be an $\mathcal{ELH}'$-terminology and let $\Sigma$ be a signature. Then Algorithm 13 applied on $\mathcal{I}$ and $\Sigma$ computes a minimal module of $\mathcal{I}$ for $\Sigma$.

**Proof** Let $\mathcal{M}$ be the module of $\mathcal{I}$ returned by Algorithm 13 applied on $(\mathcal{I}, \Sigma)$.

Furthermore, let $\mathcal{M}_0, \ldots, \mathcal{M}_n$ be the sequence of modules of $\mathcal{I}$ computed by Algorithm 13 such that $\mathcal{M}_0 = \mathcal{I}$ and $\mathcal{M}_n = \mathcal{M}$.

If we assume towards a contradiction that $\mathcal{M}$ is not minimal, then there exists an axiom $\alpha \in \mathcal{M}$ such that $\text{cDiff}(\mathcal{I}, \mathcal{M}_{\text{min}} \setminus \{\alpha\}) = 0$. Hence, there exists $0 \leq i \leq n$ such that $\text{cDiff}(\mathcal{I}, \mathcal{M}_i \setminus \{\alpha\}) \neq 0$. As $\mathcal{M}_n \subseteq \mathcal{M}_i$, we can infer that $\mathcal{M}_n \setminus \{\alpha\} \subseteq \mathcal{M}_i \setminus \{\alpha\}$ and $\text{cDiff}(\mathcal{I}, \mathcal{M}_i \setminus \{\alpha\}) \subseteq \text{cDiff}(\mathcal{I}, \mathcal{M}_n \setminus \{\alpha\})$ by Lemma 27. Thus, $\text{cDiff}(\mathcal{I}, \mathcal{M}_n \setminus \{\alpha\}) \neq 0$, contradicting our assumption. □

As checking the existence of a logical difference can be costly in practice, we now introduce a refinement of the previous algorithm that potentially allows it to reduce the number of logical difference checks that are required for computing a minimal module. The refined procedure SINGLE-MINIMAL-MODULE-BUBBLE is shown in Algorithm 14.

Intuitively, instead of checking whether the removal of a single axiom leads to a logical difference, the refined procedure removes a set $\mathcal{B}$ of axioms from $\mathcal{I}$ at once. Such a set $\mathcal{B}$ is also called a bubble. As an additional optimisation we introduce the notion of logical difference core, which will become relevant in the context of computing all minimal modules when the algorithm for computing one minimal module has to be executed frequently.

**Definition 101 (Logical Difference Core)** Let $\mathcal{I}$ be an $\mathcal{ELH}'$-terminology and let $\Sigma$ be a signature. A subset $\mathcal{C} \subseteq \mathcal{I}$ is said to be a logical difference core of $\mathcal{I}$ w.r.t. $\Sigma$ iff for every $\alpha \in \mathcal{C}$ it holds that $\text{cDiff}(\mathcal{I}, \mathcal{I} \setminus \{\alpha\}) \neq 0$.

Given a logical difference core $\mathcal{C}$ of $\mathcal{I}$ w.r.t. $\Sigma$ and a minimal module $\mathcal{M}$ of $\mathcal{I}$ w.r.t. $\Sigma$, it is easy to see that $\mathcal{C} \subseteq \mathcal{M}$ must hold. The maximal logical difference core can be computed by collecting all the axioms $\alpha \in \mathcal{I}$ for which $\text{cDiff}(\mathcal{I}, \mathcal{I} \setminus \{\alpha\}) \neq 0$.
Algorithm 14: Computing a Single Minimal Module w.r.t. a Signature using Axiom Bubbles

1 function SINGLE-MINIMAL-MODULE-BUBBLE (\( \mathcal{I}, \Sigma, n, \mathcal{C} \))
2 \( \mathcal{M} := \mathcal{I} \)
3 \( \mathcal{Q} := \text{SPLIT}(\mathcal{I} \setminus \mathcal{C}, n) \)
4 while \( \mathcal{Q} \neq \emptyset \) do
5 \( \mathcal{B} := \text{HEAD}(\mathcal{Q}) \)
6 \( \mathcal{Q} := \text{TAIL}(\mathcal{Q}) \)
7 if \( \text{cDiff}(\mathcal{I}, \mathcal{M} \setminus \mathcal{B}) = \emptyset \) then
8 \( \mathcal{M} := \mathcal{M} \setminus \mathcal{B} \)
9 end
10 else
11 if \( |\mathcal{B}| > 1 \) then
12 \( \mathcal{B}_l, \mathcal{B}_r := \text{SPLIT HALF}(\mathcal{B}) \)
13 \( \mathcal{Q} := \mathcal{B}_l :: \mathcal{B}_r :: \mathcal{Q} \)
14 end
15 end
16 end
17 return \( \mathcal{M} \)

Lemma 102 Let \( \mathcal{I} \) be an \( \mathcal{EL} \mathcal{H}^+ \)-terminology and let \( \Sigma \) be a signature. Additionally, let \( \mathcal{C} \subseteq \mathcal{I} \) be a logical difference core of \( \mathcal{I} \) w.r.t. \( \Sigma \) and \( \mathcal{M} \) is the set of all minimal modules of \( \mathcal{I} \) w.r.t. \( \Sigma \). Then

\[
\mathcal{C} = \bigcap_{\mathcal{M} \in \mathcal{M}} \mathcal{M}.
\]

Proof Let \( \mathcal{I} = \bigcap_{\mathcal{M} \in \mathcal{M}} \mathcal{M} \). First, we prove that \( \mathcal{I} \subseteq \mathcal{C} \). For every axiom \( \alpha \in \mathcal{I} \), we have \( \alpha \in \bigcap_{\mathcal{M} \in \mathcal{M}} \mathcal{M} \). As \( \mathcal{M} \) is minimal w.r.t. set inclusion, we could get that \( \text{cDiff}_\Sigma(\mathcal{I}, \mathcal{I} \setminus \{\alpha\}) \neq \emptyset \). By Definition 101, we could conclude that for every axiom, \( \alpha \in \mathcal{C} \). Hence, \( \mathcal{I} \subseteq \mathcal{C} \).

Then we prove that \( \mathcal{C} \subseteq \mathcal{I} \). We assume now towards a contradiction that there exists an axiom \( \alpha \) such that \( \alpha \in \mathcal{C} \), but \( \alpha \notin \mathcal{I} \). As \( \alpha \notin \mathcal{I} \), there exist a minimal module \( \mathcal{M} \) such that \( \alpha \notin \mathcal{M} \) and \( \text{cDiff}_\Sigma(\mathcal{I}, \mathcal{M}) = \emptyset \). As \( \mathcal{M} \subseteq \mathcal{I} \setminus \{\alpha\} \). By Lemma 27, we have that \( \text{cDiff}_\Sigma(\mathcal{I}, \mathcal{I} \setminus \{\alpha\}) = \emptyset \), which contradicts to our assumption that \( \alpha \in \mathcal{C} \), which implies that \( \text{cDiff}_\Sigma(\mathcal{I}, \mathcal{I} \setminus \{\alpha\}) \neq \emptyset \). \( \square \)

Lemma 102 shows that every axiom in logical difference core is contained in every minimal module. Therefore, the black-box algorithm does not need to check the axioms in the logical different core.

Now, the procedure SINGLE-MINIMAL-MODULE-BUBBLE applied on a terminology \( \mathcal{I} \), a signature \( \Sigma \), an initial size parameter \( n \) for the bubbles, and a logical difference core \( \mathcal{C} \) of \( \mathcal{I} \) w.r.t. \( \Sigma \) operates as follows. First, the variable \( \mathcal{M} \) is set to contain all the axioms of \( \mathcal{I} \) and the bubble queue \( \mathcal{Q} \)
is initialised by partitioning the axioms contained in $\mathcal{T} \setminus \mathcal{C}$ into bubbles of size $n$. Note that the size of one bubble may be different from $n$ if $n$ is not a divisor of $|\mathcal{T}|$, or if $n > |\mathcal{T}|$. The resulting bubbles are then stored in the queue $\mathcal{Q}$. As long as $\mathcal{Q}$ is not empty, the first bubble $\mathcal{B}$ is extracted from the queue (lines 5 and 6). Note that the empty queue is denoted with $\emptyset$. Subsequently, it is verified in Line 7 whether the removal of the axioms in $\mathcal{B}$ from the minimal module candidate $\mathcal{M}$ leads to a logical difference. If not, all the axioms in $\mathcal{B}$ can safely be removed from $\mathcal{M}$ in Line 8. Otherwise, if the bubble contained more than one axiom (Line 10), we have to identify the subsets of $\mathcal{B}$ whose removal does not yield a logical difference. To that end, $\mathcal{B}$ is split into two bubbles $\mathcal{B}_l$ and $\mathcal{B}_r$ (Line 11) such that $\mathcal{B}_l, \mathcal{B}_r \subseteq \mathcal{B}$, $|\mathcal{B}_l| = \lfloor \frac{1}{2} \cdot |\mathcal{B}| \rfloor$, and $|\mathcal{B}_r| = \lceil \frac{1}{2} \cdot |\mathcal{B}| \rceil$. The bubbles $\mathcal{B}_l$ and $\mathcal{B}_r$ are then prepended to the queue (Line 12), and the algorithm continues with the next iteration.

The correctness of Algorithm 14 can be shown as before with Algorithm 13. Termination on any input follows from the fact that every axiom in $\mathcal{T}$ appears in at most one bubble in $\mathcal{Q}$ and that in each iteration either the overall number of bubbles is reduced, or one bubble that contains more than one axiom is split into two smaller bubbles. Note that once a bubble $\mathcal{B}$ of size 1 has been selected in Line 5, it will not be contained in $\mathcal{Q}$ in subsequent iterations. We obtain the following result.

**Theorem 103** Let $\mathcal{T}$ be an $\mathcal{EL}^\mathcal{H}$-terminology and let $\Sigma$ be a signature. Additionally, let $\mathcal{C} \subseteq \mathcal{T}$ be a logical difference core of $\mathcal{T}$ w.r.t. $\Sigma$. Then Algorithm 14 applied on $\mathcal{T}$, $\Sigma$, and $\mathcal{C}$ computes a minimal module of $\mathcal{T}$ for $\Sigma$.

Regarding computational complexity, we observe that the decomposition of every bubble $\mathcal{B}$ induces a binary tree in which the nodes are labelled with the bubbles resulting from splitting the parent bubble. In our algorithm, given a bubble $\mathcal{B}$, such a decomposition tree has a depth of at most $|\log_2 |\mathcal{B}||$ and the number of nodes in a decomposition tree corresponds to the number of logical difference checks. As the number of nodes in a binary tree of depth $h$ is bounded by $2^{h+1} - 1$, we hence obtain that every initial bubble $\mathcal{B}$ results in at most $2 \cdot |\mathcal{B}| - 1$ logical difference checks. Overall, we can infer that the procedure **SINGLE-MINIMAL-MODULE-BUBBLE** runs in polynomial time in the size of $\mathcal{T}$, $\Sigma$, and $n$.

### 4.2.2 Computing All Minimal Modules

A naïve way to compute all minimal modules is to enumerate all subsets of the input TBox $\mathcal{T}$ and to check their logical difference w.r.t. $\mathcal{T}$ and a given signature. For $\mathcal{EL}^\mathcal{H}$-terminologies the logical difference problem can be decided in polynomial time [23]. Example 99 shows that there are $\mathcal{EL}^\mathcal{H}$-terminologies with exponentially many minimal modules. Consequently, computing all minimal modules of an $\mathcal{EL}^\mathcal{H}$-terminology can only be achieved in time exponential in the size of the terminology in the worst case.

For that reason, upper approximations of (the union of) all minimal modules such as the syntactic locality-based module notions that can be extracted more efficiently have been introduced [16]. In our algorithm for computing all minimal modules (and in our experiments for extracting one minimal
module) we will make use of syntactic $\bot\top$-locality modules to speed up computations. These modules are among the smallest modules based on syntactic locality notions [42]. They can be obtained by iterating the process of extracting a syntactic $\bot$-local module followed by extracting a syntactic $\top$-local module until a fixpoint is reached. We will extract syntactic $\bot\top$-locality modules using the OWLAPI. Note that any syntactic $\bot\top$-locality module $M_\alpha$ of an $\mathcal{EL}H'\mathcal{R}$-terminology $\mathcal{T}$ w.r.t. a signature $\Sigma$ contains all the minimal modules of $\mathcal{T}$ w.r.t. $\Sigma$.

In our algorithm for computing all minimal modules, we make use of a technique developed for computing all minimal hitting sets [38]. Our algorithm is based on the following observation: given a minimal module $M$ of $\mathcal{T}$ w.r.t. a signature $\Sigma$, then for any other minimal module $M'$ of $\mathcal{T}$ w.r.t. $\Sigma$ there must exist $\alpha \in M'$ such that $\alpha \not\in M$, i.e. $M'$ must be contained in $\mathcal{T} \setminus \{\alpha\}$ for some $\alpha \in M$.

Similarly to [38], our algorithm organises the search space using a labelled, directed tree $\tau$, called module search tree for $\mathcal{T}$, that is extended during the run of the algorithm. Formally, $\tau$ is a tuple $(\mathcal{V}, \mathcal{E}, \mathcal{L}, \rho)$, where $\mathcal{V}$ is a non-empty, finite set of nodes, $\mathcal{E} \subseteq \mathcal{V} \times \mathcal{V}$ is a set of edges, $\mathcal{L}$ is an edge labelling function, mapping every edge $e \in \mathcal{E}$ to an axiom $\alpha \in \mathcal{T}$, and $\rho \in \mathcal{V}$ is the root node of $\tau$. The procedure ALL-MINIMAL-MODULES shown in Algorithm 15 operates on a queue $Q$ that contains the nodes of $\tau$ that still have to be expanded. Intuitively, the labels of the edges on the unique path from the root node to a node $v \in \mathcal{V}$ are the axioms that should be excluded from the search for minimal modules. In each iteration a node $v$ is extracted from $Q$ and the set $\mathcal{T}_{ex} \subseteq \mathcal{T}$ of exclusion axioms is computed by analysing the path from the root node to $v$. The procedure SINGLE-MINIMAL-MODULE-BUBBLE is then used to find a minimal module $M$ of $\mathcal{T} \setminus \mathcal{T}_{ex}$ w.r.t. $\Sigma$. Subsequently, the tree $\tau$ is extended by adding a child $v_\alpha$ of $v$ for every $\alpha \in M$ and the search for all minimal modules continues in the next iteration on the newly added nodes $v_\alpha$.

We now describe the ALL-MINIMAL-MODULES procedure in detail, together with the optimisations that we implemented. Some of the improvements to prune the search space have been proposed in [38] already.

Given an $\mathcal{EL}H'\mathcal{R}$-terminology $\mathcal{T}$, a signature $\Sigma$, a bubble size $n \geq 1$, and a logical difference core $\mathcal{C} \subseteq \mathcal{T}$ of $\mathcal{T}$ w.r.t. $\Sigma$ as input, in the lines 2 and 3 a syntactic $\bot\top$-locality module $\mathcal{R}_\Sigma$ of $\mathcal{T}$ w.r.t. $\Sigma$ is extracted from $\mathcal{T}$, the variable $\tau$ is initialised to represent a module search tree for $\mathcal{T}$ having only one node $\rho$. Moreover, the variables $\mathcal{M} \subseteq 2^{\mathcal{R}_\Sigma}$, containing the minimal modules that have been computed so far, and $\mathcal{W} \subseteq \mathcal{V}$, containing the already explored nodes of $\tau$, are both initialised with the empty set. The queue $Q$ of nodes in $\tau$ that still have to be explored is also set to contain the node $\rho$ as its only element.

The algorithm then enters a while-loop in the lines 4 to 29 in which it remains as long as $Q$ is not empty. In each iteration the first element $v$ is extracted from $Q$ and $v$ is added to $\mathcal{W}$ (lines 5 to 7). Subsequently, the axioms labelling the edges of the path $\pi_v$ from $\rho$ to $v$ in $\tau$ are collected in the set $\mathcal{T}_{ex}$ (Line 8). The algorithm then checks whether $\pi_v$ is redundant, in which case the next iteration of the while-loop starts.

The path $\pi_v$ is redundant if there exists an already explored node $w \in \mathcal{W}$ such that (a) the axioms in $\mathcal{T}_{ex}$ are exactly the axioms labelling the edges of the path $\pi_w$ from $\rho$ to $w$ in $\tau$, or (b) $w$ is a leaf node
Algorithm 15: Computing All Minimal Modules w.r.t. a Signature

