HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

## Thèse de doctorat de

## L'Université de Rennes

École Doctorale No 601
Mathématiques, Télécommunications, Informatique, Signal, Systèmes, Électronique
Spécialité : Mathémathiques et interactions
Par
Marc ABBOUD

## Sur la dynamique des endomorphismes des surfaces affines

Thèse présentée et soutenue à Rennes, le 7 juillet 2023
Unité de recherche : UMR CNRS 6625, IRMAR

## Rapporteurs avant soutenance :

$\begin{array}{ll}\text { Thomas GAUTHIER } & \text { Professeur des universités à l'Université Paris-Saclay } \\ \text { Mattias JONSSON } & \text { Professeur des universités à University of Michigan }\end{array}$
Mattias JONSSON Professeur des universités à University of Michigan

## Composition du Jury :

Président:
Examinateurs: Jérémy BLANC
Serge CANTAT
Charles FAVRE
Thomas GAUTHIER Mattias JONSSON
Juan SOUTO
Junyi XIE
Susanna ZIMMERMAN
Professeur des universités à l'Université de Bâle
Directeur de recherche à l'Université de Rennes
Directeur de recherche au Centre de mathématiques Laurent Schwartz
Professeur des universités à l'Université Paris-Saclay
Professeur des universités à University of Michigan
Directeur de recherche à l'Université de Rennes
Professeur au Beijing International Center for Mathematical Research
Professeure des universités à l'université Paris-Saclay
Dir. de thèse : Serge CANTAT
Co-dir. de thèse : Junyi XIE
Directeur de recherche à l'université de Rennes
Professeur au Beijing International Center for Mathematical Research

## Remerciements

Mes premiers remerciements vont tout naturellement à mes directeurs Serge et Junyi. Serge, merci d'avoir été autant disponible pendant ces 3 années. Ta porte de bureau était toujours ouverte et toi toujours prêt à répondre à mes questions, trouver des contre exemples à mes affirmations ou me donner des pistes pour démontrer les travaux présents dans cette thèse. Merci pour l'accompagnement et les conseils que tu m'as donné que ce soit en mathématiques ou pour ma carrière académique.

Junyi, même si nous n'avons pas pu nous voir en personne pendant ces trois années, merci de t'être rendu disponible pour répondre à mes questions. J'ai hâte de continuer ce travail en venant te rendre visite à Pékin. Serge et toi vous êtes très bien complétés et on peut difficilement espérer avoir de meilleurs directeurs que vous deux.

Je remercie également les membres de mon jury de thèse : Jérémy Blanc, Charles Favre, Juan Souto, Suzanna Zimmerman. Je remercie tout particulièrement Thomas Gauthier et Mattias Jonsson pour avoir accepter d'être rapporteurs et pour leurs retours sur mon mémoire.

Je pense maintenant à mes parents, Edvick et Ziad. Papa, Maman, merci pour votre soutien, merci de m'avoir toujours suivi dans mes choix. J'espère vous rendre fier avec cette thèse et continuer à le faire durant les années futures. On ne peut penser avoir des parents plus aimants que vous deux, votre dévouement pour vos enfants est sans égal. Je vous en remercie et j'espère vous montrer ma gratitude tous les jours. Je garde en tête ces mots que tu dis si bien Maman

Docteur Marianne, alors voilà je rejoins le club des docteurs quelques mois après toi. Merci de ton soutien et de ta bienveillance. Je sais que je peux toujours compter sur toi, notre complicité est sans égale. Merci d'être la meilleure soeur qu'on puisse espérér avoir. Docteurs Abboud forever.

Merci à ma famille, du côté de ma mère : André, Pierre, Teta, Antoine, Baptiste et Thibault. J'ai une pensée toute particulière pour Agnès. Je pense également à Jeddo. Du côté de mon père, plus éloigné certes mais très proche dans mon coeur, Chantal, Désirée, Fayez, Joe, Tyler, Alexandra, Sophie, Jean-Pierre, Ralph et Kim. Je pense également à Ali et Aida. Je remercie également Fares, Wajih, Sourad et Gisèle pour leur bonté et leur accueil lors de ma visite cet hiver. J'ai hâte de vous revoir aux événements familiaux futurs.

J'ai une pensée pour les différents professeurs de mathématiques que j'ai eu au cours de ma scolarité. Ceux qui m'ont donné le goût des maths et sans qui je n'aurai probablement pas continué dans cette voie. Merci Monsieur Parent, Merci Monsieur Ciren, Merci Monsieur Selles.

On ne peut pas réussir et garder une certaine motivation pour faire une thèse sans être bien entouré. Voici maintenant le temps de remercier mes amis. Beaucoup d'amitiés se sont établies pendant mes études et je suis très heureux d'avoir pu les maintenir.

Dali, Hugo, Pierre, Shams, voilà maintenant 10 ans qu'on se connaît. Que de chemins parcourus depuis. Je suis très heureux que nous ayons pu maintenir cette amitié au fur et à mesure des années malgré la distance. On dit souvent que la prépa est un moment dur à passer, grâce à vous j'en garde un excellent souvenir. Je remercie tout particulièrement Hugo qui à maintes reprises durant ces trois années m'a hébergé lors de mes passages impromptus à Paris.

Merci au Filtre, Cyril, David, Jean, Rémy, Seginus, Simon, Thibaut et Ulysse. Je me rappelle encore de cette semaine à New-York où notre amitié s'est forgé. Je repense aux différents moments que nous avons vécu ensemble : la ballade jusqu'à Colin Maçon avec Thibaut, les mariages d'Ulysse et de Cyril, la montée du Ventoux... Déjà tellement de souvenirs et ce n'est que le début!

Merci à Arnaud, Benjamin, Charlie, Marine, Paul. Je suis très reconnaissant d'avoir une telle bande d'amis. Je repense à cette coloc avec Benji, à notre 3ème année au carré tous ensemble. Hâte qu'on se retrouve au prochain Luna Park!

Alexane, Cécile, Chloé, Yue merci d'être les amies que vous êtes et du soutien que vous m'avez apporté.

Merci également à Jean, Samuel et Tony pour ces écoles d'étés dans ce lieu si beau qu'est le lac d'Aiguebelette.

Je veux remercier Augustin, David, Jean, Pierre et Sébastien pour ces supers séjours en Bretagne qui m'ont permis de prendre du repos lorsque j'en avais grandement besoin.

Bastien, notre amitié dure depuis tant d'années, c'est un réel plaisir de te compter à mes côtés. Merci pour tout et il est grand temps qu'on le fasse ce resto ! De Lille, je veux remercier également Sixtine et Margaux, cela fait bien longtemps que nous sommes amis et j'ai hâte de voir ce que nous réserve la suite.

Merci au CPB volley pour ces deux saisons. Aloïs, Alexandre, Baptiste, Esteban, Florent, Guillaume, Jules, Julien, Mael, Nam, Nico, Quentin Libéro, Quentin R4, Théo, Thomas, ça a été un plaisir de jouer avec vous. Merci également à nos coachs Laurent et Yacine, tellement fier d'avoir gagner le championnat à vos côtés !

Lorsque je suis arrivé à Rennes, je ne connaissais personne. J'ai eu la chance de rencontrer Alice, Grégoire, Louis, Merriadec et Quentin. Une bande d'amis déjà établie qui m'a accepté comme je suis et qui a marqué mon expérience de cette belle ville bretonne.

Évidemment, je me dois de réserver un paragraphe pour le bureau 334. Merci à Louis, Emeline, Marie, Adrien et Nicolas. Lorsque le bureau est plein, il est clair que nous ne sommes pas les plus efficaces. Mais la force de ce bureau est que nous savons être à l'écoute des uns et des autres. Dans ce bureau on s'entraide, on casse nos maths et on les répare.

Je tiens à remercier le personnel administratif de l'IRMAR, merci à Aude, Éric, Florian, Hélène, Marie-Aude, Olivier, Sandra. Merci pour l'aide apportée pendant ces 3 années.

Je réserve ces dernières lignes pour les membres de l'IRMAR que je n'ai pas encore mentionné. Merci à Alice pour sa joie et sa spontanéité, merci à Louis qui me rrrrrrégale tous les jours, merci à Léo pour sa bigorexie débordante. Yago, je suis heureux et fier de te compter parmi mes amis. Merci également à François, Hugo, Matilde, Mattia, Milan, Rémy, Sergio, Virgile, Xabi et tous les autres. Un grand merci en particulier à Pierre, aka maître $\mathrm{LAT}_{\mathrm{E}} \mathrm{X}$, pour son aide lors de la rédaction de ce manuscrit.

Je veux enfin remercier les chercheurs et chercheuses de l'IRMAR avec qui j'ai pu discuter pendant ces trois années. Merci à l'équipe de Théorie Ergodique : Anna, Bachir, Barbara, François, Jean-Pierre, Juan, Ludovic, Rémy, Sébastien, Serge et Vincent. Je souhaite également remercier Françoise qui m'a beaucoup accompagné pendant ces trois années, notamment sur mes projets de diffusion mathématiques. Merci aussi à Benoît, Christophe, Delphine, Frank, Matthieu, Miguel et Rémy et au reste des membres permanents de l'IRMAR. Ce laboratoire est un excellent cadre pour effectuer sa thèse et j'en garderai un très bon souvenir pour la suite.

## INTRODUCTION

Une variété affine $X_{0}$ sur un corps algébriquement clos $\mathbf{k}$ est un sous espace de $\mathbf{k}^{N}$ défini par des équations polynomiales. Un endomorphisme polynomial de $X_{0}$ est alors une transformation polynomiale de $\mathbf{k}^{N}$ qui préserve $X_{0}$ au sens où $f\left(X_{0}\right) \subset X_{0}$. Lorsque la dimension de $X_{0}$ vaut 2, on dira que $X_{0}$ est une surface affine. Le but de ma thèse est d'étudier le système dynamique donné par $X_{0}$ une surface affine et $f: X_{0} \rightarrow X_{0}$ un endomorphisme polynomial de $X_{0}$. Les différentes questions que j'aborderai sont les suivantes : y a-t-il des orbites denses ou Zariski-denses? Si l'orbite d'un point part à l'infini, peut on contrôler sa vitesse de fuite? Y a-t-il beaucoup d'orbites périodiques? Comment construire des mesures invariantes qui sont dynamiquement intéressantes? Pour répondre à ces questions, j'utilise des techniques valuatives. Le système dynamique ( $X_{0}, f$ ) induit un système dynamique ( $\mathcal{V}_{\infty}, f_{*}$ ) où $\mathcal{V}_{\infty}$ est l'espace des valuations centrées à l'infini de $X_{0}$. C'est l'étude de cette action qui sera au cœur de ce mémoire et permettra d'aborder ensuite les questions évoquées ci-dessus.

### 1.1 Endomorphismes

### 1.1.1 Degrés dynamiques

### 1.1.1.1 Transformations polynomiales de l'espace affine complexe

Une transformation polynomiale $f$ de $\mathbf{C}^{N}$ est la donnée de $N$ polynômes $f_{i} \in \mathbf{C}\left[x_{1}, \cdots, x_{N}\right]$ tels que $f=\left(f_{1}, \cdots, f_{N}\right)$. On définit le degré de $f$ comme le maximum des degrés des $f_{i}$; on le note $\operatorname{deg} f$. On note $f^{k}$ pour le $k$-ième itéré de $f$. Lorsqu'on itère $f$ le degré des formules de $f^{k}$ croît typiquement de façon exponentielle. Il est donc naturel de considérer la quantité suivante :

$$
\begin{equation*}
\lambda_{1}(f):=\lim _{k}\left(\operatorname{deg} f^{k}\right)^{1 / k}, \tag{1.1}
\end{equation*}
$$

introduite dans [RS97], que l'on appellera le premier degré dynamique de $f$ dans la suite. Les auteurs montrent que cette quantité est bien définie. On peut définir le premier degré dyna-
mique de n'importe quelle transformation rationnelle de l'espace projectif $\mathbf{P}^{N}$ avec un procédé similaire.

### 1.1.1.2 Définitions générales

Soit $X$ une variété projective lisse sur un corps algébriquement clos et soit $d$ sa dimension. Pour $d$ diviseurs de Cartier $D_{1}, \cdots, D_{d}$ de $X$ on peut définir le produit d'intersection $D_{1} \cdots D_{d} \in \mathbf{Z}$ (voir [Laz04]). Si $f: X \rightarrow X$ est une transformation rationnelle dominante, on définit pour $0 \leqslant l \leqslant d$ le $l$-ième degré dynamique de $f$ par

$$
\begin{equation*}
\lambda_{k}(f):=\lim _{n \rightarrow \infty}\left(\left(f^{n}\right)^{*} H^{k} \cdot H^{d-k}\right)^{1 / n} \tag{1.2}
\end{equation*}
$$

où $H$ est un diviseur ample de $X$. On peut montrer que ces quantités sont bien définies, indépendantes du choix de $H$. En particulier, $\lambda_{0}(f)=1$. De plus, les degrés dynamiques sont des invariants birationnels: si $\varphi: X \rightarrow Y$ est une application birationnelle, alors

$$
\begin{equation*}
\lambda_{l}(f)=\lambda_{l}\left(\varphi \circ f \circ \varphi^{-1}\right), \quad \forall 0 \leqslant l \leqslant d \tag{1.3}
\end{equation*}
$$

On a que $\lambda_{d}(f)$ est le degré topologique de $f$ où le degré topologique est définie comme le degré de l'extension induit par $f^{*}$ sur le corps des fonctions rationnelles de $X$. Les inégalités de Khovanskii-Teissier (voir [Gro90], [DN05]) impliquent que la suite $\left(\lambda_{l}\right)_{0 \leqslant l \leqslant d}$ est log-concave; c'est à dire

$$
\begin{equation*}
\frac{\log \lambda_{l-1}+\log \lambda_{l+1}}{2} \leqslant \log \lambda_{l}, \quad \forall 1 \leqslant l \leqslant d-1 . \tag{1.4}
\end{equation*}
$$

En particulier, on a $\forall 1 \leqslant l \leqslant d, \lambda_{1}(f)^{l} \geqslant \lambda_{k}(f)$.
Soit $X_{0}$ une variété affine lisse de dimension $d$ et $f: X_{0} \rightarrow X_{0}$ un endomorphisme de $X_{0}$. On définit les degrés dynamiques de $f$ de la façon suivante. Une complétion de $X_{0}$ est une variété projective lisse $X$ munie d'une immersion ouverte $\mathfrak{\imath}: X_{0} \hookrightarrow X$ telle que $\mathfrak{l}\left(X_{0}\right)$ est dense dans $X$. L'endomorphisme $f$ induit une transformation rationnelle de $X$ par $\tilde{f}=\mathfrak{\imath} \circ f \circ \mathfrak{l}^{-1}$ et on définit les degrés dynamiques

$$
\begin{equation*}
\lambda_{l}(f):=\lambda_{l}(\widetilde{f}) \tag{1.5}
\end{equation*}
$$

Comme les degrés dynamiques sont des invariants birationnels, cette quantité ne dépend pas du choix de la complétion $X$. En particulier, si $X_{0}=\mathbf{k}^{N}$ et $X=\mathbf{P}_{\mathbf{k}}^{N}$ on retrouve la définition du premier degré dynamique donnée au premier paragraphe.

La connaissance de ces degrés dynamiques donne des informations sur le système dyna-
mique. Par exemple sur C, Dinh et Sibony ont montré dans [DS03] que pour toute transformation rationnelle $f: X \rightarrow X$

$$
\begin{equation*}
h_{\text {top }}(f) \leqslant \max _{0 \leqslant l \leqslant d} \log \left(\lambda_{l}\right) \tag{1.6}
\end{equation*}
$$

où $h_{\text {top }}$ est l'entropie topologique de $f$, Gromov avait au préalable montré ce résultat pour les endomorphismes de $\mathbf{P}^{N}$ dans [Gro03]. Yomdin a montré dans [Yom87] l'égalité des deux membres si $f$ est un endomorphisme. Récemment, Favre, Truong et Xie ont montré dans [FTX22] que l'inégalité (2.6) était encore valable dans le cadre non-archimédien; cependant l'égalité n'est pas vérifiée même pour des endomorphismes.

### 1.1.2 Degrés dynamiques sur les surfaces projectives

Une question naturelle est de se demander quels nombres peuvent apparaître comme le premier degré dynamique d'une transformation rationnelle d'une surface projective. On peut d'abord mentionner le résultat suivant dû à Bonifant et Fornaess dans [BF00] pour $\mathbf{P}_{\mathbf{C}}^{N}$ et généralisé par Urech

Théorème 1.1.1 ([प्यre16]). L'ensemble

$$
\begin{equation*}
\left\{\lambda_{1}(f)\right\} \tag{1.7}
\end{equation*}
$$

où $f$ parcourt l'ensemble des transformations rationnelles de toute variété projective lisse sur n'importe quel corps, est dénombrable.