\end{align*}
```
of \( \tau \) and the edges of \( \pi_w \) are only labelled with axioms from \( \mathcal{R}_{\text{ex}} \). Condition (a) corresponds to early path termination in [38, 20]: the existence of \( \pi_w \) implies that all possible extensions of \( \pi_t \) have already been considered. Condition (b) implies that the axioms labelling the edges of \( \pi_w \) lead to a logical difference when removed from \( \mathcal{R}_E \). Consequently, removing \( \mathcal{R}_{\text{ex}} \) from \( \mathcal{R}_E \) also induces a logical difference by monotonicity of \( \models \), implying that \( \pi_t \) and all its extensions do not have to be explored. Moreover, the current iteration can also be terminated immediately if \( \text{cDiff}(\mathcal{R}_E, \mathcal{R}_E \setminus \mathcal{R}_{\text{ex}}) \neq \emptyset \) (lines 12 to 14) as no subset of \( \mathcal{R}_E \setminus \mathcal{R}_{\text{ex}} \) can be a module of \( \mathcal{R}_E \) (and therefore of \( \mathcal{T} \) w.r.t. \( \Sigma \)).

Subsequently, in Line 15 the variable \( \mathcal{M} \) that will hold a minimal module of \( \mathcal{R}_E \setminus \mathcal{R}_{\text{ex}} \) is initialised with \( \emptyset \). At this point we can check if a minimal module \( \mathcal{M}' \in \mathcal{M} \) has already been computed for which \( \mathcal{R}_{\text{ex}} \cap \mathcal{M}' = \emptyset \) (lines 16 and 17) holds, in which case we set \( \mathcal{M} \) to \( \mathcal{M}' \). This optimisation step can also be found in [38, 20] and it allows us to avoid a costly call to the \textsc{Single-Minimal-Module-Bubble} procedure. Otherwise, in the lines 18 to 24 we have to apply \textsc{Single-Minimal-Module-Bubble} on \( \mathcal{R}_E \setminus \mathcal{R}_{\text{ex}} \) to obtain a minimal module of \( \mathcal{R}_E \setminus \mathcal{R}_{\text{ex}} \) w.r.t. \( \Sigma \). The algorithm then checks whether \( \mathcal{M} \) is equal to \( \mathcal{C} \) (lines 20 to 22), in which case the search for additional modules can be aborted. If the logical difference core \( \mathcal{C} \) is a minimal module itself, we can infer that no other minimal module exists since \( \mathcal{C} \) is a subset of all the minimal modules. Otherwise, the module \( \mathcal{M} \) is added to \( \mathcal{M} \) in Line 23. Finally, in the lines 25 to 28 the tree \( \tau \) is extended by adding a child \( v_\alpha \) to \( v \) for every \( \alpha \in \mathcal{M} \setminus \mathcal{C} \), connected by an edge labelled with \( \alpha \). Note that it is sufficient to take \( \alpha \notin \mathcal{C} \) as a set \( \mathcal{M} \) with \( \mathcal{C} \subseteq \mathcal{M} \) cannot be a minimal module of \( \mathcal{T} \) w.r.t. \( \Sigma \). The procedure finishes by returning the set \( \mathcal{M} \) in Line 30.

Regarding correctness of Algorithm 15, we note that only minimal modules are added to \( \mathcal{M} \). For completeness, one can show that the locality-based module \( \mathcal{R}_E \) of \( \mathcal{T} \) w.r.t. \( \Sigma \) contains all the minimal modules of \( \mathcal{T} \) w.r.t. \( \Sigma \). Moreover, it is easy to see that the proposed optimisations do not lead to a minimal module not being computed. Overall, we obtain the following result.

**Theorem 104** Let \( \mathcal{T} \) be an \( \mathcal{ELS} \) terminology and let \( \Sigma \) be a signature. Additionally, let \( n \geq 1 \), and let \( \mathcal{C} \subseteq \mathcal{T} \) be a logical difference core of \( \mathcal{T} \) w.r.t. \( \Sigma \).

Then the procedure \textsc{All-Minimal-Modules} shown in Algorithm 15 and applied on \( \mathcal{T}, \Sigma, n, \) and \( \mathcal{C} \), exactly computes all the minimal modules of \( \mathcal{T} \) for \( \Sigma \).

Algorithm 15 terminates on any input as the paths in the module search tree \( \tau \) for \( \mathcal{T} \) that is constructed during the execution represent all the permutations of the axioms in \( \mathcal{T} \) that are relevant for finding all minimal modules. It is easy to see that the procedure \textsc{All-Minimal-Modules} runs in exponential time in size of \( \mathcal{T} \) (and polynomially in \( \Sigma, n, \) and \( \mathcal{C} \)) in the worst case.

The following proposition shows the situation that there exists only one minimal module, which can be considered as an approximation of Algorithm 15.

**Proposition 105** Let \( \mathcal{T} \) be an \( \mathcal{ELS} \) terminology and \( \Sigma \) a signature. Additionally, let \( \mathcal{C} \subseteq \mathcal{T} \) be a logical difference core of \( \mathcal{T} \) w.r.t. \( \Sigma \), \( \mathcal{M} \) be the set of all minimal modules of \( \mathcal{T} \) w.r.t. \( \Sigma \) and \( \mathcal{M} \in \mathcal{M} \).

It holds that \( \mathcal{C} = \mathcal{M} \) iff \( |\mathcal{M}| = 1 \).
4.3 Glass-Box Algorithm

An alternative to the black-box approach for computing minimal modules is to directly select the relevant axioms from an ontology that preserve the desired entailments, which can be done by combining subsumption justification of every concept and role name in signature. In this section, we introduce a glass-box algorithm based on computing subsumption justifications that we introduce in Chapter 3.

The following theorems show how to use subsumption justifications to compute all minimal modules for $\mathcal{ELH}$-terminology (Theorem 106) and $\mathcal{ELH}^\prime$-terminology (Theorem 107).

**Theorem 106** Let $\mathcal{T}$ be an acyclic and normalised $\mathcal{ELH}$-terminology, $\Sigma$ be a signature and $A \in \Sigma \cap N_C$. Additional, let $J^\mathcal{T}_\Sigma(A, \Sigma)$ be the set of all $\langle A, \Sigma \rangle$-subsumer justifications of $\mathcal{T}$ w.r.t. $\Sigma$. Similarly, let $J^\mathcal{T}_\Sigma(A, \Sigma)$ be the set of all $\langle A, \Sigma \rangle$-subsume justifications of $\mathcal{T}$ w.r.t. $\Sigma$ and $J^\mathcal{T}_\Sigma(r, \Sigma)$ be the set of all $\langle r, \Sigma \rangle$-role subsumption justifications of $\mathcal{T}$ w.r.t. $\Sigma$. Then the set of all minimal basic $\mathcal{ELH}$-modules of $\mathcal{T}$ w.r.t. $\Sigma$ is

$$M^\mathcal{T}_\Sigma := \text{Minimize}_\Sigma \left( \bigotimes_{r \in \Sigma \cap N_R} J^\mathcal{T}_\Sigma(r, \Sigma) \otimes \bigotimes_{A \in \Sigma \cap N_C} J^\mathcal{T}_\Sigma(A, \Sigma) \otimes \bigotimes_{A \in \Sigma \cap N_C} J^\mathcal{T}_\Sigma(A, \Sigma) \right).$$

Theorem 106 can be proved by Theorem 24 and Proposition 57. The idea of the proof is that we need one subsumption justification, for every potential difference witness (cf. Theorem 24), to be contained in a minimal module in order to prevent the witness (cf. Proposition 57).

As the concept $\text{dom}(r)$ and $\text{ran}(r)$, $r \in \Sigma$ can also be primitive witness on the left-hand side for $\mathcal{ELH}^\prime$ terminology, so compared with $\mathcal{ELH}$ terminology, additionally we need to combine all $\langle \varphi', \Sigma \rangle$-subsumer justifications, $\varphi' \in \{ \text{dom}(t), \text{ran}(t) \mid t \in N_R \cap \Sigma \}$ for computing all minimal modules for $\mathcal{ELH}^\prime$-terminologies.

**Theorem 107** Let $\mathcal{T}$ be an acyclic and normalised $\mathcal{ELH}^\prime$-terminology, $\Sigma$ be a signature and $A \in \Sigma \cap N_C$. Additional, let $J^\mathcal{T}_\Sigma(\varphi, \Sigma)$ be the set of all $\langle \varphi, \Sigma \rangle$-subsumer justifications of $\mathcal{T}$ w.r.t. $\Sigma$ and $\varphi \in (\Sigma \cap N_C) \cup \Sigma_{\text{dom}} \cup \Sigma_{\text{ran}}$. Similarly, let $J^\mathcal{T}_\Sigma(A, \Sigma)$ be the set of all $\langle A, \Sigma \rangle$-subsume justifications of $\mathcal{T}$ w.r.t. $\Sigma$, where $\Sigma_{\text{dom}} = \{ \text{dom}(t) \mid t \in N_R \cap \Sigma \}$ and $\Sigma_{\text{ran}} = \{ \text{ran}(t) \mid t \in N_R \cap \Sigma \}$. Then the set of all minimal basic $\mathcal{ELH}^\prime$-modules of $\mathcal{T}$ w.r.t. $\Sigma$ is

$$M^\mathcal{T}_\Sigma := \text{Minimize}_\Sigma \left( \bigotimes_{r \in \Sigma \cap N_R} J^\mathcal{T}_\Sigma(r, \Sigma) \otimes \bigotimes_{\varphi \in (\Sigma \cap N_C) \cup \Sigma_{\text{dom}} \cup \Sigma_{\text{ran}}} J^\mathcal{T}_\Sigma(\varphi, \Sigma) \otimes \bigotimes_{A \in \Sigma \cap N_C} J^\mathcal{T}_\Sigma(A, \Sigma) \right).$$

Similar to Theorem 106, Theorem 107 can be proved by Theorem 24 and Proposition 82.

4.4 Evaluation

To demonstrate the practical applicability of our approach, we have implemented Algorithms 14 and 15 in a Java prototype to compute one and all minimal basic $\mathcal{ELH}^\prime$-subsumption modules of
Extraction of Ontology Subsumption Modules

biomedical ontologies: Snomed CT (version Jan 2016), an acyclic EL-terminology consisting of 317,891 axioms, and NCIt (version 18.04e), a cyclic ELHr-terminology containing 139,748 axioms. The experiments have been carried out on machines equipped with an Intel Xeon Core 4 Duo CPU running at 2.50GHz and with 64GiB of RAM.

**Black-box Algorithm on EL- and ELHr-Terminology**

Tables 4.1 and 4.2 show the results for computing one minimal basic ELHr-subsumption module of Snomed CT and NCIt for 100 random signatures of different sizes. When the size of the signature increases, it takes more time in general to compute one minimal module and the size of their minimal module is also increasing. Moreover, in our experiments the median computation times were decreasing with an increasing bubble size for signatures with 200 concept names.

Table 4.3 shows that there exist several minimal basic subsumption modules of Snomed CT for the selected signatures (which contain concept names connected to at most 8 other axioms). Similarly, Table 4.4 also shows that there also exist several minimal basic subsumption modules of NCIt for the random signatures. In our experiments the number of minimal modules rose up to 32, and the size of the minimal modules varied from one signature to another.

Although a precomputation of the maximal logical difference core has the potential of narrowing down the search space, it requires extra computational effort, which can be potentially very time-consuming. In order to check whether the use of the logical difference core can help to speed up the process of searching for all minimal modules, we computed all the minimal modules of Snomed CT and NCIt with and without precomputing the maximal logical difference core for the same signatures. It turns out that in our experiments the precomputation of the maximal core was beneficial to the overall performance: the overall computation process was sped up by more than three times for Snomed CT.

**Comparison between Black-box and Glass-box Approaches**

In the following experiment, we compare our approaches for computing all minimal basic modules using the glass-box approach and the black-box approach in terms of computation time, as depicted in Figure 4.1. The x-axis is labelled with the sizes of the input ontologies. To obtain different sized input ontologies, we used random signatures to extract their MEX-modules [27], yielding 328 sub-ontologies of sizes ranging from 14 to 2271. Our method (red squares) was generally about 10 times faster than the search-based approach (blue triangles) except for 11 small sized input ontologies. This indicates that our approach is suitable for computing all minimal basic modules, especially for large ontologies.

Chapter 5

Extraction of Best Ontology Excerpts

Real-world ontologies are usually too large for users to comprehend. Therefore, in this section, we introduce a new notion called best ontology excerpt, a size-restricted subset of the ontology. We present an approach to computing best ontology excerpts by encoding the problem as a partial maximum satisfiability problem (Max-SAT). Then we introduce a notion of weighted signature and update our approach to computing best excerpts for weighted signature by encoding it as a weighted partial Max-SAT problem. Finally, we evaluate our approach on large ontologies.

5.1 Ontology Excerpts

In this chapter, we are interested in gaining more control over the size of a module in order to be able to reuse the knowledge contained in an ontology in a scenario where resources are restricted in terms of cognitive ability in human users, and time and space available in technical systems.

We start with a definition of ontology excerpts.

**Definition 108 (Ontology Excerpt)** Let $\mathcal{O}$ be an ontology and let $k > 0$ be a natural number. A $k$-excerpt of $\mathcal{O}$ is a subset $\mathcal{E} \subseteq \mathcal{O}$ consisting of at most $k$ axioms, i.e. $|\mathcal{E}| \leq k$.

An ontology excerpt is a subset of the ontology of a certain size. However, we are interested in those excerpts that preserve (as much as possible) the meaning of or the knowledge about the symbols in a signature of interest. To quantify the meaning of an excerpt, we need some metric $\mu$. We assume that the lower the value of $\mu$ for an excerpt is, the more meaning is preserved by the excerpt. This is made precise as follows.

**Definition 109 (Incompleteness Measure)** Let $\mathcal{O}$ be an ontology. An incompleteness measure $\mu$ is a function that maps every triple $(\mathcal{O}, \Sigma, \mathcal{E})$ consisting of an ontology $\mathcal{O}$, a signature $\Sigma$, and an excerpt $\mathcal{E} \subseteq \mathcal{O}$ to a non-negative real number.

Given an incompleteness measure, we can define the best excerpt as follows.
Definition 110 (Best \(k\)-Excerpt) Let \(\mathcal{O}\) be an ontology, let \(\Sigma\) be a signature, and let \(k > 0\) be a natural number. Additionally, let \(\mu\) be an incompleteness measure. A best \(k\)-excerpt of \(\mathcal{O}\) w.r.t. \(\Sigma\) under \(\mu\) is a \(k\)-excerpt \(E\) of \(\mathcal{O}\) such that
\[
\mu(\mathcal{O}, \Sigma, E) = \min\{ \mu(\mathcal{O}, \Sigma, E') | E' \text{ is a } k\text{-excerpt of } \mathcal{O} \}.
\]

We first use as incompleteness measure \(\mu\) the number \(c\text{Diff}(\mathcal{O}, \Sigma, E)\) of \(\mathcal{L}\)-concept inclusion difference witnesses in \(\Sigma\) w.r.t. \(\mathcal{O}\) and \(E\), which is formally defined as \(c\text{Diff}(\mathcal{O}, \Sigma, E) = |\text{Wtn}_\Sigma(\mathcal{O}, E)|\). An example of best excerpts under this incompleteness measure is illustrated below.

Example 111 (Ex. 25 contd.) Let \(\mathcal{O}\) consist of the following four axioms:
\[
\begin{align*}
\alpha_1 : & \ A \sqsubseteq B \sqcap \exists r.X & \alpha_2 : & \ B \sqsubseteq A \\
\alpha_3 : & \ X \equiv A \sqcap B & \alpha_4 : & \ Y \equiv B \sqcap \exists r.(X \sqcap \exists s.A)
\end{align*}
\]
For \(\Sigma = \{A, B\}\), the values \(c\text{Diff}(\mathcal{O}, \Sigma, E)\) for all \(2\)-excerpts \(E\) of \(\mathcal{O}\) are given in the second row of the table below.

\[
\begin{array}{cccc}
\{\alpha_1, \alpha_2\} & \{\alpha_1, \alpha_3\} & \{\alpha_1, \alpha_4\} & \{\alpha_2, \alpha_3\} & \{\alpha_2, \alpha_4\} & \{\alpha_3, \alpha_4\} \\
0 & 2 & 2 & 2 & 2 & 2
\end{array}
\]

One can thus see that \(\{\alpha_1, \alpha_2\}\) is the best \(2\)-excerpt of \(\mathcal{O}\) w.r.t. \(\Sigma\) under \(c\text{Diff}\).

The following example shows that best \(k\)-excerpt is not monotonic w.r.t. \(k\), the size of an excerpt.

Example 112 Let \(\mathcal{O}\) consist of the following four axioms:
\[
\begin{align*}
\alpha_1 : & \ A_1 \sqsubseteq A_2 & \alpha_2 : & \ A_2 \sqsubseteq A_3 \\
\alpha_3 : & \ A_3 \sqsubseteq B_1 \sqcap B_2 & \alpha_4 : & \ X \equiv Y
\end{align*}
\]
For \(\Sigma = \{A_1, B_1, B_2, X, Y\}\), the best \(1\)-excerpt is \(\{\alpha_4\}\) and the best \(3\)-excerpt is \(\{\alpha_1, \alpha_2, \alpha_3\}\).

To preserve the largest possible amount of semantic information in a \(k\)-excerpt, it would be preferable to extract \(k\)-excerpts that have the lowest \(c\text{Diff}\)-value among all the subsets of size \(k\). However, it is difficult in general to compute all such excerpts in an exhaustive way as all the \(\binom{|\mathcal{O}|}{k}\) subsets of size \(k\) would have to be enumerated. The following experiment and example show that we need an alternative approach to computing best ontology excerpts instead of enumerating all possible ontology excerpts.

We performed an experiment on the ontology MESH\(^1\), for which we randomly extracted excerpts and computed their \(c\text{Diff}\)-values w.r.t. a considered signature containing 5000 concept names and

\(^1\)http://bioportal.bioontology.org/ontologies/MESH
5.1 Ontology Excerpts

Figure 5.1 Distribution of 93170 Random Excerpts over Respective cDiff-Values

no role names and the corresponding locality-based module contained 1610 axioms. To limit the search space, we selected a subset of MESH containing 2491 axioms, from which we randomly extracted 93170 many $k$-excerpts, for $k = 100$. Indeed, for an ontology of that size and a $k$-value of 100, there exist around $6.2 \times 10^{180}$ $k$-excerpts, which renders an exhaustive search through all the excerpts impossible. The results that we obtained are summarized in Table 5.1. The total number of possible $k$-excerpts is given in the first column, and the cDiff-values that we observed, except for the value 1416, were regrouped into several intervals that are shown in the 6 right-most columns of the table. The percentage of $k$-excerpts whose cDiff-values fell into the respective intervals is shown in the second row of these columns. The results show that the performance of ontology excerpts varies a lot. It is necessary to develop an algorithm to compute approximate or even best excerpts.

**IR Excerpt**

We introduced an approximate approach to compute excerpts, called IR excerpts [9], based on the technique of Information Retrieval (IR).

In the field of IR, vector representations of documents and queries are a fundamental tool for modelling problems, based on which different retrieval strategies can be applied. We first define the vector representation for axioms and signatures.

In the remainder of this section, we assume that every ontology $\mathcal{O}$ is associated with a strict total order $\prec$ on the elements of $\text{sig}(\mathcal{O})$. Whenever we want to access the $i$-th signature element of $\mathcal{O}$ we refer to the $i$-element w.r.t. the assumed order $\prec$, starting from the smallest element. For a signature $\Sigma \subseteq \text{sig}(\mathcal{O})$ or axiom $\alpha \in \mathcal{O}$, we can define the signature vector of $\Sigma$ and the axiom vector of $\alpha$ as follows.

**Definition 113 (Signature and Axiom Vector)** For a signature $\Sigma \subseteq \text{sig}(\mathcal{O})$, the signature vector of $\Sigma$, written $\overrightarrow{\Sigma} = [v_1, v_2, \cdots]$, is a vector of length $|\text{sig}(\mathcal{O})|$ such that $v_i = 1$ if the $i$-th element of $\text{sig}(\mathcal{O})$ appears in $\Sigma$, otherwise $v_i = 0$. Similarly, for an axiom $\alpha \in \mathcal{O}$ we define $\overrightarrow{\alpha} = \text{sig}(\alpha)$. 
Example 114 (Ex. 111 contd.) Let $\mathcal{O}$ be the ontology defined as in Example 25, and let $\Sigma = \{A, B, r\}$. We assume the strict total order $\prec \subseteq \text{sig}(\mathcal{O}) \times \text{sig}(\mathcal{O})$ given by $A \prec B \prec X \prec Y \prec r \prec s$. Then we obtain the following signature vector for $\Sigma$ and axiom vectors for each axiom of $\mathcal{O}$:

\begin{align*}
\mathbf{\Sigma}^- &= [1, 1, 0, 0, 1, 0] & \mathbf{\alpha}_1^- &= [1, 1, 1, 0, 1, 0] & \mathbf{\alpha}_2^- &= [1, 1, 0, 0, 0, 1] \\
\mathbf{\alpha}_3^- &= [1, 1, 1, 0, 0, 0] & \mathbf{\alpha}_4^- &= [1, 1, 1, 1, 1]
\end{align*}

Then we can define the distance of an axiom and a set of signature by the distances measures between the axiom and signature vectors. A first measure is the cosine value, resulting in the COS-k-module.

Definition 115 (COS-distance between Axiom and Signature) Given an axiom $\alpha$ and a signature set $\Sigma$, the COS-distance between $\alpha$ and $\Sigma$ is defined as follows:

$$d_{cos}(\alpha, \Sigma) = \cos(\mathbf{\alpha}, \mathbf{\Sigma}) = \frac{\sum_{i=1}^{n} x_i y_i}{\sqrt{\sum_{i=1}^{n} x_i^2} \sqrt{\sum_{i=1}^{n} y_i^2}},$$

where $\mathbf{\alpha} = [x_1, x_2, ..., x_n]$ and $\mathbf{\Sigma} = [y_1, y_2, ..., y_n]$.

Example 116 (Ex. 114 contd.) Let $\mathcal{O}$ be the ontology defined as in Example 25, let $\prec$ be the total order on $\text{sig}(\mathcal{O})$ as defined in Example 114, and let $\Sigma = \{A, B, r\}$. Then we have that:

\begin{align*}
&d_{cos}(\alpha_1, \Sigma) = 3/(\sqrt{4\sqrt{3}}) \approx 0.8660 & d_{cos}(\alpha_2, \Sigma) = 2/(\sqrt{2\sqrt{3}}) \approx 0.8164 \\
&d_{cos}(\alpha_3, \Sigma) = 2/(\sqrt{3\sqrt{3}}) \approx 0.6667 & d_{cos}(\alpha_4, \Sigma) = 3/(\sqrt{6\sqrt{3}}) \approx 0.7071
\end{align*}

Therefore, the ranking of the axioms will be $\alpha_1 \succ \alpha_2 \succ \alpha_3 \succ \alpha_4$.

In general, IR-excerpts are computed mainly by the following three steps:

(i) represent each axiom and signature as a vector;

(ii) compute the cosine similarity (COS) value between each axiom vector and a signature vector;

(iii) rank all axioms according to its similarity value and the top-$k$ ranked axioms are IR $k$-excerpts;

Obviously, the ranking based on vector similarity is stable so that IR-excerpts are monotonic with respect to a given terminology and a signature.

Figure 5.1 shows the distribution of the gain value over the 93 170 excerpts of the MESH-fragment, i.e. each bar in the chart shows the number of excerpts that have the cDiff-value shown on the $x$-axis that is associated with the bar (no excerpts having a cDiff-value of 1435 or 1445 were found). We note that the excerpt extracted using the IR-technique had a Gain value (lowest cDiff-value of 1416) that was higher than the values of all the random excerpts we extracted.

Judging from the experimental results that we obtained so far, one could draw the conclusion that excerpts produced by the IR-technique appear to result in low cDiff-values in general. To test this

Table 5.1 Percentage of $k$-Excerpts Falling into Various cDiff-Value Intervals

hypothesis, we conducted another experiment in which we limited the size of the ontology in such a way that an exhaustive enumeration of all its excerpts is feasible.

We performed an exhaustive computation of all the $k$-excerpts, with $1 \leq k \leq 19$, together with the cDiff-values of a fragment $\mathcal{O}_j$ of SNOMED CT that contains 19 axioms, using $\Sigma = \text{sig}(\mathcal{O}_j)$ as signature. For every $1 \leq k \leq 19$ we also computed the excerpts returned by the IR method for $\Sigma$. The results that we obtained are shown in Table 5.2. The first column indicates the value of $k$ and the total number of possible $k$-excerpts is given in the second column. The 24 cDiff-values that we observed were then regrouped into 8 intervals of three elements, and the percentage of $k$-excerpts whose cDiff-value fell into the respective intervals is shown in the last 8 columns. The interval that contained the cDiff-value for the excerpt computed by the IR-method is indicated using a background coloured in gray. One can see that in none of the cases for $k < 19$, the $k$-excerpt obtained using the IR-based technique had the lowest cDiff-value. In other words, the IR-based technique fails to extract the best excerpt for $k < 19$.

The previous experiment has thus established that our hypothesis was wrong, i.e., the IR-based technique cannot guarantee to find the best excerpts in every case. Moreover, we can derive an ever stronger conclusion using the following example.

Example 117 Let $\mathcal{O}$ consist of the following three axioms:

$$\alpha_1 : A_1 \sqsubseteq B_1 \sqcap \exists r.X, \quad \alpha_2 : A_3 \sqsubseteq A_2 \sqcap B_3, \quad \alpha_3 : A_2 \sqsubseteq B_2$$

Let $\Sigma = \text{sig}(\mathcal{O})$. Then the cDiff-values for all 1- and 2-excerpts of $\mathcal{O}$ are respectively shown in the left- and right-hand side of the table below:

<table>
<thead>
<tr>
<th>{\alpha_1}</th>
<th>{\alpha_2}</th>
<th>{\alpha_3}</th>
</tr>
</thead>
<tbody>
<tr>
<td>cDiff</td>
<td>4</td>
<td>5</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>{\alpha_1, \alpha_2}</th>
<th>{\alpha_1, \alpha_3}</th>
<th>{\alpha_2, \alpha_3}</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>4</td>
<td>2</td>
</tr>
</tbody>
</table>

The COS-distance between each of the three axioms $\alpha_i$ and $\Sigma$ is as follows (using an implicit order on the signature elements): $d_{\text{cos}}(\alpha_1, \Sigma) \approx 0.707$, $d_{\text{cos}}(\alpha_2, \Sigma) \approx 0.612$, $d_{\text{cos}}(\alpha_3, \Sigma) = 0.5$. Thus, we obtain the following IR-ranking for the axioms: $\alpha_1 \triangleright \alpha_2 \triangleright \alpha_3$. Although the best 1-excerpt is ${\alpha_1}$, the best 2-excerpt is given by ${\alpha_2, \alpha_3}$ without having the highest ranked axiom $\alpha_1$.

Table 5.2 Percentage of $k$-Excerpts Falling into Various cDiff-Value Intervals

5.2 Encoding Approach of Computing Best Excerpt

In this section, we aim to find an exact algorithm to compute best excerpts. We achieve this based on subsumption justifications introduced in Chapter 3 together with an encoding of the best $k$-excerpt problem into a partial Max-SAT problem, with the aim of delegating the task of finding the best excerpt to a Max-SAT solver. In that way we can leverage the decades of research efforts dedicated to developing efficient SAT solvers for our problem setting. We continue with reviewing basic notions relating to propositional logic and Max-SAT.

The objective of a partial Max-SAT problem is hence to find a propositional valuation that satisfies all the hard clauses in $H$ and that satisfies a maximal number of the soft clauses in $S$. Note that a partial Max-SAT problem may nevertheless admit several solutions.

The objective of a partial Max-SAT problem is hence to find a propositional valuation that satisfies all the hard clauses in $H$ and that satisfies a maximal number of the soft clauses in $S$. Note that a partial Max-SAT problem may nevertheless admit several solutions.

The objective of a partial Max-SAT problem is hence to find a propositional valuation that satisfies all the hard clauses in $H$ and that satisfies a maximal number of the soft clauses in $S$. Note that a partial Max-SAT problem may nevertheless admit several solutions.

The objective of a partial Max-SAT problem is hence to find a propositional valuation that satisfies all the hard clauses in $H$ and that satisfies a maximal number of the soft clauses in $S$. Note that a partial Max-SAT problem may nevertheless admit several solutions.

Note that our encoding requires that a cover of the $\langle A, \Sigma \rangle$-subsumption justifications has already been computed for every concept name $A \in \Sigma$. Moreover, our partial Max-SAT encoding is language agnostic, i.e., it works for any TBox as long as its subsumption justifications can be computed.
5.2 Encoding Approach of Computing Best Excerpt

As we are interested in finding a subset $\mathcal{M} \subseteq \mathcal{T}$ of a TBox $\mathcal{T}$ that fulfills certain properties, we encode the presence of an axiom $\alpha \in \mathcal{T}$ in $\mathcal{M}$ using a propositional variable $p_\alpha$. Intuitively, in a solution $v$ to our partial Max-SAT problem we will have that $v(p_\alpha) = 1$ if, and only if, the axiom $\alpha$ is contained in the best $k$-excerpt.

First, we define the set $\Upsilon^{\mathcal{L}}_\Sigma$. Let $\mathcal{L}$ be the language that the terminology is formulated in and let $\Sigma$ be a signature. We set $\Upsilon^{\mathcal{L}}_\Sigma$ to be the set $\text{Wtn}_\Sigma(\mathcal{T}_1, \mathcal{T}_2)$, where $\mathcal{T}_1$ and $\mathcal{T}_2$ are $\mathcal{L}$-terminologies. Then it follows from the primitive theorems theorems in [23] that

- $\Upsilon^{\mathcal{L}}_\Sigma = \Sigma \cap N_\mathcal{C}$,
- $\Upsilon^{\mathcal{L}, \mathcal{R}}_\Sigma = \Sigma$,
- $\Upsilon^{\mathcal{L}, \mathcal{R}'}_\Sigma = \Sigma \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in \Sigma \cap N_\mathcal{R} \}$.

For encoding the set of all $\langle \sigma, \Sigma \rangle$-subsumption justifications $J_\sigma$ ($\sigma \in \Sigma$), we next introduce an encoding method for a sub-terminology.

**Definition 118 (Encoding of Terminology Subsets)** Let $\mathcal{T}$ be an $\mathcal{L}$-terminology. For every axiom $\alpha \in \mathcal{T}$, let $p_\alpha \in \Pi$ be a fresh propositional variable.

For a subset $\mathcal{M} \subseteq \mathcal{T}$, we define the propositional formula $F_{\mathcal{M}}$ that encodes $\mathcal{M}$ as $F_{\mathcal{M}} := \bigwedge_{\alpha \in \mathcal{M}} p_\alpha$. Moreover, for a set $\mathbf{M} \subseteq 2^\mathcal{T}$, we define the propositional formula $G_{\mathbf{M}}$ associated with $\mathbf{M}$ as

$$G_{\mathbf{M}} := \bigvee_{\mathcal{M} \in \mathbf{M}} F_{\mathcal{M}} = \bigvee \left( \bigwedge_{\alpha \in \mathcal{M}} p_\alpha \right).$$

**Example 119** Let $\mathcal{T} = \{ \alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5 \}, \mathcal{M} = \{ \alpha_1, \alpha_2, \alpha_3 \}$, and $\mathbf{M} = \{ \{ \alpha_2, \alpha_3 \}, \{ \alpha_1, \alpha_4 \} \}$. Then $F_{\mathcal{M}} = p_{\alpha_1} \land p_{\alpha_2} \land p_{\alpha_3}$ and $G_{\mathbf{M}} = (p_{\alpha_2} \land p_{\alpha_3}) \lor (p_{\alpha_1} \land p_{\alpha_3})$.

**Definition 120 (Encoding of the Best Excerpt Problem)** For every $\sigma \in \Upsilon^{\mathcal{L}}_\Sigma$, let $J_\sigma$ be the set of all the $\langle \sigma, \Sigma \rangle$-subsumption justifications of an $\mathcal{L}$-terminology $\mathcal{T}$, and let $q_\sigma$ be a fresh propositional variable. The partial Max-SAT problem for finding best $k$-excerpts of $\mathcal{T}$ w.r.t. $\Sigma$, denoted with $P_k(\mathcal{T}, \Sigma)$, is defined as follows. We set $P_k(\mathcal{T}, \Sigma) := (H_k(\mathcal{T}), S_k(\mathcal{T}, \Sigma))$, where

$$H_k(\mathcal{T}) := \text{Card}(\mathcal{T}, k) \cup \bigcup_{\sigma \in \Upsilon^{\mathcal{L}}_\Sigma} \text{Clauses}(q_\sigma \leftrightarrow G_{J_\sigma}),$$

$$S_k(\mathcal{T}, \Sigma) := \{ q_\sigma \mid \sigma \in \Upsilon^{\mathcal{L}}_\Sigma \},$$

and $\text{Card}(\mathcal{T}, k)$ is the set of clauses specifying that at most $k$ clauses from the set $\{ p_\alpha \mid \alpha \in \mathcal{T} \}$ must be satisfied.

In the hard part of our partial Max-SAT problem, the clauses in $\text{Card}(\mathcal{T}, k)$ specify that the cardinality of the resulting excerpt $E \subseteq \mathcal{T}$ must be equal to $k$. We do not fix a certain encoding that should be used to obtain $\text{Card}(\mathcal{T}, k)$, but we note that there exist several techniques that require a
Extraction of Best Ontology Excerpts

polynomial number of clauses in \( k \) and in the size of \( \mathcal{T} \) (see e.g. [44]). Moreover, for every sigma symbol \( \sigma \in \Upsilon_L^\Sigma \), the variable \( q_\sigma \) is set to be equivalent to the formula \( G_\sigma \), i.e. \( q_\sigma \) will be satisfied in a valuation if and only if the resulting excerpt will have the property that the knowledge of \( \sigma \) w.r.t. \( \Sigma \) in \( \mathcal{T} \) is preserved. Note that \( \sigma \in \Upsilon_L^\Sigma \), which depends on the description language that \( \mathcal{T} \) is formulated on. Finally, the set \( S_k(\mathcal{T}, \Sigma) \) of soft clauses specifies that a maximal number of \( q_\sigma \) must be satisfied, enforcing that the resulting excerpt \( \mathcal{E} \) will yield the smallest possible number of difference witnesses (whilst obeying the constraint that \(|\mathcal{E}| \leq k\)).

**Example 121** Let \( \mathcal{T} \) consist of the following four axioms:

\[
\begin{align*}
\alpha_1 & : = A \sqsubseteq X_1 \sqcap X_2 \sqcap Y \\
\alpha_2 & : = X_1 \sqsubseteq B \\
\alpha_3 & : = X_2 \sqsubseteq B \\
\alpha_4 & : = r \sqsubseteq s
\end{align*}
\]

Let \( \Sigma = \{A, B, Y, r, s\} \) be a signature. Then, for \( \sigma \in \Upsilon_L^\Sigma = \Sigma \), we obtain the following \( (\sigma, \Sigma) \)-subsumption justifications \( J_\sigma \):

\[
\begin{align*}
J_A & = \{\{\alpha_1, \alpha_2\}, \{\alpha_1, \alpha_3\}\}. \\
J_B & = \{\{\alpha_1, \alpha_2\}, \{\alpha_1, \alpha_3\}\}. \\
J_Y & = \{\{\alpha_1\}\}. \\
J_r & = \{\{\alpha_4\}\}. \\
J_s & = \{\{\alpha_4\}\}.
\end{align*}
\]

Each subsumption justification \( J_\sigma \) is encoded as a propositional logic formula \( G_\sigma \) as follows:

\[
\begin{align*}
G_A & = ((p_1 \land p_2) \lor (p_1 \land p_3)), \\
G_B & = ((p_1 \land p_2) \lor (p_1 \land p_3)), \\
G_Y & = p_1, \\
G_r & = p_4, \\
G_s & = p_4.
\end{align*}
\]

By using SAT solver, we obtain the assignments of truth values for the propositional variables in the tuple \( \langle p_1, p_2, p_3, p_4 \rangle \) (in this order) for different \( k \) value:

- when \( k=1 \): \( \langle 0, 0, 0, 1 \rangle \);
- when \( k=2 \): \( \langle 1, 0, 0, 1 \rangle \);
- when \( k=3 \): \( \langle 1, 1, 0, 1 \rangle \) and \( \langle 1, 0, 1, 1 \rangle \);
Finally, we have that for \( \Sigma \), the best 1-excerpt is \( \{ \alpha_4 \} \), the best 2-excerpt is \( \{ \alpha_1, \alpha_4 \} \), the best 3-excerpts are \( \{ \alpha_1, \alpha_2, \alpha_4 \} \) and \( \{ \alpha_1, \alpha_3, \alpha_4 \} \), and the best 4-excerpt is \( \mathcal{T} \).

The encoding has the following properties.

**Lemma 122** Let \( \mathcal{T} \) be an \( \mathcal{L} \)-terminology and \( \Sigma \) be a signature. Additionally, let \( 0 \leq k \leq |\mathcal{T}| \) and let \( v \) be a valuation that satisfies \( H_k(\mathcal{T}) \).

Then it holds that for \( \mathcal{E} := \{ \alpha \in \mathcal{T} \mid v(\alpha) = 1 \} \), the following statement holds:

\[
cDiff_\Sigma(\mathcal{T}, \mathcal{E}) = \{ \sigma \in \Upsilon_\Sigma^{\mathcal{E}} \mid v(q_{\sigma}) = 0 \}.
\]

**Proof** It is not difficult to get the conclusions that the following statements are equivalent:

1. \( \sigma \in cDiff_\Sigma(\mathcal{T}, \mathcal{E}) \).
2. For every \( J \in \mathbb{J}_\sigma \), \( J \notin \mathcal{E} \).
3. For each \( J \), there exists an axiom \( \alpha \in \mathcal{T} \cap J \) such that \( v(\alpha) = 0 \). i.e., \( v(\land_{\alpha \in J} p_{\alpha}) = 0 \).
4. \( v(G_{\mathcal{J}_\sigma}) = v(\lor_{J \in \mathbb{J}_{\sigma}} (\land_{\alpha \in J} p_{\alpha})) = 0 \).
5. \( v(q_{\sigma}) = 0 \).
6. \( \sigma \in \{ \sigma \in \Upsilon_\Sigma^{\mathcal{E}} \mid v(q_{\sigma}) = 0 \} \).

The equivalence between the statements 4 and 5 is based on the fact that \( \text{Clauses}(q_{\sigma} \leftrightarrow G_{\mathcal{J}_\sigma}) \) is in the hard part of the encoding.

**Lemma 123** Let \( \mathcal{T} \) be an \( \mathcal{L} \)-terminology and let \( \Sigma \) be a signature. Additionally, let \( 0 \leq k \leq |\mathcal{T}| \) and let \( \mathcal{E} \subseteq \mathcal{T} \) with \( |\mathcal{E}| = k \). Then there exists a valuation \( v \) such that \( \mathcal{E} = \{ \alpha \in \mathcal{T} \mid v(p_{\alpha}) = 1 \} \), \( v \) satisfies \( H_k(\mathcal{T}) \) and \( \Upsilon_\Sigma^{\mathcal{E}} \setminus cDiff_\Sigma(\mathcal{T}, \mathcal{E}) = \{ \sigma \in \Upsilon_\Sigma^{\mathcal{E}} \mid v(q_{\sigma}) = 1 \} \).

**Proof** Let \( v \) be a valuation defined by setting: first, for every \( \alpha \in \mathcal{T} \), let \( v(p_{\alpha}) = 1 \) iff \( \alpha \in \mathcal{E} \). Additionally, for every \( \sigma \in \Upsilon_\Sigma^{\mathcal{E}} \) we set \( v(q_{\sigma}) = 1 \) iff \( v(G_{\mathcal{J}_\sigma}) = 1 \). Finally, We assume that \( v \) is extended to the additional variables in \( \text{Card}(\mathcal{T}, k) \) and \( \bigcup_{\sigma \in \Upsilon_\Sigma^{\mathcal{E}}} \text{Clauses}(q_{\sigma} \leftrightarrow G_{\mathcal{J}_\sigma}) \) such that \( v \) satisfies \( \text{Card}(\mathcal{T}, k) \) and \( \bigcup_{\sigma \in \Upsilon_\Sigma^{\mathcal{E}}} \text{Clauses}(q_{\sigma} \leftrightarrow G_{\mathcal{J}_\sigma}) \). Note that such an extension is possible as exactly \( k \) variables from \( \{ p_{\alpha} \mid \alpha \in \mathcal{T} \} \) are initially set to 1.

Now it follows from Lemma 122 that \( \Upsilon_\Sigma^{\mathcal{E}} \setminus cDiff_\Sigma(\mathcal{T}, \mathcal{E}) = \{ \sigma \in \Upsilon_\Sigma^{\mathcal{E}} \mid v(q_{\sigma}) = 1 \} \).

We can now show the correctness of our encoding, i.e. a best \( k \)-excerpt can be obtained from a solution to the partial Max-SAT problem \( P_k(\mathcal{T}, \Sigma) \).

**Theorem 124 (Correctness & Completeness)** Let \( \mathcal{T} \) be an \( \mathcal{L} \)-terminology, let \( \Sigma \) be a signature, and let \( 0 \leq k \leq |\mathcal{T}| \). It holds that \( \mathcal{E} \subseteq \mathcal{T} \) is a best \( k \)-excerpt of \( \mathcal{T} \) w.r.t. \( \Sigma \) if there exists a solution \( v \) of the partial Max-SAT problem \( P_k(\mathcal{T}, \Sigma) \) such that \( \mathcal{E} = \{ \alpha \in \mathcal{T} \mid v(p_{\alpha}) = 1 \} \).
Proof First we prove the correctness.

Let $\mathcal{M} := \{ \alpha \in \mathcal{T} \mid v(p_\alpha) = 1 \}$. We have to show that there does not exist a set $\mathcal{E} \subseteq \mathcal{T}$ with $|\mathcal{E}| \leq k$ and $|cDiff_\Sigma(\mathcal{T}, \mathcal{E})| < |cDiff_\Sigma(\mathcal{T}, \mathcal{M})|$. We now assume towards a contradiction that there exists a set $\mathcal{E} \subseteq \mathcal{T}$ with $|\mathcal{E}| \leq k$ and $|cDiff_\Sigma(\mathcal{T}, \mathcal{E})| < |cDiff_\Sigma(\mathcal{T}, \mathcal{M})|$.

Note that $v(q_\alpha) = 1$ implies $\sigma \not\in cDiff_\Sigma(\mathcal{T}, \mathcal{M})$ for every $\sigma \in \Sigma_\Sigma^\alpha$.

Then by Lemma 123 there exists a valuation $v'$ such that $\mathcal{E} = \{ \alpha \in \mathcal{T} \mid v'(p_\alpha) = 1 \}$, $v'$ satisfies $H_k(\mathcal{T})$ and $\Sigma_\Sigma^\alpha \setminus cDiff(\mathcal{T}, \mathcal{E}) = \{ \sigma \in \Sigma_\Sigma^\alpha \mid v'(q_\alpha) = 1 \}$.

From $|cDiff_\Sigma(\mathcal{T}, \mathcal{E})| < |cDiff_\Sigma(\mathcal{T}, \mathcal{M})|$, we can infer that

$$|\Sigma_\Sigma^\alpha| - |cDiff_\Sigma(\mathcal{T}, \mathcal{M})| < |\Sigma_\Sigma^\alpha| - |cDiff_\Sigma(\mathcal{T}, \mathcal{E})|.$$ 

Hence, by Lemma 122 we have

$$|\{ \sigma \in \Sigma_\Sigma^\alpha \mid v(q_\alpha) = 1 \}| < |\{ \sigma \in \Sigma_\Sigma^\alpha \mid v'(q_\alpha) = 1 \}|,$$

which contradicts $v$ being a solution of the partial Max-Sat problem $P_k(\mathcal{T}, \Sigma)$ (Item (ii) of Definition 49).

Then we prove the completeness. Lemma 123 shows that there exists a valuation $v$ such that $\mathcal{E} = \{ \alpha \in \mathcal{T} \mid v(p_\alpha) = 1 \}$, $v$ satisfies $H_k(\mathcal{T})$ and $\Sigma_\Sigma^\alpha \setminus cDiff(\mathcal{T}, \mathcal{E}) = \{ \sigma \in \Sigma_\Sigma^\alpha \mid v(q_\alpha) = 1 \}$.

We assume towards a contradiction that there exists a valuation $v'$ that satisfies $H_k(\mathcal{T})$ and

$$|\{ A \in \Sigma_\Sigma^\alpha \mid v(q_\alpha) = 1 \}| < |\{ A \in \Sigma_\Sigma^\alpha \mid v'(q_\alpha) = 1 \}|.$$ 

Let $\mathcal{E}' := \{ \alpha \in \mathcal{T} \mid v'(p_\alpha) = 1 \}$. Hence, by Lemma 122 it holds that

$$|\Sigma_\Sigma^\alpha| - |cDiff_\Sigma(\mathcal{T}, \mathcal{E}')} < |\Sigma_\Sigma^\alpha| - |cDiff_\Sigma(\mathcal{T}, \mathcal{E}').$$ 

Finally, it would hold that $|cDiff_\Sigma(\mathcal{T}, \mathcal{E}')} < |cDiff_\Sigma(\mathcal{T}, \mathcal{E}')|$, contradicting the fact that $\mathcal{E}'$ is a best $k$-excerpt of $\mathcal{T}$ w.r.t. $\Sigma$ (Definition 110).

Algorithm 16 shows how best excerpts are computed by using partial Max-SAT encoding. In Line 9, the algorithm iterates over every $\sigma \in \Sigma_\Sigma^{\alpha'}$ and the set of all subsumption justifications $\mathcal{J}_\sigma$ are computed. The formula $G_{\mathcal{J}_\sigma}$ is computed next and stored in a set $\mathcal{S}$. After the iteration over all element $\sigma$ in $\Sigma_\Sigma^{\alpha'}$ is complete, the partial Max-SAT problem $P_k(\mathcal{T}, \Sigma)$ is constructed with the help of the formulas $G_{\mathcal{J}_\sigma}$ that are stored in $\mathcal{S}$. Subsequently, a solution $v$ of $P_k(\mathcal{T}, \Sigma)$ is computed using a partial Max-SAT solver and the best $k$-excerpt is returned by analysing which variables $p_\alpha$ have been set to 1 in the valuation $v$. \qed
Algorithm 16: Computing Best $k$-Excerpts for an $\mathcal{L}$-terminology

1. function $\text{ComputeBestExcerpt}(\mathcal{T}, \Sigma, k)$
2. if $k = 0$ then
3. return $\emptyset$
4. end
5. if $k = |\mathcal{T}|$ then
6. return $\mathcal{T}$
7. end
8. $S := \emptyset$
9. for every $\sigma \in \mathcal{Y}_\mathcal{T}$ do
10. Compute $\langle \sigma, \Sigma \rangle$-subsumption justifications of $\mathcal{T}$: $J_\sigma$
11. Transfer $J_\sigma$ to its propositional formula $G_{J_\sigma}$
12. $S := S \cup \{G_{J_\sigma}\}$
13. end
14. Compute $P_k(\mathcal{T}, \Sigma)$ using $S$
15. Find the set of solutions $V$ of $P_k(\mathcal{T}, \Sigma)$ using partial Max-SAT solver
16. return $\{\{\alpha \in \mathcal{T} | v(p_\alpha) = 1, v \in V\}\}$

As Proposition 92 shows, the computation of all subsumption justifications runs in EXPTIME in the size of $\mathcal{T}$. Note that the cardinality encoding $\text{Card}(\mathcal{T}, k)$ can be kept in linear size of $\mathcal{T}$ and $k$ [44]. However, the second part of the hard clauses $\text{Clauses}(q_\sigma \leftrightarrow G_{J_\sigma})$ can be exponential due to the fact that the number of subsumption justifications of each $\sigma$ is exponential in the worst case. Therefore, we can construct a non-deterministic algorithm to solve the encoding problem in EXPTIME, that is, solving the encoding problem is in NEXPTIME. Together with the EXPTIME-upper bound for pre-computing all subsumption justifications, the whole problem of computing best excerpts is NEXPTIME. We arrive at the following conclusion.

Proposition 125 Let $\mathcal{T}$ be an $\mathcal{L}$-terminology, let $\Sigma$ be a signature, and let $0 \leq k \leq |\mathcal{T}|$. Then checking whether a subset $\mathcal{E} \subseteq \mathcal{T}$ is a best $k$-excerpt of $\mathcal{T}$ w.r.t. $\Sigma$ is in NEXPTIME.

5.3 Computing Best Excerpt for Weighted Signatures

Best $k$-excerpts provide users with a way to extract the most relevant axioms from a big ontology with respect to a given signature. However, in certain cases, concepts or roles in the signature can have different importance. How to reflect such importance differences among signature elements, in this section, we extend the best excerpt notion to the case of weighted signatures. For this, we propose a new incompleteness measure considering a weighted signature and study the corresponding best $k$-excerpts.

First, we introduce the definition of weighted signature.
Definition 126 (Weighted Signature) A weight function is a function \( w : N_C \cup N_R \to \mathbb{R} \cup \{\infty\} \) mapping a symbol \( \sigma \in N_C \cup N_R \) to a value \( w(\sigma) \in \mathbb{R} \) or to \( w(\sigma) = \infty \). Given a signature \( \Sigma \) and a weight function \( w \), a weighted signature \( \Sigma_w \) is the set \( \Sigma_w = \{ (\sigma, w(\sigma)) \mid \sigma \in \Sigma \} \).

A signature \( \Sigma \) is weighted uniformly under a weight function \( w \) if, and only if, \( w \) assigns the same value to every symbol in \( \Sigma \), i.e., \( w(\sigma_1) = w(\sigma_2) \) for every \( \sigma_1, \sigma_2 \in \Sigma \). For a weight function \( w \) whose range equals \( \{1.0\} \) (i.e., \( w \) maps every symbol to 1.0), we also write \( \Sigma^w \) instead of \( \Sigma_w \). For instance, \( \Sigma_w = \{(A, 2.0), (B, 0.9), (r, 1.3)\} \) is the weighted signature for the signature \( \Sigma = \{A, B, r\} \) and a weight function \( w \) satisfying \( w(A) = 2.0, w(B) = 0.9 \) and \( w(r) = 1.3 \). On the other hand, a weight function \( w' \) satisfying \( w'(A) = w'(B) = w'(r) = 1.4 \) weighs the symbols in \( \Sigma \) uniformly resulting in \( \Sigma_w' = \{(A, 1.4), (B, 1.4), (r, 1.4)\} \), whereas \( \Sigma^w = \{(A, 1.0), (B, 1.0), (r, 1.0)\} \).

For best k-excerpts under a weighted signature \( \Sigma_w \), we use, as an incompleteness measure \( \mu^\Sigma_\mathcal{T} \) for \( \Sigma_w \) and \( \mathcal{T} \), the sum of the weights of the \( \mathcal{E}, \mathcal{L} \)-concept inclusion difference witnesses and role inclusion difference witnesses in \( \Sigma \) w.r.t. \( \mathcal{T} \) and \( \mathcal{E} \), formally:

\[
\mu^\Sigma_\mathcal{T}(\mathcal{E}) = \sum_{\sigma \in \text{Win}_w(\mathcal{T}, \mathcal{E})} w(\sigma).
\]

For computing the best k-excerpts for a weighted signature, similar to the case of \( \Sigma^w \) (equivalent to unweighted case), we present an encoding approach, but to a weighted partial Max-SAT problem, with the aim of delegating the task of finding the best excerpt to a Max-SAT solver.

Definition 127 (Encoding of the Best Excerpt Problem for Weighted Signature) Let \( \mathcal{T} \) be an \( \mathcal{L} \)-terminology, let \( \Sigma_w \) be a weighted signature, and let \( 0 \leq k \leq |\mathcal{T}| \). Additionally, for every \( \sigma \in \mathcal{Y}_w^\mathcal{T} \), let \( \mathcal{J}_\sigma \) be the set of the \( \langle \sigma, \Sigma_w \rangle \)-subsumption justifications of \( \mathcal{T} \), and let \( q_\sigma \) be a fresh propositional variable.

The weighted partial Max-SAT problem for finding best k-excerpts of \( \mathcal{T} \) w.r.t. \( \Sigma_w \), denoted with \( P_k(\mathcal{T}, \Sigma_w) \), is defined as follows.

We set \( P_k(\mathcal{T}, \Sigma_w) := (H_k(\mathcal{T}), S_k(\mathcal{T}, \Sigma_w)) \), where

\[
H_k(\mathcal{T}) := \text{Card}(\mathcal{T}, k) \cup \bigcup_{\sigma \in \mathcal{Y}_w^\mathcal{T}} \text{Clauses}(q_\sigma \leftrightarrow G_{\mathcal{T}, \sigma}),
\]

\[
S_k(\mathcal{T}, \Sigma_w) := \{ (q_\sigma, w(\sigma)) \mid \sigma \in \mathcal{Y}_w^\mathcal{T} \},
\]

and \( \text{Card}(\mathcal{T}, k) \) is a set of clauses specifying that at most \( k \) clauses from the set \( \{ p_\alpha \mid \alpha \in \mathcal{T} \} \) must be satisfied.

In the hard part of our weighted partial Max-SAT problem, the clauses are the same as the unweighted case given in Definition 120.

In the soft part of the problem, the set \( S_k(\mathcal{T}, \Sigma_w) \) specifies that the sum of the weights of the concept names in the signature must be maximal by a solution of the problem, enforcing that the
resulting excerpt $\delta$ will yield the smallest possible sum of weights of difference witnesses (whilst obeying the constraint that $|\delta| \leq k$).

We can now show the correctness of our encoding, i.e. a best $k$-excerpt for a weighted signature can be exactly obtained from any solution to the weighted partial Max-SAT problem $P_k(\mathcal{T}, \Sigma_w)$.

**Theorem 128 (Correctness & Completeness)** Let $\mathcal{T}$ be an $\mathcal{L}$-terminology, and let $\Sigma_w$ be a weighted signature. Then: $v$ is a solution of the weighted partial Max-SAT problem $P_k(\mathcal{T}, \Sigma_w)$ iff \{ $\alpha \in \mathcal{T}$ | $v(p_\alpha) = 1$ \} is a best $k$-excerpt of $\mathcal{T}$ w.r.t. $\Sigma_w$.

The proof of Theorem 128 is similar to Theorem 124.

Our algorithm for finding a best $k$-excerpt given a TBox $\mathcal{T}$ and a weighted signature $\Sigma_w$ (and $k$ with $0 \leq k \leq |\mathcal{T}|$) as input is shown in Algorithm 17. First, the algorithm checks whether $k = 0$ or $k = |\mathcal{T}|$, in which case the empty set or $\mathcal{T}$ itself is the best $k$-excerpt, respectively. Otherwise, the algorithm continues by computing subsumption justifications for each concept name or role name $\sigma$ in $\Sigma_w$ and then transfers them to propositional formula $G_{J_\sigma}$. After the iteration over all the concept names and role names $\sigma$ in $\Sigma_w$ is complete, the weighted partial Max-SAT problem $P_k(\mathcal{T}, \Sigma_w)$ is constructed with the help of the formulas $G_{J_\sigma}$ that are stored in $S$. Subsequently, a solution $v$ of $P_k(\mathcal{T}, \Sigma_w)$ is computed using a weighted partial Max-SAT solver and the best $k$-excerpt is returned by analyzing which variables $p_\alpha$ have been set to 1 in the valuation $v$.

Similar to Proposition 125, we have the same complexity for computing best excerpts regarding a weighted signature, as stated below.

**Proposition 129** Let $\mathcal{T}$ be an $\mathcal{L}$-terminology, let $\Sigma_w$ be a weighted signature, and let $0 \leq k \leq |\mathcal{T}|$. Then checking whether a subset $\delta \subseteq \mathcal{T}$ is a best $k$-excerpt of $\mathcal{T}$ w.r.t. $\Sigma_w$ is in NEXPTIME.

### Algorithm 17: Computing Best $k$-Excerpts of $\mathcal{T}$ for Weighted Signature $\Sigma$

1. function ComputeBestExcerpt($\mathcal{T}, \Sigma_w, k$)
2.   if $k = 0$ then
3.     return $\emptyset$
4.   end
5.   if $k = |\mathcal{T}|$ then
6.     return $\mathcal{T}$
7.   end
8.   $S := \emptyset$
9.   for every $\sigma \in \Upsilon^\mathcal{L}_{\mathcal{T}, \Sigma_w}$ do
10.      Compute $\langle \sigma, \Sigma_w \rangle$-subsumption justifications of $\mathcal{T}$: $\mathcal{J}_\mathcal{T}(\sigma, \Sigma_w)$
11.      Transfer $\mathcal{J}_\mathcal{T}(\sigma, \Sigma_w)$ to its propositional formula $G_{J_\sigma}$
12.      $S := S \cup \{ G_{J_\sigma} \}$
13.   end
14.   Compute $P_k(\mathcal{T}, \Sigma_w)$ using $S$
15.   Find the set of solutions $V$ of $P_k(\mathcal{T}, \Sigma_w)$ using weighted partial Max-SAT solver
16.   return \{ $\{ \alpha \in \mathcal{T} | v(p_\alpha) = 1, v \in V \}$\}
Example 130  Let $\mathcal{F}$ consist of the following five axioms:
\begin{align*}
\alpha_1 &:= A \sqcap X_1 \sqcap X_2 \sqcap X_3 \sqcap X_4 & \alpha_2 &:= X_1 \sqcap B_1 \\
\alpha_3 &:= X_2 \sqcap B_1 & \alpha_4 &:= X_3 \sqcap B_2 \\
\alpha_5 &:= X_4 \sqcap B_2
\end{align*}

Let $\Sigma = \{A, B_1, B_2\}$ be a signature. Then, for $\sigma \in \Sigma$, we obtain the following $(\sigma, \Sigma)$-subsumption justifications $\mathcal{J}_\sigma$:
\begin{align*}
\mathcal{J}_A &= \{\{\alpha_1, \alpha_2\}, \{\alpha_1, \alpha_3\}, \{\alpha_1, \alpha_4\}, \{\alpha_1, \alpha_5\}\}, \\
\mathcal{J}_{B_1} &= \{\{\alpha_1, \alpha_2\}, \{\alpha_1, \alpha_3\}\}, \text{ and} \\
\mathcal{J}_{B_2} &= \{\{\alpha_1, \alpha_4\}, \{\alpha_1, \alpha_5\}\}.
\end{align*}

Each subsumption justification $\mathcal{J}_\sigma$ is encoded as a propositional logic formula $\mathcal{G}_\sigma$ as follows:
\begin{align*}
\mathcal{G}_A &= ((p_1 \land p_2) \lor (p_1 \land p_3) \lor (p_1 \land p_4) \lor (p_1 \land p_5)), \\
\mathcal{G}_{B_1} &= ((p_1 \land p_2) \lor (p_1 \land p_3)), \text{ and} \\
\mathcal{G}_{B_2} &= ((p_1 \land p_4) \lor (p_1 \land p_5)).
\end{align*}

Now let $w_1, w_2, w_3$ be weight functions such that
\begin{align*}
w_1(A) &= w_1(B_1) = w_1(B_2) = 1.0, \\
w_2(A) &= w_2(B_1) = 1.0 \text{ and } w_2(B_2) = 2.0, \text{ and} \\
w_3(A) &= w_3(B_2) = 1.0, w_3(B_1) = 2.0.
\end{align*}

Feeding the resulting weighted signatures $\Sigma_{w_1}$, $\Sigma_{w_2}$ and $\Sigma_{w_3}$ together with $k = 2$ to a SAT solver yields the following solutions. For $\Sigma_{w_1}$, we obtain four assignments of truth values for the propositional variables in the tuple $(p_1, p_2, p_3, p_4, p_5)$ (in this order): $\langle 1, 1, 0, 0, 0 \rangle$, $\langle 1, 0, 1, 0, 0 \rangle$, $\langle 1, 0, 0, 1, 0 \rangle$ and $\langle 1, 0, 0, 0, 1 \rangle$. Then we decode the assignments to sets of axioms. We obtain the following best 2-excerpts for $\Sigma_{w_1}$: $\{\alpha_1, \alpha_2\}$, $\{\alpha_1, \alpha_3\}$, $\{\alpha_1, \alpha_4\}$ and $\{\alpha_1, \alpha_5\}$.

In the case of $\Sigma_{w_2}$, however, the solutions returned by the SAT-solver are the assignments $\langle 1, 0, 0, 1, 0 \rangle$ and $\langle 1, 0, 0, 0, 1 \rangle$. Consequently, the best 2-excerpts for $\Sigma_{w_2}$ are $\{\alpha_1, \alpha_5\}$ and $\{\alpha_1, \alpha_5\}$.

Finally, for $\Sigma_{w_3}$, the SAT-solver yields $\langle 1, 1, 0, 0, 0 \rangle$ and $\langle 1, 0, 0, 1, 0 \rangle$ resulting in $\{\alpha_1, \alpha_2\}$ and $\{\alpha_1, \alpha_4\}$ as the best 2-excerpts for $\Sigma_{w_3}$.

Example 130 shows that, different weights of $\Sigma$-symbols can influence the final results of best excerpts. By giving higher weights on preferring $\Sigma$-concept names (like $\Sigma_{w_2}$ or $\Sigma_{w_3}$), users can reduce the number of best k-excerpts. However, in some extreme cases, as shown in the following example where a signature has a much higher weight than the others, the best excerpts for the weighted signature can be totally irrelevant to those w.r.t. $\Sigma^\circ$. 
5.4 Ranking Axioms in Best Excerpts

Example 131 Let \( \mathcal{T} \) consist of the following five axioms:

\[
\begin{align*}
\alpha_1 &:= \alpha_1 := A_1 \sqsubseteq X & \alpha_2 &:= X \sqsubseteq Y \\
\alpha_3 &:= Y \sqsubseteq Z & \alpha_4 &:= A_2 \sqsubseteq B_1 \\
\alpha_5 &:= A_3 \sqsubseteq B_2
\end{align*}
\]

Let \( \Sigma = \{A_1, A_2, A_3, B_1, B_2, Y, Z\} \) be a signature. Now let \( w_1, w_2 \) be weight functions such that \( w_1(A_1) = w_1(A_2) = w_1(A_3) = w_1(B_1) = w_1(B_2) = w_1(Y) = w_1(Z) = 1.0 \) (i.e., \( \Sigma_{w_1} \) is \( \Sigma^0 \)) and \( w_2(A_1) = w_2(A_2) = w_2(A_3) = w_2(Y) = 1.0 \) and \( w_2(Z) = 9.0 \). We obtain that the best 3-excerpt \( \delta_{\Sigma_{w_1}} \) for \( \Sigma^0 \) is \( \{\alpha_4, \alpha_5\} \). We have that the best 3-excerpt \( \delta'_{\Sigma_{w_2}} \) for \( \Sigma_{w_2} \) only contains two axioms \( \alpha_2 \) and \( \alpha_5 \), as for any best 3-excerpt \( \delta' \), \( \mu_{\mathcal{T}}^0(\delta') = \mu_{\mathcal{T}}^2(\{\alpha_2, \alpha_5\}) \). The best 3-excerpt \( \delta_{\Sigma_{w_2}} \) for \( \Sigma_{w_2} \) is \( \{\alpha_1, \alpha_2\} \). However, \( |\text{Wtn}_{\Sigma_{w_2}}(\mathcal{T}, \delta_{\Sigma_{w_2}})| = |\{A_1, Y, Z\}| = 3 \) and \( |\text{Wtn}_{\Sigma_{w_2}}(\mathcal{T}, \delta'_{\Sigma_{w_2}})| = |\{A_2, A_3, B_1, B_2\}| = 4 \).

In Example 131 the value of \( w_2(Z) \) is significantly greater than the value of \( w_2 \) for the other concept names in the signature. Therefore, \( \delta_{\Sigma_{w_2}} \) is not the same as \( \delta_{\Sigma_{w_1}} \). In such situations, where the weight of a signature symbol is much larger than for the other symbols, the number of difference witnesses has diminishing impact. We aim to remedy the situation in the following proposition, i.e., Proposition 132, by increasing the impact of the number of difference witnesses. This is achieved by ensuring that the weight of any \( \Sigma \)-symbol is smaller than the sum of any other two \( \Sigma \)-symbols.

Proposition 132 Let \( \mathcal{T} \) be an \( \mathcal{L} \)-terminology, \( \Sigma_w \) be a weighted signature and let \( \Sigma^0 \) be a uniform signature under the weight function \( w \). Then the following statements hold:

(i) If \( 1 \leq w(\sigma) \leq 1 + \frac{1}{|Y_{\Sigma_w}|} \) for every \( \sigma \in 2^Y_{\Sigma_w} \), then every best \( k \)-excerpt of \( \mathcal{T} \) w.r.t. \( \Sigma_w \) will be a best \( k \)-excerpt of \( \mathcal{T} \) w.r.t. \( \Sigma^0 \), but not vice versa.

(ii) If \( \sum_{\sigma \in \Sigma_1} w_{\sigma} > \sum_{\sigma \in \Sigma_2} w_{\sigma} \), for any \( \Sigma_1, \Sigma_2 \in 2^Y_{\Sigma_w} \) and \( |\Sigma_1| > |\Sigma_2| \), then every best \( k \)-excerpt of \( \mathcal{T} \) w.r.t. \( \Sigma_w \) is a best \( k \)-excerpt of \( \mathcal{T} \) w.r.t. \( \Sigma^0 \).

5.4 Ranking Axioms in Best Excerpts

Real-world ontologies are usually too large for human user to browse and comprehend. Best excerpts can help human users to better understand ontologies in order to, say, choose between different ontologies. Ontology excerpts usually consist of more than one axiom. In order to present ontology excerpts in a way that is more friendly to human users, in this section, we present an approach to ranking axioms in excerpts according to a weighted signature.

To obtain an axiom ranking, we first define a notion for weighing axioms.

Definition 133 (Weighted Axiom) An axiom weight function \( \phi \) is a function \( \phi : \mathcal{T} \to \mathbb{R}^+ \) mapping an axiom \( \alpha \in \mathcal{T} \) to a value \( \phi(\alpha) \in \mathbb{R}^+ \).
Next we introduce our definition for an axiom ranking. The idea is that an axiom with a larger weight should be ranked at a higher position in the ranking order.

**Definition 134 (Axiom Ranking)** Let \( \mathcal{T} \) be an \( \mathcal{L} \)-terminology, \( \phi \) an axiom weight function and \( \alpha, \beta \in \mathcal{T} \) be two axioms. We say that \( \alpha \) is preferred over \( \beta \), denoted as \( \alpha \succeq \beta \), iff \( \phi(\alpha) \geq \phi(\beta) \).

Now we present an axiom weight function. Intuitively, an axiom that appears in subsumption justifications of several \( \Sigma \)-symbols with higher weights should receive a higher weight.

**Definition 135** Let \( \mathcal{T} \) be a terminology, \( \Sigma_w \) be a signature with a weight function \( w \). Additionally, let \( J_\sigma \) be the set of the \( \langle \sigma, \Sigma_w \rangle \)-subsumption justifications of \( \mathcal{T} \) and \( J_\sigma = \bigcup_{\mathcal{J} \in J_\sigma} \mathcal{J} \). The axiom weight function \( \phi(\cdot) \) induced by \( w \) is defined as following:

\[
\phi_{\Sigma_w}(\alpha) = \sum_{\{\sigma \in \Sigma_w \cap \text{sig}(\alpha) \mid \alpha \in J_\sigma\}} w(\sigma).
\]

We denote with \( \succeq_{\Sigma_w} \) the axiom ranking induced by \( \phi_{\Sigma_w} \).

**Example 136 (Ex. 130 contd.)** Note that \( \alpha_1 \) (resp. \( \alpha_2, \alpha_3, \alpha_4, \alpha_5 \)) is contained in at least one of the subsumption justifications of \( \Sigma \)-symbols \( \{A, B_1, B_2\} \) (resp. \( \{A, B_1\}, \{A, B_2\}, \{A, B_2\} \)). For \( w_3 \), as \( \alpha_1 \in J_A, J_{B_1} \) and \( J_{B_2} \), so \( \phi(\alpha_1) = w(A) + w(B_1) + w(B_2) = 4.0 \). Similarly, we have that \( \phi(\alpha_2) = \phi(\alpha_3) = w(A) + w(B_1) = 2.0 \), and \( \phi(\alpha_4) = \phi(\alpha_5) = w(A) + w(B_2) = 3.0 \). Hence, the 2-best excerpts w.r.t. \( w_3 \) are \( \{\alpha_1, \alpha_2\} \) and \( \{\alpha_1, \alpha_4\} \), we can order the axioms by \( \alpha_1 \succeq_{\Sigma_w} \alpha_2 \) and \( \alpha_1 \succeq_{\Sigma_w} \alpha_4 \).

It can readily be seen that the axiom ranking function \( \phi(\cdot) \) in Definition 135 gives a total ordering over the axioms in \( \mathcal{T} \) w.r.t. to a given weighted signature \( \Sigma_w \). Note that the axiom weight function only depends on the terminology and weighted signature. For a terminology and a weighted signature, the relative order of two axioms is always the same as long as both axioms are contained in the excerpts, which is easy to see by Definition 135. That is, \( \succeq \) is a stable ordering of the axioms given a weighted signature. However, note that the axioms in best \( k \)-excerpts are not monotonic (cf. Example 112).

### 5.5 Evaluation

We have implemented our algorithms for computing best excerpts in Java. We used the prominent medical ontologies Snomed CT (version Jan 2016) consisting of 317,891 axioms, and the NCI Thesaurus (NCI, version 16.03d) containing 165,341 axioms.

**Computation Time of Partial Max-SAT Encoding**

The first experiment is to test the efficiency of our encoding method. Table 5.3 shows the time needed to compute best excerpts of NCI and Snomed CT for randomly generated signatures of different

sizes (10/30/50 concept names and 10/30/50 roles names). In total over 3000 signatures have been considered. After precomputing the subsumption justifications for every concept name in every signature, the time was measured as that needed to prepare the input and run the partial Max-SAT solver to compute best $k$-excerpts for every size $k$. The minimal, maximal, median, and standard deviation of the execution times show that computing best excerpts of any size using Max-SAT is very efficient given that the subsumption justifications have been computed.

Performance of Best Excerpts

In the second experiment, we compare the size of locality based modules with the number of axioms in best excerpts needed to preserve a certain amount of knowledge. We denote with $\#(\text{Preserved}_\Sigma(best) = n)$, for $n \in \{1, 2\}$, the minimal number of axioms needed by a best excerpt to preserve the knowledge of $n$ concept names w.r.t. the signature $\Sigma$ (i.e., the number $k$ of axioms of a best excerpt $E$ of $\mathcal{T}$ such that $n = |\Sigma \cap N_C \setminus cWtn_\Sigma(\mathcal{T}, E)|$). Instead of using random signatures, however, we consider a scenario where a user searches for sub-ontologies of Snomed CT related to a particular concept name. We computed 2500 different signatures each consisting of a concept name related to diseases, the TOP-concept (called ‘SNOMED CT Concept’) and all role names of Snomed CT. All weights of $\Sigma$-symbols are equal in this experiment.
In Figure 5.2, the 2500 signatures are presented along the x-axis in ascending order w.r.t. the size of their respective \( \bot T^+ \)-local modules (black line). The y-axis represents the number of axioms in the module and excerpts for a signature. The red (resp. green) line presents the sizes of best excerpts that preserve the knowledge for one (resp. two) concept name(s), i.e., \( \#\text{Preserved}_{\Sigma}(\text{best}) = 1 \) (resp. \( \#\text{Preserved}_{\Sigma}(\text{best}) = 2 \)). Best excerpts provide a conciser way for zooming in on an ontology, in particular, when sacrificing completeness is acceptable. For this experiment, after computing the subsumption justifications of all concept names in a signature, it only took 0.15s on average to compute the best excerpts.

**Performance Comparison between Best Excerpts and IR Excerpts**

In the third experiment, we compare the performance of best excerpts with IR excerpts [9] using the same set of signatures as in Fig. 5.2.

<table>
<thead>
<tr>
<th>Time (s)</th>
<th>#Axioms in excerpts</th>
<th>#Preserved_{\Sigma}=1</th>
<th>#Preserved_{\Sigma}=2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Best excerpts</td>
<td>94.20</td>
<td>5.90</td>
<td>28.34</td>
</tr>
<tr>
<td>IR excerpts</td>
<td>0.01</td>
<td>68.83</td>
<td>112.83</td>
</tr>
</tbody>
</table>

Table 5.4 Performance comparison of best and IR excerpts

Table 5.4 shows the average values of time and minimal size of best excerpts and IR excerpts when \( \#\text{Preserved}_{\Sigma} \) is 1 and 2, respectively. Note that the computation time of best excerpts in Table 5.4 includes the computation time of subsumption justifications. Table 5.3 already shows that our encoding method is very efficient. Most of the computation time of best excerpts is used to compute subsumption justifications. We observed that it took only 0.01s to compute IR excerpts, which is much faster than computing best excerpts. However, for preserving the knowledge completeness \( \#\text{Preserved}_{\Sigma} = 1 \) or 2, the average minimal size of best excerpt is much less than IR excerpts. In other words, best excerpt is more succinct compared with IR excerpt w.r.t. the knowledge in signature.
Chapter 6

Extraction of Ontology Projection Module

Ontology comparison helps understanding the overlap and differences among ontologies, which is often desired while a user manipulates multiple knowledge sources. To understand the relations among these ontologies, in this chapter, we propose a novel notion called projection module that entails all queries that follow from a reference ontology. The aim is to study the techniques to extract projection modules which allow us to compare the reasoning capacities of different ontologies.