En 2021, Bell, Diller et Jonsson ont montré dans [BDJ20] l'existence d'une transformation rationnelle $\sigma: \mathbf{P}^{2} \rightarrow \mathbf{P}^{2}$ telle que $\lambda_{1}(\sigma)$ est transcendant. Les trois auteurs et Krieger ont montré dans [BDJ20] que cet exemple peut se généraliser pour donner un exemple de transformation birationnelle de $\mathbf{P}^{N}, N \geqslant 3$ avec un premier degré dynamique transcendant. Mais en dimension 2, il y a de fortes contraintes sur $\lambda_{1}(f)$ pour $f$ birationnelle. Dans [DF01], Diller et Favre ont montré que le premier degré dynamique d'une transformation birationnelle d'une surface projective est un entier algébrique. Plus précisément c'est un nombre de Pisot ou de Salem. Dans [BC13], Blanc et Cantat ont obtenu les résultats suivants

Théorème 1.1.2. Soit $X$ une surface projective sur un corps algébriquement clos.

1. Soit $f: X \rightarrow X$ une transformation birationnelle telle que $\lambda_{1}(f)$ est un nombre de $S a-$ lem, alors il existe une application birationnelle $\varphi: X \rightarrow Y$ telle que $\varphi \circ f \circ \varphi^{-1}$ est un automorphisme de $Y$.
2. Si $X$ est rationnelle sur un corps $\mathbf{k}$, alors l'ensemble $\Lambda(X):=\left\{\lambda_{1}(f) \mid f \in \operatorname{Bir}(X)\right\} \subset \mathbf{R}$ est bien ordonné. Il est fermé si $\mathbf{k}$ n'est pas dénombrable.

En particulier, $\Lambda(X)$ est un ordinal et Bot montre dans [Bot22] que cet ordinal est exactement $\omega^{\omega}$ où $\omega$ est l'ordinal des entiers naturels. On ne peut cependant pas espérer obtenir une information sur les degrés des entiers algébriques obtenus. En effet Bedford, Kim et McMullen construisent dans [BK06] et [McM07] des exemples de transformations birationnelles de surfaces projectives dont le premier degré dynamique est un entier algébrique de degré arbitrairement grand. En particulier le théorème 1.1 de [McM07] établit que pour tout $d \geqslant 10$ on peut trouver une surface projective avec un automorphisme de premier degré dynamique entier algébrique de degré $d$.

### 1.1.3 Degrés dynamiques des endomorphismes des surfaces affines

Dans ma thèse je considère des endomorphismes de surfaces affines. Le premier exemple de surface affine est le plan complexe $\mathbf{C}^{2}$. Un endomorphisme est alors une transformation polynomiale. Même dans ce cas, le premier degré dynamique n'est pas nécessairement un entier. En effet, soit

$$
A=\left(\begin{array}{ll}
a & b  \tag{1.8}\\
c & d
\end{array}\right)
$$

une matrice à coefficients entiers positifs tels que $a d-b c \neq 0$. Considérons la transformation monomiale suivante

$$
\begin{equation*}
f(x, y)=\left(x^{a} y^{b}, x^{c} y^{d}\right) \tag{1.9}
\end{equation*}
$$

alors $f^{N}$ est la transformation monomiale dont les monômes sont donnés par les coefficients de $A^{N}$ et $\boldsymbol{\lambda}_{1}(f)$ est égal au rayon spectral de $A$. Ainsi, $\boldsymbol{\lambda}_{1}(f)$ est un entier algébrique de degré 2 car il vérifie l'équation

$$
\begin{equation*}
\lambda_{1}(f)^{2}-\operatorname{Tr}(A) \lambda_{1}(f)+\operatorname{det}(A)=0 . \tag{1.10}
\end{equation*}
$$

Ainsi, il existe des transformation polynomiales $f$ du plan avec $\lambda_{1}(f)$ entier ou entier algébrique de degré 2 . Favre et Jonsson ont montré qu'il n'y a pas d'autres possibilités.

Théorème 1.1.3. FJ07] Soit $f: \mathbf{C}^{2} \rightarrow \mathbf{C}^{2}$ une transformation polynomiale dominante, alors $\lambda_{1}(f)$ est un entier algébrique de degré $\leqslant 2$.

Le premier résultat de ma thèse est d'étendre ce résultat à toutes les surfaces affines et en toute caractéristique. Même si on peut trouver des surfaces affines où le monoïde des endomorphismes peut changer de façon drastique. Par exemple, Blanc et Dubouloz, dans [BD13],
construisent des surfaces affines lisses avec un gros groupe d'automorphismes, bien plus riche que celui du plan affine. Bot a utilisé cette construction pour montrer l'existence de surfaces affines rationnelles lisses avec une infinité non dénombrable de formes réelles (voir [Bot23]). Le travail établi dans ma thèse montre que même si du point de vue de la structure algébrique, ces groupes sont bien plus riche ; du point de vue de la dynamique individuelle de chaque automorphisme, ce n'est pas le cas.

Théorème A. Soit $X_{0}$ une surface affine normale sur un corps $\mathbf{k}$ algébriquement clos. Si $f: X_{0} \rightarrow X_{0}$ est un endomorphisme dominant, alors $\lambda_{1}(f)$ est un entier algébrique de degré $\leqslant 2$.

La preuve utilise des techniques valuatives que je décris dans la section suivante. Si la caractéristique de $\mathbf{k}$ est nulle, $\mathbf{j}$ 'obtiens des résultats sur la dynamique de l'endomorphisme $f$. Je donnerai un énoncé précis dans le cas des automorphismes (voir Théorème C).

### 1.2 Valuations, Diviseurs à l'infini et dynamique

### 1.2.1 Existence d'une valuation propre

Soit $A$ l'anneau des fonctions régulières d'une surface affine normale $X_{0}$ sur un corps algébriquement clos $\mathbf{k}$. Une valuation est une fonction $v: A \rightarrow \mathbf{R} \cup\{\infty\}$ telle que

1. $v(P Q)=v(P)+v(Q)$;
2. $v(P+Q) \geqslant \min (v(P), v(Q))$;
3. $v(0)=\infty$;
4. $v_{\mid \mathbf{k}^{\times}}=0$

Deux valuations $v$ et $\mu$ sont équivalentes s'il existe $t>0$ tel que $v=t \mu$. Par exemple, si $X$ est une complétion de $X_{0}$, pour toute courbe irréductible $E \subset X$, la fonction $\operatorname{ord}_{E}$ telle que $\operatorname{ord}_{E}(P)$ est l'ordre d'annulation de $P$ le long de $E$ est une valuation. Toute valuation de la forme $\lambda \operatorname{ord}_{E}$ avec $\lambda>0$ est dite divisorielle. Si $f$ est un endomorphisme de $X_{0}$, alors $f$ induit un homomorphisme d'anneaux $f^{*}: A \rightarrow A$. On peut alors définir le poussé en avant $f_{*} v$ d'une valuation $v$ par

$$
\begin{equation*}
f_{*} v(P)=v\left(f^{*} P\right) . \tag{1.11}
\end{equation*}
$$

On dit qu' une valuation est centrée à l'infini s'il existe $P \in A$ tel que $v(P)<0$. Si $X$ est une complétion de $X_{0}$ les valuations divisorielles centrées à l'infini sont exactement celles qui correspondent aux composantes irréductibles de $X \backslash X_{0}$. Soit $\mathcal{V}_{\infty}$ l'ensemble des valuations centrées à l'infini et $\widehat{\mathcal{V}}_{\infty}$ celui des valuations centrées à l'infini modulo équivalence. Supposons pour simplifier que $f$ est un automorphisme de $X_{0}$, alors $f_{*}$ induit une bijection de $\mathcal{V}_{\infty}$ et de $\hat{\mathcal{V}}_{\infty}$ qui sera en fait un homéomorphisme pour une topologie que l'on décrira dans le mémoire.

Si $X_{0}$ est le plan affine complexe, alors Favre et Jonsson prouvent l'existence d'une valuation $\nu_{*} \in \mathcal{V}_{\infty}$ telle que $f_{*} \nu_{*}=\lambda_{1}(f) \nu_{*}$. Une telle valuation est appelée valuation propre de $f$. Pour ce faire, ils montrent dans [FJ04] que $\hat{\mathcal{V}}_{\infty}$ a une structure d'arbre réel et $f_{*}$ est compatible avec cette structure. L'existence de $v_{*}$ provient alors d'un théorème de point fixe sur les arbres. L'existence de cette valuation propre a un grand impact sur la dynamique de $f$. Elle permet notamment de trouver une bonne complétion $X$ de $\mathbf{C}^{2}$ qui admet un point fixe attractif de $f$ à l'infini. Xie utilise cette construction de valuation propre pour démontrer la conjecture des orbites Zariskidenses et la conjecture de Mordell-Lang dynamique pour les endomorphismes du plan affine ([Xie17b]). Jonsson et Wulcan utilisent ces techniques pour construire une hauteur canonique pour les endomorphismes du plan affine complexe avec petit degré topologique dans [JW12].

Théorème B. Soit $X_{0}$ une surface affine normale sur un corps $\mathbf{k}$ algébriquement clos (de caractéristique quelconque) et $f$ un endomorphisme dominant de $X_{0}$. Sous les hypothèses suivantes

1. $\mathbf{k}\left[X_{0}\right]^{\times}=\mathbf{k}^{\times}$.
2. Pour toute complétion $X$ de $X_{0}, \operatorname{Pic}^{0}(X)=0$.
3. $\lambda_{1}(f)^{2}>\lambda_{2}(f)$.

Il existe une valuation centrée à l'infini $\mathrm{v}_{*}$, unique à équivalence près, de f telle que

$$
\begin{equation*}
f_{*}(v)=\lambda_{1}(f) v_{*} . \tag{1.12}
\end{equation*}
$$

Les techniques que j'emploie n'exploite pas la géométrie globale de $\hat{\mathcal{V}}_{\infty}$ au sens où cet espace n'est plus nécessairement un arbre. Soit $X$ une complétion de $X_{0}$, je montre qu'à toute valuation $v$ centrée à l'infini on peut associer un unique diviseur $Z_{v, X}$ de $X$ supporté en dehors de $X_{0}$, de plus si $Y$ est une autre complétion de $X_{0}$, il y a une compatibilité entre $Z_{v, X}$ et $Z_{v, Y}$ (voir Proposition 3.6.6). Cette construction fait intervenir l'espace de Picard-Manin de $X_{0}$. L'analyse spectrale des opérateurs $f_{*}, f^{*}$ définit par $f$ sur cet espace (voir [BFJ08, Can11]) permet de construire la valuation propre $v_{*}$ et de prouver son unicité. Ce procédé est similaire aux techniques de [ $\overline{\mathrm{DF} 21]}$ §6.

### 1.2.2 Discussion des hypothèses du théorème

Les hypothèses du théorème $B$ peuvent paraître arbitraires mais elles ne sont pas restrictives. En effet, si les hypothèses (1) ou (2) ne sont pas vérifiées, alors on peut montrer que l'endomorphisme $f$ préserve une fibration vers une variété ${ }^{1}$ quasi-abélienne. On peut décomposer la dynamique de $f$ par cette fibration et elle devient plus simple à étudier.

Si l'hypothèse (3) n'est pas satisfaite alors on a $\lambda_{1}(f)^{2}=\lambda_{2}(f)$. Notons que dans ce cas $\lambda_{1}(f)$ est automatiquement un entier algébrique de degré $\leqslant 2$ car $\lambda_{2}(f)$ est le degré topologique de $f$, donc un entier. Dans le cas du plan affine complexe, Favre et Jonsson arrivent à une classification des endomorphismes polynomiaux satisfaisant $\lambda_{1}^{2}=\lambda_{2}$ : ou bien ils préservent une fibration rationnelle, ou bien il existe une complétion $X$ de $\mathbf{A}_{\mathbf{C}}^{2}$ avec au plus des singularités quotients à l'infini telle que $f$ s'étende en un endomorphisme de $X$. Je m'attends à ce qu'une classification similaire existe dans le cas général, tous les exemples que j’ai étudié jusqu'à présent satisfont cette dichotomie. On peut remarquer que dans le cas inversible, une telle classification existe déjà : Par [Giz69] et [Can01], toute transformation birationnelle $\sigma: X \rightarrow X$ d'une surface projective lisse telle que $\lambda_{1}(\sigma)=1$ est un automorphisme de $X$ ou préserve une fibration rationnelle ou elliptique.

### 1.2.3 Énoncé du résultat dans le cas des automorphismes

En caractéristique nulle, l'existence de cette valuation propre a des conséquences sur la dynamique de $f$. Je prouve également pour n'importe quel endomorphisme l'existence d'une complétion $X$ de $X_{0}$ qui admet un point fixe attractif de $f$ à l'infini et dans le cas des automorphismes loxodromiques (c'est à dire avec $\lambda_{1}>1$ ), je démontre le résultat suivant

Théorème C. Soit $X_{0}$ une surface affine normale sur $\mathbf{C}$ telle que $\mathbf{C}\left[X_{0}\right]^{\times}=\mathbf{C}^{\times}$. Si $f$ est un automorphisme de $X_{0}$ tel que $\lambda_{1}(f)>1$, alors il existe une complétion $X$ de $X_{0}$ tel que

1. $f$ admet un point fixe attractif $p \in X(\mathbf{C}) \backslash X_{0}(\mathbf{C})$ à l'infini.
2. Un itéré de $f$ contracte $X \backslash X_{0}$ sur $p$.
3. Il existe des coordonnées analytiques locales centrées sur p telles que $f$ est localement de la forme

[^0](a)
\[

$$
\begin{equation*}
f(z, w)=\left(z^{a} w^{b}, z^{c} w^{d}\right) \tag{1.13}
\end{equation*}
$$

\]

avec $a, b, c, d$ des entiers $\geqslant 1$, dans ce cas $\lambda_{1}(f)$ est le rayon spectral de $\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$.
En particulier, $\lambda_{1}(f) \in \mathbf{R} \backslash \mathbf{Q}$, c'est un entier algébrique de degré 2.
(b) ou bien

$$
\begin{equation*}
f(z, w)=\left(z^{a}, \lambda z^{c} w+P(z)\right) \tag{1.14}
\end{equation*}
$$

avec $a \geqslant 2, c \geqslant 1$ et $P \not \equiv 0$ un polynôme, dans ce cas $\lambda_{1}(f)=a$ est un entier.
4. Les points fixes attractifs de fet $f^{-1}$ sont distincts.
5. La forme normale de $f^{-1}$ à son point fixe attractif est la même que celle de $f$.

Les cas (3)(a) et (3)(b) sont mutuellement exclusifs au sens suivant
Théorème D. Soit $X_{0}$ une surface affine normale sur $\mathbf{C}$ telle que $\mathbf{C}\left[X_{0}\right]^{\times}=\mathbf{C}^{\times}$et $f \in \operatorname{Aut}\left(X_{0}\right)$ un automorphisme loxodromique. On a la dichotomie suivante :

- Si $\lambda_{1}(f) \in \mathbf{Z}_{\geqslant 0}$, alors pour tout automorphisme loxodromique $g$ de $X_{0}$, on a $\lambda_{1}(g) \in \mathbf{Z}_{\geqslant 0}$ et la forme normale de $g$ à son point attractif p est de la forme (1.14).
- Si $\lambda_{1}(f) \notin \mathbf{Z}_{\geqslant 0}$ alors c'est un entier algébrique de degré 2 et cela reste vrai pour tout automorphisme loxodromique $g$ de $X_{0}$. En particulier, la forme normale de $g$ à son point fixe attractif est de la forme monomiale (2.13).

On donne deux exemples : le plan affine et la surface de Markov (voir §1.2.3.2). Les théorèmes $\mathrm{Cet} D$ montrent qu'il suffit de comprendre ces deux exemples pour comprendre la dynamique d'un automorphisme d'une surface affine.

### 1.2.3.1 Le plan affine

Soit $X_{0}=\mathbf{A}_{\mathbf{C}}^{2}$, considérons l'automorphisme

$$
\begin{equation*}
f(x, y)=\left(y+x^{2}, x\right) \tag{1.15}
\end{equation*}
$$

C'est un automorphisme de Hénon et on a $\lambda_{1}(f)=2$. On considère la complétion $X=\mathbf{P}_{\mathbf{C}}^{2}$ avec les coordonnées homogènes $X, Y, Z$ telles que $x=X / Z$ et $y=Y / Z$. La transformation birationnelle induite par $f$ possède un point fixe $p_{+}=[1: 0: 0]$ et un point d'indétermination
$p_{-}=[0: 1: 0]$. La droite à l'infini $\{Z=0\}$ est contractée par $f$ sur $p_{+}$et par $f^{-1}$ sur $p_{-}$. Prenons les coordonnées locales $(u, v)$ en $p_{+}$données par $u=Y / X$ et $v=Z / X$, on a

$$
\begin{equation*}
f(u, v)=\left(\frac{v}{1+u v}, \frac{v^{2}}{1+u v}\right) . \tag{1.16}
\end{equation*}
$$

Et il existe un changement de coordonnées analytiques telle que $f$ a la forme normale (1.14). (Voir [Fav00] §2).

### 1.2.3.2 La surface de Markov

Considérons la surface de Markov $\mathcal{M}_{0} \subset \mathbf{A}_{\mathbf{C}}^{3}$ donnée par l'équation

$$
\begin{equation*}
x^{2}+y^{2}+z^{2}=x y z \tag{1.17}
\end{equation*}
$$

C'est une surface normale avec une singularité quotient en $(0,0,0)$. On décrira plus en détail ces propriétés dans le paragraphe 1.4 . Une complétion naturelle de $\mathcal{M}_{0}$ est la surface projective $X \subset \mathbf{P}_{\mathbf{C}}^{3}$ qui est définie comme l'adhérence de Zariski de $\mathcal{M}_{0}$ dans $\mathbf{P}_{\mathbf{C}}^{3}$. L'équation de $X$ est

$$
\begin{equation*}
T\left(X^{2}+Y^{2}+Z^{2}\right)=X Y Z \tag{1.18}
\end{equation*}
$$

On voit que $X \backslash \mathcal{M}_{0}$ a pour équation

$$
\begin{equation*}
T=0, X Y Z=0 \tag{1.19}
\end{equation*}
$$

C'est donc un triangle de 3 courbes rationnelles. Par le théorème 3.1 de [Can09], si $f$ est un automorphisme loxodromique de $\mathscr{M}_{0}$ algébriquement stable sur $X$ alors $f$ possède un point fixe attractif $p_{+} \in X \backslash \mathcal{M}_{0}$ qui est un des sommets du triangle et un point d'indétermination $p_{-} \in X \backslash \mathcal{M}_{0}$ qui est un autre sommet du triangle. De plus, $f$ admet une forme normale monomiale (i.e du type (2.13) en $p_{+}$.

Remarque 1.2.1. On voit que pour toute complétion $X$ du plan affine, le graphe dual de $X \backslash \mathbf{A}_{\mathbf{C}}^{2}$ est un arbre. En revanche, dans le cas de $\mathscr{M}_{0}$ le graphe dual de $X \backslash \mathcal{M}_{0}$ se rétracte sur un cercle pour toute complétion $X$. On montrera en fait que toute surface affine (possédant un automorphisme loxodromique) satisfait cette dichotomie. C'est cette dichotomie de la géométrie des graphes duaux qui donnent la dichotomie de la dynamique (voir Théorème 4.4.4).

### 1.3 Dynamique des automorphismes des surfaces affines

### 1.3.1 Dynamique des transformations de Hénon : Fonction de Green

Soit $\operatorname{Aut}\left(\mathbf{A}_{\mathbf{C}}^{2}\right)$ le groupe des automorphismes polynomiaux du plan affine complexe. Les transformations affines sont des exemples de tels automorphismes. En voici un autre : soit

$$
\begin{equation*}
f(x, y)=(x, y+P(x)) \tag{1.20}
\end{equation*}
$$

où $P$ est un polynôme. L'automorphisme $f$ préserve les droites d'équations $x=\alpha$ et agit par translation sur ces droites, le vecteur de translation est donnée par un polynôme en $x$ à savoir $P(x)$. Un tel automorphisme est appelé élémentaire. On note $E$ l'ensemble des automorphismes élémentaires de $\mathbf{A}_{\mathbf{C}}^{2}$, ces automorphismes forment un groupe isomorphe à $(\mathbf{C}[x],+)$. Le théorème de Jung ([Jun42]) affirme que $\operatorname{Aut}\left(\mathbf{C}^{2}\right)$ a une structure de produit amalgamé

$$
\begin{equation*}
\operatorname{Aut}\left(\mathbf{A}_{\mathbf{C}}^{2}\right)=\operatorname{Aff}\left(\mathbf{A}_{\mathbf{C}}^{2}\right) *_{S} E \tag{1.21}
\end{equation*}
$$

où $S=\operatorname{Aff}\left(\mathbf{A}_{\mathbf{C}}^{2}\right) \cap E$.
Un automorphisme de type Hénon est un automorphisme $f$ qui n'est conjugué ni à un élément de $\operatorname{Aff}\left(\mathbf{A}_{\mathbf{C}}^{2}\right)$ ni à un élément de $E$. Ils sont caractérisés par le fait qu'il vérifie $\lambda_{1}(f)>1$. Un exemple d'automorphisme de type Hénon que nous utiliserons dans la suite est le suivant

$$
\begin{equation*}
f(x, y)=\left(y+x^{2}, x\right) . \tag{1.22}
\end{equation*}
$$

L'extension de $f$ à $\mathbf{P}^{2}$ a un point fixe à l'infini $p_{+}=[1: 0: 0]$ et un point d'indétermination $p_{-}=[0: 1: 0]$. La droite à l'infini est contractée par $f$ sur $p_{+}$. De même $p_{+}$est le seul point d'indétermination de $f^{-1}$ et $p_{-}$est un point fixe de $f^{-1}$ sur lequel la droite à l'infini est contractée par $f^{-1}$. Un automorphisme $h$ sera dit régulier si les points d'indéterminations de $h$ et de $h^{-1}$ sont distincts. En particulier $f$ est régulier et tout automorphisme de type Hénon est conjugué à un automorphisme régulier [FM89]. Pour tout automorphisme de type Hénon $h, \lambda_{1}(h)$ est un entier que l'on notera $d$, en particulier $\lambda_{1}(f)=2$.

On considère la norme $\|(x, y)\|=\max (|x|,|y|)$ sur $\mathbf{C}^{2}$. Si $h$ est un automorphisme régulier de type Hénon, on peut définir les fonctions de Green de $h$ (voir [FM89], [BS91a] et leurs références)

$$
\begin{equation*}
G^{+}(p):=\lim _{N} \frac{1}{d^{N}} \log ^{+}\left\|h^{N}(p)\right\|, \quad G^{-}(p):=\lim _{N} \frac{1}{d^{N}} \log ^{+}\left\|h^{-N}(p)\right\| \tag{1.23}
\end{equation*}
$$

où $\log ^{+}=\max (0, \log )$. On a alors les propriétés suivantes (voir [BS91a] $)$.

1. $G^{+}$est bien définie, continue et plurisousharmonique sur $\mathbf{C}^{2}$
2. $G^{+} \circ h=d G^{+}$
3. La fonction $p \mapsto G^{+}(p)-\log ^{+}(\|p\|)$ s'étend en une fonction continue sur $\mathbf{P}^{2} \backslash p_{-}$.
4. $G^{+}(p)=0$ si et seulement si l'orbite $\left(h^{N}(p)\right)_{N \geqslant 0}$ est bornée.

La fonction $G^{-}$jouit de propriétés similaires. On peut alors définir les courants de Green $T^{+}=d d^{c} G^{+}$et $T^{-}=d d^{c} G^{-}$. Ce sont des $(1,1)$-courants positifs fermés. La mesure

$$
\begin{equation*}
\mu:=T^{+} \wedge T^{-} \tag{1.24}
\end{equation*}
$$

est alors bien définie car $G^{+}, G^{-}$sont continues, elle est de masse totale finie et on peut supposer que c'est une mesure de probabilité. On l'appelle la mesure d'équilibre de $h$. Elle est $h$-invariante et son support est contenu dans l'ensemble de Julia de $h$.

On définit la fonction de Green suivante

$$
\begin{equation*}
G:=\max \left(G^{+}, G^{-}\right) \tag{1.25}
\end{equation*}
$$

qui satisfait les propriétés

1. $G$ est une fonction continue, plurisousharmonique de $\mathbf{C}^{2}$ et est limite uniforme de

$$
\begin{equation*}
\max \left(\frac{1}{d^{N}} \log ^{+}\left(\left\|f^{N}(p)\right\|\right), \frac{1}{d^{N}} \log ^{+}\left(\left\|f^{-N}(p)\right\|\right)\right) \tag{1.26}
\end{equation*}
$$

2. $p \mapsto G(p)-\log ^{+}\|p\|$ s'étend en une fonction continue sur $\mathbf{P}^{2}$.
3. $G(p)=0$ si et seulement si l'orbite $\left(f^{N}(p)\right)_{N \in \mathbf{Z}}$ est bornée.

### 1.3.2 Dynamique des automorphismes des surfaces affines

Grâce au théorème C, je démontre le résultat suivant :
Théorème $\mathbf{E}$. Soit $X_{0}$ une surface affine normale sur $\mathbf{C}$, soit $X$ une complétion de $X_{0}$ qui vérifie le théorème $C$ Soit $X \hookrightarrow \mathbf{P}^{N}$ un plongement de $X$ qui induit un plongement $X_{0} \hookrightarrow \mathbf{C}^{N}$ et soit $\|\cdot\|$
une norme sur $\mathbf{C}^{N}$. Si f est un automorphisme de $X_{0}$ tel que $\lambda_{1}(f)>1$, la fonction de Green

$$
\begin{equation*}
G^{+}(p):=\lim _{N} \frac{1}{\lambda_{1}^{N}} \log ^{+}\left(\left\|f^{N}(p)\right\|\right) \tag{1.27}
\end{equation*}
$$

vérifie les propriétés suivantes

1. $G^{+}$est bien définie, continue et plurisousharmonique sur $X_{0}(\mathbf{C})$.
2. $G^{+} \circ f=\lambda_{1} G^{+}$
3. $G^{+}$est à croissance logarithmique (voir Proposition 5.2.5).
4. $G^{+}(p)=0$ si et seulement si l'orbite $\left(f^{N}(p)\right)_{N \geqslant 0}$ est bornée.

On peut alors considérer la fonction $G=\max \left(G^{+}, G^{-}\right)$qui va jouir de propriétés similaires au cas Hénon. Il y a cependant une différence majeure. En général, le maximum de deux fonctions à croissance logarithmique n'est pas à croissance logarithmique. Il y a donc une difficulté supplémentaire ici. Il s' avère que nous avons deux comportements différents : si $\lambda_{1}(f) \in \mathbf{Z}_{\geqslant 0}, G$ est encore à croissance logarithmique et tout se passe comme dans le cas Hénon. Si $\lambda_{1}(f) \notin \mathbf{Z}_{\geqslant 0}$, alors $G$ n'est pas à croissance logarithmique et donc ce n'est pas la bonne fonction à considérer, il faut alors utiliser les travaux récents de Yuan et Zhang sur les fibrés en droite adéliques sur les variétés quasiprojectives, Je serai plus précis dans la section suivante.

### 1.3.3 Dynamique aux places non-archimédiennes

Soit $\mathbf{K}$ un corps de nombre. Une valeur absolue $|\cdot|$ sur $\mathbf{K}$ est une fonction $|\cdot|: \mathbf{K} \rightarrow \mathbf{R}_{+}$qui vérifie les axiomes suivants

- $|x|=0 \Leftrightarrow x=0$,
- $\forall x, y \in \mathbf{K},|x y|=|x| \cdot|y|$,
- $\forall x, y \in \mathbf{K},|x+y| \leqslant|x|+|y|$.

Deux valeurs absolues $|\cdot|_{1},|\cdot|_{2}$ sont équivalentes si $|\cdot|_{1}=|\cdot|{ }_{2}^{s}$ pour un certain $s>0$. Une place est une classe d'équivalence de valeur absolue, on note $\mathcal{M}(\mathbf{K})$ l'ensemble des places de $\mathbf{K}$. Si $|\cdot|$ est une valeur absolue de $\mathbf{K}$, on peut considérer la complétion de $\mathbf{K}$ par rapport à $|\cdot|$. Cette complétion ne dépend en fait que de la place $v$ de $|\cdot|$, on la note $\mathbf{K}_{v}$. La valeur absolue $|\cdot|$ s'étend alors à $\mathbf{K}_{v}$ et admet une extension naturelle à $\overline{\mathbf{K}}_{v}$. On note $\mathbf{C}_{v}$ le complété de $\overline{\mathbf{K}}_{v}$ par rapport à
$|\cdot|$. Cette construction ne dépend que de la place $v$. On dit que $|\cdot|$ est non-archimédienne si elle vérifie l'inégalité suivante

$$
\begin{equation*}
\forall x, y \in \mathbf{K},|x+y| \leqslant \max (|x|,|y|) . \tag{1.28}
\end{equation*}
$$

Une place $v$ est non-archimédienne si un de ses représentants l'est. Pour toute place archimédienne $v$, on a $\mathbf{C}_{v}=\mathbf{C}$. Les énoncés du paragraphe $\S 1.3 .1$ ont des analogues lorsque $\mathbf{C}$ est remplacé par un corps algébriquement clos complet non archimédien $\mathbf{C}_{v}$. En effet, Kawaguchi montre dans [Kaw09] que la fonction de Green d'un automorphisme de type Hénon est bien définie également dans le cas non-archimédien. $\mathrm{Si} \mathbf{C}_{v}$ est non-archimédien, la fonction de Green $G=\max \left(G^{+}, G^{-}\right)$induit un fibré en droites métrisé semipositif sur l'analytifié de Berkovich de $\mathbf{P}_{\mathbf{C}_{v}}^{2}$ que l'on note $\left(\mathbf{P}_{\mathbf{C}_{v}}^{2}\right)^{\text {an }}$ (voir [Zha93] pour la définition). La mesure d'équilibre associée est une mesure positive sur $\left(\mathbf{P}_{\mathbf{C}_{v}}^{2}\right)^{\text {an }}$, elle est construite dans [Cha03]. Il est à noter que des travaux plus récents de Chambert-Loir et Ducros [CD] permettent de construire les courants $T^{ \pm}=d d^{c} G^{ \pm}$et de définir la mesure d'équilibre de la même manière que dans le cas complexe $\mu=T^{+} \wedge T^{-}$. De plus, Lee montre dans [Lee13] que l'orbite de Galois de toute suite ${ }^{2}$ générique de points périodiques de $f$ est équidistribuée par rapport à la mesure $\mu=T^{+} \wedge T^{-}$et ce à toutes les places en utilisant le théorème d'équidistribution de Yuan dans [Yua08].

Je prouve également un analogue du théorème $\mathbb{C}$ dans le cas non archimédien. On définit également les fonctions $G^{+}, G^{-}, G$ dans ce contexte. Cependant les problèmes évoquées à la fin du paragraphe 1.3 .2 subsiste. Si $\lambda_{1}(f) \in \mathbf{Z}_{\geqslant 0}$, alors la donnée des fonctions de Green $\left(G_{v}\right)$ pour chaque place $v$ de $\mathbf{K}$ induit un fibré en droites adélique semipositif (cf [Zha93]) sur une complétion $X$ de $X_{0}$ et le théorème d'équidistribution arithétique de Yuan s'applique.

Maintenant si $\lambda_{1}(f) \notin \mathbf{Z}_{\geqslant 0}$, on ne peut pas appliquer la théorie des fibrés en droite adélique sur la complétion $X$. Le bon point de vue est de considérer non pas une complétion de $X_{0}$ mais l'ensemble de toutes les complétions $X$ de $X_{0}$. C'est le point de vue développé par Yuan et Zhang dans [YZ22]. Les auteurs définissent alors la notion de fibré en droites adélique associé à une variété quasiprojective $U$ comme une limite de fibrés en droites adéliques sur des complétions de $U$. Ils démontrent dans ce contexte un théorème d'équidistribution arithmétique similaire au théorème de Yuan. Je conjecture dans mon mémoire le fait suivant (voir Conjecture F) :

Conjecture F. La donnée de $\left(G_{v}^{+}\right)$et $\left(G_{v}^{-}\right)$pour toute place $v$ de $\mathbf{K}$ induisent deux fibrés en droites adéliques nef f-invariant sur la variété quasiprojective $X_{0}$. En particulier, on peut définir la mesure d'équilibre $\mu_{v}$ de fà toute place comme la mesure de probabilité proportionelle à $d d^{c} G_{v}^{+} \wedge d d^{c} G_{v}^{-}$et l'orbite de Galois de toute suite générique de points périodiques de $f$ est

[^1]équidistribuée par rapport à $\mu_{v}$ pour toute place $v$.
Je pense que les travaux établis dans ce mémoire et les travaux de Yuan et Zhang permettront de prouver cette conjecture à l'aide d'une construction similaire au §4 de [YZ17](voir §1.5.1).

### 1.3.4 Des automorphismes avec une infinité de points périodiques communs

Si $X_{0}$ une surface affine normale sur $\mathbf{K}$, un corps de nombre, et $f$ un automorphisme loxodromique de $X_{0}$, on peut mener l'étude de la section précédente aux places archimédiennes et non-archimédiennes. On obtient ainsi une mesure d'équilibre $\mu_{f, v}$ pour $f$ à toutes les places $v$ de $\mathbf{K}$. Grâce aux techniques d'équidistributions arithmétiques mentionnées dans le paragraphe précédent, je démontre le résultat suivant.