We develop a unified algorithm for computing minimal projection modules of acyclic ELH\(^r\)-terminologies for subsumption, instance and conjunctive queries. The algorithms are based on simulation notions developed for detecting logical differences between ELH\(^r\)-terminologies. Moreover, we prove that the relevant theoretic results are correct. Finally, we do some experimental evaluations to show that there exist projection modules between large biomedical ontologies, which shows the overlap and differences existing among different real-world ontologies.

6.1 Projection Modules

A projection module of an ontology gives a way to explain how the knowledge that is encoded in a reference ontology is implemented in the target ontology. We are interested in computing all projection modules, since it provides a complete list of all implementations of an ontology regarding a reference, each of which may be necessary to be checked. To enable a manual validation by domain experts, we need to present only necessary information, so we focus on computing minimal projection modules.

A terminology \(\mathcal{T}_1\) together with a signature \(\Sigma\) and a query language \(Q\) determine a set \(\Phi\) of queries from \(Q\) formulated using only symbols from \(\Sigma\) that follow from \(\mathcal{T}_1\). A projection module of another terminology \(\mathcal{T}_2\) is a subset of \(\mathcal{T}_2\) that entails the queries in \(\Phi\). For convenience, we bundle the parameters together in a tuple \(\rho = (\mathcal{T}_1, \Sigma, \mathcal{T}_2)\), which we call a projection setting.
Definition 137 (Projection Module) Let $\mathcal{T}_1, \mathcal{T}_2$ be two $\mathcal{EL}$-terminologies and $\Sigma$ a signature. Additionally, let $\rho = \langle \mathcal{T}_1, \Sigma, \mathcal{T}_2 \rangle$ be a projection setting, and $\mathcal{A}$ be a $\Sigma$-ABox. A subset $\mathcal{M} \subseteq \mathcal{T}_2$ is a subsumption (resp. instance, conjunctive query) projection module under projection setting $\rho$, denoted as $\mathcal{M}_\rho^\text{c}$ (resp. $\mathcal{M}_\rho^\text{i}$, $\mathcal{M}_\rho^\text{q}$) if:

- $\mathcal{M}_\rho^\text{c}$: for each $\mathcal{EL}$-inclusion $\alpha$, $\mathcal{T}_1 \models \alpha$ implies $\mathcal{M} \models \alpha$;
- $\mathcal{M}_\rho^\text{i}$: for each $\Sigma$-instance assertion $\lambda$, $\langle \mathcal{T}_1, \mathcal{A} \rangle \models \lambda$ implies $\langle \mathcal{M}, \mathcal{A} \rangle \models \lambda$;
- $\mathcal{M}_\rho^\text{q}$: for each $q(\bar{a})$, $\langle \mathcal{T}_1, \mathcal{A} \rangle \models q(\bar{a})$ implies $\langle \mathcal{M}, \mathcal{A} \rangle \models q(\bar{a})$, where $\bar{a}$ is a tuple of individual names in $\mathcal{A}$ and $q(\bar{a})$ is a $\Sigma$-conjunctive query.

A minimal subsumption (resp. instance, query) projection module is a projection module $\mathcal{M}_\rho^\text{c}$ (resp. $\mathcal{M}_\rho^\text{i}, \mathcal{M}_\rho^\text{q}$) minimal w.r.t. $\subseteq$.

Projection module is a notion more fine-grained than logical difference in the sense that when an ontology $\mathcal{T}_1$ has no logical difference with the other $\mathcal{T}_2$, we can further extract sub-ontologies of $\mathcal{T}_1$ that contain the knowledge in the reference ontology $\mathcal{T}_2$.

Example 138 Let $\mathcal{T}_1 = \{A_1 \subseteq A_2, A_2 \subseteq A_3\}$, $\mathcal{T}_2 = \{A_1 \subseteq A_3 \cap B_1, B_1 \subseteq \exists r A_3\}$, and $\Sigma = \{A_1, A_3, r\}$. Additionally, let $\rho = \langle \mathcal{T}_1, \Sigma, \mathcal{T}_2 \rangle$. We have that $\text{cDiff}_\Sigma(\mathcal{T}_1, \mathcal{T}_2) = \emptyset$. However, $\mathcal{M}_\rho^\text{c} = \{A_1 \subseteq A_3 \cap B_1\}$. So we have that $\mathcal{M}_\rho^\text{c} \subseteq \mathcal{T}_2$, which means that a strict sub-ontology of $\mathcal{T}_2$ is sufficient to capture all concept subsumption information of $\mathcal{T}_1$ about $\Sigma$. Moreover, $\mathcal{T}_2$ also entails a consequence $A_1 \subseteq \exists r A_3$, which is not the case for $\mathcal{T}_1$.

The following example shows that the three notions of projection modules based on different query languages are distinct.

Example 139 Let $\Sigma = \{X, Y, Z, B, r, s\}$ and $\mathcal{T} = \{X \subseteq Y, Y \subseteq \exists r Z, \text{ran}(r) \subseteq A_1, \text{ran}(s) \subseteq A_2, B \equiv A_1 \cap A_2\}$. Additionally, let $\rho = \langle \mathcal{T}, \Sigma, \mathcal{T} \rangle$. We have that $\mathcal{M}_\rho^\text{c} = \{X \subseteq Y\}$, $\mathcal{M}_\rho^\text{i} = \mathcal{M}_\rho^\text{c} \cup \{\text{ran}(r) \subseteq A_1, \text{ran}(s) \subseteq A_2, B \equiv A_1 \cap A_2\}$ and $\mathcal{M}_\rho^\text{q} = \mathcal{T}$.

Note that there might exist several, even exponentially many, subsumption projection modules given a reference ontology, an implement ontology, and a signature.

Example 140 Let $\mathcal{T}_1 = \{X \subseteq Z\}$ and $\mathcal{T}_2 = \{X \subseteq Y_1 \cap Y_2, Y_1 \subseteq Z, Y_2 \subseteq Z\}$ and $\Sigma = \{X, Z\}$. Additionally, let $\rho = \langle \mathcal{T}_1, \Sigma, \mathcal{T}_2 \rangle$. We have that both $\{X \subseteq Y_1 \cap Y_2, Y_1 \subseteq Z\}$ and $\{X \subseteq Y_1 \cap Y_2, Y_2 \subseteq Z\}$ are subsumption projection modules under $\rho = \langle \mathcal{T}_1, \Sigma, \mathcal{T}_2 \rangle$.

Definition 141 ($Q$-Projection Simulation) Let $\mathcal{T}_1, \mathcal{T}_2$ be two $\mathcal{EL}$-terminologies and $\Sigma$ be a signature. Additionally, let $Q \in \{c, i, q\}$. We say that $\mathcal{T}_1$ is $Q$-projection simulated by $\mathcal{T}_2$ under the setting $\rho = \langle \mathcal{T}_1, \Sigma, \mathcal{T}_2 \rangle$ (written $\mathcal{T}_1 \sim_Q^\rho \mathcal{T}_2$) iff there exists a $Q$-projection module $\mathcal{M}_\rho^Q \subseteq \mathcal{T}_2$ under $\rho$. 

Example 142 Let $\mathcal{T}_1 = \{X \subseteq Z\}$ and $\mathcal{T}_2 = \{X \subseteq Y, Y \subseteq Z\}$ and $\Sigma = \{X, Z\}$. Additionally, let $\rho = \langle \mathcal{T}_1, \Sigma, \mathcal{T}_2 \rangle$. We have that $\mathcal{M}_\rho^Q = \mathcal{T}_2$ for $Q \in \{c, i, q\}$. So $\mathcal{T}_1 \sim^Q_\Sigma \mathcal{T}_2$.

The $Q$-projection relation satisfies the monotonicity properties as described below:

Proposition 143 Let $\mathcal{T}_1, \mathcal{T}_2, \mathcal{T}_3$ be $\mathcal{ELH}$-terminologies, $\Sigma$ be a signature and $Q \in \{c, i, q\}$. If $\mathcal{T}_2 \subseteq \mathcal{T}_3$ and $\mathcal{T}_1 \sim^Q_\Sigma \mathcal{T}_2$, then $\mathcal{T}_1 \sim^Q_\Sigma \mathcal{T}_3$.

This proposition shows that if we extend the ontology from $\mathcal{T}_2$ to $\mathcal{T}_3$, the larger ontology $\mathcal{T}_3$ will $Q$-projection simulate all the ontologies that $\mathcal{T}_2$ $Q$-projection simulates.

Proposition 144 Let $\mathcal{T}_1, \mathcal{T}_2, \mathcal{T}_3$ be $\mathcal{ELH}$-terminologies, $\Sigma$ be a signature and $Q \in \{c, i, q\}$. If $\mathcal{T}_1 \subseteq \mathcal{T}_2$ and $\mathcal{T}_2 \sim^Q_\Sigma \mathcal{T}_3$ then $\mathcal{T}_1 \sim^Q_\Sigma \mathcal{T}_3$.

By this proposition, if an ontology $\mathcal{T}_3$ $Q$-projection simulates $\mathcal{T}_1$, then $\mathcal{T}_3$ also $Q$-projection simulates all sub-ontologies of $\mathcal{T}_1$.

Now we consider projection modules under a special setting of the form $\rho^\ominus = \langle \mathcal{T}, \Sigma, \mathcal{T} \rangle$, that is, the reference ontology is also the implementing ontology (Example 139). A projection module under $\rho^\ominus$ is also called an automorphic projection module.

Proposition 145 Let $\mathcal{T}$ be an $\mathcal{ELH}$-terminology, $\Sigma$ a signature and $\rho^\ominus = \langle \mathcal{T}, \Sigma, \mathcal{T} \rangle$. Additionally, let $\mathcal{M}_\rho^c$ be a subsumption projection module under $\rho^\ominus$. Then $\mathcal{M}_\rho^c$ is a basic $\mathcal{ELH}$-subsumption module of $\mathcal{T}$ w.r.t. $\Sigma$.

This proposition can be obtained from Definition 93 and Definition 137. It shows that we can compute basic $\mathcal{ELH}$-subsumption modules by computing automorphic projection modules.

In Example 138, the automorphic projection module of $\mathcal{T}_2$ is $\mathcal{T}_2$ itself, which is different from its projection module w.r.t. $\mathcal{T}_1$ as discussed above. It shows that automorphic projection module is indeed a different notion from projection module.

### 6.2 Computing Role Projection Justifications

**Definition 146 (Role Projection Justification)** Let $\mathcal{T}_1$ and $\mathcal{T}_2$ be $\mathcal{ELH}$-terminologies and $\Sigma$ be a signature. Additionally, let $\rho = \langle \mathcal{T}_1, \Sigma, \mathcal{T}_2 \rangle$. A set $\mathcal{M} \subseteq \mathcal{T}_2$ is called a role projection module under $\rho$, denoted by $\mathcal{J}_\rho$, iff for every $s \in \Sigma \cap \mathcal{N}_R$, $\mathcal{T}_1 \models r_1 \subseteq s$ implies $\mathcal{M} \models r_2 \subseteq s$. A role projection justification under $\rho$ is the role subsumption module under $\rho$ that is minimal w.r.t. $\subseteq$.

We denote the set of all role projection justifications under $\rho$ as $\mathbb{J}_\rho^R$.

**Example 147** Let $\mathcal{T}_1 = \{r \subseteq t\}$ and $\mathcal{T}_2 = \{r \subseteq s, s \subseteq t\}$ and $\Sigma = \{r, t\}$. Additionally, let $\rho = \langle \mathcal{T}_1, \Sigma, \mathcal{T}_2 \rangle$. We have that $\mathbb{J}_\rho^R = \{\mathcal{T}_2\} = \{\{r \subseteq s, s \subseteq t\}\}$.
Algorithm 18: Computing the set of all Projection Justifications for Role Inclusions

1. function \( \text{COVER}^R (\mathcal{T}_1, \Sigma, \mathcal{T}_2) \)
2. \( M = \{ \emptyset \} \)
3. for every \( r, s \in \Sigma \cap N_R \) such that \( \mathcal{T}_1 \models r \sqsubseteq s \) do
4. \( M := M \otimes \text{Just}_{\mathcal{T}_2} (r \sqsubseteq s) \)
5. end
6. return \( \text{Minimise}_\subseteq (M) \)

Lemma 148 Let \( \mathcal{T}_1 \) and \( \mathcal{T}_2 \) be \( \mathcal{ELH}^r \)-terminologies and \( \Sigma \) be a signature. Additionally, let \( \rho = \langle \mathcal{T}_1, \Sigma, \mathcal{T}_2 \rangle \). If \( J_{\mathcal{R}} \in J_{\mathcal{R}^e} \), then \( \text{roleWtn}_{\Sigma} (\mathcal{T}_1, J_{\mathcal{R}}) = \emptyset \).

Algorithm 18 shows how to collect relevant \( \Sigma \)-role inclusions by Definition 146. The set of all role projection justifications of an \( \mathcal{ELH}^r \)-terminology can therefore be computed in polynomial time.

Theorem 149 Let \( \mathcal{T}_1 \) and \( \mathcal{T}_2 \) be \( \mathcal{ELH}^r \)-terminologies and \( \Sigma \) be a signature. Additionally, let \( \rho = \langle \mathcal{T}_1, \Sigma, \mathcal{T}_2 \rangle \). Let \( M := \text{COVER}^R (\mathcal{T}_1, \Sigma, \mathcal{T}_2) \) computed by Algorithm 18. Then \( M \) is the set of all role projection modules under \( \rho \).

This theorem follows from Definition 47 and Definition 146.

6.3 Computing Subsumption Projection Justifications

The notion of projection justification between terminologies depends on several parameters. To better manage these parameters, we wrap them in a subsumption setting \( \chi \), which is a tuple of the form \( \langle \mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, L \rangle \), where \( \mathcal{T}_1 \) and \( \mathcal{T}_2 \) are the normalised \( \mathcal{ELH}^r \)-terminologies, \( \Sigma \) is a signature, \( X_1, X_2 \in N_C \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in N_R \} \), and \( L \in \{ \mathcal{ELH}^r, \mathcal{EL}^{\text{ran}}, \mathcal{EL}^{\text{ran}, \sqcup, u} \} \). We recall that \( \text{ran}, \text{Ran} \) and \( \text{Ran}^{\sqcup, u} \) are abbreviations for \( \mathcal{ELH}^r \), \( \mathcal{EL}^{\text{ran}} \) and \( \mathcal{EL}^{\text{ran}, \sqcup, u} \), respectively. Besides, \( L \) means \( \mathcal{L} \)-concept that only consists of the concept and role names in \( \Sigma \).

Definition 150 (Subsumption Projection Justification) Let \( \mathcal{L} \in \{ \text{ran}, \text{Ran}, \text{Ran}^{\sqcup, u} \} \). Additionally, let \( \chi = \langle \mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, L \rangle \), where \( X_1, X_2 \in N_C \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in N_R \} \). A set \( \mathcal{M} \subseteq \mathcal{T}_2 \) is called a subsumer projection module under \( \chi \) iff for every \( C \in \mathcal{L}_\Sigma \), \( \mathcal{T}_1 \models X_1 \sqsubseteq C \) implies \( \mathcal{M} \models X_2 \sqsubseteq C \).

A set \( \mathcal{M} \subseteq \mathcal{T}_2 \) is called a subsumee projection module under \( \chi \) iff for every \( C \in \mathcal{L}_\Sigma \), \( \mathcal{T}_1 \models C \sqsubseteq X_1 \) implies \( \mathcal{M} \models C \sqsubseteq X_2 \).

\( \mathcal{M} \) is called a subsumption projection module under \( \chi \) iff \( \mathcal{M} \) is a subsumer projection module and a subsumee projection module under \( \chi \). A subsumee (resp. subsumer, subsumption) projection justification under \( \chi \) is a subsumee (resp. subsumer, subsumption) projection projection module under \( \chi \) that is minimal w.r.t. \( \subseteq \).
We denote the set of all subsumee (resp. subsumer, subsumption) projection justifications under $\chi$ as $\mathbb{J}X_\chi^+$ (resp. $\mathbb{J}X_\chi^-$, $\mathbb{J}X_\chi^0$), where $\chi = \langle R_1, X_1, \Sigma, R_2, X_2, L \rangle$.

**Proposition 151** Let $\mathcal{T}$ be a normalised $\mathcal{ELH}$-terminology, let $\Sigma$ be a signature, and let $X \in \text{NC}$. Additionally, let $\chi = \langle \mathcal{T}, X, \Sigma, \mathcal{T}, X, \text{ran} \rangle$. Then a subsumer (resp. subsumee, subsumption) projection module under $\chi$ is a $\langle X, \Sigma \rangle$-subsumer (resp. subsumee, subsumption) module. Similarly, a subsumer (resp. subsumee, subsumption) projection justification under $\chi$ is a $\langle X, \Sigma \rangle$-subsumer (resp. subsumee, subsumption) justification.

This proposition follows from Definition 79 and Definition 137.

Using Definition 93 and Definition 19, we obtain the following lemma stating the absense of certain concept names, and domain and range restrictions of role names as left-hand and right-hand difference witnesses between a reference terminology $T_1$ and a subsumer and subsumee justification of a second terminology $T_2$.

**Lemma 152** Let $\chi(\phi) = \langle T, T, \Sigma, T_2, \phi, L \rangle$ and $\chi(A) = \langle T, A, \Sigma, T_2, A, L \rangle$, where $\phi \in (\Sigma \cap \text{NC}) \cup \Sigma^\text{dom} \cup \Sigma^\text{ran}$, $A \in \Sigma \cap \text{NC}$ and $L \in \{\text{ran}, \text{ran}, \text{ran}\}$. Then we have that for every $J\chi(\phi)$, $\phi \not\in \text{lhsWtn}_\chi^C (T, \chi(\phi))$, and for every $J\chi(A)$, $A \not\in \text{rhsWtn}_\chi^C (T, \chi(A))$.

To obtain subsumption modules, we can use the operator $\odot$ to combine sets of role projection justifications, subsumer and subsumee projection justifications, one justification for each potential difference witness that needs to be prevented; cf. Lemma 152 and 148. This is made precise in the following theorem.

**Theorem 153** Let $L \in \{\text{ran}, \text{ran}, \text{ran}\}$ and $M^L_\rho$ be the set of all $L$-projection modules under $\rho = \langle T_1, \Sigma, T_2 \rangle$ that are minimal w.r.t. $\subseteq$. Then

$$M^L_\rho = \text{Minimize}_C \left( \bigotimes_{\phi \in (\Sigma \cap \text{NC}) \cup \Sigma^\text{dom} \cup \Sigma^\text{ran}} J\chi(\phi) \bigotimes_{A \in \Sigma \cap \text{NC}} J\chi(A) \right)$$

where $\chi(\psi) = \langle T_1, \psi, \Sigma, T_2, \psi, L \rangle$.

In [23], it is shown that concept difference on $\mathcal{EL}^\text{ran}$ and $\mathcal{EL}^\text{ran, ran}$ captures exactly the instance and query difference in $\mathcal{ELH}$-terminology, respectively. So we can convert the problem of computing instance and conjunctive query projection modules to the problem of computing subsumption projection modules on $\mathcal{EL}^\text{ran}(\text{Ran})$ and $\mathcal{EL}^\text{ran, ran}(\text{Ran})$ respectively. Therefore, in the following subsections, we present a general algorithm for computing subsumer and subsumee projection justifications for subsumption, conjunctive and instance query by three different logics: $\mathcal{ELH}^\text{ran}(\text{Ran})$, $\mathcal{ELH}^\text{ran}(\text{Ran})$ and $\mathcal{ELH}^\text{ran, ran}(\text{Ran})$.

Due to the fact that there may exist exponentially many minimal modules in the worst case, our algorithm introduced later runs in exponential-time in the worst case.

As in Chapter 3, we use the notion of covers to characterise the output of our algorithms to ensure that all justifications have been computed. We recall that $L_2$ is a $L$ concept that only constructed by the concept and role names in $\Sigma$. 
6.3.1 Computing Subsumer Projection Justifications

In this section, we introduce our algorithm to compute all subsumer projection justifications. The algorithm relies on the notion of a subsumer simulation between terminologies.

In [23] it was shown that

\[
\text{lhsWtn}^\text{ran}_{2}(\mathcal{R}_1, \mathcal{R}_2) = \text{lhsWtn}^\text{ran}_{2}(\mathcal{R}_1, \mathcal{R}_2);
\]

\[
\text{lhsWtn}^\text{ran}_{2}(\mathcal{R}_1, \mathcal{R}_2) \neq \text{lhsWtn}^\text{ran}_{2\cup}(\mathcal{R}_1, \mathcal{R}_2).
\]

Therefore, we just need algorithms to deal with two query languages, i.e., Ran and Ran^{\Lambda,w}.

To handle existential restrictions via the universal role in the query language Ran^{\Lambda,w}, we use a notion of reachability in terminologies. Let N_{C}^{\text{dom,ran}} = N_{C} \cup \{ \text{dom}(r) \mid r \in N_{R} \} \cup \{ \text{ran}(r) \mid r \in N_{R} \}.

For \( \varphi \in N_{C}^{\text{dom,ran}} \) and a normalised \( \mathcal{E}LH^* \)-terminology \( \mathcal{T} \), let \( F_{\mathcal{T}}(\varphi) \subseteq N_{C}^{\text{dom,ran}} \) be the smallest set closed under the following conditions:

- \( \varphi \in F_{\mathcal{T}}(\varphi) \);
- \( Y \in F_{\mathcal{T}}(\varphi) \) if \( \psi \in F_{\mathcal{T}}(\varphi) \), \( \mathcal{T} \models \psi \subseteq X' \) and \( X' \ni \exists Y \in \mathcal{T} \);
- \( \text{dom}(r) \in F_{\mathcal{T}}(\varphi) \) if \( \text{ran}(r) \in F_{\mathcal{T}}(\varphi) \).

Intuitively, for concept names \( X \), the set \( F_{\mathcal{T}}(X) \) contains \( X \) together with all directly and indirectly implied role successors of \( X \), independent of any signature. For example, let \( \mathcal{T} = \{ Y \subseteq X, X \equiv \exists r Z, Z \subseteq \exists r B \} \). Then it holds that \( F_{\mathcal{T}}(Y) = \{ Y, Z, B \} \), \( F_{\mathcal{T}}(X) = \{ X, Z, B \} \), \( F_{\mathcal{T}}(Z) = \{ Z, B \} \), \( F_{\mathcal{T}}(B) = \{ B \} \), \( F_{\mathcal{T}}(\text{dom}(r)) = \{ \text{dom}(r) \} \) and \( F_{\mathcal{T}}(\text{ran}(r)) = \{ \text{dom}(r), \text{ran}(r) \} \).

In order to deal with Ran^{\Lambda,w}subsumption queries, we extend Definition 83 and get the following definition.

**Definition 154 (Subsumer Simulation for Ran and Ran^{\Lambda,w} Subsumption Query)** Let \( \mathcal{R}_1 \) and \( \mathcal{R}_2 \) be two normalised \( \mathcal{E}LH^* \)-terminologies, and let \( \Sigma \) be a signature. Moreover, let \( \mathcal{L} \in \{ \text{Ran}, \text{Ran}^{\Lambda,w} \} \) and let \( N(\mathcal{T}, \Sigma) = \{ X, \text{dom}(r), \text{ran}(r) \mid X, r \in (\text{sig}(\mathcal{T}) \cup \Sigma), \exists X \in N_{C}, r \in N_{R} \} \), where \( \mathcal{T} \) ranges over terminologies. A relation \( S \subseteq N(\mathcal{T}_1, \Sigma) \times N(\mathcal{T}_2, \Sigma) \) is a \( (\Sigma, \mathcal{L}) \)-subsumer simulation from \( \mathcal{T}_1 \) to \( \mathcal{T}_2 \) iff the following conditions \((S_{N_{C}}^{\Lambda,\mathcal{L}})\) and \((S_{\Sigma}^{\Lambda,w,\mathcal{L}})\) are both satisfied:

- \((S_{N_{C}}^{\Lambda,\mathcal{L}})\) if \( (X_1, X_2) \in S \), then for every \( \varphi \in \Sigma \cup \Sigma_{\text{dom}} \) with \( \mathcal{T}_1 \models X_1 \subseteq \varphi \), it holds that \( \mathcal{T}_2 \models X_2 \subseteq \varphi \);
- \((S_{\Sigma}^{\Lambda,w,\mathcal{L}})\) if \( (X_1, X_2) \in S \) and \( X'_1 \ni \varphi \), \( \exists \text{Y}_1 \in \mathcal{T}_1 \) with \( \varphi \ni \text{Y}_1 \in \mathcal{T}_1 \) with \( \varphi \ni \text{Y}_1 \) in \( \{ \subseteq, \equiv \} \) such that \( \mathcal{T}_1 \models X_1 \subseteq X'_1 \) and \( \mathcal{T}_1 \models r \subseteq s \) for some \( s \in \Sigma \), then for every \( s \in \Sigma \) with \( \mathcal{T}_1 \models r \subseteq s \), there exists \( X'_2 \ni \exists r \), \( Y_2 \in \mathcal{T}_2 \) with \( \varphi \ni Y_2 \) in \( \{ \subseteq, \equiv \} \) such that \( \mathcal{T}_2 \models X_2 \subseteq X'_2 \) and \( \mathcal{T}_2 \models r' \subseteq s \) for every \( s \in \Sigma \) with \( \mathcal{T}_1 \models r \subseteq s \), it holds that \( \mathcal{T}_2 \models r' \subseteq s \) and \( (Y_1, Y_2) \in S \).
6.3 Computing Subsumption Projection Justifications

We write $\mathcal{T}_1 \sim_{\Sigma, \text{Ran}}^\rightarrow \mathcal{T}_2$ iff there exists a $(\Sigma, \text{Ran})$-subsumer simulation $S$ from $\mathcal{T}_1$ to $\mathcal{T}_2$ such that for every $\phi \in (\Sigma \cap N_C) \cup \Sigma^{\text{dom}} \cup \Sigma^{\text{ran}}$: $(\phi, \phi) \in S$.

Moreover, we write $\mathcal{T}_1 \sim_{\Sigma, \text{Ran}^{\cap \cup}}^\rightarrow \mathcal{T}_2$ iff there exists a $(\Sigma, \text{Ran}^{\cap \cup})$-subsumer simulation $S$ from $\mathcal{T}_1$ to $\mathcal{T}_2$ such that for every $\phi \in (\Sigma \cap N_C) \cup \Sigma^{\text{dom}} \cup \Sigma^{\text{ran}}$: $(\phi, \phi) \in S$, and for every $\psi \in F_{\mathcal{T}_1}(\phi)$, there exists a $\psi' \in F_{\mathcal{T}_2}(\psi)$ such that $(\psi, \psi') \in S$.

For $X_1, X_2 \in N_C$ and $\mathcal{L} \in \{\text{Ran}, \text{Ran}^{\cap \cup}\}$, we write $\langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \mathcal{L}}^\rightarrow \langle \mathcal{T}_2, X_2 \rangle$ iff there exists a $(\Sigma, \mathcal{L})$-subsumer simulation $S$ from $\mathcal{T}_1$ to $\mathcal{T}_2$ with $(X_1, X_2) \in S$ for which $\mathcal{T}_1 \sim_{\Sigma, \mathcal{L}}^\rightarrow \mathcal{T}_2$.

This definition of subsumer simulation is extended from Definition 83 to additionally handle $\text{Ran}^{\cap \cup}$-subsumption queries.

A subsumer simulation conveniently captures the set of subsumers in the following sense: If a $\Sigma$-subsumer simulation from $\mathcal{T}_1$ to $\mathcal{T}_2$ contains the pair $(X_1, X_2)$, then $X_2$ entails w.r.t. $\mathcal{T}_2$ all subsumers of $X_1$ w.r.t. $\mathcal{T}_1$ that are formulated in the signature $\Sigma$. Formally, we obtain the following theorem from [34].

**Theorem 155** We have the following conclusions:

- $\mathcal{T}_1 \sim_{\Sigma, \text{Ran}}^\rightarrow \mathcal{T}_2$ iff $\text{lhsWtn}_{\Sigma, \text{Ran}}^\rightarrow (\mathcal{T}_1, \mathcal{T}_2) = \emptyset$;
- $\mathcal{T}_1 \sim_{\Sigma, \text{Ran}}^\rightarrow \mathcal{T}_2$ iff $\text{lhsWtn}_{\Sigma, \text{Ran}}^\rightarrow (\mathcal{T}_1, \mathcal{T}_2) = \emptyset$;
- $\mathcal{T}_1 \sim_{\Sigma, \text{Ran}^{\cap \cup}}^\rightarrow \mathcal{T}_2$ iff $\text{lhsWtn}_{\Sigma, \text{Ran}^{\cap \cup}}^\rightarrow (\mathcal{T}_1, \mathcal{T}_2) = \emptyset$.

**Theorem 156** If $\langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \mathcal{L}}^\rightarrow \langle \mathcal{T}_2, X_2 \rangle$, then $\mathcal{T}_2 \models X_2 \subseteq D$ for every $\mathcal{L} \in \mathcal{L}_\Sigma$ such that $\mathcal{T}_1 \models X_1 \subseteq D$.

Note that $\mathcal{T}_2 \models X_2 \subseteq D$ for every $\mathcal{L} \in \mathcal{L}_\Sigma$ such that $\mathcal{T}_1 \models X_1 \subseteq D$ does not imply that $\langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \mathcal{L}}^\rightarrow \langle \mathcal{T}_2, X_2 \rangle$, because $\mathcal{T}_1 \sim_{\Sigma, \mathcal{L}}^\rightarrow \mathcal{T}_2$ is the one of conditions that $\langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \mathcal{L}}^\rightarrow \langle \mathcal{T}_2, X_2 \rangle$ holds (cf. Definition 154).

For example, let $\mathcal{T}_1 = \{X_1 \subseteq A, B \subseteq B'\}$, $\mathcal{T}_2 = \{X_2 \subseteq A\}$ and $\Sigma = \{A, B, B'\}$. Then $B \not\in F_{\mathcal{T}_1}(X_1)$. Note that $\mathcal{T}_1 \sim_{\Sigma, \mathcal{L}}^\rightarrow \mathcal{T}_2$ does not hold as $B$ in $\mathcal{T}_1$ is not simulated by anything in $\mathcal{T}_2$. Therefore, also $\langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \mathcal{L}}^\rightarrow \langle \mathcal{T}_2, X_2 \rangle$ does not hold. However, we have that for every $\mathcal{L} \in \mathcal{L}_\Sigma$: $\mathcal{T}_1 \models X_1 \subseteq D$ implies $\mathcal{T}_2 \models X_2 \subseteq D$. In particular, $\mathcal{T}_1 \models X_1 \subseteq A$ and $\mathcal{T}_2 \models X_2 \subseteq A$.

When computing subsumer projection justification, in Algorithm 26, it distinguishes different cases. If $\mathcal{L} = \text{Ran}$ or $\text{Ran}$, then the algorithm calls Algorithm 23 and Algorithm 22.

In order to collect the axioms necessary to satisfy the conditions of Definition 154, we develop Algorithm 19 for Case $(S_{\Sigma, \text{Ran}}^{-})$, Algorithm 20 for Case $(S_{\Sigma, \text{Ran}}^{\cap \cup})$, and Algorithm 21 for Case $(S_{\Sigma, \text{Ran}^{\cap \cup}}^{-})$. Note that Algorithm 19 is same for $\text{Ran}$-, $\text{Ran}$- and $\text{Ran}^{\cap \cup}$-subsumption queries.

Observe that $\text{COVER}_{\text{Ran}}(\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \mathcal{L})$ may be called several times during the execution of Algorithm 22. The algorithm can be optimised by caching the return value of the first execution, and retrieving it from memory for subsequent calls.
Additionally, let \( \chi \)

We now introduce algorithms of computing subsumee projection justifications based on subsumee simulation. The basic idea of the algorithm is to collect as few axioms from \( \mathcal{T}_2 \) as possible to maintain the subsumee simulation between \( \Sigma \)-concept names. In [23], we know that

- \( \text{rhsWtn}^{\text{ran}}_2(\mathcal{T}_1, \mathcal{T}_2) \neq \text{rhsWtn}^{\text{ran}}_2(\mathcal{T}_1, \mathcal{T}_2); \)
- \( \text{rhsWtn}^{\text{ran}}_2(\mathcal{T}_1, \mathcal{T}_2) = \text{rhsWtn}^{\text{ran}+\Sigma}_2(\mathcal{T}_1, \mathcal{T}_2). \)

**6.3.2 Computing Subsumee Projection Justifications**

We now introduce algorithms of computing subsumee projection justifications based on subsumee simulation. The basic idea of the algorithm is to collect as few axioms from \( \mathcal{T}_2 \) as possible to maintain the subsumee simulation between \( \Sigma \)-concept names. In [23], we know that

**Algorithm 19:** Computing the set of all Subsumer Projection Justifications (\( S^\Sigma_{\text{nc}} \))

1. function \( \text{COVER}^{\Sigma}_{\text{nc}}(\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2) \)
2. \( M^\Sigma_{X_1} = \{ \emptyset \} \)
3. for every \( B \in (\Sigma \cap \mathcal{N}_C) \cup \{ \text{dom}(r) \mid r \in \Sigma \} \) such that \( \mathcal{T}_1 \models X_1 \subseteq B \)
4. \( M^\Sigma_{X_2} := M^\Sigma_{X_1} \otimes \text{Just}_{\mathcal{T}_1}(X_2 \subseteq B) \)
5. end
6. return Minimise_\( C \)(\( M^\Sigma_{X_2} \))

**Algorithm 20:** Computing the set of all Subsumer Projection Justifications (\( S^\Sigma_{\text{ran}} \)) \((\mathcal{L} \in \{\text{ran}, \text{Ran}\})\)

1. function \( \text{COVER}^{\Sigma}_{\text{ran}}(\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \mathcal{L}) \)
2. \( M^\Sigma_X = \{ \emptyset \} \)
3. for every \( Y \models X \exists r Z \in \mathcal{T}_1 \) (\( \models \in \{\subseteq, \equiv\} \)) and \( s \in \Sigma \cap \mathcal{N}_R \) such that \( \mathcal{T}_1 \models X \subseteq Y \) and \( \mathcal{T}_2 \models r \subseteq s \)
4. \( M^\Sigma_{Y \exists r Z} := \{ \emptyset \} \)
5. for every \( \langle Y' \models X' \exists r' Z' \in \mathcal{T}_2 \) (\( \models \in \{\subseteq, \equiv\} \)) such that \( \mathcal{T}_2 \models X' \subseteq Y' \), \( \mathcal{T}_2 \models r' \subseteq s \), and \( \langle \mathcal{T}_1, z \rangle \sim_{\Sigma, \mathcal{L}} \langle \mathcal{T}_2, z' \rangle \)
6. \( M^\Sigma_{Z'} := \text{COVER}_{\Sigma}(\mathcal{T}_1, Z, \Sigma, \mathcal{T}_2, Z', \mathcal{L}) \)
7. \( M^\Sigma_{Z \exists r Z} := M^\Sigma_{Z'} \cup \{ \{ Y' \models X' \exists r' Z' \} \otimes M^\Sigma_{Z'} \otimes \text{Just}_{\mathcal{T}_1}(X \subseteq Y') \otimes \text{Just}_{\mathcal{T}_2}(r' \subseteq s) \} \)
8. end
9. \( M^\Sigma_X := M^\Sigma_Y \otimes M^\Sigma_{Z \exists r Z} \)
10. end
11. return Minimise_\( C \)(\( M^\Sigma_X \))

The following theorem shows that Algorithm 22 indeed computes the set of subsumer projection justifications.

**Theorem 157** Let \( \mathcal{T}_1 \) and \( \mathcal{T}_2 \) be acyclic, normalised \& \( \mathcal{L} \mathcal{H}^\Sigma \)-terminologies, and let \( \Sigma \) be a signature. Additionally, let \( \chi = (\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \mathcal{L}) \) and \( M := \text{COVER}_{\Sigma}(\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \mathcal{L}) \) computed by Algorithm 22. If \( \mathcal{T}_1 \sim_{\Sigma, \mathcal{L}} \mathcal{T}_2 \), then \( M \) is the set of all subsumer projection justifications under \( \chi \).
Therefore, it is sufficient to have algorithms of computing all subsumee projection justifications for query languages ran and Ran.

The axioms of the form ran(r) ⊆ X might cause non-trivial entailments. For example, let \( \mathcal{R}_1 = \{ X \models \exists r Y, Y \equiv A_1 \cap A_2 \} \), \( \mathcal{R}_2 = \mathcal{R}_1 \cup \{ \text{ran}(r) \subseteq A_1 \} \), \( \Sigma = \{ X, A_1, A_2, r \} \). Then we have \( \mathcal{R}_1 \models \exists r (A_1 \cap A_2) \). However, as the axiom \( \alpha \text{ ran}(r) \subseteq A_1 \in \mathcal{R}_2 \), the conjunct \( A_1 \) of \( Y \) is already covered by \( \alpha \). Hence, when we define the notion of \( \Sigma \)-entailment, additional parameter \( \zeta \in \{ \epsilon \} \cup (N_R \cap \Sigma) \) is used. We call this additional parameter context of a role, i.e. an expression of the form \( \text{ran}(\zeta) \).

We treat \( \epsilon \) as a special role name and set \( \text{ran}(\epsilon) = \top \). The set of all role contexts, in symbols \( \mathcal{C}^\Sigma \), is defined as \( \mathcal{C}^\Sigma = \{ \epsilon \} \cup (N_R \cap \Sigma) \).

For a signature \( \Sigma \), let \( \Sigma^\text{dom} = \{ \text{dom}(t) \mid t \in N_R \cap \Sigma \} \) and \( \Sigma^\text{ran} = \{ \text{ran}(t) \mid t \in N_R \cap \Sigma \} \) be the sets consisting of concepts of the form \( \text{dom}(t) \) and \( \text{ran}(t) \) for every role name \( t \) in \( \Sigma \), respectively. Furthermore let \( \Sigma^{\text{ran} \epsilon} = \Sigma \cup \Sigma^\text{dom} \cup \{ \text{ran}(\zeta) \mid \zeta \neq \epsilon \} \) and \( \Sigma^{\text{ran} \zeta} = \Sigma \cup \Sigma^\text{dom} \cup \Sigma^\text{ran} \), for \( \zeta \in \mathcal{C}^\Sigma \). Note that \( \Sigma^{\text{ran} \zeta} = \Sigma^{\text{ran} \zeta'} \) for every \( \zeta, \zeta' \in \mathcal{C}^\Sigma \). For example, let \( \Sigma = \{ A, B, r \} \) be a signature. Then \( \Sigma^\text{dom} = \{ \text{dom}(r) \}, \Sigma^\text{ran} = \{ \text{ran}(s) \}, \mathcal{C}^\Sigma = \{ r, \epsilon \}, \Sigma^{\text{ran} \zeta} = \{ A, B, r, \text{dom}(r), \text{ran}(\zeta) \} \) and \( \Sigma^{\text{ran} \epsilon} = \{ A, B, r, \text{dom}(r), \text{ran}(\epsilon) \} \).

In order to deal with Ran-subsumption query, we extend Definition 86 in Section 3.2.2 and get the following definitions.
### Algorithm 22: Computing the set of all Subsumer Projection Justifications