Théorème G. Soit $X_{0}$ une surface affine normale défini sur un corps de nombres $\mathbf{K}$. Si $f, g$ sont deux automorphismes loxodromiques de $X_{0}$ tels que $\lambda_{1}(f) \in \mathbf{Z} \geqslant 0$, les assertions suivantes sont équivalentes

1. $\operatorname{Per}(f) \cap \operatorname{Per}(g)$ est Zariski-dense.
2. $\forall v \in \mathscr{M}(\mathbf{K}), \mu_{v, f}=\mu_{v, g}$
3. $\operatorname{Per}(f)=\operatorname{Per}(g)$.

Dans le cas $\lambda_{1}(f) \notin \mathbf{Z}_{\geqslant 0}$, en admettant la conjecture $F$ on a que si $\operatorname{Per}(f) \cap \operatorname{Per}(g)$ est Zariski-dense, alors $\forall v \in \mathcal{M}(\mathbf{K}), \mu_{f, v}=\mu_{g, v}$.

En utilisant des méthodes similaires, ce genre d'énoncé a d'abord été obtenu par Baker, DeMarco dans [BD11a] pour les endomorphismes de $\mathbf{P}^{1}$ de degré $\geqslant 2$ sur $\mathbf{C}$ puis a été généralisé par Yuan et Zhang pour les endomorphismes polarisables de $\mathbf{P}^{m}$ sur un corps de nombres dans [YZ17] et récemment dans [YZ21] sur n'importe quel corps de caractéristique nulle. Dans [CD20], Cantat et Dujardin utilisent ces mêmes outils de dynamique arithmétique pour montrer des résultats de rigidité sur les groupes d'automorphismes de surfaces projectives.

La conjecture $F$ ne suffit pas à montrer l'égalité $\operatorname{Per}(f)=\operatorname{Per}(g)$ car la preuve utilise une version arithmétique du théorème de l'indice de Hodge qui n'a pas encore été démontré pour les fibrés en droites adéliques sur les variétés quasi-projectives (voir Théorème 5.1.20).

### 1.4 Un résultat de rigidité pour la surface de Markov

Dans [DF17] Dujardin et Favre montrent un résultat plus fort que celui du théorème G] Ils obtiennent que si deux automorphismes de Hénon vérifient une des assertions du théorème G alors $f$ et $g$ ont des itérés communs : il existe deux entiers $M, N \in \mathbf{Z}$ tels que $f^{N}=g^{M}$. Ce résultat de rigidité ne peut pas être vrai pour toute surface affine. En effet, si $X_{0}=\mathbf{C}^{\times} \times \mathbf{C}^{\times}$. Soit $A=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right) \in \operatorname{SL}_{2}(\mathbf{Z})$ telle que $(\operatorname{Tr} A)^{2}>4$, alors on définit l'automorphisme

$$
\begin{equation*}
f_{A}(x, y)=\left(x^{a} y^{b}, x^{c} y^{d}\right) \tag{1.29}
\end{equation*}
$$

Si $\mathbb{S}^{1}=\{z \in \mathbf{C}| | z \mid=1\}$, alors $\mathbb{S}^{1} \times \mathbb{S}^{1}$ est un compact invariant par $f_{A}$. C'est l'ensemble de Julia de $f_{A}$ et les points périodiques de $f_{A}$ sont exactement les points $\left(\omega_{1}, \omega_{2}\right) \in \mathbb{S}^{1} \times \mathbb{S}^{1}$ où $\omega_{1}, \omega_{2}$ sont des racines de l'unité. Ainsi, tous les automorphismes obtenus ainsi vérifie le théorème G mais n'ont pas d'itérés communs.

Soit $D \in \mathbf{C}$, on définit la surface de Markov $\mathcal{M}_{D}$ comme la surface dans $\mathbf{C}^{3}$ définie par

$$
\begin{equation*}
x^{2}+y^{2}+z^{2}=x y z+D \tag{1.30}
\end{equation*}
$$

Cette famille de surfaces est à la frontière de plusieurs domaines (voir [Can09]). Notamment, si $\mathbb{T}^{1}$ est le tore épointé, son groupe fondamental $\pi:=\pi_{1}\left(\mathbb{T}^{1}\right)$ est un groupe libre à deux générateurs que l'on note $a$ et $b$. On peut s'intéresser à la variété de caractères

$$
\begin{equation*}
X:=\operatorname{Hom}\left(\pi, \mathrm{SL}_{2}(\mathbf{C})\right) / / \mathrm{SL}_{2}(\mathbf{C}) \tag{1.31}
\end{equation*}
$$

où l'action de $\mathrm{SL}_{2}(\mathbf{C})$ est donnée par la conjugaison et // est le quotient au sens de la théorie géométrique des invariants (GIT). On note $[a, b]:=a b a^{-1} b^{-1}$ le commutateur de $a$ et $b$. Soit $\rho \in \mathcal{X}$, si on note $x=\operatorname{Tr} \rho(a), y=\operatorname{Tr} \rho(b), z=\operatorname{Tr} \rho(a b)$, alors on a que

$$
\begin{align*}
X & \rightarrow \mathbf{A}_{\mathbf{C}}^{3}  \tag{1.32}\\
\rho & \mapsto(x, y, z) \tag{1.33}
\end{align*}
$$

est un isomorphisme. C'est un résultat de Fricke (voir [Gol09]). De plus on a l'égalité suivante

$$
\begin{equation*}
x^{2}+y^{2}+z^{2}=x y z+\operatorname{Tr}(\rho([a, b]))+2 . \tag{1.34}
\end{equation*}
$$

Autrement, dit la variété algébrique $\mathcal{X}$ est feuilleté par la famille des surfaces de Markov et la surface $\mathcal{M}_{D}$ représente une ligne de niveau pour la fonction régulière $\rho \mapsto \operatorname{Tr}(\rho([a, b]))$.

Théorème H. Soit $D=0$ ou bien $D=2-2 \cos (2 \pi / q)$ avec $q \geqslant 2$. Si $f, g$ sont deux automorphismes loxodromiques de $\mathfrak{M}_{D}$, alors en admettant la conjecture $F$ les assertions suivantes sont équivalentes:

1. $\operatorname{Per}(f) \cap \operatorname{Per}(g)$ est Zariski-dense.
2. $\operatorname{Per}(f)=\operatorname{Per}(g)$.
3. $f$ et $g$ ont des itérés communs : il existe $N, M \in \mathbf{Z}$ tels que $f^{N}=g^{M}$.

La conjecture $F$ et le théorème $G$ donnent l'égalité des mesures d'équilibres de $f$ et $g$. Pour montrer le résultat on utilise la théorie des représentations fuchsiennes et quasi-fuchisiennes pour construire un point fixe hyperbolique $q(f)$ au bord de l'ouvert des représentations quasifuchsiennes dans $\mathscr{M}_{D}(\mathbf{C})$. Cette construction utilise le théorème de paramétrisation de Bers [Ber60], sa prolongation par Minsky [Min99] et le théorème d'hyperbolisation des variétés de dimension 3 qui fibre sur un cercle de Thurston (voir [Ota96, McM96]). On démontre ensuite grâce à des techniques de théorie des courants en géométrie complexe, notamment grâce au courant d'Ahlfors-Nevanlinna, que ce point fixe hyperbolique doit appartenir au support de $\mu_{\mathbf{C}, f}=\mu_{\mathbf{C}, g}$ qui est un compact invariant par le groupe $\langle f, g\rangle$. Enfin on montre que l'orbite de $q(f)$ sous $g$ est non bornée si $g$ n'a pas d'itérés communs avec $f$ grâce à la théorie des laminations mesurées ce qui donne une contradiction.

### 1.5 Questions et compléments

### 1.5.1 La conjecture $\sqrt{F}$

Comme établi dans cette introduction, je pense que la conjecture F doit se démontrer avec les travaux de ce mémoire. Notamment, je montre dans la proposition 5.2.5 que la fonction $G^{+}$ s'obtient par un procédé itératif à partir d'une fonction de Green de n'importe quel diviseur. Ce procédé itératif appliqué aux fibrés en droite adéliques sur $X_{0}$ doit donner un fibré en droites adéliques nef au sens [YZ22]. En effet, dans le cadre projectif si $f$ est un endomorphisme polarisé d'une variété projective $X$ et $L$ un fibré en droites ample sur $X$ tel que $f^{*} L=L^{\otimes d}$, alors Yuan et Zhang montrent dans [YZ17] que pour n'importe quelle extension adélique $\bar{L}$ de $L$, la
suite

$$
\begin{equation*}
\frac{1}{d^{n}}\left(f^{n}\right)^{*} \bar{L} \tag{1.35}
\end{equation*}
$$

converge vers un fibré en droites adélique semipositif $\bar{L}_{f}$ tel que $f^{*} \overline{L_{f}}=d \overline{L_{f}}$. Au niveau des fonctions de Green ce processus itératif est le même que celui qui apparait dans la section 5.2 (voir les propositions $5.2 .5 \mathrm{et}[5.2 .12$ ), donc je m'attends à ce que tout passe dans ce cadre.

Pour obtenir le théorème $\mathbb{G}$ il faudra ensuite démontrer le théorème de l'indice de Hodge arithmétique dans le cas des surfaces affines. Il me suffit d'une version affaiblie qui semble démontrable dans le cas précis qui m'intéresse.

### 1.5.2 les travaux de Danilov et Gizatullin

On dit qu'une surface affine $X_{0}$ est complétable par un zigzag s'il existe une complétion $X$ de $X_{0}$ tel que $X \backslash X_{0}$ est un zigzag, c'est à dire une chaîne de courbes rationnelles lisses. Le plan affine est complétable par un zigzag mais pas la surface de Markov $\mathcal{M}_{0}$ par exemple. Dans [GD75], Danilov et Gizatullin étudient le groupe d'automorphismes des surfaces affines complétable par un zigzag. Ils montrent que ce groupe agit sur un arbre dont les sommets sont les complétions dont le bord est un zigzag. Si $X_{0}$ est complétable par un zigzag, alors son espace des valuations centrées à l'infini $\widehat{\mathcal{V}_{\infty}}$ est aussi un arbre sur lequel agit $\operatorname{Aut}\left(X_{0}\right)$. Il serait intéressant de comparer l'approche de Danilov et Gizatullin aux travaux de mon mémoire. Il est à noter que les travaux de Gizatullin (voir [Giz71b, Giz70, Giz71c]) préliminaires aux résultats de [GD75] sont également utilisé dans mon mémoire pour étudier la dynamique des automorphismes loxodromiques (voir \$4.4.1).

### 1.5.3 Complexité dynamique vs complexité algébrique de $\operatorname{Aut}\left(X_{0}\right)$

J'ai démontré dans mon mémoire que l'étude de la dynamique d'un automorphisme loxodromique sur une surface affine est similaire ou bien à la dynamique d'un automorphisme de type Hénon, ou bien à un automorphisme de la surface de Markov. Cependant on sait qu'il existe des surfaces affines avec un groupe d'automorphisme bien plus compliqué que celui du plan affine par les travaux de Blanc et Dubouloz mentionnés précédemment. Prenons $X_{0}$ une telle surface, il serait intéressant d'appliquer les techniques valuatives de ce mémoire à tout un sous groupe d'automorphismes de $X_{0}$. Par exemple si $f, g$ sont deux automorphismes loxodromiques tels que tout élément du sous groupe $\Gamma=\langle f, g\rangle$ qui n'est pas l'identité est loxodromique, que peut on dire de l'ensemble $\left\{v_{*}(h): h \in \Gamma\right\} \subset \widehat{\mathcal{V}_{\infty}}$ où $v_{*}(h)$ est la valuation propre de $h$ ? Peut on
retrouver la complexité algébrique du groupe $\operatorname{Aut}\left(X_{0}\right)$ en utilisant des techniques valuatives?

### 1.5.4 Des résultats de dynamique arithmétique utilisant des techniques valuatives

En utilisant les techniques valuatives de Favre et Jonsson pour le plan affine, Junyi Xie montrent dans [Xie17b] la conjecture des orbites Zariski dense pour les endomorphismes polynomiaux du plan affine complexe. Cette conjecture affirme qu'un endomorphisme $f$ admet une orbite Zariski dense si et seulement si $f$ n'admet pas de fonctions rationnelles non constantes invariantes. La preuve utilise la dynamique à l'infini provenant de l'existence de valuation propre. L'auteur montre également dans [Xie17a] la conjecture dynamique de Mordell-Lang pour les endomorphismes polynomiaux du plan affine : si $x \in \mathbf{A}^{2}(\mathbf{C})$ et $C \subset \mathbf{A}_{\mathbf{C}}^{2}$ est une courbe alors $\left\{n \geqslant 0: f^{n}(x) \in C\right\}$ est une union d'un ensemble fini et d'une union finie de progressions arithmétiques.

Pour ces deux conjectures, on peut établir leur analogue dans le cas de n'importe quelle surface affine en utilisant les techniques valuatives de ce mémoire en supposant $\lambda_{1}^{2}>\lambda_{2}$. Pour le cas d'égalité, Xie s'appuie sur la classification des endomorphismes vérifiant $\lambda_{1}^{2}=\lambda_{2}$ établie par Favre et Jonsson. Il est donc nécessaire d'établir une telle classification en général. Pour l'instant les techniques développées dans ce mémoire ne permettent pas de traiter le cas $\lambda_{1}^{2}=\lambda_{2}$. En particulier, je ne sais pas pour l'instant construire de valuations propres associées à un endomorphisme $f$ vérifiant $\lambda_{1}(f)^{2}=\lambda_{2}(f)$.

### 1.5.5 Fonctions de Green et hauteurs canoniques pour les petits degrés topologiques

Soit $f$ un endomorphisme polynomial du plan affine défini sur un corps de nombre $\mathbf{K}$ tel que $\lambda_{1}(f)>\lambda_{2}(f)$. Dans [FJ11] et [JW12] Favre, Jonsson et Wulcan utilise l'existence d'une unique valuation propre de $f$ pour construire une fonction de Green pour $f$ à toutes les places. Jonsson et Wulcan construisent ensuite une hauteur canonique $h_{f}$ associé à $f$ qui satisfait la propriété suivante : $p \in \mathbf{A}^{2}(\bar{K}), h_{f}(p)=0$ si et seulement si pour toute place $v,\left\|f^{n}(p)\right\|_{v}$ croît au plus comme $\mu^{n}$ avec $0<\mu \leqslant \lambda_{2}<\lambda_{1}$.

Il semble que cette construction doit se généraliser à toute surface affine avec les travaux de ce mémoire. La construction de fonctions de Green et d'hauteurs canoniques permettrait de prouver une version faible de l'alternative de Tits de la forme suivante : Si $f, g \in \operatorname{End}\left(X_{0}\right)$
satisfont $\lambda_{1}(f)>\lambda_{2}(f), \lambda_{1}(g)>\lambda_{2}(g)$, alors si $h_{f} \neq h_{g}$ quitte à remplacer $f$ et $g$ par des itérés, le semi groupe engendré par $f$ et $g$ est libre. Ce résultat a été établi pour les transformations polynomiales de $\mathbf{A}_{\mathbf{C}}^{1}$ dans [BHPT21].

### 1.5.6 En dimension plus grande

Soit $d \geqslant 3$ un entier, dans [DF21] §6, Dang et Favre montrent que le degré dynamique d'une transformation polynomiale $f: \mathbf{A}_{\mathbf{C}}^{d} \rightarrow \mathbf{A}_{\mathbf{C}}^{d}$ tel que $\lambda_{1}(f)^{2}>\lambda_{2}(f)$ est un nombre algébrique de degré $\leqslant d$. Pour se faire ils construisent une valuation propre de $f$ centrée à l'infini à l'aide de l'analyse spectral de l'opérateur $f^{*}$ sur un espace $N_{\Sigma}^{1}(X)$ qui est un analogue de l'espace de Picard-Manin en dimension 2. Ils utilisent ensuite l'inégalité d'Abhyankhar (voir [Abh56]) de la façon suivante : $\operatorname{Si} \mathrm{V}_{*}$ est une valuation propre de $f$, i.e $f_{*} \nu_{*}=\lambda_{1} \nu_{*}$, alors $f_{*}$ induit une application linéaire sur $\Gamma_{\nu_{*}} \otimes \mathbf{Q}$ où $\Gamma_{\nu_{*}}$ est le groupe des valeurs de $\nu_{*}$. L'inégalité d'Abhyankhar affirme que $\operatorname{dim}_{\mathbf{Q}} \Gamma_{v_{*}} \otimes \mathbf{Q} \leqslant d$. Ainsi, $\lambda_{1}$ est valeur propre d'une matrice $d \times d$ à coefficients rationnels, donc un nombre algébrique de degré $\leqslant d$.

J'affirme que la construction de la valeur propre dans le cas des surfaces affines que j'établis dans ce mémoire se généralise en dimension plus grande. En particulier, les sections 3.6 et 3.7 s'appliquent directement en toute dimension. La construction de la valuation propre provient alors d'un équivalent du théorème 4.1.16 où l'espace $L^{2}\left(X_{0}\right)$ doit être remplacé par son analogue $N_{\Sigma}^{1}(X)$. On peut alors appliquer l'inégalité d'Abhyankhar et énoncer le résultat suivant :
si $X_{0}$ est une variété affine de dimension $d \geqslant 3$ sur un corps $\mathbf{k}$ algébriquement clos de caractéristique nulle telle que

- $\mathbf{k}\left[X_{0}\right]^{\times}=\mathbf{k}^{\times}$;
- Pour toute complétion $X$ de $X_{0}, \operatorname{Pic}^{0}(X)=0$;

Si $f: X_{0} \rightarrow X_{0}$ est un endomorphisme tel que $\lambda_{1}(f)^{2}>\lambda_{2}(f)$, alors $\lambda_{1}(f)$ est un nombre algébrique de degré $\leqslant d$.

## Introduction

An affine variety $X_{0}$ over an algebraically closed field $\mathbf{k}$ is a subspace of $\mathbf{k}^{N}$ defined by polynomial equations. A polynomial endomorphism of $X_{0}$ is a polynomial transformation of $\mathbf{k}^{N}$ that preservers $X_{0}$ in the sense that $f\left(X_{0}\right) \subset X_{0}$. When the dimension of $X_{0}$ is 2 , we say that $X_{0}$ is an affine surface. The goal of my thesis is to study the dynamical system given by an affine surface $X_{0}$ and $f: X_{0} \rightarrow X_{0}$ a polynomial endomorphism of $X_{0}$. The different questions one can ask are: are there dense orbits or Zariski-dense orbits ? If the orbit of a point goes to infinity, can we control the speed of divergence? Is there a lot of periodic orbits? Can we construct interesting invariant probability measures? To answer these questions, I use valuative techniques. The dynamical system $\left(X_{0}, f\right)$ induces a dynamical system $\left(\mathcal{V}_{\infty}, f_{*}\right)$ where $\mathcal{V}_{\infty}$ is the space of valuations centered at infinity of $X_{0}$. The study of this dynamical system is the main goal of this memoir and it will allow to answer the questions mentioned above.

### 2.1 Endomorphisms

### 2.1.1 Dynamical degrees

### 2.1.1. Polynomial transformations of the complex affine plane

A polynomial transformation $f$ of $\mathbf{C}^{N}$ is given by $N$ polynomials $f_{i} \in \mathbf{C}\left[x_{1}, \cdots, x_{N}\right]$ such that $f=\left(f_{1}, \cdots, f_{N}\right)$. The degree of $f$ is defined as the maximum of the degrees of the $f_{i}^{\prime} s$; we denote it by $\operatorname{deg} f$. Let $f^{k}$ be the $k$-th iterate of $f$. When we iterate $f$, the degree of the formulas of $f^{k}$ must typically grow exponentially. It is therefore natural to consider the following quantity:

$$
\begin{equation*}
\lambda_{1}(f):=\lim _{k}\left(\operatorname{deg} f^{k}\right)^{1 / k}, \tag{2.1}
\end{equation*}
$$

introduced in [RS97], which we call the first dynamical degree of $f$. The authors show that this quantity is well defined. We can define the first dynamical degree of any rational transformation of the projective space $\mathbf{P}_{\mathbf{C}}^{N}$ with a similar definition.

### 2.1.1.2 General definitions

Let $X$ be a smooth projective variety over an algebraically closed field and let $d$ be its dimension. For $d$ Cartier divisors $D_{1}, \cdots, D_{d}$ of $X$ we can define the intersection product $D_{1} \cdots D_{d} \in \mathbf{Z}$ (see [Laz04]). If $f: X \longrightarrow X$ is a dominant rational transformation of $X$, we define for $0 \leqslant l \leqslant d$ the $l$-th dynamical degree of $f$ by

$$
\begin{equation*}
\lambda_{k}(f):=\lim _{n \rightarrow \infty}\left(\left(f^{n}\right)^{*} H^{k} \cdot H^{d-k}\right)^{1 / n} \tag{2.2}
\end{equation*}
$$

where $H$ is an ample divisor over $X$. We can show that these quantities are well defined and do not depend on the choice of $H$. In particular, $\lambda_{0}(f)=1$. Furthermore, the dynamical degrees are birational invariants: if $\varphi: X \rightarrow Y$ is a birational map, then

$$
\begin{equation*}
\lambda_{l}(f)=\lambda_{l}\left(\varphi \circ f \circ \varphi^{-1}\right), \quad \forall 0 \leqslant l \leqslant d . \tag{2.3}
\end{equation*}
$$

We have that $\lambda_{d}(f)$ is the topological degree of $f$. The Khovanskii-Teissier inequalities (see [Gro90], [DN05]) imply that the sequence $\left(\lambda_{l}\right)_{0 \leqslant l \leqslant d}$ is log-concave; i.e

$$
\begin{equation*}
\frac{\log \lambda_{l-1}+\log \lambda_{l+1}}{2} \leqslant \log \lambda_{l}, \quad \forall 1 \leqslant l \leqslant d-1 . \tag{2.4}
\end{equation*}
$$

In particular, one has $\forall 1 \leqslant l \leqslant d, \lambda_{1}(f)^{l} \geqslant \lambda_{k}(f)$.
Let $X_{0}$ be a smooth affine variety of dimension $d$ and $f: X_{0} \rightarrow X_{0}$ an endomorphism of $X_{0}$. We define the dynamical degrees of $f$ as follows. A completion of $X_{0}$ is a smooth projective variety $X$ equipped with an open immersion $\mathfrak{\imath}: X_{0} \hookrightarrow X$ such that $\mathfrak{l}\left(X_{0}\right)$ is dense in $X$. The endomorphism $f$ induces a dominant rational transformation of $X$ via $\tilde{f}=\mathfrak{\imath} \circ f \circ \mathfrak{l}^{-1}$ and we define the dynamical degrees

$$
\begin{equation*}
\lambda_{l}(f):=\lambda_{l}(\tilde{f}) \tag{2.5}
\end{equation*}
$$

As the dynamical degrees are birational invariants, these quantities do not depend on the choice of the completion $X$. In particular, if $X_{0}=\mathbf{k}^{N}$ and $X=\mathbf{P}_{\mathbf{k}}^{N}$ we recover the definition of the first dynamical degree defined in the first paragraph.

The data of these dynamical degrees gives information on the dynamical system. For example over C, Dinh and Sibony showed in [DS03] that for all dominant rational transformation $f: X \rightarrow X$

$$
\begin{equation*}
h_{\text {top }}(f) \leqslant \max _{0 \leqslant l \leqslant d} \log \left(\lambda_{l}\right) \tag{2.6}
\end{equation*}
$$

where $h_{\text {top }}$ is the topological entropy of $f$, Gromov showed this result for endomorphisms of $\mathbf{P}^{N}$ in [Gro03]. Yomdin showed in [Yom87] that we have an equality if $f$ is an endomorphism. Recently, Favre, Truong and Xie showed in [FTX22] that the inequality (2.6) still holds in the non archimedean case; however the equality does not hold even for endomorphisms.

### 2.1.2 Dynamical degrees on projective surfaces

A natural question is to ask what numbers can appear as the first dynamical degree of a rational transformation of a projective surface. We first mention the following result due to Bonifant and Fornaess in [ $\left[\right.$ BF00] for $\mathbf{P}_{\mathbf{C}}^{N}$ and generalised by Urech

Théorème 2.1.4 ([Ure16]). The set

$$
\begin{equation*}
\left\{\lambda_{1}(f)\right\} \tag{2.7}
\end{equation*}
$$

where $f$ runs through the set of rational transformations over every projective variety over every field, is countable.

In 2021, Bell, Diller and Jonsson showed in [BDJ20] that there exists a dominant rational transformation $\sigma: \mathbf{P}^{2} \rightarrow \mathbf{P}^{2}$ such that $\lambda_{1}(\sigma)$ is transcendental. The authors with Krieger showed in [BDJ20] this example can be generalised to give an example of a birational transformation of $\mathbf{P}^{N}, N \geqslant 3$ with a transcendental first dynamical degree. However in dimension 2, there are strong constraints on $\lambda_{1}(f)$ for $f$ birational. In [DF01], Diller and Favre showed that the first dynamical degree of a birational transformation of a projective surface is an algebraic integer. More precisely, it is a Salem or a Pisot number. In [BC13], Blanc and Cantat obtained the following results

Theorem 2.1.1. Let $X$ be a smooth projective surface over an algebraically closed field.

1. Let $f: X \rightarrow X$ be a birational transformation such that $\lambda_{1}(f)$ is a Salem number, then there exists a birational map $\varphi: X \rightarrow Y$ such that $\varphi \circ f \circ \varphi^{-1}$ is an automorphism of $Y$.
2. If $X$ is rational over a field $\mathbf{k}$, then the set $\Lambda(X):=\left\{\lambda_{1}(f) \mid f \in \operatorname{Bir}(X)\right\} \subset \mathbf{R}$ is well ordered. It is closed if $\mathbf{k}$ is not countable.

In particular, $\Lambda(X)$ is an ordinal and Bot shows in [Bot22] that this ordinal is exactly $\omega^{\omega}$ where $\omega$ is the ordinal of the natural integers. However, we cannot hope to get an information of the degree of the algebraic numbers obtained. Indeed, Bedford, Kim and McMullen have given in [BK06] and [McM07] examples of birational transformations of projective surfaces with
first dynamical degree an algebraic integer of arbitrary large degree. In particular, Theorem 1.1 of McM07] states that for all $d \geqslant 10$ we can find a smooth projective surface with an automorphism with first dynamical degree an algebraic integer of degree $d$.

### 2.1.3 Dynamical degrees of endomorphisms of affine surfaces

In my thesis, I consider endomorphisms of affine surfaces. The first example of an affine surface is the complex affine plane $\mathbf{C}^{2}$. An endomorphism is then a polynomial transformation. Even in that case, the first dynamical degree is not necessarily an integer. Indeed, let

$$
A=\left(\begin{array}{ll}
a & b  \tag{2.8}\\
c & d
\end{array}\right)
$$

be a matrix with nonnegative integer coefficients such that $a d-b c \neq 0$. Consider the following monomial transformation

$$
\begin{equation*}
f(x, y)=\left(x^{a} y^{b}, x^{c} y^{d}\right) \tag{2.9}
\end{equation*}
$$

then $f^{N}$ is the monomial transformation where the monomials are given by the coefficients of $A^{N}$ and $\lambda_{1}(f)$ is equal to the spectral radius of $A$. Hence, $\boldsymbol{\lambda}_{1}(f)$ is an algebraic integer of degree 2 because it satisfies the equation

$$
\begin{equation*}
\lambda_{1}(f)^{2}-\operatorname{Tr}(A) \lambda_{1}(f)+\operatorname{det}(A)=0 \tag{2.10}
\end{equation*}
$$

Thus, there exist polynomial transformations $f$ of the affine plane with $\lambda_{1}(f)$ an integer or an algebraic integer of degree 2 . Favre and Jonsson showed that these are the only two possibilities.

Theorem 2.1.2. FJ07] Let $f: \mathbf{C}^{2} \rightarrow \mathbf{C}^{2}$ be a dominant polynomial transformation, then $\lambda_{1}(f)$ is an algebraic integer of degree $\leqslant 2$.

The first result of my thesis is to extend this result to all affine surfaces, in any characteristic. Even if there are affine surfaces for which the semigroup of endomorphism can change drastically. For example, Blanc and Dubouloz, in [BD13], build smooth affine surfaces with a big group of automorphisms, much bigger than the one of the affine plane. Bot used this construction to show the existence of smooth complex rational affine surfaces with uncountably many real forms (see [Bot23]). The result in my thesis show that even though structure wise, these groups are a lot more complicated; from the point of view of the dynamics of a single element, this is not the case.

Theorem A. Let $X_{0}$ be a normal affine surface over a field $\mathbf{k}$. If $f: X_{0} \rightarrow X_{0}$ is a dominant endomorphism, then $\lambda_{1}(f)$ is an algebraic integer of degree $\leqslant 2$.

The proof uses valuative techniques which $I$ describe in the next section. If char $\mathbf{k}=0$, I also obtain results on the dynamics of $f$. I will give a precise statement in the case of automorphisms (see Theorem C).

### 2.2 Valuations, Divisors at infinity and dynamics

### 2.2.1 Existence of an eigenvaluation

Let $A$ be the ring of regular functions of a normal affine surface $X_{0}$ over an algebraically closed field $\mathbf{k}$. A valuation is a map $v: A \rightarrow \mathbf{R} \cup\{\infty\}$ such that

1. $v(P Q)=v(P)+v(Q) ;$
2. $v(P+Q) \geqslant \min (v(P), v(Q))$;
3. $v(0)=\infty$;
4. $v_{\mid \mathbf{k}^{\times}}=0$

Two valuations $v$ are $\mu$ are equivalent if there exists $t>0$ such that $v=t \mu$. For example, if $X$ is a completion of $X_{0}$, for all irreducible curve $E \subset X$, the map $\operatorname{ord}_{E}$ defined by $\operatorname{ord}_{E}(P)$ being the order of vanishing of $P$ along $E$ is a valuation. Any valuation of the form $\lambda \operatorname{ord}_{E}$ with $\lambda>0$ is called divisorial. If $f$ is an endomorphism of $X_{0}$, then $f$ induces a ring homomorphism $f^{*}: A \rightarrow A$. We can then define the pushforward $f_{*} v$ of a valuation $v$ by

$$
\begin{equation*}
f_{*} v(P)=v\left(f^{*} P\right) . \tag{2.11}
\end{equation*}
$$

We say that a valuation is centered at infinity if there exists $P \in A$ such that $v(P)<0$. If $X$ is a completion of $X_{0}$, the divisorial valuations centered at infinity are exactly the one corresponding to the irreducible components of $X \backslash X_{0}$. Let $\mathcal{V}_{\infty}$ the set of valuations centered at infinity and $\hat{\mathcal{V}}_{\infty}$ the set of valuations centered at infinity modulo equivalence. Suppose for the sake of simplicity that $f$ is an automorphism of $X_{0}$, then $f_{*}$ induces a bijection of $\mathcal{V}_{\infty}$ and of $\hat{\mathcal{V}}_{\infty}$ which will in fact be a homeomorphism for a topology that will be described in this memoir.

If $X_{0}$ is the complex affine plane, then Favre and Jonsson proved the existence of a valuation $\nu_{*} \in \mathcal{V}_{\infty}$ such that $f_{*} \nu_{*}=\lambda_{1}(f) \nu_{*}$. Such a valuation is called an eigenvaluation of $f$. To
do so, they show in [FJ04] that $\hat{\mathcal{V}}_{\infty}$ has a real tree structure and $f_{*}$ is compatible with this structure. The existence of $v_{*}$ follows from a fixed point theorem on trees. The existence of this eigenvaluation has a big impact on the dynamics of $f$. In particular, it allows one to find a good completion $X$ of $\mathbf{C}^{2}$ which admits an attracting fixed point of $f$ at infinity. Xie uses this construction to prove the conjecture of Zariski-dense orbits and the dynamical Mordell-Lang conjecture for polynomial endomorphisms of the complex affine plane ([Xie17b]). Jonsson and Wulcan use these techniques to build canonical heights for polynomial endomorphisms of the complex affine plane with small topological degree in [JW12].

Theorem B. Let $X_{0}$ be a normal affine surface over an algebraically closed field $\mathbf{k}$ (of any characteristic) and let $f$ be a dominant endomorphism of $X_{0}$. Suppose that

1. $\mathbf{k}\left[X_{0}\right]^{\times}=\mathbf{k}^{\times}$.
2. For all completions $X$ of $X_{0}, \operatorname{Pic}^{0}(X)=0$.
3. $\lambda_{1}(f)^{2}>\lambda_{2}(f)$.

Then, there exists an eigenvaluation $v_{*}$, unique up to equivalence, of $f$ such that

$$
\begin{equation*}
f_{*}(v)=\lambda_{1}(f) v_{*} . \tag{2.12}
\end{equation*}
$$

The techniques I use do not use the global geometry of $\hat{\mathcal{V}}_{\infty}$ because it not necessarily a tree anymore. If $X$ is a completion of $X_{0}$, I show that for any valuation $v$ centered at infinity, one can associate a unique divisor $Z_{v, X}$ of $X$ supported outside of $X_{0}$. Furthermore if $Y$ is another completion of $X_{0}$, there is a compatibility relation between $Z_{v, X}$ and $Z_{v, Y}$ (see Proposition 3.6.6). This construction involves the space of Eicard-Manin of $X_{0}$. The spectral analysis of the operators $f_{*}, f^{*}$ induced by $f$ on this space (see [BFJ08, Can11]) allows one to construct the eigenvaluation $v_{*}$ and show its uniqueness. This process is similar to the techniques of [DF21] §6.