```plaintext
function COVER→ (Σ, T₁, T₂, X₁, X₂)

if L ∈ {ran, Ran} then
  M_{(X₁,X₂)} := COVER₁₃(Σ, T₁, T₂, X₁, X₂) ⊕ COVER₁₃(Σ, T₁, T₂, X₁, X₂, Ran)
end

if L = Ran{∧, ∨} then
  M_{(X₁,X₂)} := {∅}
  for every ψ₁ ∈ F_{Σ₁} (X₁) do
    M_{ψ₁} := {∅}
    for every ψ₂ ∈ F_{Σ₂} (X₂) do
      M_{ψ₁,ψ₂} := COVER₁₃(Σ, ψ₁, T₁, T₂, ψ₂) ⊕ COVER₁₃(Σ, ψ₁, T₁, T₂, ψ₂, Ran{∧, ∨})
      M_{ψ₁} := M_{ψ₁} ∪ M_{ψ₁,ψ₂}
    end
  end
end
return MinimiseC(M_{(X₁,X₂)})
```

### Definition 158 (Σ-Entailment)
Let Σ be a normalised $\mathcal{E}_{\mathcal{H}}$-terminology and Σ be a signature. For $L \in \{\text{ran}, \text{Ran}\}$, $\zeta \in \mathbb{N}_{\text{R}} \cup \{\varepsilon\}$, $A \in \mathbb{N}_{\Sigma}$ and $s \in \mathbb{N}_{\text{R}}$, the following statements hold:

(i) $A \in \mathbb{N}_{\Sigma}$ is $(\Sigma, \text{ran}, \zeta)$-entailed in $\mathcal{I}$ iff there is an $\mathcal{E}_{\mathcal{L}_{\Sigma}}$-concept $C$ such that $\mathcal{I} \models \text{ran}(\zeta) \cap C \subseteq A$;

(ii) $A \in \mathbb{N}_{\Sigma}$ is $(\Sigma, \text{Ran}, \zeta)$-entailed in $\mathcal{I}$ iff there is an $\mathcal{E}_{\mathcal{L}_{\Sigma}}$-concept $D$ such that $\mathcal{I} \models D \subseteq A$;

(iii) $s \in \mathbb{N}_{\text{R}}$ is $\Sigma$-entailed in $\mathcal{I}$ iff there exists $s' \in \mathbb{N}_{\Sigma} \cap \Sigma$ such that $\mathcal{I} \models s' \sqsubseteq s$.

We then get the following definition by extending the Definition 87 in Section 3.2.2 for Ran-subsumption query.

### Definition 159 (Complex Σ-Entailment)
Let $\mathcal{I}$ be a normalised and acyclic $\mathcal{E}_{\mathcal{L}_{\mathcal{H}}}$-terminology, let $\Sigma$ be a signature, and let $X \in \mathbb{N}_{\Sigma}$.

We say that $X$ is complex $(\Sigma, \mathcal{L}, \zeta)$-entailed w.r.t. $\mathcal{I}$ iff for every $Y \in \text{non-conj}_{\mathcal{I}} (X)$ one of the following conditions holds:

1. there exists $B \in \Sigma(\Sigma, \zeta)$ such that $\mathcal{I} \models B \sqsubseteq Y$ and $\mathcal{I} \not\models B \sqsubseteq X$;

2. there exists $Y \equiv \exists rZ \in \mathcal{I}$ and $r$ and $Z$ are each $(\Sigma, \mathcal{L}, \zeta)$-entailed in $\mathcal{I}$.

Otherwise, $X$ is said to be simply $(\Sigma, \mathcal{L}, \zeta)$-entailed.
The concept name \( X \) being complex Sigma-entailed w.r.t. \( \mathcal{T} \) states that every conjunct of \( X \) is either defined as a \( \Sigma \)-entailed existential restriction (Condition 2) or it is entailed by a \( \Sigma \)-concept name, dom- or ran-concept by which \( X \) is not entailed.

We now define the notion of a subsumee simulation from \( \mathcal{T}_1 \) to \( \mathcal{T}_2 \) in a role context as a subset of \( \text{sig}^N_c(\mathcal{T}_1) \times \text{sig}^N_c(\mathcal{T}_2) \times \mathcal{C}^S_{\mathcal{T}_1} \), where \( \mathcal{C}^S_{\mathcal{T}_1} := \{ \varepsilon \} \cup (\mathcal{N}_R \cap (\Sigma \cup \text{sig}(\mathcal{T}_1))) \) is the range of role contexts.

We extend Definition 88 and obtain the following notion of subsumee simulation. The new definition works also for Ran-subsumption queries.

**Definition 160 (Subsumee Simulation)** Let \( \mathcal{T}_1 \) and \( \mathcal{T}_2 \) be two normalised \( \mathcal{EL} \mathcal{H}^\mathcal{R} \)-terminologies, and let \( \Sigma \) be a signature. A relation \( S \subseteq \text{sig}^N_c(\mathcal{T}_1) \times \text{sig}^N_c(\mathcal{T}_2) \times \mathcal{C}^S_{\mathcal{T}_1} \) is a \( (\Sigma, \mathcal{L}) \)-subsumee simulation from \( \mathcal{T}_1 \) to \( \mathcal{T}_2 \) iff \( S \) satisfies the following conditions:

\[
(S^c_1) \quad \text{if } (X_1, X_2, \zeta) \in S, \text{ then for every } \phi \in \Sigma(\mathcal{L}, \zeta) \text{ and for every } X'_2 \in \text{non-conj}_\mathcal{T}_2(X_2) \text{ with } \mathcal{T}_2 \models \text{ran}(\zeta) \subseteq X'_2, \mathcal{T}_1 \models \phi \subseteq X_1 \text{ implies } \mathcal{T}_2 \models \phi \subseteq X'_2;
\]

\[
(S^c_2) \quad \text{if } (X_1, X_2, \zeta) \in S \text{ and } X_1 \equiv \exists r. Y_1 \in \mathcal{T}_1 \text{ such that } \mathcal{T}_1 \models s \subseteq r \text{ for } s \in \Sigma \text{ and } Y_1 \text{ is } (\Sigma, \mathcal{L}, s)\text{-entailed in } \mathcal{T}_1, \text{ then for every } X'_2 \in \text{non-conj}_\mathcal{T}_2(X_2) \text{ not entailed by } \text{dom}(s) \text{ w.r.t. } \mathcal{T}_2, \text{ there exists } X'_2 \equiv \exists r'. Y_2 \in \mathcal{T}_2 \text{ such that } \mathcal{T}_2 \models s \subseteq r' \text{ and } (Y_1, Y_2, s) \in S;
\]

\[
(S^c_3) \quad \text{if } (X_1, X_2, \zeta) \in S \text{ and } X_1 \equiv Y_1 \cap \ldots \cap Y_n \in \mathcal{T}_1 \text{, then for every } Y_2 \in \text{non-conj}_\mathcal{T}_2(X_2) \text{ not entailed by } \text{ran}(\zeta) \text{ w.r.t. } \mathcal{T}_2, \text{ there exists } Y_1 \in \text{non-conj}_\mathcal{T}_1(X_1) \text{ not entailed by } \text{ran}(\zeta) \text{ w.r.t. } \mathcal{T}_2 \text{ with } (Y_1, Y_2, \varepsilon) \in S.
\]

We write \( \mathcal{T}_1 \sim_{\Sigma, \text{ran}} \mathcal{T}_2 \iff \) there is a \( \Sigma \)-subsumee simulation \( S \) from \( \mathcal{T}_1 \) to \( \mathcal{T}_2 \) such that for every \( A, r \in \Sigma \): \( (A, A, r) \in S \) and \( (A, A, r) \in S \).

We write \( \mathcal{T}_1 \sim_{\Sigma, \text{Ran}} \mathcal{T}_2 \iff \) there is a \( \Sigma \)-subsumee simulation \( S \) from \( \mathcal{T}_1 \) to \( \mathcal{T}_2 \) such that for every \( A \in \mathcal{N}_C \cap \Sigma : (A, A, r) \in S \).

For \( \mathcal{L} \in \{ \text{ran}, \text{Ran} \} \) and \( \zeta \in \Sigma \cap \mathcal{N}_R \), we write \( \langle \mathcal{T}_1, X_1 \rangle \sim^\mathcal{L}_{\Sigma, \zeta} \langle \mathcal{T}_2, X_2 \rangle \iff \) there is a \( \Sigma \)-subsumee simulation \( S \) from \( \mathcal{T}_1 \) to \( \mathcal{T}_2 \) with \( (X_1, X_2, \zeta) \in S \) for which \( \mathcal{T}_1 \sim_{\mathcal{L}, \zeta} \mathcal{T}_2 \).

Analogously to subsumer simulations, a subsumee simulation captures the set of subsumees as it is made precise in the following theorem from [34].

**Theorem 161** We have the following conclusions:

- \( \mathcal{T}_1 \sim_{\mathcal{L}, \text{ran}} \mathcal{T}_2 \iff \text{rhotsWtn}^\text{ran}_{\mathcal{L}}(\mathcal{T}_1, \mathcal{T}_2) = \emptyset; \)
- \( \mathcal{T}_1 \sim^\mathcal{L}_{\Sigma, \text{Ran}} \mathcal{T}_2 \iff \text{rhotsWtn}^\text{Ran}_{\mathcal{L}}(\mathcal{T}_1, \mathcal{T}_2) = \emptyset. \)

**Theorem 162** Let \( \langle \mathcal{T}_1, X_1 \rangle \sim^\mathcal{L}_{\Sigma, \zeta} \langle \mathcal{T}_2, X_2 \rangle. \) Then:

- \( Q = \text{ran}: \) for every \( C \in \mathcal{EL} \mathcal{H} \) with \( \mathcal{T}_1 \models \text{ran}(\zeta) \cap C \subseteq X_1, \) it holds that \( \mathcal{T}_2 \models \text{ran}(\zeta) \cap C \subseteq X_2; \)
Algorithm 23: Computing the set of all Subsumee Projection Justifications \( \mathcal{S}_{\mathcal{N}_C}^{\mathcal{L}_1} \)

1. function \( \text{COVER}_{\mathcal{N}_C}(\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \mathcal{L}_1, \zeta) \)
2. \( M_{(X_1, X_2)}^{+} = \{\} \)
3. for every \( B \in \Sigma(X) \) such that \( \mathcal{T}_1 \models B \sqsubseteq X_1 \) do
4.   for every \( X_2 \in \text{non-conf}\_\Sigma(X_1) \) such that \( \zeta = \varepsilon \) or \( \mathcal{T}_2 \models \text{ran}(\zeta) \sqsubseteq X_2 \) do
5.     \( M_{(X_1, X_2)}^{+} := M_{(X_1, X_2)}^{+} \otimes \text{Just}_{\mathcal{T}_2}(B \sqsubseteq X_2) \)
6. end
7. return \( \text{Minimise}_{\subseteq}(M_{(X_1, X_2)}^{+}) \)

- \( Q = \text{Ran: for every } C \in \mathcal{L}_2^{\text{ran}} \text{ with } \mathcal{T}_1 \models C \sqsubseteq X_1, \text{ it holds that } \mathcal{T}_2 \models C \sqsubseteq X_2. \)

In order to collect the axioms necessary to satisfy the conditions of Definition 160, we develop Algorithm 23 (for Case \( (S_{\mathcal{N}_C}^{\mathcal{L}_1}) \)), Algorithm 24 (for Case \( (S_{\mathcal{F}_3}^{\mathcal{L}_1}) \)) and Algorithm 25 (for Case \( (S_{\mathcal{F}_1}^{\mathcal{L}_1}) \)).

The algorithm for computing subsumee projection justifications relies on the notion of subsumee simulation between terminologies [12, 34]. First we present some auxiliary notions for handling conjunctions on the left-hand side of subsumptions.

Like in Section 3.1.3, we define for each concept name \( X \) a so-called definitorial forest consisting of sets of axioms of the form \( Y \equiv Y_1 \sqcap \ldots \sqcap Y_n \) which can be thought of as forming trees. Any \( \langle X, \Sigma \rangle \)-subsumee projection justification contains the axioms of a selection of these trees, i.e., one tree for every conjunction formulated over \( \Sigma \) that entails \( X \) w.r.t. \( \mathcal{T} \).

In our algorithms, definitorial forest is used to enumerate all possible situations and find all possible sub-trees such that \( \text{Case}(S_{\mathcal{F}_3}^{\mathcal{L}_1}) \) can be satisfied.

For the next algorithm, we recall the definition of \( \text{def}_{\mathcal{F}} \). \( \text{def}_{\mathcal{F}} := \{ X \in \text{sig}^{\mathcal{N}_C}(\mathcal{T}) \mid X \equiv Y_1 \sqcap \ldots \sqcap Y_n \in \mathcal{T} \} \) is the set of concept names that are conjunctively defined in \( \mathcal{T} \). For every \( X \in \text{def}_{\mathcal{F}} \), we set \( \text{def}_{\mathcal{F}}(X) := \alpha \), where \( \alpha = X \equiv Y_1 \sqcap \ldots \sqcap Y_n \in \mathcal{T} \).

The axiom \( \alpha_{X_1} := X_1 \equiv Y_1 \sqcap \ldots \sqcap Y_m \in \mathcal{T} \) in Line 2 of Algorithm 25 is guaranteed by Line 12 of Algorithm 26. In the case where \( X_2 \) is defined as a conjunction in \( \mathcal{T}_2 \), the pair consisting of \( \mathcal{T}_2 \) containing only a partial conjunctive tree rooted at \( X_2 \) and \( X_2 \) needs to be considered to be sufficient to subsumee simulate \( X_1 \) in \( \mathcal{T}_1 \). Therefore Algorithm 25 considers every partial conjunctive tree \( \Gamma \) from \( \text{DefForest}_{\mathcal{T}_2}(X_2) \) in Line 4 and removes the axioms in \( \delta_{\mathcal{T}} \) connecting the leaves of \( \Gamma \) with the remaining conjunctive tree from \( \mathcal{T}_2 \) in Lines 11.

The following theorem shows the correctness of the algorithms 26 can compute minimal subset of \( \mathcal{T}_2 \) that maintains subsumee simulation w.r.t. ran-subsumption query.
6.3 Computing Subsumption Projection Justifications

Algorithm 24: Computing the set of all Subsume Projection Justifications (S^{+}⁻_{\mathcal{F}})

1. function COVER⁺⁻_{\mathcal{F}}(\mathcal{T}_1, X_1, \Sigma, \mathcal{B}_2, X_2, \mathcal{L}, \xi)  
2. Let \alpha_{X_1} := X_1 \equiv \exists r. Y_1 \in \mathcal{T}_1  
3. \mathcal{M}_{(X_1,X_2)} := \{\text{max-tree} \overline{\mathcal{F}}(X_2)\}  
4. for every $s \in \Sigma \cap N_R$ such that $\mathcal{T}_1 \models s \subseteq r$ do  
5. for every $Y_2' \in \text{non-conj}_{\mathcal{F}}(X_2)$ such that $\xi \neq \epsilon$ implies $\mathcal{B}_2 \not\models \text{ran}(\xi) \subseteq X_2'$ and  
6. Let $\alpha_{Y_2} := Y_2' \equiv \exists r'. Y_2' \in \mathcal{B}_2$  
7. \mathcal{M}_{Y_2} := COVER⁺⁻_{\mathcal{F}}(\mathcal{T}_1, Y_1, \Sigma, \mathcal{B}_2, Y_2', \mathcal{L}, s)  
8. \mathcal{M}_{(X_1,X_2)} := \mathcal{M}_{(X_1,X_2)} \otimes \{\alpha_{Y_2}\} \otimes \text{Just}_{\mathcal{B}_2}(s \subseteq r) \otimes \mathcal{M}_{Y_2}  
9. end  
10. end  
11. return Minimise⁺⁻(\mathcal{M}_{(X_1,X_2)})

Algorithm 25: Computing the set of all Subsume Projection Justifications (S^{+}⁻_{\mathcal{F}})

1. function COVER⁺⁻_{\mathcal{F}}(\mathcal{T}_1, X_1, \Sigma, \mathcal{B}_2, X_2, \mathcal{L}, \xi)  
2. let $\alpha_{X_1} := X_1 \equiv Y_1 \cap \ldots \cap Y_m \in \mathcal{T}_1$  
3. \mathcal{M}_{(X_1,X_2)} := \emptyset  
4. for every $\Gamma \in \text{DefForest}⁺⁻_{\mathcal{F}}(X_2)$ do  
5. Let $\delta_{\Gamma} := \{\text{def}⁺⁻_{\mathcal{F}}(X') \mid X' \in \text{leaves}(\Gamma) \cap \text{def}⁺⁻_{\mathcal{F}}\}$  
6. \mathcal{M}_{\Gamma} := \{\Gamma\}  
7. for every $X_2' \in \text{leaves}(\Gamma)$ such that $\xi = \epsilon$ or $\mathcal{B}_2 \not\models \text{ran}(\xi) \subseteq X_2'$ do  
8. \mathcal{M}_{X_2'} := \emptyset  
9. for every $X_1' \in \text{non-conj}_{\mathcal{F}}(X_1)$ such that $\xi = \epsilon$ or $\mathcal{B}_2 \not\models \text{ran}(\xi) \subseteq X_1'$ do  
10. if $(\mathcal{T}_1, X_1') \sim_{\mathcal{L}} (\mathcal{B}_2 \setminus \delta_{\Gamma}, X_1')$ then  
11. \mathcal{M}_{X_1'} := \mathcal{M}_{X_1} \cup \text{COVER⁺⁻}_{\mathcal{F}}(\mathcal{T}_1, X_1', \Sigma, \mathcal{B}_2 \setminus \delta_{\Gamma}, X_1', \mathcal{L}, \epsilon)  
12. end  
13. end  
14. \mathcal{M}_{\Gamma} := \mathcal{M}_{\Gamma} \otimes \mathcal{M}_{X_2'}  
15. end  
16. \mathcal{M}_{(X_1,X_2)} := \mathcal{M}_{(X_1,X_2)} \cup \mathcal{M}_{\Gamma}  
17. end  
18. return Minimise⁺⁻(\mathcal{M}_{(X_1,X_2)})
Theorem 163 Let $\chi = \langle \mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \mathcal{L} \rangle$, where $\mathcal{T}_1$ and $\mathcal{T}_2$ are two acyclic and normalised $\mathcal{E}\mathcal{L}\mathcal{H}'$-terminologies, $\Sigma$ is a signature and $X_1, X_2 \in \Sigma \cap N_C$. Additionally, let

$$M := \text{COVER}_\leftarrow (\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \mathcal{L}, \mathcal{R}, \zeta).$$

If $\mathcal{T}_1 \mathcal{R} \mathcal{T}_2$, then for every $M \in M$, it holds that $(\mathcal{T}_1, X_1) \sim_{\Sigma, \chi}^{\mathcal{L}} (\mathcal{M}, X_2)$ and $\mathcal{M}$ is minimal w.r.t. set inclusion.

The following theorem shows that the set of all subsumee projection justifications can be computed by Algorithm 26.

Theorem 164 Let $\chi_{\text{ran}} = \langle \mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \mathcal{R}, \zeta \rangle$, $\chi_{\text{ran}} = \langle \mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \mathcal{R}, \zeta \rangle$, where $\mathcal{T}_1$ and $\mathcal{T}_2$ are two acyclic and normalised $\mathcal{E}\mathcal{L}\mathcal{H}'$-terminologies, $\Sigma$ is a signature and $X_1, X_2 \in \Sigma \cap N_C$. Additionally, let

$$M_{\text{ran}} := \text{Minimise}_\subseteq (\text{COVER}_\leftarrow (\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \mathcal{R}, \zeta)) \otimes \bigotimes_{r \in \Sigma \cap N_C} \text{COVER}_\leftarrow (\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \mathcal{R}, r),$$

$$M_{\text{ran}} := \text{COVER}_\leftarrow (\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \mathcal{R}, \zeta).$$

If $\mathcal{T}_1 \mathcal{R} \mathcal{T}_2$, then $M_{\text{ran}}$ is the set of all subsumee justifications under $\chi_{\text{ran}}$ and $M_{\text{ran}}$ is the set of all subsumee justifications under $\chi_{\text{ran}}$.

Theorem 164 follows from Definition 137, Theorem 162 and Theorem 163.
The number of (minimal) projection justifications depends on \( \mathcal{T}_1, \mathcal{T}_2 \) and \( \Sigma \) and exponential bounded in the size of the terminologies. The simulation checks can be performed in polynomial time [12, 34]. Algorithm 26 runs in exponential time in the number of axioms contained in the input terminologies, in the worst case. On the one hand, the algorithm uses justifications (see Line 6 of Alg. 24 and Line 5 of Alg. 23) whose number grows exponentially for role inclusions as well as concept name inclusions. The different justifications are each incorporated using the operator \( \otimes \) resulting in possibly different subsumption justifications. The majority of the running time will be spent on computing justifications. Another source of exponential blowup is contained in Line 4 of Algorithm 25. The number of elements in the set DefForest\( _2^\uparrow \mathcal{F} \) grows exponentially in \( |\mathcal{F}| \).

According to our experience so far, however, it seems plausible to assume that definitorial forests in practical ontologies remain rather small and, thus, they do not cause a serious slowdown of the algorithm.

6.4 Proofs

6.4.1 Proof Regarding Subsumption Projection Justification

**Lemma 152** Let \( \chi(\varphi) = (\mathcal{T}_1, \varphi, \Sigma, \mathcal{T}_2, \varphi, \mathcal{L}) \) and \( \chi(A) = (\mathcal{T}_1, A, \Sigma, \mathcal{T}_2, A, \mathcal{L}) \), where \( \varphi \in (\Sigma \cap N_\mathcal{C}) \cup \Sigma^{\text{dom}} \cup \Sigma^{\text{ran}} \), \( A \in \Sigma \cap N_\mathcal{C} \) and \( \mathcal{L} \in \{ \text{ran, Ran, Ran}^{\neg \mathcal{V}} \} \). Then we have that for every \( J_X(\varphi) \in J_X(\varphi)^\uparrow \), \( \varphi \notin \text{lhsWtn}^\varphi_X(\mathcal{T}_1, J_X(\varphi)) \), and for every \( J_X(A) \in J_X(A)^\uparrow \), \( A \notin \text{rhsWtn}^\varphi_X(\mathcal{T}_1, J_X(A)) \).

**Proof** We first prove that \( \varphi \notin \text{lhsWtn}^\varphi_X(\mathcal{T}_1, J_X(\varphi)) \), where \( \mathcal{L} = \{ \text{ran, Ran, Ran}^{\neg \mathcal{V}} \} \) for every \( J_X(\varphi) \in J_X(\varphi)^\uparrow \). According to the Theorem 40 and 61 in [23], we have that the sets \( \text{lhsWtn}^\varphi_X(\mathcal{T}_1, J_X(\varphi)) \subseteq \Sigma \cap N_\mathcal{C} \cup \{ \text{dom}(r) | r \in \Sigma \} \cup \{ \text{ran}(r) | r \in \Sigma \} \) of left-hand subsumption query difference witnesses consist of the left-hand sides of the type-\( \delta_1 \) inclusions in \( \text{cDiff}^\varphi_X(\mathcal{T}_1, \mathcal{T}_2) \). As \( \delta_1 := A \sqsubseteq C | \text{dom}(r) \sqsubseteq C | \text{ran}(r) \sqsubseteq C \), we can get that \( \varphi \notin \text{lhsWtn}^\varphi_X(\mathcal{T}_1, J_X(\varphi)) \) for every \( J_X(\varphi) \in J_X(\varphi)^\uparrow \) by Definition 137.

Then we prove that \( A \notin \text{rhsWtn}^\varphi_X(\mathcal{T}_1, J_A) \) for every \( J_A \in J_A^\uparrow \). According to the Theorem 40 and 61 in [23], we have that the sets \( \text{rhsWtn}^\varphi_X(\mathcal{T}_1, \mathcal{T}_2) \subseteq N_\mathcal{C} \cap \Sigma \) of right-hand subsumption query difference witnesses consist of the right-hand sides of type-\( \delta_2 \) and type-\( \delta_3 \) inclusions in \( \text{cDiff}^\varphi_X(\mathcal{T}_1, \mathcal{T}_2) \), respectively, depending on the query language \( \mathcal{L} \). We distinguish according to the different query languages:

- when \( \mathcal{L} = \text{Ran or Ran}^{\neg \mathcal{V}} \): we consider type-\( \delta_3 \) inclusions. As \( \delta_3 := D \sqsubseteq A \) and Definition 137, we have that \( A \notin \text{rhsWtn}^\varphi_X(\mathcal{T}_1, J_A) \) for every \( J_A \in J_A^\uparrow \).
- when \( \mathcal{L} = \text{ran} \): we consider type-\( \delta_2 \) inclusions. As \( \delta_2 := C \sqsubseteq A | \text{ran}(r) \cap C \sqsubseteq A \), we have that \( A \notin \text{rhsWtn}^\varphi_X(\mathcal{T}_1, J_A) \) for every \( J_A \in J_A^\uparrow \).

\( \square \)
Theorem 153 Let \( \mathcal{L} \in \{ \text{ran, Ran, Ran}^{\cup, \cap} \} \) and \( M_{\rho}^{\mathcal{L}} \) be the set of all \( \mathcal{L} \)-projection modules under \( \rho = (\mathcal{F}, \Sigma, \mathcal{J}) \) that are minimal w.r.t. \( \subseteq \). Then

\[
M_{\rho}^{\mathcal{L}} = \text{Minimize}_{\mathcal{L}} \left( \bigoplus_{\varphi \in (\Sigma \cap \text{dom}) \cup \Sigma^{\text{ran}}} J_{\chi(\varphi)} \otimes \bigotimes_{A \in \Sigma \cap \text{dom}} J_{\chi(A)} \right)
\]

where \( \chi(\psi) = (\mathcal{F}, \psi, \Sigma, \mathcal{J}, \mathcal{L}) \).

Proof Let \( S_1 \) and \( S_2 \) be sets of sets that are each minimal w.r.t. \( \subseteq \), i.e., they satisfy: \( \forall S \in S_i \) with \( i \in \{1, 2\} \), there is no \( S' \in S_i \) such that \( S \subset S' \). We say that \( S_1 \subseteq S_2 \) iff for every \( S_2 \in S_2 \), there exists an \( S_1 \in S_1 \) such that \( S_1 \subseteq S_2 \).

Then let

\[
S_{\rho}^{\mathcal{L}} = \text{Minimize}_{\mathcal{L}} \left( \bigoplus_{\varphi \in (\Sigma \cap \text{dom}) \cup \Sigma^{\text{ran}}} J_{\chi(\varphi)} \otimes \bigotimes_{A \in \Sigma \cap \text{dom}} J_{\chi(A)} \right)
\]

It can readily be seen that \( S_1 \subseteq S_2 \) and \( S_2 \subseteq S_1 \) implies \( S_1 = S_2 \), using the property of minimality w.r.t. \( \subseteq \) of \( S_1 \) and \( S_2 \). Therefore, to show the lemma, it is sufficient to show that \( M_{\rho}^{\mathcal{L}} \subseteq S_{\rho}^{\mathcal{L}} \) and \( S_{\rho}^{\mathcal{L}} \subseteq M_{\rho}^{\mathcal{L}} \).

We first show that \( M_{\rho}^{\mathcal{L}} \subseteq S_{\rho}^{\mathcal{L}} \). By Theorem 24, the set of all \( \mathcal{L} \)-subsumption difference witnesses is defined as

\[
\text{Wtn}_{\mathcal{L}}^{\mathcal{L}} (\mathcal{F}, \mathcal{J}_1, \mathcal{J}_2) = \text{roleWtn}_{\mathcal{L}}^{\mathcal{L}} (\mathcal{F}, \mathcal{J}_1, \mathcal{J}_2) \cup \text{lhsWtn}_{\mathcal{L}}^{\mathcal{L}} (\mathcal{F}, \mathcal{J}_1, \mathcal{J}_2) \cup \text{rhsWtn}_{\mathcal{L}}^{\mathcal{L}} (\mathcal{F}, \mathcal{J}_1, \mathcal{J}_2),
\]

where the set \( \text{roleWtn}_{\mathcal{L}}^{\mathcal{L}} (\mathcal{F}, \mathcal{J}_1, \mathcal{J}_2) = \{ r \in \Sigma \cap \text{dom} \, | \, r \subseteq s \in \text{cDiff}^{\mathcal{L}} (\mathcal{F}, \mathcal{J}_1, \mathcal{J}_2) \text{ or } s \subseteq r \in \text{cDiff}^{\mathcal{L}} (\mathcal{F}, \mathcal{J}_1, \mathcal{J}_2) \} \), the set \( \text{lhsWtn}_{\mathcal{L}}^{\mathcal{L}} (\mathcal{F}, \mathcal{J}_1, \mathcal{J}_2) = \{ \varphi \in (\Sigma \cap \text{dom}) \cup \Sigma^{\text{ran}} \, | \, \varphi \subseteq \text{rhs}(\alpha) \text{ and } \alpha \text{ is a type-} \delta_i \text{ or type-} \gamma_i \text{ inclusion in the set } \text{cDiff}^{\mathcal{L}} (\mathcal{F}, \mathcal{J}_1, \mathcal{J}_2) \text{ and the set } \text{rhsWtn}_{\mathcal{L}}^{\mathcal{L}} (\mathcal{F}, \mathcal{J}_1, \mathcal{J}_2) = \{ A \in \Sigma \cap \text{dom} \, | \, \text{lhs}(\alpha) \subseteq A \text{ and } \alpha \text{ is a type-} \delta_i \text{ or type-} \gamma_i \text{ inclusion in the set } \text{cDiff}^{\mathcal{L}} (\mathcal{F}, \mathcal{J}_1, \mathcal{J}_2) \} \} \) respectively, depending on the query language \( \mathcal{L} \). With Lemma 148, Lemma 152 and Lemma 72, we have that \( \text{Wtn}_{\mathcal{L}}^{\mathcal{L}} (\mathcal{F}, M) = \emptyset \) for every \( M \in S_{\rho}^{\mathcal{L}} \). Consequently, by Definition 137 and Definition 19, every \( M \in S_{\rho}^{\mathcal{L}} \) is a projection module under \( \rho \), which means there exists \( M' \in M_{\rho}^{\mathcal{L}} \) such that \( M' \subseteq M \). Hence, \( M_{\rho}^{\mathcal{L}} \subseteq S_{\rho}^{\mathcal{L}} \).

Now we show that \( S_{\rho}^{\mathcal{L}} \subseteq M_{\rho}^{\mathcal{L}} \). Let \( M \in M_{\rho}^{\mathcal{L}} \) be a minimal projection module under \( \rho \). Since \( \text{Wtn}_{\mathcal{L}}^{\mathcal{L}} (\mathcal{F}, M) = \emptyset \), there exists \( J_R \in J_{\rho}^{\mathcal{L}} \) such that \( J_R \subseteq M \); for every \( \varphi \in (\Sigma \cap \text{dom}) \cup \Sigma^{\text{ran}} \), there exists \( J_{\varphi} \in J_{\chi(\varphi)}^{\mathcal{L}} \) such that \( J_{\varphi} \subseteq M \); and for every \( A \in \Sigma \cap \text{dom} \), there exists \( J_A \in J_{\chi(A)}^{\mathcal{L}} \) such that \( J_A \subseteq M \). Consequently, there exists \( S \in S_{\rho}^{\mathcal{L}} \) such that \( S \subseteq M \). Hence, \( S_{\rho}^{\mathcal{L}} \subseteq M_{\rho}^{\mathcal{L}} \). \( \square \)

6.4.2 Canonical Model & Helpful Lemmas

The material of this section comes from an unpublished appendix of [34]. As it has not been published yet, we list relevant definitions and lemmas in this section in order to make the proofs in this thesis
self-contained. We assume that \( \mathbb{N}_1 \) is countably infinite set of individual names disjoint with \( \mathbb{N}_C \) and \( \mathbb{N}_R \). An ABox \( \mathcal{A} \) is a non-empty finite set of assertions of the form \( \top(a), A(a) \) and \( r(a,b) \), where \( a,b \in \mathbb{N}_1, A \in \mathbb{N}_C, \) and \( r \in \mathbb{N}_R \). By \( \text{obj}(\mathcal{A}) \) we denote the set of individual names in \( \mathcal{A} \). An \( \mathcal{ELH} \)-knowledge base \( \mathcal{K} \) is a pair \((\mathcal{T}, \mathcal{A})\) consisting of an \( \mathcal{ELH} \)-TBox \( \mathcal{T} \) and an ABox \( \mathcal{A} \). Assertions of the form \( C(a) \) and \( r(a,b) \), where \( a,b \in \mathbb{N}_1, C \) an \( \mathcal{EL} \)-concept or an \( \mathcal{EL}^\cap u \)-concept, and \( r \in \mathbb{N}_R \), are called instance assertions.

We define a canonical model, \( \mathcal{I}_\mathcal{K} \), for \( \mathcal{ELH} \)-knowledge bases \( \mathcal{K} \). \( \mathcal{I}_\mathcal{K} \) can be constructed in polynomial time and gives the same answers to instance queries as \( \mathcal{K} \); i.e., \( \mathcal{I}_\mathcal{K} \models \alpha \) if, and only if, \( \mathcal{K} \models \alpha \), for any instance assertion \( \alpha \).

Let \( \text{sub}(\mathcal{T}) \) denote the set of all subconcepts of concepts used in \( \mathcal{T} \), \( \text{sig}^{\mathcal{K}_R}(\mathcal{T}) \) the set of all role names occurring in \( \mathcal{T} \). Take fresh individual names \( x_{\text{ran}(r),D} \) for every \( r \in \text{rol}(\mathcal{T}) \) and \( D \in \text{sub}(\mathcal{T}) \) and set
\[
\text{Nil}_{\text{aux}} := \{ x_{\text{ran}(r),D} \mid r \in \text{sig}^{\mathcal{K}_R}(\mathcal{T}) \text{ and } D \in \text{sub}(\mathcal{T}) \}.
\]
Now define the generating interpretation \( \mathcal{W}_\mathcal{K} \) of a KB \( \mathcal{K} = (\mathcal{T}, \mathcal{A}) \) as follows:
\[
\begin{align*}
\Delta^{\mathcal{W}_\mathcal{K}} & := \text{obj}(\mathcal{A}) \cup \text{Nil}_{\text{aux}}; \\
A^{\mathcal{W}_\mathcal{K}} & := \{ a \in \text{obj}(\mathcal{A}) \mid \mathcal{K} \models A(a) \} \cup \{ x_{\text{ran}(r),D} \in \text{Nil}_{\text{aux}} \mid \mathcal{T} \models \text{ran}(r) \cap D \subseteq A \}; \\
r^{\mathcal{W}_\mathcal{K}} & := \{ (a,b) \in \text{obj}(\mathcal{A}) \times \text{obj}(\mathcal{A}) \mid s(a,b) \in \mathcal{A} \text{ and } \mathcal{T} \models s \subseteq r \} \cup \{ (a,x_{\text{ran}(s),D}) \in \text{obj}(\mathcal{A}) \times \text{Nil}_{\text{aux}} \mid \mathcal{K} \models \exists s. D(a) \text{ and } \mathcal{T} \models s \subseteq r \} \cup \{ (x_{\text{ran}(s),D}, x_{\text{ran}(s'),D'}) \in \text{Nil}_{\text{aux}} \times \text{Nil}_{\text{aux}} \mid \mathcal{T} \models \text{ran}(s) \cap D \subseteq s'. D', \mathcal{T} \models s' \subseteq r \}; \\
a^{\mathcal{W}_\mathcal{K}} & := a, \text{ for all } a \in \text{obj}(\mathcal{A}).
\end{align*}
\]
A path in \( \mathcal{W}_\mathcal{K} \) is a finite sequence \( d_0 r_1 \cdots r_n d_n, n \geq 0 \), where \( d_0 \in \text{obj}(\mathcal{A}) \) and, for all \( i < n, (d_i, d_{i+1}) \in r^{\mathcal{W}_\mathcal{K}} \). We use \( \text{paths}(\mathcal{W}_\mathcal{K}) \) to denote the set of all paths in \( \mathcal{W}_\mathcal{K} \). If \( p \in \text{paths}(\mathcal{W}_\mathcal{K}) \), then \( \text{tail}(p) \) denotes the last element \( d_n \) in \( p \).

The canonical model \( \mathcal{I}_\mathcal{K} \) of a knowledge base \( \mathcal{K} \) is the restriction of \( \mathcal{W}_\mathcal{K} \) to all domain elements \( d \) such that there is a path in \( \mathcal{W}_\mathcal{K} \) with tail \( d \). The following result summarizes the main properties of \( \mathcal{I}_\mathcal{K} \).

**Theorem 165** Let \( \mathcal{K} = (\mathcal{T}, \mathcal{A}) \) be an \( \mathcal{ELH} \)-KB. Then
\[
\begin{align*}
(\text{i}) & \quad \mathcal{I}_\mathcal{K} \text{ is a model of } \mathcal{K}; \\
(\text{ii}) & \quad \mathcal{I}_\mathcal{K} \text{ can be computed in polynomial time in the size of } \mathcal{K}; \\
(\text{iii}) & \quad \text{for all } x_{C,D} \in \Delta^{\mathcal{W}_\mathcal{K}} \text{ and all } a \in \text{obj}(\mathcal{A}), \text{ if } C_0 \text{ is a } \mathcal{EL}^\cap u \text{-concept or of the form } \text{ran}(r), \text{ then the following holds:}
\end{align*}
\]
\[
\begin{align*}
&\quad \mathcal{K} \models C_0(a) \text{ iff } a^{\mathcal{W}_\mathcal{K}} \in C_0^{\mathcal{W}_\mathcal{K}}; \text{ and} \\
&\quad \mathcal{T} \models C \cap D \subseteq C_0 \text{ iff } x_{C,D} \in C_0^{\mathcal{W}_\mathcal{K}}.
\end{align*}
\]
Proof. See Theorem 2 (Extended Version) in [23]. \□

Lemma 166. Let \( \mathcal{T} \) be an \( \mathcal{EL}^{\mathcal{H}'} \)-terminology, let \( A \in \mathbb{N}_C \), \( r \in \mathbb{N}_R \), and let \( C \) be an \( \mathcal{EL}^{\mathcal{L},u} \)-concept. Then the following statements hold:

(i) \( \mathcal{T} \models A \sqsubseteq C \iff (\mathcal{T}, \{A(a)\}) \models C(a) \);
(ii) \( \mathcal{T} \models \text{ran}(r) \sqcap A \sqsubseteq C \iff (\mathcal{T}, \{r(a,b), A(b)\}) \models C(b) \);
(iii) \( \mathcal{T} \models \exists rA \sqsubseteq C \iff (\mathcal{T}, \{r(a,b), A(b)\}) \models C(a) \);
(iv) \( \mathcal{T} \models \text{ran}(r) \sqsubseteq C \iff (\mathcal{T}, \{r(a,b)\}) \models C(b) \);
(v) \( \mathcal{T} \models \text{dom}(r) \sqsubseteq C \iff (\mathcal{T}, \{r(a,b)\}) \models C(a) \).

Proof. Follows immediately from the definition of logical entailment w.r.t. TBoxes or knowledge bases. \□

Lemma 167. Let \( \mathcal{T} \) be a normalised \( \mathcal{EL}^{\mathcal{H}'} \)-terminology. Assume \( \mathcal{T} \models D \sqsubseteq \exists u.C \), where \( D \) is either a concept name or of the form \( \text{ran}(r) \), \( \text{dom}(r) \), or \( \text{ran}(r) \sqcap A \) with \( A, r \in \text{sig}(\mathcal{T}) \cup \Sigma \). Then one of the following statements holds:

- if \( \mathcal{T} \models A \sqsubseteq \exists u.C \), then there exist \( n \geq 0 \) and \( r_1, \ldots, r_n \in \mathbb{N}_R \) such that \( \mathcal{T} \models A \sqsubseteq \exists r_1 \ldots \exists r_n.C \);
- if \( \mathcal{T} \models \text{ran}(r) \sqcap A \sqsubseteq \exists u.C \), then there exist \( n \geq 0 \) and \( r_1, \ldots, r_n \in \mathbb{N}_R \) such that
  - \( \mathcal{T} \models \text{ran}(r) \sqcap A \sqsubseteq \exists r_1 \ldots \exists r_n.C \), or
  - \( \mathcal{T} \models \exists rA \sqsubseteq \exists r_1 \ldots \exists r_n.C \);
- if \( \mathcal{T} \models \text{ran}(r) \sqsubseteq \exists u.C \), then there exist \( n \geq 0 \) and \( r_1, \ldots, r_n \in \mathbb{N}_R \) such that
  - \( \mathcal{T} \models \text{dom}(r) \sqsubseteq \exists r_1 \ldots \exists r_n.C \), or
  - \( \mathcal{T} \models \text{ran}(r) \sqsubseteq \exists r_1 \ldots \exists r_n.C \);
- if \( \mathcal{T} \models \text{dom}(r) \sqsubseteq \exists u.C \), then there exist \( n \geq 0 \) and \( r_1, \ldots, r_n \in \mathbb{N}_R \) such that
  - \( \mathcal{T} \models \text{dom}(r) \sqsubseteq \exists r_1 \ldots \exists r_n.C \), or
  - \( \mathcal{T} \models \text{ran}(r) \sqsubseteq \exists r_1 \ldots \exists r_n.C \).
6.4 Proofs

Proof If \( \mathcal{T} \models A \sqsubseteq \exists u. C \), it follows from Lemma 166 that \( \mathcal{K} \models \exists u. C(a) \) for \( \mathcal{K} = (\mathcal{T}, \{A(a)\}) \). Hence, by Theorem 165 we have \( a^\mathcal{K} \in (\exists u. C)^\mathcal{K} \), i.e. there exists \( x \in \Delta^\mathcal{K} \) with \( x \in C^\mathcal{K} \). If \( x \in \text{obj}(\mathcal{A}) \), we have \( \mathcal{T} \models A \sqsubseteq C \) by Theorem 165 and Lemma 166. We can now assume that \( x \notin \text{obj}(\mathcal{A}) \), i.e. there exists a finite sequence \( d_0 \cdot d_1 \cdots d_n, n \geq 1 \), where \( d_0 = a, d_n = x \) and, for all \( i < n, (d_i, d_{i+1}) \in r_i^\mathcal{A} \). By definition of \( \mathcal{A} \mathcal{K} \) and by Theorem 165 we have \( \mathcal{K} \models (\exists r_1 \ldots \exists r_n.C)(a) \), and consequently \( \mathcal{K} \models A \sqsubseteq \exists r_1 \ldots \exists r_n.C \) by Lemma 166.

If \( \mathcal{T} \models \text{ran}(r) \sqcap A \sqsubseteq \exists u. C \), it follows from Lemma 166 that \( \mathcal{K} \models \exists u. C(a) \) for

\[ \mathcal{K} = (\mathcal{T}, \{r(a, b), A(b)\}) \]

Hence, by Theorem 165 we have \( a^\mathcal{K} \in (\exists u. C)^\mathcal{K} \), i.e. there exists \( x \in \Delta^\mathcal{K} \) with \( x \in C^\mathcal{K} \). If \( x \in \text{obj}(\mathcal{A}) \), we either have \( \mathcal{T} \models \text{ran}(r) \sqcap A \sqsubseteq C \) or \( \mathcal{T} \models \exists r. A \sqsubseteq C \) by Theorem 165 and Lemma 166. We can now assume that \( x \notin \text{obj}(\mathcal{A}) \), i.e. there exists a finite sequence \( d_0 \cdot d_1 \cdots d_n, n \geq 1 \), where \( d_0 \in \text{obj}(\mathcal{A}) \), \( d_0 = x \) and, for all \( i < n, (d_i, d_{i+1}) \in r_i^\mathcal{A} \). By definition of \( \mathcal{A} \mathcal{K} \) and by Theorem 165 we have \( \mathcal{K} \models (\exists r_1 \ldots \exists r_n.C)(d_0) \). Consequently, by Lemma 166, \( \mathcal{T} \models \text{ran}(r) \sqcap A \sqsubseteq \exists r_1 \ldots \exists r_n.C \) if \( d_0 = b \) and \( \mathcal{T} \models \exists r. A \sqsubseteq \exists r_1 \ldots \exists r_n.C \) otherwise.

The cases for \( \mathcal{T} \models \text{dom}(r) \sqsubseteq \exists u. C \) and \( \mathcal{T} \models \text{ran}(r) \sqsubseteq \exists u. C \) can be proved analogously to the previous case.

In the following we also make use of the following easy equivalence, which allows to characterise conjunctions of roles in terms of simple roles.

Lemma 168 (See [23]) Let \( \mathcal{T} \) be a normalised \( \mathcal{L} \mathcal{H}^r \)-terminology, let \( C \) be an \( \mathcal{L} \mathcal{ran} \)-concept, and let \( D \) be an \( \mathcal{L} \mathcal{ran} \)-concept which contains the occurrences \( S_i = r_{i,1} \cap \ldots \cap r_{i,m_i} \) of intersections of roles, \( 1 \leq i \leq k \). Then, \( \mathcal{T} \models C \sqsubseteq D \) holds if, and only if, there exist role names \( s_i, 1 \leq i \leq k \), such that \( s_i \subseteq \mathcal{T} r_{i,j} \) for \( 1 \leq i \leq k, 1 \leq j \leq m_i \) and \( \mathcal{T} \models C \sqsubseteq D' \), where \( D' \) is obtained from \( D \) by replacing \( S_i \) with \( s_i \).

Lemma 169 Let \( \mathcal{T} \) a normalised \( \mathcal{L} \mathcal{H}^r \)-terminology \( \mathcal{T} \) and \( \Sigma \) a signature. Additionally, let \( \mathcal{V} := \mathcal{N}_C \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in \Sigma \cup \text{sig}(\mathcal{T}) \} \) and \( X \in \mathcal{V} \). Let \( E \) be an \( \mathcal{L} \mathcal{ran} \)-concept such that \( \mathcal{T} \models X \sqsubseteq \exists r. D \). Then there exists \( Y \models \exists s. Z \in \mathcal{T} (\models \in \{\sqsubseteq, =\}) \) such that \( \mathcal{T} \models X \sqsubseteq Y, \mathcal{T} \models s \sqsubseteq r \) and \( \mathcal{T} \models Z \sqsubseteq D \).

Proof Let \( C \) be the \( \mathcal{L} \)-concept obtained from \( E \) by replacing the intersection of roles with simple roles as in Lemma 168. If \( X \) is either a concept name or of the form \( \text{ran}(r) \) or \( \text{dom}(r) \), the lemma can be proved by analysing the structure of the derivation \( X \vdash \mathcal{T} \exists r. C \). For the case where \( X = \text{ran}(r) \sqcap A \), it follows from Lemma 35 that either \( \mathcal{T} \models A \sqsubseteq \exists r.C \) or \( \mathcal{T} \models \text{ran}(r) \sqsubseteq \exists r.C \), i.e. we can apply one of the previous cases.

6.4.3 Proof Regarding Subsumer Projection Justification

The followings notions are required to handle concepts of the form \( \exists u.C \).
Definition 170 Let $\mathcal{T}$ be a normalised $\mathcal{EL} \mathcal{H}^n$-terminology and a signature $\Sigma$. Let $\mathcal{V} := \mathcal{N}_C \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in \Sigma \cup \text{sig}(\mathcal{T}) \}$ and $\psi \in \mathcal{V}$. The relation $\rho : \mathcal{V} \times \mathcal{V}$ is inductively defined as follows:

(i) $\{ \psi \} \rho \{ \psi \}$;

(ii) $\{ \psi \} \rho \{ \psi' \}$ if $\{ \psi \} \rho \{ X \}$ and $\mathcal{T} \models X \subseteq \exists r. \psi'$.

For $\psi \in \mathcal{V}$, we define $\text{ForwardReach}_\mathcal{T}(\psi) = \{ \psi' \mid \{ \psi \} \rho \{ \psi' \} \}$.

Definition 171 Let $\mathcal{T}$ be a normalised $\mathcal{EL} \mathcal{H}^n$-terminology $\mathcal{T}$ and $\Sigma$ a signature. Additionally, let $\phi \in \mathcal{N}_C \cup \{ \text{domain}(r), \text{range}(r) \mid r \in \mathcal{N}_R \}$.

If $\phi = \text{range}(r)$, we define

$$\text{Reach}_\mathcal{T}(\phi) := \text{ForwardReach}_\mathcal{T}(\phi) \cup \text{ForwardReach}_\mathcal{T}(\text{domain}(r))$$

otherwise, let $\text{Reach}_\mathcal{T}(\phi) := \text{ForwardReach}_\mathcal{T}(\phi)$.

The definition of $\text{Reach}_\mathcal{T}(X)$ coincides with the definition of $F_{\mathcal{T}}(C)$ in Section 6.3.1

Lemma 172 Let $\mathcal{T}$ be a normalised $\mathcal{EL} \mathcal{H}^n$-terminology $\mathcal{T}$ and $\Sigma$ a signature. Additionally, let $\mathcal{V} := \mathcal{N}_C \cup \{ \text{domain}(r), \text{range}(r) \mid r \in \Sigma \cup \text{sig}(\mathcal{T}) \}$ and $X \in \mathcal{V}$, let $E$ be an $\mathcal{EL}^{\mathcal{L}}$-concept, and let $r_1, \ldots, r_n \in \mathcal{N}_R$ ($n \geq 0$) such that $\mathcal{T} \models X \subseteq \exists r_1 \ldots \exists r_n E$. Then there exists $Y \in \text{ForwardReach}_\mathcal{T}(X)$ such that $\mathcal{T} \models Y \subseteq E$.

Proof By induction on $n$. For $n = 0$, nothing remains to be shown as $X \in \text{ForwardReach}_\mathcal{T}(X)$.

Let now $n \geq 1$. Then it follows from Lemma 169 that there exists an axiom $Y \equiv \exists Z \in \mathcal{T}$ ($\equiv \in \{ \subseteq, = \}$) such that $\mathcal{T} \models X \subseteq Y$, $\mathcal{T} \models s \subseteq r$, and $\mathcal{T} \models Z \subseteq \exists r_2 \ldots \exists r_n E$. Furthermore, we obtain from the induction hypothesis that there exists $Z' \in \text{ForwardReach}_\mathcal{T}(Z)$ such that $\mathcal{T} \models Z' \subseteq E$. As $\{ X \} \rho \{ Z \}$, it is then easy to see that $Z' \in \text{ForwardReach}_\mathcal{T}(X)$.

Lemma 173 Let $\mathcal{T}$ be a normalised $\mathcal{EL} \mathcal{H}^n$-terminology $\mathcal{T}$ and $\Sigma$ a signature. Additionally, let $x_X \in \mathcal{V}$ with $X \in \mathcal{N}_C \cup \{ \text{domain}(r) \mid r \in \mathcal{N}_R \} \cup \{ \text{range}(r) \mid r \in \mathcal{N}_R \}$ and let $D$ be an $\mathcal{EL}^{\mathcal{L}}$-concept. Then $\mathcal{T} \models X \subseteq \exists u.D$ iff there exists $x_Y \in \text{Reach}_\mathcal{T}(x_X)$ such that $\mathcal{T} \models Y \subseteq D$.

Proof The direction “$\subseteq$” follows immediately from the definition of the set $\text{Reach}_\mathcal{T}(x_X)$ and of the relation $\rho$.

For the direction “$\Rightarrow$” assume that $\mathcal{T} \models X \subseteq \exists u.D$ holds. We now distinguish between the following cases.

If $X = A$, it follows from Lemma 167 that there exist $n \geq 0$ and $r_1, \ldots, r_n \in \mathcal{N}_R$ such that $\mathcal{T} \models A \subseteq \exists r_1 \ldots \exists r_n D$. Thus, by Lemma 172 there exists $x_Y \in \text{ForwardReach}_\mathcal{T}(x_A) \subseteq \text{Reach}_\mathcal{T}(x_A)$ such that $\mathcal{T} \models Y \subseteq D$.
Lemma 174. Let $T$ be a normalised $\mathcal{E}_\Sigma$-terminology, let $X$ be a concept name, let $\exists r.D$ be an $\mathcal{E}_\Sigma$-concept such that $T \models X \sqsubseteq \exists r.D$. Then there exists an axiom $Y \bowtie \exists s.Z \in T \ (\bowtie \in \{\sqsubseteq, \equiv\})$ such that $T \models Y \sqsubseteq X$, $T \models s \sqsubseteq r$ and $T \models Z \sqsubseteq D$.

**Proof.** Let $\Delta$ be the derivation of the inclusion $X \sqsubseteq \exists r.D$ w.r.t. $T$. We assume now towards a contradiction that there does not exist an application of the (DefL), (PDefL) or (Sub) rule w.r.t. an axiom $Y \bowtie \exists r.Z \in T$ in $\Delta$. It is then easy to see that no concept of the form $\exists r.E$ occurs on the left-hand side of any inclusion in $\Delta$. We can infer that no concept of the form $\exists r.E$ occurs on the right-hand side of any inclusion in $\Delta$ as well, i.e. $\Delta$ is not a derivation of the inclusion $A \sqsubseteq \exists r.D$, which contradicts our assumption. \hfill $\Box$

Lemma 175. Let $T_1$ and $T_2$ be normalised $\mathcal{E}_\Sigma$-terminologies, let $\Sigma$ be a signature. Moreover, let $X_1, X_2 \in N_\Sigma \cup \text{dom}(r) \cup \text{ran}(r), r \in N_R$.

Then: If $(T_1, X_1) \sim^\Sigma_{\text{ran}} (T_2, X_2)$ holds, then $T_2 \models X_2 \sqsubseteq C$ holds for every $C \in \mathcal{E}_\Sigma$ such that $T_1 \models X_1 \sqsubseteq C$.

**Proof.** We prove by induction on the structure of $C$ that for every $X_1, X_2 \in N_\Sigma \cup \text{dom}(r) \cup \text{ran}(r) \cup \{\top\}$ with $(T_1, X_1) \sim^\Sigma_{\text{ran}} (T_2, X_2)$ and $T_1 \models X_1 \sqsubseteq C$ it holds that $T_2 \models X_2 \sqsubseteq C$.

Let $C \in \mathcal{E}_\Sigma$ and let $\phi_1, \phi_2 \in N_\Sigma$ such that $(X_1, X_2) \in S$ and $T_1 \models \phi \sqsubseteq C$. We now distinguish between the following cases.

1. $C = \top$: then we are done, since $T_2 \models X_2 \sqsubseteq \top$ always holds.

2. $C \in \Sigma \cap N_\Sigma$ or $C = \text{dom}(r)$: then we have $T_2 \models X_2 \sqsubseteq C$ by Definition 154.

3. $C = \exists r.E$: then by Lemma 174 there exists an axiom $Y_1 \bowtie_1 \exists x.X_1 \in T_1 \ (\bowtie_1 \in \{\sqsubseteq, \equiv\})$ such that $T_1 \models X_1 \sqsubseteq Y_1$, $T_1 \models \psi_1 \sqsubseteq E$ and $T \models s \sqsubseteq r$. As $S$ is $\Sigma$-subsumer simulation, there exists $Y_2 \bowtie_2 \exists s'.\psi_2 \in T_2$ with $T_2 \models X_2 \sqsubseteq Y_2$, $\bowtie_2 \in \{\sqsubseteq, \equiv\}$, $T \models s' \sqsubseteq r$ and $(X_1, X_2) \in S$. By applying the induction hypothesis we have $T \models \psi_2 \sqsubseteq E$. Consequently, it holds that $T_2 \models X_2 \sqsubseteq \exists r.E$. If $X = \text{ran}(r)$, it follows from Lemma 167 that there exist $n \geq 0$ and $r_1, \ldots, r_n \in N_R$ such that either

- $T \models \text{ran}(r) \sqsubseteq \exists r_1 \ldots \exists r_n.D$, or
- $T \models \text{dom}(r) \sqsubseteq \exists r_1 \ldots \exists r_n.D$.

In the former case we can prove the statement of the lemma analogously to the case for $X = A$. In the latter case we observe that by Lemma 172 there exists $x_y \in \text{ForwardReach}_T(x_{\text{dom}(r)}) \subseteq \text{Reach}_T(x_x)$ such that $T \models Y \sqsubseteq D$.

The case for $X = \text{dom}(r)$ can be shown analogously. \hfill $\Box$

6.4 Proofs

Lemma 176. Let $\Sigma$ be a signature. Moreover, let $X_1, X_2 \in N_\Sigma \cup \text{dom}(r) \cup \text{ran}(r), r \in N_R$.

Then: If $(T_1, X_1) \sim^\Sigma_{\text{ran}} (T_2, X_2)$ holds, then $T_2 \models X_2 \sqsubseteq C$ holds for every $C \in \mathcal{E}_\Sigma$ such that $T_1 \models X_1 \sqsubseteq C$.

**Proof.** We prove by induction on the structure of $C$ that for every $X_1, X_2 \in N_\Sigma \cup \text{dom}(r) \cup \text{ran}(r) \cup \{\top\}$ with $(T_1, X_1) \sim^\Sigma_{\text{ran}} (T_2, X_2)$ and $T_1 \models X_1 \sqsubseteq C$ it holds that $T_2 \models X_2 \sqsubseteq C$.

Let $C \in \mathcal{E}_\Sigma$ and let $\phi_1, \phi_2 \in N_\Sigma$ such that $(X_1, X_2) \in S$ and $T_1 \models \phi \sqsubseteq C$. We now distinguish between the following cases.

1. $C = \top$: then we are done, since $T_2 \models X_2 \sqsubseteq \top$ always holds.

2. $C \in \Sigma \cap N_\Sigma$ or $C = \text{dom}(r)$: then we have $T_2 \models X_2 \sqsubseteq C$ by Definition 154.

3. $C = \exists r.E$: then by Lemma 174 there exists an axiom $Y_1 \bowtie_1 \exists x.X_1 \in T_1 \ (\bowtie_1 \in \{\sqsubseteq, \equiv\})$ such that $T_1 \models X_1 \sqsubseteq Y_1$, $T_1 \models \psi_1 \sqsubseteq E$ and $T \models s \sqsubseteq r$. As $S$ is $\Sigma$-subsumer simulation, there exists $Y_2 \bowtie_2 \exists s'.\psi_2 \in T_2$ with $T_2 \models X_2 \sqsubseteq Y_2$, $\bowtie_2 \in \{\sqsubseteq, \equiv\}$, $T \models s' \sqsubseteq r$ and $(X_1, X_2) \in S$. By applying the induction hypothesis we have $T \models \psi_2 \sqsubseteq E$. Consequently, it holds that $T_2 \models X_2 \sqsubseteq \exists r.E$. If $X = \text{ran}(r)$, it follows from Lemma 167 that there exist $n \geq 0$ and $r_1, \ldots, r_n \in N_R$ such that either

- $T \models \text{ran}(r) \sqsubseteq \exists r_1 \ldots \exists r_n.D$, or
- $T \models \text{dom}(r) \sqsubseteq \exists r_1 \ldots \exists r_n.D$.

In the former case we can prove the statement of the lemma analogously to the case for $X = A$. In the latter case we observe that by Lemma 172 there exists $x_y \in \text{ForwardReach}_T(x_{\text{dom}(r)}) \subseteq \text{Reach}_T(x_x)$ such that $T \models Y \sqsubseteq D$.

The case for $X = \text{dom}(r)$ can be shown analogously. \hfill $\Box$
\[ C = C_1 \cap C_2 \] then we have \( \mathcal{T}_1 \models X_1 \subseteq C_i \) for \( i \in \{1, 2\} \) and by induction \( \mathcal{T}_2 \models X_2 \subseteq C_i \) for \( i \in \{1, 2\} \), which finally yields \( \mathcal{T}_2 \models X_2 \subseteq C \).

\[ \square \]

**Theorem 176** Let \( \chi = (\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \text{Ran}) \) where \( \mathcal{T}_1 \) and \( \mathcal{T}_2 \) are two acyclic normalised \( \mathcal{BLH} \)-terminologies, \( \Sigma \) is a signature and \( X_1, X_2 \in \text{N}_C \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in \text{N}_R \} \). Additionally, let

\[ M_\chi^\rightarrow := \text{Cover}\_\rightarrow((\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \text{Ran}). \]

If \( \mathcal{T}_1, X_1 \sim_{\Sigma, \text{Ran}} \mathcal{T}_2, X_2 \), then \( M_\chi^\rightarrow \) is the set of subsumer projection justification under \( \chi \).

**Proof** We first prove that \( M_\chi^\rightarrow \) is a cover of the set such that \( M \in M_\chi^\rightarrow \) is a subsumer projection module under \( \chi \). By Theorem 156, we have that proving \( M_\chi^\rightarrow \) is the set of \( M \) such that subsumer projection module under \( \chi \) is equal to prove \( M_\chi^\rightarrow := \{ M \subseteq \mathcal{T}_2 \mid (\mathcal{T}_1, X_1) \sim_{\Sigma, \text{Ran}} (M, X_2) \} \) for Ran-subsumption query.

(i) We show that every \( M \in M_\chi^\rightarrow \) is an subsumer projection module under \( \chi \).

First, we define the relation \( >_\mathcal{T} \subseteq \text{N}_C \times \text{N}_C \) as follows: let \( \mathcal{T} \) be an \( \mathcal{BLH} \) terminology. For \( X, Y \in \text{N}_C \) we set \( X >_\mathcal{T} Y \) iff there exists \( X' \bowtie \exists r Y \in \mathcal{T} \) with \( \mathcal{T} \models X \sqsubseteq X' \) and \( \bowtie \in \{ \sqsubseteq, \sqsubseteq \} \). Note that \( >_\mathcal{T} \) is well-founded as \( \mathcal{T} \) is acyclic. The proof now proceeds by induction on \( >_\mathcal{T} \).

Let \( X_1, X_2 \in \text{N}_C \) and let \( M \in M_\chi^\rightarrow \). We now distinguish between the following cases.

- If there does not exist \( Y \in \text{N}_C \) with \( X_1 >_\mathcal{T} Y \), let \( D \in \mathcal{BL}_\Sigma \) such that \( \mathcal{T}_1 \models X_1 \subseteq D \). The proof now continues by induction on the structure of \( D \). For \( D = \top \) or \( D = X \), it immediately follows that \( M \models X_2 \subseteq D \). For \( D = B \in \text{N}_C \) and \( B \neq X \), there exists \( J \in \text{Just}_\mathcal{T}(X_2 \subseteq B) \) with \( J \subseteq M \) (Line 4 in Algorithm 19), i.e. \( M \models X \subseteq D \). Similar with the case when \( D = \text{dom}(r) \) and \( r \in \text{N}_R \). For \( D = D_1 \cap D_2 \) we obtain \( M \models X_2 \subseteq D_1 \) and \( M \models X_2 \subseteq D_2 \) by applying the induction hypothesis on \( D_1 \) and \( D_2 \). Consequently, it holds that \( M \models X_2 \subseteq D \). Note that \( D \) cannot be of the form \( \exists r. E \) by Lemma 174.

- Otherwise, let \( D \in \mathcal{BL}_\Sigma \) such that \( \mathcal{T}_1 \models X_1 \subseteq D \). The proof now continues by induction on the structure of \( D \). The cases of \( D = \top, D = A \in \text{N}_C, D = \text{dom}(s), s \in \text{N}_R \) and \( D = D_1 \cap D_2 \) can be proved as above. For \( D \) is of the form \( \exists s. D' \), there exists \( Y \bowtie \exists r. Z \in \mathcal{T}_1 \) such that \( \mathcal{T}_1 \models X_1 \subseteq Y, \mathcal{T}_1 \models r \subseteq s \) and \( \mathcal{T}_1 \models Z \subseteq D' \) by Lemma 174. As \( (\mathcal{T}_1, X_1) \sim_{\Sigma, \text{Ran}} (\mathcal{T}_2, X_2) \), we have \( \mathcal{T}_2 \models X_2 \subseteq \exists s. D' \). Consequently, we have that there exists \( \alpha = Y \bowtie_{\mathcal{T}_2} \exists r'. Z' \in \mathcal{T}_2 \) such that \( \mathcal{T}_2 \models X_2 \subseteq Y' \) and \( \mathcal{T}_2 \models r' \subseteq s \) by Lemma 174, and \( \alpha \in M \). Furthermore, there exists \( M' \in \text{Cover}\_\rightarrow((\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \text{Ran}) \) such that \( M \subseteq M' \). As \( X >_\mathcal{T} Z' \), it follows from the induction hypothesis \( M' \) is a subsumer projection module under \( \chi' = \{ \mathcal{T}_1, Z, \Sigma, \mathcal{T}_2, Z', \text{Ran} \} \), i.e. for every \( D'' \in \mathcal{BL}_\Sigma, \mathcal{T}_1 \models Z \subseteq D'' \) implies \( M' \models Z' \subseteq D'' \). Hence, we can infer that \( M_{\exists r} \models X_2 \subseteq \exists r. D' \) (Line 7 in Algorithm 20 ).
(ii) We show that for every subsumer projection module under $\chi$, there exists $\mathcal{M}' \in \mathbb{M}^r$ such that $\mathcal{M}' \subseteq \mathcal{M}$.

The proof now proceeds by induction on $\triangleright$. Let $X_1, X_2 \in \mathbb{N}_C$ and let $\mathcal{M}$ be a subsumer projection module under $\chi = \{ \mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \text{Ran} \}$. We now distinguish between the following cases.

- If there does not exist $Y \in \mathbb{N}_C$ with $X_1 \triangleright Y$, let $B \in \Sigma$. As $\mathcal{M}$ is a $(\mathcal{T}_1, X_1, \Sigma)$ subsumer projection module of $\mathcal{T}_2$, there exists $S_B \in \text{Just}_{\mathcal{T}_1}(X_2 \sqsubseteq B)$ with $S_B \subseteq \mathcal{M}$. Consequently, it is easy to see that there exists $\mathcal{M}' \in \mathbb{M}^r_{X_2}$ with $\mathcal{M}' \triangleleft \bigcup_{B \subseteq \Sigma} S_B$ as there does not exist $X' \triangleright \exists Y \in \mathcal{T}_2$ with $\mathcal{T}_2 \triangleright \exists X' \cap X'$ and $\mathcal{T}_2 \triangleright s \sqsubseteq r$.

- Otherwise, $\langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \text{Ran}} \langle \mathcal{T}_2, X_2 \rangle$. Similarly to the previous case, for every $B \in \Sigma$ there exists $S_B \in \text{Just}_{\mathcal{T}_1}(X \sqsubseteq B)$ with $S_B \subseteq \mathcal{M}$.

Now let $\{ Y \triangleright \exists r Z \in \mathcal{T}_1 \mid r \in \Sigma, \mathcal{T}_1 \triangleright X_1 \sqsubseteq Y \text{ and } \mathcal{T}_1 \triangleright s \sqsubseteq r \} = \{ Y_1 \triangleright \exists r_1 Z_1, \ldots, Y_n \triangleright \exists r_n Z_n \}$ and let $1 \leq i \leq n$. Thus, as $\langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \text{Ran}} \langle \mathcal{T}_2, X_2 \rangle$, by the definition of subsumer simulation (Definition 154), there exists $Y'_i \triangleright_{\mathcal{T}_1} \exists s_i Z'_i \in \mathcal{M}$ such that $\mathcal{M} \triangleright X \sqsubseteq Y'_i$ and $\mathcal{M} \triangleright s_i \sqsubseteq r_i$ with $\langle \mathcal{T}_1, Z_i \rangle \sim_{\Sigma, \text{Ran}} \langle \mathcal{T}_2, Z'_i \rangle$ holds. Consequently, there exists $S_{Y'_i} \in \text{Just}_{\mathcal{T}_1}(X \sqsubseteq Y'_i)$ with $S_{Y'_i} \subseteq \mathcal{M}$ and $S_{s_i} \in \text{Just}_{\mathcal{T}_1}(s_i \sqsubseteq r_i)$ with $S_{s_i} \subseteq \mathcal{M}$. Moreover, as $(Z_i, Z'_i) \in S$, we have that $\mathcal{M}$ is a $(Z'_i, \Sigma)$-subsumer module of $\mathcal{T}_2$. It follows from the induction hypothesis that there exists $\mathcal{M}'_{Z'_i} \in \mathbb{M}^r_{Z'_i} : = \text{COVER}^{-1} (\mathcal{T}_1, Z_i, \Sigma, \mathcal{T}_2, Z'_i)$ with $\mathcal{M}'_{Z'_i} \subseteq \mathcal{M}$. Let

$$\mathcal{M}' := \bigcup_{B \in \Sigma} S_B \bigcup \bigcup_{i=1}^n \left( S_{Y'_i} \cup \left( \bigcup_{s_i} \cup \left( \bigcup_{s_i} \mathcal{M}' \cup \mathcal{M}'_{Z'_i} \right) \right) \right).$$

It is easy to see that $\mathcal{M}' \in \mathbb{M}^r$ and $\mathcal{M}' \subseteq \mathcal{M}$.

Then we prove that for any $\mathcal{M} \in \mathbb{M}^r$, $\mathcal{M}$ is a subsumer projection justification under $\chi$. We assume that $\mathcal{M}$ is a subsumer projection justification under $\chi$ and there exist a redundant axiom $\alpha \in \mathcal{M}$, such that $\mathcal{M} \setminus \{ \alpha \}$ is still a subsumer module under $\chi$. Once we go through all possible cases when $S$ is $\otimes$ to $\mathbb{M}^r$ such that $\alpha \in S$ and $S \in S$, we have that if $\alpha$ is removed from $S$, the subsumer simulation does not hold anymore. By Theorem 156, we have that there exists $D \in \mathcal{E} \mathcal{L}^{	ext{Ran}}_{\Sigma}$, such that $\mathcal{T}_1 \triangleright X_1 \sqsubseteq D$ does not imply $\mathcal{T}_2 \triangleright X_2 \sqsubseteq D$. So, $\mathcal{M}$ is not a subsumer projection justification under $\chi$, which contradict our assumption.

\[ \square \]

**Lemma 177** Let $\mathcal{T}_1$ and $\mathcal{T}_2$ be two acyclic normalised $\mathcal{E} \mathcal{L} \mathcal{H}$-terminologies, $\Sigma$ is a signature and $X, X' \in \mathbb{N}_C \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in \mathbb{N}_R \}$. If $\langle \mathcal{T}_1, X \rangle \sim_{\Sigma, \text{Ran}} \langle \mathcal{T}_2, X' \rangle$, then $\mathcal{T}_2 \triangleright X' \sqsubseteq C$ for every $C \in \mathcal{E} \mathcal{L}^\Sigma_{\mathcal{U}}$ such that $\mathcal{T}_1 \triangleright X \sqsubseteq C$.

**Proof** Let $\langle \mathcal{T}_1, X \rangle \sim_{\Sigma, \text{Ran}} \langle \mathcal{T}_2, X' \rangle$ and let $C$ be an $\mathcal{E} \mathcal{L}^\Sigma_{\mathcal{U}}$-concept $C$ with $\mathcal{T}_1 \triangleright X \sqsubseteq C$. The proof now proceeds by induction on the structure of $C$.  

• \( C = \top \): then we are done, since \( \mathcal{B}_2 \models A \sqsubseteq \top \) always holds.

• \( C \in N_C \) or \( C = \text{dom}(r) \): then we have \( \mathcal{T}_1 \models X \sqsubseteq C \) implies \( \mathcal{B}_2 \models X' \sqsubseteq C \) by Definition 154.

• \( C = C_1 \cap \ldots \cap C_m \): then we have \( \mathcal{T}_1 \models X \sqsubseteq C_i \) for every \( 1 \leq i \leq n \) and by induction \( \mathcal{B}_2 \models X' \sqsubseteq C_i \), which finally yields \( \mathcal{B}_2 \models X' \sqsubseteq C \).

• \( C = \exists R.D \) with \( R = r_1 \cap \ldots \cap r_n \) \((n \geq 1)\) and \( D \) an \( \mathcal{L}^\Sigma_\Sigma \)-concept: let \( r \in N_R \) such that \( \mathcal{T}_1 \models r \sqsubseteq r_i \) for every \( 1 \leq i \leq n \) and \( \mathcal{T}_1 \models X \sqsubseteq \exists r.D \) (cf. Lemma 168). Then by Lemmas 169 there exists a \( Z \bowtie \exists s.Y \in \mathcal{T}_1 \) \((\bowtie \in \{\sqsubseteq, \equiv\})\) such that \( \mathcal{T}_1 \models X \sqsubseteq Z \), \( \mathcal{T}_1 \models s \sqsubseteq r \) and \( \mathcal{T}_1 \models Y \sqsubseteq D \).

By Definition 154, there exists a \( Z' \bowtie \exists s'.Y' \in \mathcal{B}_2 \) \((\bowtie \in \{\sqsubseteq, \equiv\})\) such that \( \mathcal{B}_2 \models X' \sqsubseteq Z' \), \( \mathcal{B}_2 \models s' \sqsubseteq r_i \) for every \( i \in [1,n] \) and \( \mathcal{B}_2 \models Y' \sqsubseteq D \). Thus we get \( \mathcal{B}_2 \models Y' \sqsubseteq D \) by applying the induction hypothesis. Hence we have \( \mathcal{B}_2 \models X' \sqsubseteq \exists r.D \).

Let now \( X \in (N_C \cap \Sigma) \cup \{ \text{dom}(r) \mid r \in \Sigma \} \cup \{ \text{ran}(r) \mid r \in \Sigma \} \), and let \( D \) be an \( \mathcal{L}^\Sigma_\Sigma \)-concept such that \( \mathcal{T}_1 \models X \sqsubseteq D \). Now, let \( D' \) be the \( \mathcal{L}^\Sigma_\Sigma \)-concept of the form \( D'_0 \cap \prod_{i=1}^n \exists u.D_i^u \), where \( D'_0 \) and \( D_i^u \) \((1 \leq i \leq n)\) are \( \mathcal{L}^\Sigma_\Sigma \)-concepts, such that \( \models D \equiv D' \). It then follows from the previous parts of the proof that \( \mathcal{B}_2 \models X \sqsubseteq D'_0 \) holds. Let now \( 1 \leq i \leq n \). It then follows from Lemma 173 that there exists \( x \in \text{Reach}(\mathcal{T}_1(x)) \) such that \( \mathcal{T}_1 \models Y \sqsubseteq D_i^u \). By definition of \( \langle \mathcal{T}_1, X \rangle \sim_{\mathcal{L}_\Sigma} \langle \mathcal{B}_2, X \rangle \) (Definition 154), there is \( y \in \text{Reach}(\mathcal{B}_2(y)) \) such that \( x \leadsto y \). We thus obtain \( \mathcal{B}_2 \models Y' \sqsubseteq D_i^u \) from the previous parts of the proof, and it follows that \( \mathcal{B}_2 \models X \sqsubseteq \exists u.D_i^u \) holds by Lemma 173. Overall, we can conclude that \( \mathcal{B}_2 \models X \sqsubseteq D' \), i.e. \( \mathcal{B}_2 \models X \sqsubseteq D \).

\[ \square \]