### 2.2.2 Discussion of the assumptions of the Theorem

The assumptions of Theorem B may seem arbitrary but they are not restrictive. Indeed, if assumption (1) or (2) is not satisfied, then one can show that $f$ preserves a fibration over a ${ }^{1}$ quasi-abelian. We can decompose the dynamics of $f$ with this fibration and it becomes easier

1. a quasi-abelian variety is an algebraic group such that there exists an algebraic torus $T$ and an abelian variety $A$ such that the sequence of algebraic groups $0 \rightarrow T \rightarrow X \rightarrow A \rightarrow 0$ is exact.
to study.
If Assumption (3) is not satisfied, then we have $\lambda_{1}(f)^{2}=\lambda_{2}(f)$. In that case, $\lambda_{1}(f)$ is automatically an algebraic integer of degree $\leqslant 2$ because $\lambda_{2}(f)$ is the topological degree of $f$, hence an integer. In the case of the complex affine plane, Favre and Jonsson manage to classify all polynomial transformations of the complex affine plane for which $\lambda_{1}^{2}=\lambda_{2}$ : either they preserve a rational fibration, or there exists a completion $X$ of $\mathbf{A}_{\mathbf{C}}^{2}$ with at most quotient singularities at infinity such that $f$ extends to an endomorphism of $X$. I expect that such a classification should exist in general, all the examples I have studied up until now satisfy this dichotomy. One can notice that in the invertible case, such a classification exists: By [Giz69] and [Can01], every birational transformation $\sigma: X \rightarrow X$ of a smooth projective surface such that $\lambda_{1}(\sigma)=1$ lifts to an automorphism or preserves a rational or elliptic fibration.

### 2.2.3 Statement of the theorem in the case of automorphisms

In characteristic zero, the existence of the eigenvaluation has an impact on the dynamics of $f$. I show that for every endomorphism, there exists a completion $X$ of $X_{0}$ with an attracting fixed point of $f$ at infinity. In the case of loxodromic automorphism (i.e with $\lambda_{1}>1$ ) I show the following

Theorem C. Let $X_{0}$ be a normal affine surface over $\mathbf{C}$ such that $\mathbf{C}\left[X_{0}\right]^{\times}=\mathbf{C}^{\times}$. If $f$ is an automorphism of $X_{0}$ such that $\lambda_{1}(f)>1$, then there exists a completion $X$ of $X_{0}$ such that

1. $f$ admits an attracting fixed point $p \in X(\mathbf{C}) \backslash X_{0}(\mathbf{C})$ at infinity.
2. An iterate of $f$ contracts $X \backslash X_{0}$ to $p$.
3. There exists local analytic coordinates centered at p such that $f$ is locally of the form
(a)

$$
\begin{equation*}
f(z, w)=\left(z^{a} w^{b}, z^{c} w^{d}\right) \tag{2.13}
\end{equation*}
$$

with $a, b, c, d$ integers $\geqslant 1$, in that case $\lambda_{1}(f)$ is the spectral radius of $\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$. In particular, $\lambda_{1}(f) \in \mathbf{R} \backslash \mathbf{Q}$, it is an algebraic integer of degree 2 .
(b) or

$$
\begin{equation*}
f(z, w)=\left(z^{a}, \lambda z^{c} w+P(z)\right) \tag{2.14}
\end{equation*}
$$

with $a \geqslant 2, c \geqslant 1$ and $P \not \equiv 0$ a polynomial, in that case $\lambda_{1}(f)=a$ is an integer.
4. The attracting fixed points of $f$ and $f^{-1}$ are distinct.
5. The local normal form of $f^{-1}$ at its attracting fixed point is the same as $f$.

The cases (3)(a) et (3)(b) are mutually exclusive in the following way

Theorem D. Let $X_{0}$ be a normal affine surface over $\mathbf{C}$ such that $\mathbf{C}\left[X_{0}\right]^{\times}=\mathbf{C}^{\times}$and $f \in \operatorname{Aut}\left(X_{0}\right)$ a loxodromic automorphism. We have the following dichotomy

- If $\lambda_{1}(f) \in \mathbf{Z}_{\geqslant 0}$, then for any loxodromic automorphism $g$ of $X_{0}$, we have $\lambda_{1}(g) \in \mathbf{Z}_{\geqslant 0}$ and the local normal form of $g$ at its attracting fixed point is given by (2.14).
- If $\lambda_{1}(f) \notin \mathbf{Z}_{\geqslant 0}$ then it is an algebraic integer of degree 2 and this holds for any loxodromic automorphism $g$ of $X_{0}$. In particular, the local normal form of $g$ at its attracting fixed point is given by (2.13).

We give two examples: the affine plane and the Markov surface (see $\$ 2.2 .3 .2$ ). Theorem $C$ and $D$ show that it suffices to understand these two examples to understand the dynamics of a single automorphism of an affine surface.

### 2.2.3.1 The affine plane

Suppose that $X_{0}=\mathbf{A}_{\mathbf{C}}^{2}$, consider the automorphism

$$
\begin{equation*}
f(x, y)=\left(y+x^{2}, x\right) . \tag{2.15}
\end{equation*}
$$

It is a Hénon automorphism and we have $\lambda_{1}(f)=2$. Let $X=\mathbf{P}_{\mathbf{C}}^{2}$ be a completion of $X$ ) with homogeneous coordinates $X, Y, Z$ such that $x=X / Z$ et $y=Y / Z$. The birational transformation induced by $f$ has fixed point $p_{+}=[1: 0: 0]$ and an indeterminacy point $p_{-}=[0: 1: 0]$. The line at infinity $\{Z=0\}$ is contracted by $f$ to $p_{+}$and by $f^{-1}$ to $p_{-}$. Let $(u, v)$ be the local coordinates at $p_{+}$given by $u=Y / X$ et $v=Z / X$, one has

$$
\begin{equation*}
f(u, v)=\left(\frac{v}{1+u v}, \frac{v^{2}}{1+u v}\right) . \tag{2.16}
\end{equation*}
$$

And there exits a local analytic change of coordinates such that $f$ has the normal form (2.14) (see [Fav00] §2).

### 2.2.3.2 The Markov surface

Consider the Markov surface $\mathcal{M}_{0} \subset \mathbf{A}_{\mathbf{C}}^{3}$ given by the equation

$$
\begin{equation*}
x^{2}+y^{2}+z^{2}=x y z \tag{2.17}
\end{equation*}
$$

It is a normal affine surface with a quotient singularity at $(0,0,0)$. We will describe in detail its properties in $\S 2.4$. A natural completion of $\mathscr{M}_{0}$ is the projective surface $X \subset \mathbf{P}_{\mathbf{C}}^{3}$ defined by the Zariski closure of $\mathcal{M}_{0}$ in $\mathbf{P}_{\mathbf{C}}^{3}$. The equation of $X$ is

$$
\begin{equation*}
T\left(X^{2}+Y^{2}+Z^{2}\right)=X Y Z \tag{2.18}
\end{equation*}
$$

We see that $X \backslash \mathcal{M}_{0}$ has equation

$$
\begin{equation*}
T=0, X Y Z=0 . \tag{2.19}
\end{equation*}
$$

Thus it is a triangle of 3 rational curves. By Theorem 3.1 of [Can09], if $f$ is a loxodromic automorphism of $\mathcal{M}_{0}$ algebraically stable over $X$ then $f$ admits an attracting fixed point $p_{+} \in X \backslash \mathcal{M}_{0}$ which is one of the vertex of the triangle and one indeterminacy point $p_{-} \in X \backslash \mathcal{M}_{0}$ which is another vertex of the triangle. Furthermore, $f$ admits a local normal form of monomial type (i.e given by (2.13) at $p_{+}$.

Remark 2.2.1. We see that for all completion $X$ the affine plane, the dual graph of $X \backslash \mathbf{A}_{\mathbf{C}}^{2}$ is a tree. However, in the case of $\mathcal{M}_{0}$ the dual graph of $X \backslash \mathcal{M}_{0}$ retracts to a circle for every completion $X$. We will show in fact that every affine surface (with a loxodromic automorphism) satisfies this dichotomy. It is the dichotomy of the geometry of these dual graphs that gives the dichotomy on the dynamics (see Theorem 4.4.4).

### 2.3 Dynamics of automorphisms of affine surfaces

### 2.3.1 Dynamics of Hénon maps: Green functions

Let $\operatorname{Aut}\left(\mathbf{A}_{\mathbf{C}}^{2}\right)$ be the group of polynomial automorphisms of the complex affine plane. The affine transformations are examples of such automorphisms. Here is another example: let

$$
\begin{equation*}
f(x, y)=(x, y+P(x)) \tag{2.20}
\end{equation*}
$$

where $P$ is a polynomial. The automorphism $f$ preserves the pencil of lines $x=\alpha$ and acts by translation on these lines, the vector of translation is given by $P(x)$. Such an automorphism is called elementary. We denote by $E$ the set of all elementary automorphisms of $\mathbf{A}_{\mathbf{C}}^{2}$, they form a group isomorphic to $(\mathbf{C}[x],+))$. Jung's theorem $\left([J\right.$ un42] $)$ states that $\operatorname{Aut}\left(\mathbf{C}^{2}\right)$ has the structure of an amalgamated product

$$
\begin{equation*}
\operatorname{Aut}\left(\mathbf{A}_{\mathbf{C}}^{2}\right)=\operatorname{Aff}\left(\mathbf{A}_{\mathbf{C}}^{2}\right) *_{S} E \tag{2.21}
\end{equation*}
$$

where $S=\operatorname{Aff}\left(\mathbf{A}_{\mathbf{C}}^{2}\right) \cap E$.
An automorphism of Henon type is an automorphism $f$ which is not conjugated to an element of $\operatorname{Aff}\left(\mathbf{A}_{\mathbf{C}}^{2}\right)$ nor to an element of $E$. They are characterised by the condition $\lambda_{1}(f)>1$. An example of automorphism of Henon type is the following which will use later on

$$
\begin{equation*}
f(x, y)=\left(y+x^{2}, x\right) . \tag{2.22}
\end{equation*}
$$

The extension of $f$ to $\mathbf{P}^{2}$ has a fixed point at infinity $p_{+}=[1: 0: 0]$ and an indeterminacy point $p_{-}=[0: 1: 0]$. The line at infinity is contracted by $f$ to $p_{+}$. Analogously, $p_{+}$is the only indeterminacy point of $f^{-1}$ and $p_{-}$is a fixed point of $f^{-1}$ to which the line at infinity is contracted by $f^{-1}$. An automorphism $h$ is regular if the indeterminacy points of $h$ and $h^{-1}$ are distinct. In particular $f$ is regular and every automorphism of Henon type can be conjugated to a regular one [FM89]. For all automorphism of Henon type $h, \lambda_{1}(h)$ is an integer which we denote by $d$, in particular $\lambda_{1}(f)=2$.

Consider the norm $\|(x, y)\|=\max (|x|,|y|)$ on $\mathbf{C}^{2}$. If $h$ is a regular automorphism of Henon type, we can define the Green functions of $h$ (see [FM89], [BS91a] and their references)

$$
\begin{equation*}
G^{+}(p):=\lim _{N} \frac{1}{d^{N}} \log ^{+}\left\|h^{N}(p)\right\|, \quad G^{-}(p):=\lim _{N} \frac{1}{d^{N}} \log ^{+}\left\|h^{-N}(p)\right\| \tag{2.23}
\end{equation*}
$$

where $\log ^{+}=\max (0, \log )$. We have the following properties (see [BS91a] $]$.

1. $G^{+}$is well defined, continuous and plurisubharmonic over $\mathbf{C}^{2}$,
2. $G^{+} \circ h=d G^{+}$,
3. the map $p \mapsto G^{+}(p)-\log ^{+}(\|p\|)$ extends to a continuous function over $\mathbf{P}^{2} \backslash p_{-}$.
4. $G^{+}(p)=0$ if and only if the forward orbit $\left(h^{N}(p)\right)_{N \geqslant 0}$ is bounded.

The function $G^{-}$satisfies similar properties. We define the Green currents $T^{+}=d d^{c} G^{+}$and
$T^{-}=d d^{c} G^{-}$. These are positive closed $(1,1)$-currents. The measure

$$
\begin{equation*}
\mu:=T^{+} \wedge T^{-} \tag{2.24}
\end{equation*}
$$

is then well defined because $G^{+}, G^{-}$are continuous. It is of finite total mass, thus we can suppose that it is a probability measure. We call it the equilibrium measure of $h$. It is $h$-invariant and its support is contained in the Julia set of $h$.

We define the following Green function

$$
\begin{equation*}
G:=\max \left(G^{+}, G^{-}\right) \tag{2.25}
\end{equation*}
$$

which satisfies the following properties

1. $G$ is continuous, plurisubharmonic over $\mathbf{C}^{2}$ and the uniform limit of

$$
\begin{equation*}
\max \left(\frac{1}{d^{N}} \log ^{+}\left(\left\|f^{N}(p)\right\|\right), \frac{1}{d^{N}} \log ^{+}\left(\left\|f^{-N}(p)\right\|\right)\right) \tag{2.26}
\end{equation*}
$$

2. $p \mapsto G(p)-\log ^{+}\|p\|$ extends to a continuous function over $\mathbf{P}^{2}$.
3. $G(p)=0$ if and only if the $\mathbf{Z}$-orbit $\left(f^{N}(p)\right)_{N \in \mathbf{Z}}$ is bounded.

### 2.3.2 Dynamics of automorphisms of affine surfaces

Using theorem C. I show
Theorem E. Let $X_{0}$ be a normal affine surface over $\mathbf{C}$, let $X$ be a completion of $X_{0}$ that satisfy Theorem $C$ Let $X \hookrightarrow \mathbf{P}^{N}$ be an embedding of $X$ which induces an embedding of $X_{0}$ into $\mathbf{C}^{N}$ and let $\|\cdot\|$ be a norm over $\mathbf{C}^{N}$. Let $f$ be an automorphism of $X_{0}$ such that $\lambda_{1}(f)>1$, the Green function

$$
\begin{equation*}
G^{+}(p):=\lim _{N} \frac{1}{\lambda_{1}^{N}} \log ^{+}\left(\left\|f^{N}(p)\right\|\right) \tag{2.27}
\end{equation*}
$$

satisfies the following properties

1. $G^{+}$is well defined, continuous and plurisubharmonic over $X_{0}(\mathbf{C})$.
2. $G^{+} \circ f=\lambda_{1} G^{+}$
3. $G^{+}$has logarithmic growth (see Proposition 5.2.5).
4. $G^{+}(p)=0$ if and only if the forward orbit $\left(f^{N}(p)\right)_{N \geqslant 0}$ is bounded.

We can then consider the function $G=\max \left(G^{+}, G^{-}\right)$which will satisfy similar properties as in the Henon case. There is however one major difference. In general, the maximum of two functions of logarithmic growth is not of logarithmic growth. There is a difficulty here. It turns out we get two distinct behaviour: if $\lambda_{1}(f) \in \mathbf{Z}_{\geqslant 0}, G$ is again of logarithmic growth and everything works as in the Henon case. If $\lambda_{1}(f) \notin \mathbf{Z}_{\geqslant 0}$, then $G$ is not of logarithmic growth and it is not the right function to consider. We then need to use the recent work of Yuan and Zhang on adelic line bundles over quasiprojective varieties, I will be more precise in the following section.

### 2.3.3 Dynamics at non archimedean places

Let $\mathbf{K}$ be a number field. An absolute value $|\cdot|$ over $\mathbf{K}$ is a function $|\cdot|: \mathbf{K} \rightarrow \mathbf{R}_{+}$which satisfies

- $|x|=0 \Leftrightarrow x=0$,
- $\forall x, y \in \mathbf{K},|x y|=|x| \cdot|y|$,
- $\forall x, y \in \mathbf{K},|x+y| \leqslant|x|+|y|$.