**Lemma 178** If \( \mathcal{T}_1 \sim_{\mathcal{L}_\Sigma}^{\Sigma, \text{ran}^{\Sigma}_u} \mathcal{B}_2 \), then \( \text{lhsWtn}_{\mathcal{L}_\Sigma}^{\Sigma, \text{ran}^{\Sigma}_u}(\mathcal{T}_1, \mathcal{B}_2) = 0 \).

**Proof** Let \( D \) be an \( \mathcal{L}^\Sigma_\Sigma \)-concept such that \( \mathcal{T}_1 \models X_1 \sqsubseteq D \). Now, let \( D' \) be the \( \mathcal{L}^\Sigma_\Sigma \)-concept of the form \( D'_0 \cap \prod_{i=1}^n \exists u.D_i^u \), where \( D'_0 \) and \( D_i^u \) \((1 \leq i \leq n)\) are \( \mathcal{L}^\Sigma_\Sigma \)-concepts, such that \( \models D \equiv D' \). It then follows from Lemma 177 that \( \mathcal{B}_2 \models X \sqsubseteq D'_0 \) holds. Let now \( 1 \leq i \leq n \). It then follows from Lemma 173 that there exists \( Y \in \text{Reach}(\mathcal{T}_1(x)) \) such that \( \mathcal{T}_1 \models Y \sqsubseteq D_i^u \). By definition of \( \mathcal{T}_1 \sim_{\mathcal{L}_\Sigma}^{\Sigma, \text{ran}^{\Sigma}_u} \mathcal{B}_2 \), there is \( Y' \in \text{Reach}(\mathcal{B}_2(X')) \) such that \( Y \leadsto Y' \). We thus obtain \( \mathcal{B}_2 \models Y' \sqsubseteq D_i^u \) from the previous parts of the proof, and it follows that \( \mathcal{B}_2 \models X \sqsubseteq \exists u.D_i^u \) holds by Lemma 173. Overall, we can conclude that \( \mathcal{B}_2 \models X \sqsubseteq D' \), i.e. \( \mathcal{B}_2 \models X \sqsubseteq D \).

\[ \square \]

**Lemma 179** Let \( \mathcal{T}_1, \mathcal{B}_2 \) be two normalised \( \mathcal{L}^\Sigma_\Sigma \)-terminology and \( \Sigma \) a signature. Additionally, let \( X \in N_R \cap \text{sig}(\mathcal{T}_1) \cap \{ \text{dom}(r), \text{ran}(r) \mid r \in N_R \} \) and \( X \in N_R \cap \text{sig}(\mathcal{T}_1) \cap \{ \text{dom}(r), \text{ran}(r) \mid r \in N_R \} \) and \( X \in N_R \cap \text{sig}(\mathcal{B}_2) \) such that \( \mathcal{T}_1 \models X \sqsubseteq C \) entails \( \mathcal{B}_2 \models X' \sqsubseteq C \) for every \( \mathcal{L}^\Sigma_\Sigma \)-concept \( C \). Moreover, let \( A \bowtie \exists r.Y \in \mathcal{T}_1 \) \((\bowtie \in \{\sqsubseteq, \equiv\})\) such that there exists \( s \in \Sigma \) with \( \mathcal{T}_1 \models r \sqsubseteq s \) and \( \mathcal{T}_1 \models X \sqsubseteq A \).

Then there exists \( A' \bowtie \exists r'.Y' \in \mathcal{B}_2 \) such that the following holds:

• \( \mathcal{B}_2 \models X' \sqsubseteq A' \);
• \( \mathcal{T}_2 \models r' \subseteq s \) for every \( s \in \Sigma \) with \( \mathcal{T}_2 \models s \subseteq r \); and

• if \( \mathcal{T}_1 \models Y \subseteq C \), then \( \mathcal{T}_2 \models Y' \subseteq C \) for every \( C \)-concept \( C \).

**Proof** Let \( S = \{ s \in \Sigma \mid \mathcal{T}_1 \models s \subseteq r \} \) and let

\[
\bigcup_{i=1}^{n} \{ A'_i \subseteq \exists r'_i Y'_i \} = \{ A' \subseteq \exists r'.X' \mid \mathcal{T}_2 \models X' \subseteq A' \},
\]

\( A' \supseteq \exists r'.Y' \in \mathcal{T}_2, \exists s \in \{ c, \equiv \}, \forall s \in S: \mathcal{T}_2 \models r' \subseteq s \}.

Let \( R = \bigcap_{s \in S} s \). As \( \mathcal{T}_1 \models A \subseteq \exists R.T \), we have \( \mathcal{T}_2 \models A \subseteq \exists R.T \), and therefore \( n \geq 1 \) by Lemmas 168 and 169. If we assume for every \( 1 \leq i \leq n \) that there exists a \( \mathcal{L}^\Sigma_1 \)-concept \( C_i \) with \( \mathcal{T}_1 \models \text{ran}(r_i) \cap Y \subseteq C_i \) and \( \mathcal{T}_2 \not\models \text{ran}(r'_i) \cap X'_i \subseteq C_i \), it would follow that \( \mathcal{T}_1 \models X \subseteq \exists R.(C_1 \cap \ldots \cap C_n) \) and hence, \( \mathcal{T}_2 \models X \subseteq \exists R.(C_1 \cap \ldots \cap C_n) \). By Lemmas 168 and 169 we could infer that there exists \( 1 \leq j \leq n \) such that \( \mathcal{T}_2 \models A'_j \subseteq \exists r'_j X'_j \) and \( \mathcal{T}_2 \models \text{ran}(r'_j) \cap X'_j \subseteq C_i \) for every \( 1 \leq i \leq n \), which contradicts our assumption. \( \square \)

**Lemma 180** If \( \text{lhsWtn}_{\mathcal{L}^\Sigma_2}^{\text{ran}^{\equiv}}(\mathcal{T}_1, \mathcal{T}_2) = \emptyset \), then \( \mathcal{T}_1 \sim_{\Sigma, \text{ran}^{\equiv}} \mathcal{T}_2 \).

**Proof** Let

\[
S = \{ (X, X') \mid \forall C \in \mathcal{L}^\Sigma_1: \mathcal{T}_1 \models X \subseteq C \implies \mathcal{T}_2 \models X' \subseteq C \}.
\]

Clearly, \( (X, X) \in S \) for every \( X \in (N_C \cap \Sigma) \cup \{ \text{dom}(r) \mid r \in N_R \} \). We now show that \( S \) is a \( \langle \Sigma, \text{ran}^{\equiv} \rangle \)-simulation:

• Let \( (X, X') \in S \) with \( \mathcal{T}_1 \models X \subseteq Z \), and thus by definition of \( S \) also \( \mathcal{T}_2 \models X' \subseteq Z \), which satisfying Condition (\( S_1^{\equiv} \)) of Definition 154.

• Let \( (X, X') \in S \) with \( X \models \exists_1 \exists r Y \in \mathcal{T}_1 \models s \in \{ c, \equiv \} \) such that \( \mathcal{T}_1 \models r \subseteq s \) for some \( s \in \Sigma \)

Then by 179, there exists \( X'_1 \models \exists_2 \exists r'.Y' \in \mathcal{T}_2 \models \exists_2 \in \{ c, \equiv \} \) such that \( \mathcal{T}_2 \models X_2 \subseteq X'_2 \) and for every \( s \in \Sigma \) with \( \mathcal{T}_1 \models r \subseteq s \), and \( \mathcal{T}_1 \models X \subseteq C \) implies \( \mathcal{T}_2 \models X' \subseteq C \) for all \( \mathcal{L}^\Sigma_1 \)-concepts \( C \). But then \( (Y, Y') \in S \) by definition, satisfying Condition (\( S_3^{\equiv} \)) of Definition 154 overall.

Let now \( X \in (N_C \cap \Sigma) \cup \{ \text{dom}(r) \mid r \in \Sigma \} \cup \{ \text{ran}(r) \mid r \in \Sigma \} \). We assume towards a contradiction that there exists \( x_y \in \text{Reach}_{\mathcal{T}_1}(x_X) \) such that \( (x_Y, x_Y') \not\in S \) for every \( x_{Y'} \in \text{Reach}_{\mathcal{T}_2}(x_X) \). Hence, for every \( x_{Y'} \in \text{Reach}_{\mathcal{T}_2}(x_Y) \) there exists an \( \mathcal{L}^\Sigma_1 \)-concept \( C_{Y'} \) such that \( \mathcal{T}_1 \models Y \subseteq C_{Y'} \) and \( \mathcal{T}_2 \not\models Y' \subseteq C_{Y'} \).

Let \( D = \bigcap_{x_{Y'} \in \text{Reach}_{\mathcal{T}_2}(x_Y)} C_{Y'} \). We can then infer that \( \mathcal{T}_1 \models Y \subseteq D \) but \( \mathcal{T}_2 \not\models Y' \subseteq D \) for every \( x_{Y'} \in \text{Reach}_{\mathcal{T}_2}(x_Y) \). By Lemma 173 it holds that \( \mathcal{T}_1 \models X \subseteq \exists u.D \) but \( \mathcal{T}_2 \not\models X \subseteq \exists u.D \), which contradicts with \( \text{lhsWtn}_{\mathcal{L}^\Sigma_2}^{\text{ran}^{\equiv}}(\mathcal{T}_1, \mathcal{T}_2) = \emptyset \). \( \square \)
Theorem 181 Let $\chi = \langle \mathcal{R}_1, X_1, \Sigma, \mathcal{R}_2, X_2, \text{Ran}^{\Sigma\mathcal{R}} \rangle$, $\mathcal{R}_1$ and $\mathcal{R}_2$ be two acyclic normalised $\mathcal{EL}$-terminologies, and let $\Sigma$ be a signature. Additionally, let $X \in (\mathcal{N}_C \cap \Sigma) \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in \mathcal{R}_2 \}$, and let $\mathcal{M}_X^\chi := \text{COVER}_\rightarrow \mathcal{R}_1, X_1, \Sigma, \mathcal{R}_2, X_2, \text{Ran}^{\Sigma\mathcal{R}}$.

Then: If $(\mathcal{R}_1, X_1) \sim_{\Sigma, \text{Ran}^{\Sigma\mathcal{R}}} (\mathcal{R}_2, X_2)$ holds, then $\mathcal{M}_X^\chi$ is the set of all subsumer projection justifications under $\chi$.

Proof  The proof is similar to the proof of Lemma 176(by using Lemma 179).

Theorem 156 If $(\mathcal{R}_1, X_1) \sim_{\Sigma, \text{Ran}^{\Sigma\mathcal{R}}} (\mathcal{R}_2, X_2)$, then $\mathcal{R}_2 \models X_2 \sqsubseteq D$ for every $D \in \mathcal{L}_2$ such that $\mathcal{R}_1 \models X_1 \sqsubseteq D$.

Proof  It follows from Lemma 175 (Case $\text{Ran}$) and Lemma 177 (Case $\text{Ran}^{\Sigma\mathcal{R}}$).

Lemma 182 Let $\mathcal{R}_1$ and $\mathcal{R}_2$ be two normalised $\mathcal{EL}$-terminologies and $\Sigma$ be a signature. Additionally, let $X \in \mathcal{N}_R \cap \text{sig}(\mathcal{R}_1) \cap \{ \text{dom}(r), \text{ran}(r) \mid r \in \mathcal{R}_2 \}$ and $X' \in \mathcal{N}_R \cap \text{sig}(\mathcal{R}_2) \cap \{ \text{dom}(r), \text{ran}(r) \mid r \in \mathcal{R}_2 \}$ and $X \in \mathcal{N}_R \cap \text{sig}(\mathcal{R}_1)$ be such that $\mathcal{R}_1 \models X \sqsubseteq C$ entails $\mathcal{R}_2 \models X' \sqsubseteq C$ for every $\mathcal{EL}_{\Sigma}^{\text{Ran}}$-concept $C$. Moreover, let $A \sqsubseteq \exists Y \in \mathcal{R}_1 \models \{ A, \exists \} \sqsubseteq C$ such that there exists $s \in \Sigma$ with $\mathcal{R}_1 \models r \sqsubseteq s$ and $\mathcal{R}_1 \models X \sqsubseteq A$.

Then there exists $A' \sqsubseteq \exists r'. Y' \in \mathcal{R}_2$ such that the following holds

- $\mathcal{R}_2 \models X' \sqsubseteq A'$;
- $\mathcal{R}_2 \models r' \sqsubseteq s$; and
- If $\mathcal{R}_1 \models Y \sqsubseteq C$, then $\mathcal{R}_2 \models Y' \sqsubseteq C$ for every $\mathcal{EL}_{\Sigma}^{\text{Ran}}$-concept $C$.

Proof  The lemma can be proved analogously to Lemma 179.

Let $S = \{ s \in \Sigma \mid \mathcal{R}_1 \models s \sqsubseteq r \}$ and let

$$\bigcup_{i=1}^{n} \{ A'_i \sqsubseteq \exists r'_i Y'_i \} = \{ A' \sqsubseteq \exists r'. X' \mid \mathcal{R}_2 \models X' \sqsubseteq A' \},$$

$$A' \sqsubseteq \exists r'. Y' \in \mathcal{R}_2, \exists i \in \{ \subseteq, \exists \}, \forall s \in S: \mathcal{R}_2 \models r' \sqsubseteq s \}.$$
Additionally, let

\[ \chi \]

Lemma 183

6.4.4 Proof Regarding Subsume Projection Justification

Proof We first prove \( T_1 \sim_{\Sigma, \text{ran}} T_2 \) iff \( \text{lhsWtn}^\Sigma_{\text{ran}}(T_1, T_2) = \emptyset \);

\[ \therefore \]

\[ \therefore \]

\[ \therefore \]

Theorem 157 Let \( \mathcal{T}_1 \) and \( \mathcal{T}_2 \) be acyclic, normalised \( \mathcal{EL} \tau \)-terminologies, and let \( \Sigma \) be a signature. Additionally, let \( \chi = \langle \mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \mathcal{L} \rangle \) and \( \mathcal{M} := \text{Cover}_\sim(\mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \mathcal{L}) \) computed by Algorithm 22. If \( \mathcal{T}_1 \sim_{\Sigma, \mathcal{L}} \mathcal{T}_2 \), then \( \mathcal{M} \) is the set of all subsume projection justifications under \( \chi \).

Proof It follows from Theorem 176 (Case Ran) and Theorem 181 (Case Ran\( \tau \)).

6.4.4 Proof Regarding Subsume Projection Justification

Lemma 183 Let \( \mathcal{F} \) be a normalised and acyclic \( \mathcal{EL} \Sigma \)-terminology, let \( \Sigma \) be a signature, and let \( X \in N_C \) be pseudo-primitive in \( \mathcal{F} \). Then \( X \) is not complex \( \Sigma \)-entailed w.r.t. \( \mathcal{F} \).

Proof As \( X \) is pseudo-primitive in \( \mathcal{F} \), we have \( \text{non-conj}_\mathcal{F}(X) = \{X\} \). We can infer that there cannot exist \( B \in \Sigma \) with \( \mathcal{F} \models B \subset Y \) and \( \mathcal{F} \not\models B \subset X \). Additionally, we observe that no axiom of the form \( X \equiv \exists r. Y \) is contained in \( \mathcal{F} \), which implies that \( X \) is not complex \( \Sigma \)-entailed w.r.t. \( \mathcal{F} \).

Lemma 184 Let \( \mathcal{T}_1 \) and \( \mathcal{T}_2 \) be normalised and acyclic \( \mathcal{EL} \Sigma \)-terminologies, and let \( \Sigma \) be a signature. Then: if \( \langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \mathcal{L}} \mathcal{T}_2, X_2 \rangle \) then \( \mathcal{T}_2 \models \text{ran}(\zeta) \cap C \subset X_2 \) holds for every \( C \in \mathcal{EL}_\Sigma \).\n
Proof Let \( C \) be an \( \mathcal{EL}_\Sigma \)-concept and let \( \langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \mathcal{L}} \langle \mathcal{T}_2, X_2 \rangle \) with \( X_1, X_2 \in N_C \) such that \( \mathcal{T}_1 \models C \subset X_1 \) if \( \zeta = e \), or \( \mathcal{T}_1 \models \text{ran}(r) \cap C \subset X_1 \) if \( \zeta = r \). We distinguish these three cases, which are mutually exclusive as \( \mathcal{T}_1 \) is a terminology and prove by introduction:

- \( X \) is pseudo-primitive in \( \mathcal{T}_1 \): it follows from Lemma 34 that there exists \( Z \in \Sigma^{(\text{ran}, \zeta)} \) such that \( \mathcal{T}_1 \models Z \subset X_1 \). It follows from Item \( (S_{N_C}) \) of Definition 160 that \( \mathcal{T}_2 \models Z \subset Y_2 \) for every \( Y_2 \in \text{non-conj}_\mathcal{E}_\Sigma(X_2) \) with \( \mathcal{T}_2 \not\models \text{ran}(\zeta) \subset Y_2 \) if \( \zeta \neq e \). Hence, \( \mathcal{T}_2 \models \text{ran}(\zeta) \cap D \subset X_2 \) by Lemma 34.
there exists an axiom of the form $X_1 \equiv \exists x. B_1$ in $\mathcal{T}_1$: By Lemma 34 we have that either a1) there exists $Z \in \Sigma^{(ran, \zeta)}$ such that $\mathcal{T}_1 \models Z \subseteq X_1$, or a2) there exists a conjunct $\exists y. C'$ of $C$ such that $\mathcal{T}_1 \models t \subseteq s$ and $\mathcal{T}_1 \models \text{ran}(t) \cap C' \subseteq B_1$. For a1), we proceed as above and obtain $\mathcal{T}_2 \models \text{ran}(\zeta) \cap C \subseteq X_2$. Consider a2). As $\mathcal{T}_1 \models \text{ran}(t) \cap C' \subseteq B_1$ and $C'$ is an $\mathcal{EL}_\Sigma$-concept, it holds that $B$ is $(\Sigma, \text{ran}, t)$-entailed by Definition 158. Let $Y_2 \in \text{non-conj}_{\mathcal{T}_2}(X_2)$. As $t \in \mathbb{N}_R \cap \Sigma$ with $\mathcal{T}_1 \models t \subseteq s$, we obtain by Item (5′$\mathcal{T}$) of Definition 160 that either i) $\mathcal{T}_2 \models \text{dom}(t) \subseteq Y_2$, ii) $\mathcal{T}_2 \models \text{ran}(r) \subseteq Y_2$, or iii) there exists $Y_2 \equiv \exists y. B_2 \in \mathcal{R}_2$, such that $\mathcal{T}_2 \models t \subseteq r'$ and $(B_1, B_2, r) \in S$ For i), it implies that $\mathcal{T}_2 \models \exists y. \exists t' \subseteq Y_′$. For ii), we obtain $\mathcal{T}_2 \models \text{ran}(r) \subseteq Y_2$. For iii), since $\mathcal{T}_1 \models \text{ran}(i) \cap D \subseteq B$, and $D$ is an $\mathcal{EL}_\Sigma$-concept, the induction hypothesis yields that $\mathcal{T}_2 \models \text{ran}(i) \cap D \subseteq B_2$. Then $\mathcal{T}_2 \models \exists t. (\text{ran}(i) \cap D) \subseteq \exists t. B_2$ and, thus, $\mathcal{T}_2 \models \exists t. D \subseteq Y_2$. For $\zeta = \epsilon$, we have that $\mathcal{T}_2 \models \exists t. D \subseteq Y_2$ for every $Y_2 \in \text{non-conj}_{\mathcal{T}_2}(X_2)$. Hence, $\mathcal{T}_2 \models \exists t. D \subseteq X_2$. For $\zeta = r$, we obtain that $\mathcal{T}_2 \models \exists t. D \subseteq Y_2$ or $\mathcal{T}_2 \models \text{ran}(r) \subseteq Y_2$ for every $Y_2 \in \text{non-conj}_{\mathcal{T}_2}(X_2)$. Hence, $\mathcal{T}_2 \models \text{ran}(r) \cap \exists t. D \subseteq X_2$.

there exists an axiom of the form $X \equiv X_1 \cap \ldots \cap X_n$ in $\mathcal{T}_1$: By Item (5′$\mathcal{T}$) of Definition 160 we have that b1) for $\zeta = r$: $\mathcal{T}_2 \models \text{ran}(r) \subseteq Y_2$ or there exists $i \in \{1, \ldots, n\}$ such that $\mathcal{T}_1 \not\models \text{ran}(r) \subseteq X_i$ and $(x_i, x_y, \epsilon) \in \leftarrow \text{ran}$, or b2) for $\zeta = \epsilon$: $(x_i, x_y, \epsilon) \in \leftarrow \text{ran}$ for some $i \in \{1, \ldots, n\}$. For b1), we have that $\mathcal{T}_2 \models \text{ran}(r) \subseteq Y_2$, or, since $\mathcal{T}_2 \models \text{ran}(r) \cap D \subseteq X_i$, $(x_i, x_y, \epsilon) \in \leftarrow \text{ran}$, and $X_i$ is non-conjunctive in $\mathcal{T}_1$, we have that $\mathcal{T}_2 \models \text{ran}(r) \cap D \subseteq Y' \text{ by applying one of the two previous cases}$. This implies that $\mathcal{T}_2 \models \text{ran}(r) \cap D \subseteq Y'$ for every $Y_2 \in \text{non-conj}_{\mathcal{T}_2}(X_2)$. Hence, $\mathcal{T}_2 \models \text{ran}(r) \cap D \subseteq X'$. For b2), since $\mathcal{T}_2 \models D \subseteq X_i$, $(x_i, x_y, \epsilon) \in \leftarrow \text{ran}$, and $X_i$ is non-conjunctive in $\mathcal{T}_1$ we obtain $\mathcal{T}_2 \models D \subseteq X' \text{ by applying one of the previous two cases again}$. We have established that $\mathcal{T}_2 \models D \subseteq X' \text{ for every } Y_2 \in \text{non-conj}_{\mathcal{T}_2}(X_2)$. Hence, $\mathcal{T}_2 \models D \subseteq X_2$.

\begin{lemma}
If $\langle \mathcal{T}_1, X_1 \rangle \models^{\mathcal{EL}_\Sigma}_{\Sigma, \zeta} \langle \mathcal{T}_2, X_2 \rangle$, then: for every $\mathcal{EL}_\Sigma^{\mathcal{EL}_\Sigma}$-concept $D$ such that $\mathcal{T}_1 \models D \cap \text{ran}(\zeta) \subseteq X$, it holds that $\mathcal{T}_2 \models D \cap \text{ran}(\zeta) \subseteq X'$.
\end{lemma}

\begin{proof}
We show the lemma by induction on the structure of $D$. Let $D$ be an $\mathcal{EL}_\Sigma^{\mathcal{EL}_\Sigma}$-concept and let $\langle \mathcal{T}_1, X_1 \rangle \models^{\mathcal{EL}_\Sigma}_{\Sigma, \zeta} \langle \mathcal{T}_2, X_2 \rangle$ with $X \in \mathbb{N}_C$ such that $\mathcal{T}_1 \models D \subseteq X$ if $\zeta = \epsilon$, or $\mathcal{T}_1 \models \text{ran}(r) \cap D \subseteq X$ if $\zeta = r$. Note that $D \neq \top$ if $\zeta = \epsilon$. We distinguish between the following cases, which are mutually exclusive as $\mathcal{T}_1$ is a terminology:

- $X$ is pseudo-primitive in $\mathcal{T}_1$: as $\text{ran}(\zeta) \cap D$ is an $\mathcal{EL}_\Sigma^{\mathcal{EL}_\Sigma}$-concept, it follows from Lemma 34 that there exists $Z \in \Sigma^{(\text{ran}, \zeta)}$ such that $\mathcal{T}_1 \models Z \subseteq X$.

As $\langle \mathcal{T}_1, X_1 \rangle \models^{\mathcal{EL}_\Sigma}_{\Sigma, \zeta} \langle \mathcal{T}_2, X_2 \rangle$ and $Z \in \Sigma^{(\text{ran}, \zeta)}$, it follows from Item (5′$\mathcal{T}$) of Definition 160 that $\mathcal{T}_2 \models Z \subseteq Y_2$ for every $Y_2 \in \text{non-conj}_{\mathcal{T}_2}(X)$ with $\mathcal{T}_2 \not\models \text{ran}(\zeta) \subseteq Y'$ if $\zeta \neq \epsilon$. Hence, $\mathcal{T}_2 \models \text{ran}(\zeta) \cap D \subseteq X'$. by Lemma 34.

\end{proof}
• there exists an axiom of the form $X_1 \equiv \exists s.B_1$ in $\mathcal{T}_1$: By Lemma 34 we have that either a1) there exists $Z \in \Sigma^{(\text{ran}, \zeta)}$ such that $\mathcal{T}_1 \models Z \subseteq X_1$, or a2) there exists a conjunct $\exists t.D'$ of $D$ such that $\mathcal{T}_1 \models t \subseteq s$ and $\mathcal{T}_1 \models \text{ran}(t) \cap D' \subseteq B_1$. For a1), we proceed as above and obtain $\mathcal{B}_2 \models \text{ran}(\zeta) \cap D \subseteq X$. Consider a2). As $\mathcal{T}_1 \models \text{ran}(t) \cap D' \subseteq B$ and $\text{ran}(t) \cap D'$ is an $\mathcal{E}^{\text{ran}}$-concept, it follows Definition 158 that $B$ is $(\Sigma, \text{ran}, t)$-entailed. Let $Y_2 \in \text{non-conj}_{\mathcal{T}_2}(X_2)$. As $t \in N_R \cap \Sigma$ with $\mathcal{T}_1 \models t \subseteq s$, we obtain by Item $(\mathcal{S}^{-|-\zeta})$ of Definition 160 that either i) $\mathcal{B}_2 \models \text{dom}(t) \subseteq Y_2$, ii) $\mathcal{B}_2 \models \text{ran}(r) \subseteq Y_2$ for $\zeta = r$, or iii) there exists $Y_2 \equiv \exists r'.B_2 \in \mathcal{T}_2$ with $\mathcal{B}_2 \models t \subseteq r'$ and $\langle \mathcal{T}_1, B_1 \rangle \sim^{\mathcal{E}, \text{ran}}_{\Sigma, \zeta} \langle \mathcal{T}_2, B_2 \rangle$. For i), we have that $\mathcal{B}_2 \models \exists t.D' \subseteq Y_2$. For ii), we obtain $\mathcal{B}_2 \models \text{ran}(r) \subseteq Y'$. For iii), since $\mathcal{T}_1 \models \text{ran}(t) \cap D' \subseteq B_1$, and $\text{ran}(t) \cap D'$ is an $\mathcal{E}^{\text{ran}}$-concept, the induction hypothesis yields that $\mathcal{B}_2 \models \text{ran}(t) \cap D' \subseteq B_2$. Then $\mathcal{B}_2 \models \exists t.\text{ran}(t) \cap D' \subseteq \exists t.B_2$ and, thus, $\mathcal{B}_2 \models \exists t.D' \subseteq Y_2$. For $\zeta = e$, we have that $\mathcal{B}_2 \models \exists t.D' \subseteq Y_2$ for every $Y_2 \in \text{non-conj}_{\mathcal{T}_2}(X_2)$. Hence, $\mathcal{B}_2 \models \exists t.D' \subseteq X_2$. For $\zeta = r$, we obtain that $\mathcal{B}_2 \models \exists t.D' \subseteq Y'$ or $\mathcal{B}_2 \models \text{ran}(r) \subseteq Y_2$ for every $Y_2 \in \text{non-conj}_{\mathcal{T}_2}(X_2)$. Hence, $\mathcal{B}_2 \models \text{ran}(r) \cap \exists t.D' \subseteq X_2$.

Lemma 185 If $\langle \mathcal{T}_1, X_1 \rangle \sim^{\mathcal{E}, \text{ran}}_{\Sigma, \zeta} \langle \mathcal{T}_2, X_2 \rangle$, then: for every $\mathcal{E}^{\text{ran}}$-concept $D$ such that $\mathcal{T}_1 \models D \cap \text{ran}(\zeta) \subseteq X$, it holds that $\mathcal{B}_2 \models D \cap \text{ran}(\zeta) \subseteq X'$.

Proof The statement of the lemma follows from Lemma 184 and Lemma 185.

We then give the definition of $\text{sub}(D)$ for $\mathcal{E}^{\text{ran}}$-concept $D$, which will be used in the following proof.

Definition 186 Let $D$ be an $\mathcal{E}^{\text{ran}}$-concept, $A \in N_C$ and $r \in N_R$.

We define the set $\text{sub}(D) \subseteq \mathcal{E}^{\text{ran}}$ inductively as follows:

- $\text{sub}(\top) = \{ \top \}$;
- $\text{sub}(A) = \{ A \}$;
- $\text{sub}(\text{dom}(r)) = \{ \text{dom}(r) \}$;
• sub(ran(r)) = {ran(r)};
• sub(∃r.D) = {∃r.D} ∪ sub(D);
• sub(D₁ ∩ D₂) = {D₁ ∩ D₂} ∪ sub(D₁) ∪ sub(D₂).

Moreover, we define the set sub₀(C) ⊆ ELH inductively as follows
• sub₀(⊤) = {⊤};
• sub₀(A) = {A};
• sub₀(dom(r)) = {dom(r)};
• sub₀(ran(r)) = {ran(r)};
• sub₀(∃r.C) = {∃r.C};
• sub₀(C₁ ∩ C₂) = sub₀(C₁) ∪ sub₀(C₂).

**Lemma 187** Let $\mathcal{T}$ be a normalised and acyclic $\mathcal{ELH}^r$-terminology, let $\Sigma$ be a signature, and let $X ∈ N_C$ be pseudo-primitive in $\mathcal{T}$.

Then $X$ is not complex $⟨\Sigma, L, ζ⟩$-entailed w.r.t. $\mathcal{T}$.

**Proof** As $X$ is pseudo-primitive in $\mathcal{T}$, we have non-conj $\mathcal{T}(X) = \{X\}$. We can infer that there cannot exist $B ∈ Σ$ with $\mathcal{T} ⊨ B ⊑ Y$ and $\mathcal{T} ⊭ B ⊑ X$. Additionally, we observe that no axiom of the form $X ≡ ∃r.Y$ is contained in $\mathcal{T}$, which implies that $X$ is not complex $⟨\Sigma, L, ζ⟩$ w.r.t. $\mathcal{T}$. □

**Lemma 188** Let $\mathcal{T}$ be a normalised and acyclic $\mathcal{ELH}^r$-terminology and let $X ∈ N_C$ is not complex $⟨\Sigma, Ran, ζ⟩$-entailed w.r.t. $\mathcal{T}$.

Then for every $D ∈ ELH^r$ it holds that: $\mathcal{T} ⊨ D ⊑ X$ iff there exists $B ∈ sub₀(D)$ such that $\mathcal{T} ⊨ B ⊑ X$.

**Proof** Let $D ∈ ELH^r$.

"only if": We assume that $\mathcal{T} ⊨ D ⊑ X$. Note that $\mathcal{T} ⊭ ⊤ ⊑ D$ as $\mathcal{T}$ is a normalised terminology, which implies that $⊤ ∉ sub(\mathcal{T})$. Then, as $X$ is not complex $Σ$-entailed w.r.t. $\mathcal{T}$, it follows that there exists $Y ∈ non-conj_\mathcal{T}(X)$ such that

(i) for every $B ∈ Σ^{(Ran, \xi)}$ with $\mathcal{T} ⊨ B ⊑ Y$ it holds that $\mathcal{T} ⊨ B ⊑ X$, and

(ii) for every $Y ≡ ∃s.Y′ ∈ \mathcal{T}$, it holds that either $s$ is not $Σ$-entailed or $Y′$ is not $⟨Σ, Ran, ξ⟩$-entailed in $\mathcal{T}$. 
Note that $\mathcal{T} \models D \subseteq Y$ since $\mathcal{T} \models X \subseteq Y$. We now distinguish between the following cases. If $Y$ is pseudo-primitive in $\mathcal{T}$, then it follows from Lemma 34 that there exists $B \in \text{sub}_0(D)$, $B \in N_C \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in N_R \}$ with $\mathcal{T} \models B \subseteq Y$, which implies that $\mathcal{T} \models B \subseteq X$ by (i).

Otherwise, there exists an axiom $Y \equiv \exists s Y' \in \mathcal{T}$ and it holds that $\mathcal{T} \models D \subseteq \exists s Y'$. If follows from Lemma 35 that either (a) there exists $B \in \text{sub}_0(C), B \in \text{sub}_0(D)$, $B \in N_C \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in N_R \}$ with $\mathcal{T} \models B \subseteq Y$, or (b) there exists $D' \cap \text{ran}(s') \subseteq \text{sub}(D)$ with $\mathcal{T} \models D' \cap \text{ran}(s') \subseteq Y'$ and $\mathcal{T} \models s' \subseteq s$. For (a), we have $\mathcal{T} \models B \subseteq Y$, and thus, $\mathcal{T} \models B \subseteq X$ by (i). We note that (b) cannot hold as $\text{sig}(D') \subseteq \Sigma$, which implies that $\mathcal{T} \models D' \cap \text{ran}(s) \subseteq Y'$ always holds, then $Y'$ is $\langle \Sigma, \text{ran}, \zeta \rangle$-entailed, which contradicts to (ii). So $\mathcal{T} \models B \subseteq X$.

"if" Let $B \in \text{sub}_0(D)$ such that $\mathcal{T} \models B \subseteq X$. Since $\mathcal{T} \models D \subseteq B$, it follows that $\mathcal{T} \models D \subseteq X$. □

**Lemma 189** Let $\mathcal{T}$ be a normalised and acyclic $\mathcal{EL} \mathcal{H}'$-terminology and let $X \in N_C$ is not complex $\langle \Sigma, \text{ran}, \zeta \rangle$-entailed w.r.t. $\mathcal{T}$. Then for every $C \in \mathcal{EL}_\Sigma$ it holds that: $\mathcal{T} \models C \cap \text{ran}(\zeta) \subseteq X$ iff there exists $B \in \text{sub}_0(C)$ such that $\mathcal{T} \models B \subseteq X$.

**Proof** Let $C \in \mathcal{EL}_\Sigma$.

"only if": We assume that $\mathcal{T} \models C \cap \text{ran}(\zeta) \subseteq X$. Note that $\mathcal{T} \not\models \top \subseteq C$ as $\mathcal{T}$ is a normalised terminology, which implies that $\top \not\subseteq \text{sub}(\mathcal{T})$. Then, as $X$ is not complex $\Sigma$-entailed w.r.t. $\mathcal{T}$, it follows that there exists $Y \in \text{non-conj}_\mathcal{T}(X)$ such that

(i) for every $B \in \Sigma^{(\text{ran}, \zeta)}$ with $\mathcal{T} \models B \subseteq Y$ it holds that $\mathcal{T} \models B \subseteq X$, and

(ii) for every $Y \equiv \exists s Y' \in \mathcal{T}$, it holds that either $s$ is not $\Sigma$-entailed or $Y'$ is not $\langle \Sigma, \text{ran}, \zeta \rangle$-entailed in $\mathcal{T}$.

Note that $\mathcal{T} \models C \cap \text{ran}(\zeta) \subseteq Y$ since $\mathcal{T} \models X \subseteq Y$. We now distinguish between the following cases:

If $Y$ is pseudo-primitive in $\mathcal{T}$, then it follows from Lemma 34 that there exists $B \in \text{sub}_0(C)$, $B \in N_C \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in N_R \}$ with $\mathcal{T} \models B \subseteq Y$, which implies that $\mathcal{T} \models B \subseteq X$ by (i).

Otherwise, there exists an axiom $Y \equiv \exists s Y' \in \mathcal{T}$ and it holds that $\mathcal{T} \models C \cap \text{ran}(\zeta) \subseteq \exists s Y'$. If follows from Lemma 35 that either (a) there exists $B \in \text{sub}_0(C), B \in N_C \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in N_R \}$ with $\mathcal{T} \models B \subseteq Y$, or (b) there exists $C' \cap \text{ran}(s') \subseteq \text{sub}(C)$ with $\mathcal{T} \models C' \cap \text{ran}(s') \subseteq Y'$ and $\mathcal{T} \models s' \subseteq s$. For (a), we have $\mathcal{T} \models B \subseteq Y$, and thus, $\mathcal{T} \models B \subseteq X$ by (i). We note that (b) cannot hold as $\text{sig}(C') \subseteq \Sigma$, which implies that $\mathcal{T} \models C' \cap \text{ran}(s') \subseteq Y'$ always holds, then $Y'$ is $\langle \Sigma, \text{ran}, \zeta \rangle$-entailed, which contradict to (ii). So $\mathcal{T} \models B \subseteq X$.

"if": let $B \in \text{sub}_0(C)$ such that $\mathcal{T} \models B \subseteq X$. Since $\mathcal{T} \models C \cap \text{ran}(\zeta) \subseteq B$, it follows that $\mathcal{T} \models C \cap \text{ran}(\zeta) \subseteq X$. □

**Lemma 190** Let $\chi = \langle \mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, \mathcal{R}_2, \mathcal{R}_2, \text{ran}, \zeta \rangle$ and $\mathcal{M}^\mathcal{T}_{(X_1,X_2)} := \text{COVER}_{\chi} \langle \mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, \mathcal{R}_2, \mathcal{R}_2, \text{ran}, \zeta \rangle$. If $\langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \mathcal{R}_2} \langle \mathcal{T}_2, X_2 \rangle$, then $\mathcal{M}^\mathcal{T}_{(X_1,X_2)}$ is the set such that for every $\mathcal{M} \in \mathcal{M}^\mathcal{T}_{(X_1,X_2)}$, $\langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \mathcal{R}_2} \langle \mathcal{M}, X_2 \rangle$ and for any $\mathcal{M}' \subseteq \mathcal{M}$, $\langle \mathcal{T}_1, X_1 \rangle \sim_{\Sigma, \mathcal{R}_2} \langle \mathcal{M}', X_2 \rangle$ does not hold.
Proof First we prove that $M^r_{\langle X_1, X_2 \rangle}$ is a cover of the set $M$ such that for every $M \in M^r_{\langle X_1, X_2 \rangle}$, $(T_1, X_1) \sim^r_{\Sigma, \zeta} (M, X_2)$ holds.

(i) We show that every $M \in M^r_{\langle X_1, X_2 \rangle}$, $(T_1, X_1) \sim^r_{\Sigma, \zeta} (M, X_2)$ holds. That is, we prove that for every $C \in \mathcal{E}_L$, $T_1 \models \text{ran}(\zeta) \in C \subseteq X_1$ implies that $M \models \text{ran}(\zeta) \in C \subseteq X_2$ and $M \subseteq T_2$.

First, we define the relation $\Rightarrow \subseteq \mathbb{N}_C \times \mathbb{N}_C$ as follows: for $X, Y \in \mathbb{N}_C$ we set $X \Rightarrow Y$ if either there exists $X \equiv \exists r Y \in T$ or there exists $X \equiv Y \land \ldots \land Y_n \in T$ such that $Y_i = Y$ for some $1 \leq i \leq n$.

Note that $\Rightarrow$ is well-founded as $T$ is acyclic. The proof now proceeds by induction on $\Rightarrow$.

Let $X_1, X_2 \in \mathbb{N}_C$ such that $(T_1, X_1) \sim^r_{\Sigma, \zeta} (T_2, X_2)$, and let $M \in M^r_{\langle X_1, X_2 \rangle}$. We now distinguish between the following cases.