Two absolute values $|\cdot|_{1},|\cdot|_{2}$ are equivalent if $|\cdot|_{1}=|\cdot|_{2}^{s}$ for some $s>0$. A place is an equivalence class of absolute values, we denote by $\mathcal{M}(\mathbf{k})$ the set of places of $\mathbf{K}$. If $|\cdot|$ is an absolute value of $\mathbf{K}$, we can consider the completion of $\mathbf{K}$ with respect to $|\cdot|$. This completion depend only on the place $v$ of $|\cdot|$, we denote it by $\mathbf{K}_{v}$. The absolute value $|\cdot|$ then extends to $\mathbf{K}_{v}$ and admits a natural extension to $\overline{\mathbf{K}}_{v}$. We denote by $\mathbf{C}_{v}$ the completion of $\overline{\mathbf{K}}_{v}$ with respect to $|\cdot|$. This construction depends only on the place $v$. We say that $|\cdot|$ is non archimedean if it satisfies the following inequality

$$
\begin{equation*}
\forall x, y \in \mathbf{K},|x+y| \leqslant \max (|x|,|y|) . \tag{2.28}
\end{equation*}
$$

A place $v$ is non archimedean if one of its representatives is. For all archimedean place $v$, we have $\mathbf{C}_{v}=\mathbf{C}$. The results of $\S 2.3 .1$ have analogues when $\mathbf{C}$ is replaced by an algebraically closed complete field $\mathbf{C}_{v}$. Indeed, Kawaguchi showed in [Kaw09] that the Green function of an automorphism of Henon type is well defined also in the non archimedean case. If $\mathbf{C}_{v}$ is non archimedean, the Green function $G=\max \left(G^{+}, G^{-}\right)$induces a semipositive adelic line bundle on the Berkovich analytification of $\mathbf{P}_{\mathbf{C}_{v}}^{2}$ which we denote by $\left(\mathbf{P}_{\mathbf{C}_{v}}^{2}\right)^{\text {an }}$ (see [Zha93] for the definition). The equilibrium measure is a positive measure over $\left(\mathbf{P}_{\mathbf{C}_{v}}^{2}\right)^{a n}$, it is constructed in [Cha03]. It is worth noting that recent work of Chambert-Loir and Ducros [CD] allows one to
construct the currents $T^{ \pm}=d d^{c} G^{ \pm}$and to define the equilibrium measure in the same way as in the complex case $\mu=T^{+} \wedge T^{-}$. Furthermore, Lee shows in [Lee13] that the Galois orbits of any 2 generic sequence of periodic points equidistributes with respect to the measure $\mu=T^{+} \wedge T^{-}$ at every place. This uses the equidistributes theorem of Yuan in [Yua08].

I also show an analogue of Theorem C in the non archimedean case. We define also the functions $G^{+}, G^{-}, G$ in that case. However, the difficulties mentioned at the end of $\$ 2.3 .2$ remain. If $\lambda_{1}(f) \in \mathbf{Z}_{\geqslant 0}$, then the data of the Green functions $\left(G_{v}\right)$ for every place $v$ of $\mathbf{K}$ induces a semipositive adelic line bundle (cf [Zha93]) over a completion $X$ of $X_{0}$ and the arithmetic equidistribution theorem of Yuan applies.

Now, if $\lambda_{1}(f) \notin \mathbf{Z}_{\geqslant 0}$, we cannot apply the theory of adelic line bundles over the completion $X$. The right point of view is to consider not just one completion of $X_{0}$ but all of them. This is the point of view developed by Yuan and Zhang in [YZ22]. The authors define the notion of adelic line bundles over a quasiprojective variety $U$ as a limit of adelic line bundles over completions of $U$. They show in this context an arithmetic equidistribution theorem similar to the theorem of Yuan. In my memoir, I state the following conjecture (see Conjecture F):

Conjecture F. The data of $\left(G_{v}^{+}\right)$and $\left(G_{v}^{-}\right)$at every place $v$ of $\mathbf{K}$ induces two nef $f$-invariant adelic line bundles over the quasiprojective variety $X_{0}$. In particular, we can define the equilibrium measure $\mu_{v}$ of $f$ at every place as the probability measure proportional to $d d^{c} G_{v}^{+} \wedge d d^{c} G_{v}^{-}$ and the Galois orbits of any generic sequence of periodic points of $f$ equidistributes with respect to $\mu_{v}$ at every place $v$.

I believe that the results established in this memoir and the work of Yuan and Zhang will allow one to prove this conjecture using similar techniques as in $\S 4$ of [YZ17](see $\$ 2.5 .1)$.

### 2.3.4 Automorphisms sharing infinitely many periodic points

If $X_{0}$ is a normal affine surface over $\mathbf{K}$ a number field, and $f$ a loxodromic automorphism of $X_{0}$, we can apply the results of the previous section at both archimedean and non archimedean places. We then get an equilibrium measure $\mu_{f, v}$ for $f$ at every place $v$ of $\mathbf{K}$. Using the techniques of arithmetic equidistribution mentioned in the previous paragraph, I show the following result.

Theorem G. Let $X_{0}$ be a normal affine surface defined over a number field $\mathbf{K}$. If $f, g$ are two loxodromic automorphisms of $X_{0}$ such that $\lambda_{1}(f) \in \mathbf{Z}_{\geqslant 0}$, the following are equivalent

[^2]1. $\operatorname{Per}(f) \cap \operatorname{Per}(g)$ est Zariski-dense.
2. $\forall v \in \mathscr{M}(\mathbf{K}), \mu_{v, f}=\mu_{v, g}$
3. $\operatorname{Per}(f)=\operatorname{Per}(g)$.

In the case $\lambda_{1}(f) \notin \mathbf{Z}_{\geqslant 0}$, admitting Conjecture F we have that if $\operatorname{Per}(f) \cap \operatorname{Per}(g)$ is Zariskidense, then $\forall v \in \mathcal{M}(\mathbf{K}), \mu_{f, v}=\mu_{g, v}$.

Using similar methods, these kind of results were first obtained by Baker, DeMarco in [BD11a] for endomorphisms of $\mathbf{P}^{1}$ of degree $\geqslant 2$ over $\mathbf{C}$ and then generalised by Yuan and Zhang for all polarisable endomorphisms of $\mathbf{P}^{m}$ over a number field in [YZ17] and recently in [YZ21] over any field of characteristic zero. In [CD20], Cantat and Dujardin use these same tools of arithmetic dynamics to show rigidity results on groups of automorphisms of projective surfaces.

Conjecture $F$ is not enough to show the equality $\operatorname{Per}(f)=\operatorname{Per}(g)$ because the proof uses an arithmetic version of the Hodge index theorem which has not been shown yet for adelic line bundles over quasiprojective varieties (see Theorem 5.1.20).

### 2.4 A rigidity result for Markov surfaces

In [DF17] Dujardin and Favre show a stronger result than Theorem G. They obtain that if two automorphisms of Henon type satisfy one of the assertions of Theorem G, then $f$ and $g$ share common iterates: there exist integers $M, N \in \mathbf{Z}$ such that $f^{N}=g^{M}$. This rigidity result cannot be true for any affine surface. Indeed, if $X_{0}=\mathbf{C}^{\times} \times \mathbf{C}^{\times}$. Let $A=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right) \in \operatorname{SL}_{2}(\mathbf{Z})$ be such that $(\operatorname{Tr} A)^{2}>4$, we define the automorphism

$$
\begin{equation*}
f_{A}(x, y)=\left(x^{a} y^{b}, x^{c} y^{d}\right) \tag{2.29}
\end{equation*}
$$

If $\mathbb{S}^{1}=\{z \in \mathbf{C}| | z \mid=1\}$, then $\mathbb{S}^{1} \times \mathbb{S}^{1}$ is an $f_{A}$-invariant compact subset. Ii is the Julia set of $f_{A}$ and the periodic points of $f_{A}$ are exactly of the form $\left(\omega_{1}, \omega_{2}\right) \in \mathbb{S}^{1} \times \mathbb{S}^{1}$ where $\omega_{1}, \omega_{2}$ are roots of unity. Hence, every automorphism of this form satisfies Theorem G but they don't share common iterates.

Let $D \in \mathbf{C}$, we define the Markov surface $\mathcal{M}_{D}$ as a surface in $\mathbf{C}^{3}$ defined by

$$
\begin{equation*}
x^{2}+y^{2}+z^{2}=x y z+D \tag{2.30}
\end{equation*}
$$

This family of surfaces appears in different fields of mathematics (see [Can09]). If $\mathbb{T}^{1}$ is the punctured torus, its fundamental group $\pi:=\pi_{1}\left(\mathbb{T}^{1}\right)$ is a free group with two generators that we denote by $a$ and $b$. We can look at the character variety

$$
\begin{equation*}
X:=\operatorname{Hom}\left(\pi, \mathrm{SL}_{2}(\mathbf{C})\right) / / \mathrm{SL}_{2}(\mathbf{C}) \tag{2.31}
\end{equation*}
$$

where the action of $\mathrm{SL}_{2}(\mathbf{C})$ is via conjugation and // is the quotient from Geometric Invariant Theory (GIT). Denote by $[a, b]:=a b a^{-1} b^{-1}$ the commutator of $a$ and $b$. Let $\rho \in \mathcal{X}$, if we define $x=\operatorname{Tr} \rho(a), y=\operatorname{Tr} \rho(b), z=\operatorname{Tr} \rho(a b)$, then we get that

$$
\begin{align*}
X & \rightarrow \mathbf{A}_{\mathbf{C}}^{3}  \tag{2.32}\\
\rho & \mapsto(x, y, z) \tag{2.33}
\end{align*}
$$

is an isomorphism. This is a result of Fricke (see [Gol09]). Furthermore, we have

$$
\begin{equation*}
x^{2}+y^{2}+z^{2}=x y z+\operatorname{Tr}(\rho([a, b]))+2 . \tag{2.34}
\end{equation*}
$$

Thus, the algebraic variety $X$ has a foliation of surfaces given by the family of the Markov surfaces and the surface $\mathscr{M}_{D}$ is a fiber of the regular function $\rho \mapsto \operatorname{Tr}(\rho([a, b]))$.

Theorem H. Let $D=0$ or $D=2-2 \cos (2 \pi / q)$ with $q \geqslant 2$. If $f, g$ are two loxodromic automorphisms of $\mathcal{M}_{D}$, then admitting Conjecture $F$ the following are equivalent:

1. $\operatorname{Per}(f) \cap \operatorname{Per}(g)$ is Zariski-dense.
2. $\operatorname{Per}(f)=\operatorname{Per}(g)$.
3. $f$ and $g$ share common iterates: there exist $N, M \in \mathbf{Z}$ such that $f^{N}=g^{M}$.

Conjecture F and Theorem Give the equality of the equilibrium measure of $f$ and $g$. To show the result we use the theory of Fuchsian and quasi-Fuchsian representations to construct a saddle fixed point $q(f)$ at the boundary of the open subset of $\mathcal{M}_{D}(\mathbf{C})$ consisting of quasiFuchsian representations. This construction uses the double parametrisation theorem of Bers in [Ber60], its extension by Minsky in [Min99] and Thurston's theorem of hyperbolisation of 3-manifolds fibering over a circle (see [Ota96, McM96]). We then use techniques of currents in complex geometry, in particular the current of Ahlfors-Nevanlinna, to show that this saddle fixed point must belong to the support of $\mu_{\mathbf{C}, f}=\mu_{\mathbf{C}, g}$ which is a compact subset invariant by the
group $\langle f, g\rangle$. Finally, we show that if $f, g$ do not share common iterates, then the $g$-orbit of $q(f)$ must be unbounded using measured laminations theory and this is a contradiction.

### 2.5 Questions and future projects

### 2.5.1 Conjecture $\mathbf{F}$

As mentioned in this introduction, I believe that Conjecture Fcan be shown using the results of this memoir. Namely, I show in Proposition 5.2 .5 that the function $G^{+}$is obtained via an iterating process starting from the Green function of any divisor. This iterating process applied to the theory of adelic line bundles over $X_{0}$ must yield a nef adelic line bundle in the sense of [YZ22]. Indeed, in the projective setting if $f$ is a polarised endomorphism of a projective variety $X$ and $L$ an ample line bundle over $X$ such that $f^{*} L=L^{\otimes d}$, Yuan and Zhang show in [YZ17] that for any adelic extension $\bar{L}$ of $L$, the sequence

$$
\begin{equation*}
\frac{1}{d^{n}}\left(f^{n}\right)^{*} \bar{L} \tag{2.35}
\end{equation*}
$$

converges to a semipositive adelic line bundle $\bar{L}_{f}$ such that $f^{*} \overline{L_{f}}=d \overline{L_{f}}$. At the level of Green functions, this iterating process is the same as the one in Section 5.2 (see Propositions 5.2.5 and 5.2.12). Hence, I expect everything to work as well in this setting.

To obtain Theorem G, we will then need to show the arithmetic Hodge index theorem in the case of affine surfaces. I only need a weaker version of this theorem that I believe should be not too hard to show.

### 2.5.2 The work of Danilov and Gizatullin

We say that an affine surface $X_{0}$ is completable by a zigzag if there exists a completion $X$ of $X_{0}$ such that $X \backslash X_{0}$ is a zigzag, that is a chain of smooth rational curves. The affine plane is completable by a zigzag but the Markov surface $\mathcal{M}_{0}$ is not for example. In [GD75], Danilov and Gizatullin study the group of automorphisms of an affine surface completable by a zigzag. They show that it acts on a tree which vertices are the completions where the boundary is a zigzag. If $X_{0}$ is completable by a zigzag, then the space of valuations centered at infinity $\widehat{\mathcal{V}_{\infty}}$ is also a tree on which $\operatorname{Aut}\left(X_{0}\right)$ acts. It will be interesting to compare the approach of Danilov and Gizatullin to the approach in my memoir. Note that the work of Gizatullin (see [Giz71b, Giz70, Giz71c])
prior to [GD75] are used in my memoir to study the dynamics of loxodromic automorphisms (see §4.4.1).

### 2.5.3 Dynamic complexity vs algebraic complexity of $\operatorname{Aut}\left(X_{0}\right)$

I showed in my thesis that the study of the dynamics of a loxodromic automorphism on an affine surface is similar either to the dynamics of an automorphism of Henon type, or to the dynamics of a loxodromic automorphism of the Markov surface. However, there exists affine surfaces with a much more complicated group of automorphism as shown by Blanc and Dubouloz in [BD13]. If $X_{0}$ is such a surface it will be interesting to apply the valuative techniques of this memoir tout a subgroup of automorphism of $X_{0}$. For example, if $f$ and $g$ are two loxodromic automorphisms such that every element of the subgroup $\Gamma=\langle f, g\rangle$ which is not the identity is loxodromic, what can we say about the set $\left\{v_{*}(h): h \in \Gamma\right\} \subset \widehat{\mathcal{V}}_{\infty}$ where $v_{*}(h)$ is the eigenvaluation of $h$ ? Can we recover the algebraic complexity of $\operatorname{Aut}\left(X_{0}\right)$ using valuative techniques ?

### 2.5.4 Arithmetic dynamics result using valuative techniques

Using the valuative techniques of Favre and Jonsson for the affine plane, Junyi Xie shows in [Xie17b] the Zariski dense orbit conjecture for polynomial endomorphism of the complex affine plane. This conjecture states that any endomorphism $f$ admits a Zariski dense orbit if and only if it does not admit a non-constant invariant rational function. The proof uses the dynamics of $f$ at infinity using the existence of an eigenvaluation. The author also shows in [Xie17a] the dynamical Mordell-Lang conjecture for polynomial endomorphism of the affine plane: if $x \in \mathbf{A}^{2}(\mathbf{C})$ and $C \subset \mathbf{A}_{\mathbf{C}}^{2}$ is a curve, then $\left\{n \geqslant 0: f^{n}(x) \in C\right\}$ is a union of a finite set and a finite union of arithmetic progressions.

For these two conjectures, we can establish their analogues for any affine surface using the valuative techniques of this memoir if $\lambda_{1}^{2}>\lambda_{2}$. For the equality case, Xie uses the classification of polynomial endomorphism satisfying $\lambda_{1}^{2}=\lambda_{2}$ established by Favre and Jonsson. It is therefore necessary to establish such a classification in general. For now, the techniques in this memoir do not allow to treat the case $\lambda_{1}^{2}=\lambda_{2}$. In particular, I do not know how to construct an eigenvaluation for an endomorphism $f$ satisfying $\lambda_{1}(f)^{2}=\lambda_{2}(f)$.

### 2.5.5 Green functions and canonical heights for small topological degrees

Let $f$ be a polynomial endomorphism of the affine plane defined over a number field $\mathbf{K}$ such that $\lambda_{1}(f)>\lambda_{2}(f)$. In [FJ11] and [JW12] Favre, Jonsson and Wulcan use the existence of a unique eigenvaluation of $f$ to construct a Green function for $f$ at every place. Jonsson and Wulcan construct a canonical height $h_{f}$ associated to $f$ which satisfies the following property: $p \in \mathbf{A}^{2}(\bar{K}), h_{f}(p)=0$ if and only if for every place $v,\left\|f^{n}(p)\right\|_{v}$ grows at most like $\mu^{n}$ with $0<\mu \leqslant \lambda_{2}<\lambda_{1}$.

I believe that this construction can be generalised to every affine surface using the results of this memoir. The construction of such canonical heights would allow one to show the following weak version of the Tits alternative: If $f, g \in \operatorname{End}\left(X_{0}\right)$ satisfy $\lambda_{1}(f)>\lambda_{2}(f), \lambda_{1}(g)>\lambda_{2}(g)$, then if $h_{f} \neq h_{g}$ up to replacing $f$ and $g$ by some iterates, the semigroup generated by $f$ and $g$ is free. This result has been established pour the polynomial transformations of $\mathbf{A}_{\mathbf{C}}^{1}$ in [BHPT21].