If $X_1$ is not $\langle \Sigma, \text{ran}, \zeta \rangle$-entailed in $T_1$, then $M = \emptyset$ and there does not exist $C \in \mathcal{E}_L$ with $T_1 \models \text{ran}(\zeta) \in C \subseteq X_1$. Hence, it trivially holds for every $C \in \mathcal{E}_L$ with $T_1 \models \text{ran}(\zeta) \in C \subseteq X_1$ that $M \models \text{ran}(\zeta) \in C \subseteq X_2$.

Otherwise, $X_1$ is $\langle \Sigma, \text{ran}, \zeta \rangle$-entailed w.r.t. $T_1$. We further distinguish between the following cases.

If $X_1$ is not complex $\langle \Sigma, \text{ran}, \zeta \rangle$-entailed w.r.t. $T_1$, then let $C \in \mathcal{E}_L$ such that $T_1 \models C \subseteq X_1$. Then by Lemma 189 there exists $B \in \text{sub}_0(C)$ such that $T_1 \models B \subseteq X_1$. As $(T_1, X_1) \sim^r_{\Sigma, \zeta} (T_2, X_2)$, there exists $J \in \text{Just}_T(B \subseteq X_2)$ with $J \subseteq M$, which implies that $M \models C \subseteq X_2$, hence, $M \models \text{ran}(\zeta) \in C \subseteq X_2$.

Otherwise, $X_1$ is complex $\langle \Sigma, \text{ran}, \zeta \rangle$-entailed w.r.t. $T_1$. We distinguish between the following cases:

- If $X_1 \equiv \exists r Y_1 \in T_1$ such that $r$ is not $\Sigma$-entailed or $Y_1$ is not $\langle \Sigma, \text{ran}, \zeta \rangle$-entailed w.r.t. $T_1$, then let $C \in \mathcal{E}_L$ such that $T_1 \models \text{ran}(\zeta) \in C \subseteq X_1$, and therefore $T_1 \models \text{ran}(\zeta) \in C \subseteq \exists r Y_1$. By Lemma 34 we can infer that there exists $B \in \text{sub}_0(C)$ ($B \in \mathbb{N}_C \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in \mathbb{N}_R \}$) with $T_1 \models B \subseteq \exists r Y_1$. We can then show that $M \models C \subseteq X_2$ as above.

- If $X_1 \equiv \exists r Y_1 \in T_1$ such that $T_1 \models s \subseteq r$, $s \in \Sigma$ and $Y_1$ is $\langle \Sigma, \text{ran}, \zeta \rangle$-entailed w.r.t. $T_1$, then let $C \in \mathcal{E}_L$ such that $T_1 \models C \cap \text{ran}(\zeta) \subseteq X_1$, and therefore $T_1 \models C \cap \text{ran}(\zeta) \subseteq \exists r Y_1$. By Lemma 34 either (a) there exists $B \in \text{sub}_0(C)$ ($B \in \mathbb{N}_C \cup \{ \text{dom}(r), \text{ran}(r) \mid r \in \mathbb{N}_R \}$) with $T_1 \models B \subseteq \exists r Y_1$, or (b) there exists $\exists r' C' \in \text{sub}_0(C)$ with $T_1 \models C' \cap \text{ran}(r') \subseteq Y_1$ and $T_1 \models r' \subseteq s$.

For (a), we can show that $M \models C \cap \text{ran}(\zeta) \subseteq X_2$ as above.

For (b), as $(T_1, Y_1) \sim^r_{\Sigma, \zeta} (T_2, Y_2)$, we can infer that for every $X_2' \in \text{non-conj}_{\mathcal{E}_L}(X_2)$, there exists $X_2' \equiv \exists r' Y_2' \in T_2$ not entailed by dom (s) or ran(ζ), such that $(T_1, Y_1) \sim^r_{\Sigma, \zeta} (T_2, Y_2')$. Moreover, for every $X_2' \in \text{non-conj}_{\mathcal{E}_L}(X_2)$ not entailed by dom (s) or ran(ζ), there exists $M'_2 \in M^r_{\langle Y_1, Y_2' \rangle}$ (Line 6 in Algorithm 24) such that $M'_2 \cup \{ X_2' \equiv \exists r Y_2' \} \subseteq M$ (Line 8 in Algorithm 24).

By applying the induction hypothesis we have that for every $M'_2 \in M^r_{\langle Y_1, Y_2' \rangle}$, $(T_1, Y_1) \sim^r_{\Sigma, \zeta} (M, Y_2')$ holds.

Consequently, for every $X_2' \in \text{non-conj}_{\mathcal{E}_L}(X_2)$ that does not entailed by dom (s) or ran(ζ), we have that $M \models C' \cap \text{ran}(s) \subseteq Y_2'$, which implies $M \models \exists r (C' \cap \text{ran}(s)) \subseteq \exists r Y_2' \equiv X_2'$ then we infer that $M \models \exists r (C' \cap \text{ran}(s)) \subseteq \exists r Y_2' \equiv X_2'$ for every $X_2' \in \text{non-conj}_{\mathcal{E}_L}(X_2)$ that does
not entailed by dom(s) or ran(ζ). As \( \exists r'.C' \in \text{sub}_0(C) \) and max-tree \( \mathcal{M}' \subseteq \mathcal{M} \) (Line 3 in Algorithm 24), we have \( \mathcal{M} \models \text{ran}(\xi) \cap C \subseteq X \).

If \( X_1 \equiv Y_1 \cap \ldots \cap Y_m \in \mathcal{T}_1 \), then let \( C \in \mathcal{E}_\zeta \) such that \( \mathcal{T}_1 \models \text{ran}(\xi) \cap C \subseteq X_1 \), i.e. \( \mathcal{T}_1 \models \text{ran}(\xi) \cap C \subseteq X'_1 \) for every \( X'_1 \in \text{non-conj}_{\mathcal{M}}(X_1) \) such that \( \mathcal{T}_2 \models \text{ran}(r) \subseteq X'_2 \). As \( M^\zeta_{X_1,X_2} \neq \emptyset \), we can infer that there exists \( \Gamma \in \text{Defforest}(\mathcal{T}_2)(X_2) \) such that for every \( X'_2 \in \text{leaves}(\Gamma) \), there exists \( \psi \in \text{non-conj}_{\mathcal{M}}(X_1) \) such that \( \langle \mathcal{T}_1, \psi \rangle \overset{\text{ran}}{\sim}_{\Sigma,\zeta} \langle \mathcal{T}_2 \setminus \delta_{\Gamma}, X'_2 \rangle \). We can get that there exists \( \mathcal{M}'_{X'_2} \subseteq \text{COVER}_{\mathcal{M}}(\langle \mathcal{T}_1, \mathcal{T}_2 \setminus \delta_{\Gamma}, \Sigma, \psi, X'_2, \text{ran}, e \rangle) \) with \( \mathcal{M}'_{X'_2} \subseteq \mathcal{M} \) (Lines 4 to 17 in Algorithm 25).

By applying the induction hypothesis we have for every \( X'_1 \in \text{leaves}(\Gamma) \), \( \langle \mathcal{T}_1, \psi \rangle \overset{\text{ran}}{\sim}_{\Sigma,\zeta} \langle \mathcal{M}'_{X'_1}, X'_2 \rangle \) where \( \mathcal{M}'_{X'_1} \subseteq \mathcal{M} \setminus \delta_{\Gamma} \) i.e. \( \mathcal{M}'_{X'_1} \models C \subseteq X'_2 \) (as \( \zeta = \epsilon \)) and \( \mathcal{M} \models C \subseteq X'_1 \) hold as \( \mathcal{R}_1 \models C \subseteq \psi \). Consequently, we have \( \mathcal{M} \models C \subseteq X_2 \) as \( \Gamma \subseteq \mathcal{M} \) (Line 14 in Algorithm 25).

(ii) We show that for every \( X_1, X_2 \in \mathcal{N}_C \) with \( \langle \mathcal{T}_1, X_1 \rangle \overset{\text{ran}}{\sim}_{\Sigma,\zeta} \langle \mathcal{T}_2, X_2 \rangle \), and for every subunee module \( \mathcal{M} \) such that \( \langle \mathcal{T}_1, X_1 \rangle \overset{\text{ran}}{\sim}_{\Sigma,\zeta} \langle \mathcal{T}_2, X_2 \rangle \), there exists \( \mathcal{M}' \in M^\zeta_{X_1,X_2} \) such that \( \mathcal{M}' \subseteq \mathcal{M} \).

First, we define the relation \( \triangleright \subset \mathcal{N}_C \times \mathcal{N}_C \) as follows: for \( X, Y \in \mathcal{N}_C \) we set \( X \triangleright Y \) iff either there exists \( X \equiv \exists r Y \in \mathcal{T}_1 \) or there exists \( X \equiv Y_1 \cap \ldots \cap Y_n \in \mathcal{T}_1 \) such that \( Y_i = Y \) for some \( 1 \leq i \leq n \).

Note that \( \triangleright \) is well-founded as \( \mathcal{T}_1 \) is acyclic.

The proof now proceeds by induction on \( \triangleright \). Let \( X_1, X_2 \in \mathcal{N}_C \) with \( \langle \mathcal{T}_1, X_1 \rangle \overset{\text{ran}}{\sim}_{\Sigma,\zeta} \langle \mathcal{T}_2, X_2 \rangle \) and let \( \mathcal{M} \) be a subunee module under \( \chi = \langle \mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \text{ran}, \zeta \rangle \). Additionally, let \( S \) be a \( \Sigma \)-subunee simulation from \( \mathcal{T}_1 \) to \( \mathcal{M} \) with \( \langle X_1, X_2, \zeta \rangle \in S \).

First, we observe that for every \( \phi \in \Sigma^{\text{ran},\xi} \) with \( \mathcal{T}_1 \models B \subseteq X_1 \), there exists \( J^\mathcal{M}_{\phi,X_1} \in \text{Just}_{\mathcal{T}_1}(\phi \subseteq X_2) \) with \( J^\mathcal{M}_{\phi,X_1} \subseteq \mathcal{M} \) as \( \mathcal{M} \) is a subunee module under \( \chi = \langle \mathcal{T}_1, X_1, \Sigma, \mathcal{T}_2, X_2, \text{ran}, \zeta \rangle \).

We now distinguish between the following cases. If \( X_1 \) is not \( \Sigma, \text{ran}, \zeta \)-entailed w.r.t. \( \mathcal{T}_1 \), we set \( \mathcal{M}' := \emptyset \). Then it holds that \( \mathcal{M}' \in M^\zeta_{X_1,X_2} \) (Line 3 in Algorithm 26) and \( \mathcal{M}' \subseteq \mathcal{M} \).

Otherwise, \( X_1 \) is \( \langle \Sigma, \text{ran}, \zeta \rangle \)-entailed w.r.t. \( \mathcal{T}_1 \), and we proceed as follows. If \( X_1 \) is not complex \( \langle \Sigma, \text{ran}, \zeta \rangle \)-entailed w.r.t. \( \mathcal{T}_1 \), we set \( \mathcal{M}' := \bigcup_{\phi \in \Sigma^{\text{ran},\zeta}} J^\mathcal{M}_{\phi,X_1} \). Then it holds that \( \mathcal{M}' \in M^\zeta_{X_1,X_2} \) (Line 5 in Algorithm 26 and Algorithm 23) and \( \mathcal{M}' \subseteq \mathcal{M} \).

Otherwise, \( X_1 \) is complex \( \langle \Sigma, \text{ran}, \zeta \rangle \)-entailed w.r.t. \( \mathcal{T}_1 \), which implies that \( X_1 \) is not pseudo-primitive in \( \mathcal{T}_1 \) by Lemma 187. We now distinguish between the following two cases:

1. If \( X_1 \equiv \exists r Y_1 \in \mathcal{T}_1 \), we analyse the following subcases:

   - If \( r \notin \Sigma \) or \( Y_1 \) is not \( \langle \Sigma, \text{ran}, \zeta \rangle \)-entailed w.r.t. \( \mathcal{T}_1 \), then for \( \mathcal{M}' := \bigcup_{\phi \in \Sigma} J^\mathcal{M}_{\phi,X_1} \), it holds that \( \mathcal{M}' \in M^\zeta_{X_1,X_2} \) (Line 5 in Algorithm 26 and Algorithm 23) and \( \mathcal{M}' \subseteq \mathcal{M} \).

   - Otherwise, we assume that \( Y_1 \) and \( r \) are \( \langle \Sigma, \text{ran}, \zeta \rangle \)-entailed w.r.t. \( \mathcal{T}_1 \). \( \mathcal{T}_1 \models s \subseteq r \) and \( s \in \Sigma \). By Condition \( \langle S^+ \rangle \) we have that for every \( X_1' \in \text{non-conj}_{\mathcal{M}}(X_2) \) not entailed by \( \text{dom}(s) \) or \( \text{ran}(\xi) \) w.r.t. \( \mathcal{T}_2 \) there exists \( X_2' \equiv \exists r Y_1' \in \mathcal{M} \) such that \( (Y_1, Y_1', s) \in S \).

   Now we show that max-tree \( \mathcal{M}_{\mathcal{T}_1}(X_2) \subseteq \mathcal{M} \) by showing that

   \[
   \text{max-tree}_{\mathcal{T}_1}(X_2) = \text{max-tree}_{\mathcal{M}}(X_2).
   \]
It immediately holds that max-tree_{\#}(X_2) \subseteq max-tree_{\#}(X_2) as M \subseteq T_2. Let \( \alpha \in \) max-tree_{\#}(X_2). If we assume towards a contradiction that \( \alpha \notin \) max-tree_{\#}(X_2), then there exists \( \xi \in \) leaves(max-tree_{\#}(X_2)) such that \( \xi \in \) def_{\#} and \( \xi \equiv \exists r. \psi \in M \subseteq T_2. \) We have derived a contradiction.

Let \( X'_2 \in \) non-conj_{\#}(X_2) such that \( X'_2 \) not entailed by dom(\psi) or ran(\zeta). By Condition (S_{\psi}^{ran}) there exists \( \alpha_{X'_2} = X'_2 \equiv \exists ! Y'_2 \in M \) with \( T_2 \models s \sqsubseteq r', s \in \Sigma \) and \( (Y_1, Y'_2, s) \in S \). Consequently, it holds that \( (T_1, Y_1) \sim^{\text{ran}} \langle M, X'_2 \rangle \). By applying the induction hypothesis there exists \( M'_{X'_2} \in M'_{(Y_1, X'_2)} \) such that \( M'_{X'_2} \subseteq M \).

We set

\[
M' = \bigcup_{\phi \in \Sigma^{\text{ran}, \zeta}} M_{\phi \in X_2} \cup \{ \text{max-tree}_{\#}(X_2) \} \cup \text{Just}_T(s \sqsubseteq r') \\
\bigcup_{X'_2 \in \text{non-conj}_{\#}(X_2)} \bigcup_{T_2 \models \text{ran}(\zeta) \sqsubseteq X'_2} M'_{X'_2} \cup \{ \alpha_{X'_2} \}.
\]

Then it holds that \( M' \in M'_{(X_1, X_2)} \) (Line 10 in Algorithm 26 and Line 7 in Algorithm 24) and \( M' \subseteq M \).

2. If \( X_1 \equiv Y_1 \cap \ldots \cap Y_m \in M \), then for every \( X'_2 \in \) non-conj_{\#}(X_2) that is not entailed by ran(\zeta) w.r.t. \( T_2 \), there exists \( \psi \in \) non-conj_{\#}(X_1) such that \( (T_1, \psi) \sim^{\text{ran}} (T_2 \setminus \delta_T, X'_2) \) by Condition (S_{\psi}^{ran}). Hence, for \( \Gamma \models \) max-tree_{\#}(X_2) it holds that \( \Gamma \in \text{DefForest}_{\#}(X_2) \) and \( \Gamma \subseteq M \).

Moreover, for every \( X'_2 \in \) non-conj_{\#}(X_2) that is not entailed by ran(\zeta) w.r.t. \( T_2 \), it holds that \( M \) is a subsumee module under \( X_2 = \langle T_1, \psi, \Sigma, T_2, X'_2, \text{ran}, \zeta \rangle \). By applying the induction hypothesis for every \( X'_2 \in \) non-conj_{\#}(X_2), there exists \( M'_{X'_2} \in M'_{(Y_1, X'_2)} \) such that \( M'_{X'_2} \subseteq M \).

We set

\[
M' = \bigcup_{T_2 \models \phi \in X_2} \bigcup_{\phi \in \Sigma^{\text{ran}, \zeta}} M_{\phi \in X_2} \cup \text{Just}_T(s \sqsubseteq r') \\
\bigcup_{X'_2 \in \text{non-conj}_{\#}(X_2)} \bigcup_{T_2 \models \text{ran}(\zeta) \sqsubseteq X'_2} M'_{X'_2}.
\]

Note that for every \( X'_2 \in \) non-conj_{\#}(X_2) that is not entailed by ran(\zeta) w.r.t. \( T_2 \), it holds that \( (T_1, \phi) \sim^{\text{ran}} (T_2 \setminus \delta_T, X'_2) \), as \( (\phi, X'_2, e) \in S \) and \( M \subseteq T_2 \setminus \delta_T \).

Now we have that for every \( M \in M'_{(X_1, X_2)} \), \( (T_1, X_1) \sim^{\text{ran}} (T_2, X_2) \) holds by Definition 58.

We prove by assuming towards a contradiction. We assume now towards a contradiction that there exists an \( M' \subseteq M \), that \( (T_1, X_1) \sim^{\text{ran}} (M', X_2) \) does not hold. Let \( \alpha \in M \setminus M' \). As \( M'_{X_1} \) is initialized as \( \{ \emptyset \} \), we enumerate all possible situations that \( M \) is generated in the algorithms But none of them is possible, as the absence of \( \alpha \) will break the condition of subsumee simulation. Then \( (T_1, X_1) \sim^{\text{ran}} (M', X_2) \) does not hold anymore. Finally, we have that \( M'_{X_1} \) is a cover of the set such that for every \( M \in M'_{(X_1, X_2)} \), \( (T_1, X_1) \sim^{\text{ran}} (M, X_2) \).
6.4 Proofs

**Theorem 163** Let $\chi = (T_1, X_1, \Sigma, T_2, X_2, L)$, where $T_1$ and $T_2$ are two acyclic and normalised $\mathcal{ELH}'$-terminologies, $\Sigma$ is a signature and $X_1, X_2 \in \Sigma \cap N_C$. Additionally, let

$$ M := \text{COVER}_{\xi}(T_1, X_1, \Sigma, T_2, X_2, \text{ran}, \zeta). $$

If $T_1 \sim_{\Sigma} T_2$, then for every $M \in M$, it holds that $\langle T_1, X_1 \rangle \sim_{\Sigma, \zeta}^{\xi} \langle M, X_2 \rangle$ and $M$ is minimal w.r.t. set inclusion.

**Proof** It follows from Lemma 190.

**Lemma 191** Let $\chi = (T_1, X_1, \Sigma, T_2, X_2, \text{ran})$ and

$$ M_{\text{ran}} := \text{COVER}_{\xi}(T_1, X_1, \Sigma, T_2, X_2, \text{ran}, \varepsilon) \otimes \bigotimes_{r \in \Sigma \cap N_R} \text{COVER}_{\xi}(T_1, X_1, \Sigma, T_2, X_2, \text{ran}, r). $$

If $\langle T_1, X_1 \rangle \sim_{\Sigma, \xi}^{\text{ran}} \langle T_2, X_2 \rangle$, then $M_{\text{ran}}^{\text{ran}}$ is the set of all subsumee projection justifications under $\chi$.

**Proof** By Lemma 190 and Lemma 72, we have that for every $M \in M_{\text{ran}}$, $M$ is the minimal set such that $\langle T_1, X_1 \rangle \sim_{\Sigma, \xi}^{\text{ran}} \langle M, X_2 \rangle$, and $\langle T_1, X_1 \rangle \sim_{\Sigma, \xi}^{\text{ran}} \langle M, X_2 \rangle$. By Theorem 162, we have that for every $C, C' \in \mathcal{ELH}_{\Sigma}^{\text{ran}}$ with $T_1 \models \text{ran}(r) \cap C \subseteq X_1$ and $T_1 \models C' \subseteq X_1$, it holds that $T_2 \models \text{ran}(r) \cap C \subseteq X_2$ and $T_2 \models C' \subseteq X_2$. By Definition 137, we have that $M_{\text{ran}}^{\text{ran}}$ is the set of all subsumee projection justifications under $\chi$.

**Lemma 192** Let $\chi = (T_1, X_1, \Sigma, T_2, X_2, \text{Ran})$ and $M_{\text{ran}}^{\text{ran}}(X_1, X_2) := \text{COVER}_{\xi}(T_1, X_1, \Sigma, T_2, X_2, \text{Ran}, \zeta)$. If $\langle T_1, X_1 \rangle \sim_{\Sigma, \xi}^{\text{ran}} \langle T_2, X_2 \rangle$, then $M_{\text{ran}}^{\text{ran}}(X_1, X_2)$ is the set of all subsumee projection justifications under $\chi$.

**Proof** Similar as proof of Lemma 190, we can prove that $M_{\text{ran}}^{\text{ran}}(X_1, X_2)$ is the set such that for $M \in M_{\text{ran}}^{\text{ran}}(X_1, X_2)$, $\langle T_1, X_1 \rangle \sim_{\Sigma, \xi}^{\text{ran}} \langle M, X_2 \rangle$ and $M$ is minimal w.r.t. set inclusion. By Theorem 162, we have that for every $C \in \mathcal{ELH}_{\Sigma}^{\text{ran}}$ with $T_1 \models C \subseteq X_1$, it holds that $T_2 \models C \subseteq X_2$. By Definition 137, we have that $M_{\text{ran}}^{\text{ran}}(X_1, X_2)$ is the set of all subsumee projection justifications under $\chi$.

**Theorem 164** Let $\chi_{\text{Ran}} = (T_1, X_1, \Sigma, T_2, X_2, \text{ran})$, $\chi_{\text{Ran}} = (T_1, X_1, \Sigma, T_2, X_2, \text{ran})$, where $T_1$ and $T_2$ are two acyclic and normalised $\mathcal{ELH}'$-terminologies, $\Sigma$ is a signature and $X_1, X_2 \in \Sigma \cap N_C$. Additionally, let

$$ M_{\text{ran}} := \text{Minimise}_{\xi}(\text{COVER}_{\xi}(T_1, X_1, \Sigma, T_2, X_2, \text{ran}, \varepsilon) \otimes \bigotimes_{r \in \Sigma \cap N_R} \text{COVER}_{\xi}(T_1, X_1, \Sigma, T_2, X_2, \text{ran}, r)), $$

$$ M_{\text{ran}} := \text{COVER}_{\xi}(T_1, X_1, \Sigma, T_2, X_2, \text{ran}, \varepsilon). $$

If $T_1 \sim_{\Sigma} T_2$, then $M_{\text{ran}}$ is the set of all subsumee justifications under $\chi_{\text{Ran}}$ and $M_{\text{ran}}$ is the set of all subsumee justifications under $\chi_{\text{Ran}}$. 
Proof It follows from Lemma 191 and Lemma 192.

6.5 Evaluation

We implemented the algorithms introduced above in Java. Now we present a first evaluation of the proposed projection module extraction techniques on real-world biomedical ontologies with the help of PULi [22], a state-of-the-art tool for computing justifications for $\mathcal{EL}$ ontologies. All experiments were conducted on machines equipped with an Intel Xeon Core 4 Duo CPU running at 2.50 GHz and with 64 GiB of RAM.

We consider computing projection modules between two prominent biomedical ontologies: MeSH\textsuperscript{1} and Snomed CT\textsuperscript{2}. As MeSH is a hierarchically-organized terminology for indexing and cataloging of biomedical information. Therefore, MeSH was used as reference ontology in our experiment. We chose Snomed CT as an implementing ontology since it contains overwhelmingly many axioms. Automated tool support is needed for extracting the most relevant information to be shown to users. There exist 29962 common concept names between MeSH and Snomed CT. For every common concept name, we generated a signature by including its super-concepts that are also common concept names between these two terminologies. In total, 6572 signatures were generated this way. The number of concept names contained in each signature ranges from 2 to 13. The computation of projection modules for each signature finished within 1 second.

Note that when Snomed CT was constructed, MESH was not used as a guideline or a reference ontology. However, our experiment shows that for 19.8\% of the signatures among those tested, there exist projection modules between MeSH and Snomed CT, which illustrates the overlap between these two ontologies. The resulting projection modules are relatively small, thus lending themselves to manual inspection. Table 6.1 shows the minimal, maximal and median value of $\bot\top\star$-module and projection module w.r.t. the generated signatures. One can see that, in general, projection module is smaller than the star modules of the implementing ontology SNOMED, so that users can focus on a smaller number of axioms in Snomed CT to verify how the knowledge of MESH about a signature is implemented in Snomed CT.

Chapter 7

Conclusion and Future Work

7.1 Conclusion

In this thesis, we presented a framework to assist users to extract knowledge from terminologies that are formulated in the Description Logics $\mathcal{ELH}$ and $\mathcal{ELH}^r$. We provided three different approaches catering for users’ demands: extracting minimal basic subsumption modules (Chapter 4) that preserve subsumption queries over the terms of interest, computing best excerpts (Chapter 5) that best capture users’ interest with a size restriction, and computing projection modules of a target ontology (Chapter 6) that entail subsumption, instance and conjunctive queries from a reference ontology. Computing best excerpts and minimal subsumption modules (glass-box approach) is based on a notion called subsumption justification. We presented algorithms for computing subsumption justifications of an acyclic $\mathcal{ELH}$- and $\mathcal{ELH}^r$-terminology w.r.t. a signature (Chapter 3). The black-box approach for computing minimal modules is language-independent. However, it relies on an external tool for computing the logical difference between ontologies. At present, the state-of-the-art tool for computing logical differences can only handle (cyclic) $\mathcal{ELH}^r$-terminologies. For computing projection modules, we proposed a new notion called projection justification. Contrary to subsumption justifications that only consider one ontology, a projection justification is related to two ontologies. A projection justification is a subset of a target ontology obtained from projecting into the target ontology all subsumption entailments of a reference ontology. We presented the algorithms for computing projection justifications for three different types of queries (subsumption, instance and conjunctive queries) and proved their correctness. A summary of the computational complexity of the algorithms developed in this thesis is presented in Table 7.1. In general, subsumption justifications, minimal modules, projection justifications and projection modules can all be computed in EXPTIME in the size of the input. However, computing best excerpts runs in NEXPTIME since the input clauses of the partial Max-SAT encoding can be exponentially large, which in turn is due to fact that the number of subsumption justifications is exponentially bounded. We implemented Java-prototypes of our algorithms and we evaluated them on large biomedical ontologies. The results show that the
Conclusion and Future Work

approaches we propose in this thesis can assist users to extract knowledge that is relevant to their interests from description logic terminologies.

7.2 Future Work

We conclude the thesis by discussing possible directions for future work.

**Subsumption Justification** We would like to evaluate our algorithms for computing subsumption justifications for $\mathcal{ELH}$.terminologies after an efficient tool for computing justifications for $\mathcal{ELH}$.terminologies has been developed. Moreover, we expect that the algorithms for computing subsumption justifications could be extended to deal with cyclic terminologies and general $\mathcal{EL}-TBoxes$. A complete complexity analysis is also expected.

**Basic Subsumption Modules** In the near future, we plan to generate a benchmark for basic subsumption modules on $\mathcal{ELH}$- and $\mathcal{ELH}$.fragment of Snomed CT and NCI ontology. We also expect to be able to compute basic subsumption modules of ontologies formulated in more expressive description logics. One option is to extend the algorithm to compute subsumption justifications as mentioned above. We can also benefit from the research on logical difference and uniform interpolation, as the black-box algorithm is language-independent. It has been shown that our black-box algorithm can be used to compute subsumption modules for $\mathcal{ALCH}$.ontologies in [32].

**Best Ontology Excerpts** Currently, the notion of best excerpts that has been investigated is based on the metric of logical difference. We would like to explore alternative metrics to enrich the family of ontology excerpts. One possibility is based on restricted reasoning tasks, such as instance retrieval of named concepts [41], named concept subsumption [39], or unsatisfiable concepts [18]. The intuition is that these simplified reasoning tasks are often the main concern in real applications. The current definition of ontology excerpt insists on keeping the original form of the axioms. Another interesting direction to generalise the notion of ontology excerpts is to allow for modified axioms. For this, a procedure similar to knowledge compilation appears to be promising.

Computing optimal ontology excerpts is often computationally too expensive. An alternative is to compute approximate ontology excerpts. For this, it is possible to benefit from approximating algorithms for Constraint-Satisfaction-Problems once the previous task can be conducted. A different sort of technique for extracting quasi-optimal excerpts has been proposed by using a model from Information Retrieval [9]. The empirical study shows that it gives non-trivial results compared to
a direct enumeration or random selection on large real-world ontologies but nevertheless fails to find the optimal excerpts. To improve this technique, a possibility is to take into account the logical contribution of each single axiom into the existing approximating model, which could boost its performance.

**Projection Modules** We expect that the algorithms can be extended to deal with cyclic terminologies and possibly general $\mathcal{L}_\mathcal{H}^\nu$-TBoxes and consider algorithms for ranking different projection modules, via weighted signatures for instance. Moreover, we would like to find applications for projection modules. For example, developing a uniform upper ontology to guide ontology engineers to build ontologies that satisfy certain requirements.
Bibliography

Titre : Extraction de connaissances à partir de terminologies en logique de description.

Mots clés : Représentation et raisonnement des connaissances, logique de description, Web sémantique, modularité d'ontologies, différence logique.

Résumé : Un nombre croissant d'ontologies de grande taille sont en cours de développement et rendues disponibles, par exemple dans des référentiels tels que le bioportail de NCBO. Garantir l'accès aux connaissances les plus pertinentes pour les utilisateurs contenues dans des ontologies est un défi important. Dans ce travail, nous abordons ce défi en proposant trois approches différentes pour extraire des connaissances des ontologies en logique de description: extraire les modules minimaux d'ontologies (c'est-à-dire les sous-ontologies minimales pour l'inclusion ensembliste qui préservent toutes les implications sur un vocabulaire donné) ; calculer les meilleurs extraits d'ontologie (un certain nombre, petit, d'axiomes qui capturent au mieux la connaissance du vocabulaire tout en permettant un certain degré de perte sémantique) ; et déterminer les modules de projection (sous-ontologies d'une ontologie cible qui impliquent des requêtes de subsumption, d'instance ou conjonctives qui découlent d'une ontologie de référence). Pour chacune de ces approches, nous souhaitons extraire non seulement une, mais toutes les instances de la notion correspondante de module. Pour le calcul des modules minimaux et des meilleurs extraits, nous introduisons la notion de justification de la subsumption en tant que généralisation de la notion de justification (un ensemble minimal d'axiomes nécessaires pour préserver une conséquence logique donnée) afin de capturer la connaissance déduite par subsumption sur le vocabulaire. De même, pour le calcul des modules de projection, nous introduisons la notion de justifications de projection qui préservent les réponses à l’un des trois types de requête impliquées par une ontologie de référence. Enfin, nous évaluons nos approches à l’aide d’un prototype d’implémentation des algorithmes sur de grandes ontologies.

Title : Knowledge Extraction from Description Logic Terminologies

Keywords : Knowledge Representation and Reasoning, Description Logics, Semantic Web, Ontology Modularity, Logical Difference.

Abstract : An increasing number of large ontologies are being developed and made available, e.g., in repositories such as the NCBO Bioportal. Ensuring access to the knowledge contained in ontologies that is most relevant to users has been identified as an important challenge. In this work, we tackle this challenge by proposing three different approaches to extracting knowledge from Description Logic ontologies: extracting minimal ontology modules (i.e., sub-ontologies that are minimal w.r.t. set inclusion while still preserving all entailments over a given vocabulary); computing best ontology excerpts (a certain, small number of axioms that best capture the knowledge about the vocabulary while allowing for a degree of semantic loss); and determining projection modules (sub-ontologies of a target ontology that entails subsumption, instance or conjunctive queries that follow from a reference ontology). For each of these approaches, we are interested in extracting not only one but all instances of the module notion. For computing minimal modules and best excerpts, we introduce the notion of subsumption justification as a generalisation of the notion of a justification (a minimal set of axioms needed to preserve a given logical consequence) to capture the subsumption knowledge over the vocabulary. Similarly, for computing projection modules, we introduce the notion of projection justifications that preserve the answers to one of three query types as given by a reference ontology. Finally, we evaluate our approaches using a prototype implementation of the algorithms on large ontologies.