### 2.5.6 In higher dimension

Let $d \geqslant 3$ be an integer, in [DF21] §6, Dang and Favre show that any polynomial transformation $f: \mathbf{A}_{\mathbf{C}}^{d} \rightarrow \mathbf{A}_{\mathbf{C}}^{d}$ such that $\lambda_{1}(f)^{2}>\lambda_{2}(f)$ is an algebraic number of degree $\leqslant d$. To do so, they build an eigenvaluation of $f$ centered at infinity using the spectral analysis of $f^{*}$ on the space $N_{\Sigma}^{1}(X)$ which is an analogue of the Picard Manin space in dimension 2. They use Abhyankhar's inequality (see [Abh56]) in the following way: If $v_{*}$ is an eigenvaluation of $f$, i.e $f_{*} v_{*}=\lambda_{1} v_{*}$, then $f_{*}$ induces a linear map over $\Gamma_{v_{*}} \otimes \mathbf{Q}$ where $\Gamma_{v_{*}}$ is the value group of $v_{*}$. Abhyankhar's inequality states that $\operatorname{dim}_{\mathbf{Q}} \Gamma_{\mathbf{v}_{*}} \otimes \mathbf{Q} \leqslant d$. Thus, $\lambda_{1}$ is an eigenvalue of a $d \times d$ matrix with rational coefficients, it is therefore an algebraic number of degree $\leqslant d$.

I assert that the construction of the eigenvalue in the case of affine surfaces that I establish in this memoir can be generalised in higher dimensions. In particular, Sections 3.6 and 3.7 do not use dimension 2. The construction of the eigenvaluation comes from an analog of Theorem 4.1.16 where $\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$ should be replace by its analog $N_{\Sigma}^{1}(X)$. We then can use Abhyankhar's inequality to obtain the following result:
if $X_{0}$ is an affine surface of dimension $d \geqslant 3$ over an algebraically closed field $\mathbf{k}$ of characteristic zero, such that

- $\mathbf{k}\left[X_{0}\right]^{\times}=\mathbf{k}^{\times}$;
- For all completion $X$ of $X_{0}, \operatorname{Pic}^{0}(X)=0$;

If $f: X_{0} \rightarrow X_{0}$ is an endomorphism such that $\lambda_{1}(f)^{2}>\lambda_{2}(f)$, then $\lambda_{1}(f)$ is an algebraic number of degree $\leqslant d$.

## Valuations and Algebraic <br> GEOMETRY

### 3.1 Results from algebraic geometry

Let $\mathbf{k}$ be an algebraically closed field. A variety is an integral scheme of finite type over $\mathbf{k}$. A surface is a variety of dimension 2 . An affine variety over $\mathbf{k}$ is a variety $X_{0}=\operatorname{Spec} A$ with $A$ a finitely generated $\mathbf{k}$-algebra. We will denote by $\mathbf{k}\left[X_{0}\right]$ the ring of regular functions of the affine variety $X_{0}$.

### 3.1.1 Bertini

Theorem 3.1.1 (Bertini's Theorem, Har77]). Let $X \subset \mathbf{P}^{N}$ be a smooth quasi-projective variety over an algebraically closed field $\mathbf{k}$. The set of hyperplanes $H$ of $\mathbf{P}^{N}$ such that the intersection $H \cap X$ is a smooth irreducible subvariety of $X$ is a dense open subset of $\mathbf{P} \Gamma\left(\mathbf{P}^{N}, O(1)\right)$.

### 3.1.2 Local power series and local coordinates

Let $X$ be a variety and $x \in X$ a closed point. We will write $O_{X, x}$ for the ring of germs of regular functions at $x$. A regular sequence of $O_{X, x}$ is a sequence $t_{1}, \cdots, t_{r} \in O_{X, x}$ such that $t_{1}$ is not a zero divisor in $O_{X, x}$ and for all $i \geqslant 2, t_{i}$ is not a zero divisor in $O_{X, x} /\left(t_{1}, \cdots, t_{i-1}\right)$ (see [Har77] p.184). The point $x$ is regular if the local ring $O_{X, x}$ is regular, i.e there exists a regular sequence of length $\operatorname{dim} O_{X, x}$.

Theorem 3.1.2 ([|Har77], Theorem 5.5A). Let $R$ be a regular local $\mathbf{k}$-algebra of dimension $n$ with maximal ideal $\mathfrak{m}$, then the completion of $R$ with respect to the $\mathfrak{m}$-adic topology is isomorphic to $\mathbf{k}\left[\left[t_{1}, \cdots, t_{n}\right]\right]$ where $\left(t_{1}, \cdots, t_{n}\right)$ is a regular sequence of $R$.

Let $X$ be a surface and $x$ a regular point of $X$. Then, we will say that $(z, w)$ are local coordinates at $x$ if $(z, w)$ is a regular sequence of $O_{X, x}$. If $(z, w)$ is a regular sequence of the
completion $\widehat{O_{X, x}}$ we will say that they are local formal coordinates. By Theorem 3.1.2, $\widehat{O_{X, x}}$ is isomorphic to $\mathbf{k}[[z, w]]$. Finally, If $\mathbf{k}=\mathbf{C}_{v}$, is a complete algebraically closed field (archimedean or not), we consider the local ring of germs of holomorphic functions at $x$, this is the subring of $\widehat{O_{X, x}}$ of power series with a positive radius of convergence. We denote it by $O_{X, x}^{h o l}$ it is also a local ring of dimension 2 , if $(z, w)$ is a regular sequence of $O_{X, x}^{h o l}$, we say that $(z, w)$ are local analytic coordinates. If $E, F$ are two germs of reduced irreducible curves at $x$ (algebraic, analytic of formal) we will say that $(z, w)$ are associated to $(E, F)$ if $z=0$ is a local equation of $E$ and $w=0$ is a local equation of $F$.

### 3.1.3 Boundary

Proposition 3.1.3 ([G0069], Proposition 1 and 2). Let $X_{0}$ be an affine variety and let $1: X_{0} \hookrightarrow X$ be an open embedding into a projective variety, then the subvariety $X \backslash X_{0}$ is of pure codimension 1. Furthermore, there exists a regular function $P$ on $X_{0}$ that has poles along every component of $X \backslash X_{0}$.

Set

$$
\begin{equation*}
\partial_{X} X_{0}:=X \backslash X_{0} \tag{3.1}
\end{equation*}
$$

we call it the boundary of $X_{0}$ in $X$; by Proposition 3.1.3 it is a curve when $X_{0}$ is a surface.

Theorem 3.1.4 ([G0069]). Let $X$ be a normal proper surface and $U$ an open dense affine subset of $X$ (that is an open dense subset of $X$ that is also an affine variety) such that $V:=X \backslash U$ is locally factorial (each local ring is a unique factorization domain), then there exists an ample divisor $H$ on $X$ such that $\operatorname{Supp} H=V$.

In fact, Goodman shows that Theorem 3.1 .4 holds in higher dimension with the only difference that you may need to do some blow-ups at infinity to find an ample divisor.

### 3.1.4 Surfaces

Theorem 3.1.5 ([Har77] Proposition 5.3). Let $g: S_{1} \rightarrow S_{2}$ be a birational morphism between smooth projective surfaces. Then, $g$ is a composition of blow-ups of points and of an automorphism of $S_{2}$. Furthermore, if $h: S_{1} \rightarrow S_{2}$ is a birational map, then there exists a sequence of blow-ups $\pi: S_{3} \rightarrow S_{1}$ such that $h \circ \pi: S_{3} \rightarrow S_{2}$ is regular and $S_{3}$ can be chosen minimal for this property.

Proposition 3.1.6. Let $g: S_{1} \rightarrow S_{2}$ be a birational map. Let $\pi: S_{3} \rightarrow S_{1}$ be a minimal resolution of indeterminacies of $g$ such that the lift $h: S_{3} \rightarrow S_{2}$ of $g$ is regular. Then, the first curve contracted by $h$ must be the strict transform of a curve in $S_{1}$.

Recall the Castelnuovo criterion
Theorem 3.1.7 ([Har77] Theorem V.5.7). Let C be a curve in a projective surface $S$ such that $C \simeq \mathbf{P}^{1}$ and $C^{2}=-1$, then there exists a projective surface $S^{\prime}$, a birational morphism $\pi: S \rightarrow S^{\prime}$ and a point $p \in S^{\prime}$ such that $S$ is isomorphic via $\pi$ to the blow up of $p$ and $C$ is the exceptional divisor under this isomorphism.

We will use these results for the study of automorphisms of affine surfaces as they induce birational maps. Understanding the combinatorics of the blow ups and contractions induced by the automorphism will allow us to understand their dynamics.

Our work relies heavily on the elimination of indeterminacies for rational morphism. Since we are in dimension 2, it exists in any characteristic.

Theorem 3.1.8. Let $f: S_{1} \rightarrow S_{2}$ be a dominant rational morphism between projective varieties over an algebraically closed field of any characteristic, then there exists a sequence of blow-ups $\pi: S \rightarrow S_{1}$ such that $f \circ \pi: S \rightarrow S_{2}$ is regular.

Theorem 3.1.9 ([Cut02]). Suppose chark $=0$. Let $f: S \rightarrow S^{\prime}$ be a dominant rational map between normal projective surfaces over $\mathbf{k}$. There exists blow ups $S_{1} \rightarrow S$ and $S_{1}^{\prime} \rightarrow S^{\prime}$ such that the lift $\widehat{f}: S_{1} \rightarrow S_{1}^{\prime}$ is monomial at every point. Meaning that for every closed point $p \in S_{1}$ there exists local coordinates $(x, y)$ at $p$ and local coordinates $(u, v)$ at $f(p)$ such that $f(x, y)=\left(x^{a} y^{b}, x^{c} y^{d}\right)$.

### 3.1.5 Rigid contracting germs in dimension 2 and local normal forms

Let $f:\left(\mathbf{C}^{2}, 0\right) \rightarrow\left(\mathbf{C}^{2}, 0\right)$ be the germ of a holomorphic function fixing the origin. The critical set $\operatorname{Crit}(f)$ of $f$ is the set where the Jacobian of $f$ vanishes. A germ is said to be rigid if the generalized critical set $\cup_{n \geqslant 0} f^{-n}(\operatorname{Crit}(f))=\cup_{n \geqslant 1} \operatorname{Crit}\left(f^{n}\right)$ is a divisor with simple normal crossings (see [Fav00]).

A germ is contracting if there exists an open neighbourhood $U$ of 0 such that $f(U) \Subset U$. In [Fav00], Favre classified all the rigid contracting germs in dimension 2 up to holomorphic conjugacy. There are 7 possible possibilities which we call local normal forms. We are interested in 3 of them that will appear in this memoir.

The first one is

$$
\begin{equation*}
f(x, y)=\left(x^{a}, \lambda x^{c} y+P(x)\right) \tag{3.2}
\end{equation*}
$$

with $a \geqslant 2, c \geqslant 1, \lambda \in \mathbf{C}^{\times}$and $P$ is a polynomial such that $P(0)=0$. Here the germ of curve $x=0$ is contracted by $f$ to the origin and $f$ does not admit any invariant germ of curves if and only if $P \neq 0$. We have $\operatorname{Crit}\left(f^{n}\right)=\{x=0\}$. This local normal form corresponds to Class 2 of Table II in [Fav00]. This is the local normal form of a Hénon map at its attracting fixed point in $\mathbf{P}^{2}$ (see [Fav00] §2). It will appear in the following way in this memoir. Suppose that there are local coordinates $(z, w)$ at the origin such that $f$ contracts $\{z=0\}$ with an index of ramification $a \geqslant 2, f$ admits no invariant curves and no other curves is contracted to the origin, then $f$ is of the form

$$
\begin{equation*}
f(z, w)=\left(z^{a} \varphi(z, w), z^{c} w \psi_{2}(z, w)+\psi_{1}(z)\right) \tag{3.3}
\end{equation*}
$$

with $\varphi$ invertible, $\psi_{1}(z) \neq 0$ and $\psi_{2}(0, w) \neq 0$. This is true even over any field $\mathbf{k}$ of characteristic 0 . If $\mathbf{k}=\mathbf{C}$, then the classification of Favre shows that (3.3) can be analytically conjugated to (3.2).

The second one is the monomial normal form

$$
\begin{equation*}
f(x, y)=\left(x^{a_{11}} y^{a_{12}}, x^{a_{21}} y^{a_{22}}\right) \tag{3.4}
\end{equation*}
$$

with $a_{i j} \in \mathbf{Z}_{\geqslant 1}, a_{11} a_{22}-a_{12} a_{21} \neq 0$; The germ of curves $\{x=0\},\{y=0\}$ are contracted to the origin. We have $\operatorname{Crit}\left(f^{n}\right)=\{x y=0\}$. We can characterize the matrix $A$ given by $\left(a_{i j}\right)$ in the following way. The local fundamental group of $\left(\mathbf{C}^{2}, 0\right) \backslash\{x y=0\}$ is isomorphic to $\mathbf{Z}^{2}$. The action of $f_{*}$ on $\mathbf{Z}^{2}$ is given by the matrix $A$ and we have that $|\operatorname{det}| A$ is equal to the topological degree of $f$. This corresponds to Class 6 of Table II of [Fav00]. It will arise in the following context, if $f$ is a germ of holomorphic functions such that there exists local coordinates $(z, w)$ at the origin such that both axis $\{z=0\}$ and $\{w=0\}$ are contracted and they are the only two germs of curves contracted. Then, $f$ is of the following pseudomonomial form

$$
\begin{equation*}
f(z, w)=\left(z^{a_{11}} w^{a_{12}} \varphi(z, w), z^{a_{21}} w^{a_{22}} \psi(z, w)\right) \tag{3.5}
\end{equation*}
$$

with $\varphi, \psi$ invertible. Then, the classification of Favre asserts that (3.5) is analytically conjugated to (3.4).

The third one is

$$
\begin{equation*}
f(x, y)=\left(x^{a} y^{b}(1+\varphi), \lambda y(1+\psi)\right) \tag{3.6}
\end{equation*}
$$

with $a \geqslant 2, b \geqslant 1, \lambda \in \mathbf{C}^{\times}$and $\varphi, \psi$ are germs of holomorphic function vanishing at the origin. We have that $\{y=0\}$ is contracted to the origin. The germ $\{x=0\}$ is $f$-invariant with a ramification index equal to $a$. We have $\operatorname{Crit}\left(f^{n}\right)=\{x y=0\}$ and the origin is a noncritical fixed point of
$f_{\mid\{x=0\}}$. Notice that this germ is rigid but not necessarily contracting. It is contracting if and only if $|\lambda|<1$. If the germ is contracting then the germ is conjugated to this normal form

$$
\begin{equation*}
f(z, w)=\left(z^{a} w^{b}, \lambda w\right) \tag{3.7}
\end{equation*}
$$

with the same numbers $a, b, \lambda$ as in Equation 3.6. This corresponds to Class 5 of Table II in [Fav00].

### 3.2 Definitions

Let $\mathbf{k}$ be an algebraically closed field of any characteristic and let $X_{0}$ be a normal affine surface over $\mathbf{k}$. We will denote by $A$ the ring of regular functions on $X_{0}$.

### 3.2.1 Completions and divisors at infinity

A completion of $X_{0}$ is the data of a projective surface $X$ with an open embedding ı: $X_{0} \hookrightarrow X$ such that $\mathbf{l}\left(X_{0}\right)$ is an open dense subset of $X$ and such that there exists an open smooth neighbourhood of $\partial_{X} X_{0}$ in $X$. We will say that a completion is good if $\partial_{X} X_{0}$ is an effective divisor with simple normal crossings, From any completion of $X$, one obtains a good one by a finite number of blow ups at infinity (i.e on $\partial_{X} X_{0}$ ) see for example [Har77] Theorem 3.9 p. 391 .

Let $X$ be a completion of $X_{0}$ with the embedding $\mathrm{l}_{X}: X_{0} \rightarrow X$, we will still denote $\mathrm{l}_{X}\left(X_{0}\right)$ by $X_{0}$ and we will denote by $O_{X}\left(X_{0}\right)$ the subring of $\mathbf{k}(X)$ of functions $f \in \mathbf{k}(X)$ which are regular on $X_{0}$. By Proposition 3.1.3, the boundary $\partial_{X} X_{0}$ is a possibly reducible connected curve. We denote by $\operatorname{Div}(X)$ the group of divisors of $X$ and by $\operatorname{Div}_{\infty}(X)$ the subgroup of divisors of $X$ supported on $\partial_{X} X_{0}$. For $\mathbf{A}=\mathbf{Z}, \mathbf{Q}, \mathbf{R}$, we set $\operatorname{Div}(X)_{\mathbf{A}}:=\operatorname{Div}(X) \otimes \mathbf{A}$ and $\operatorname{Div}_{\infty}(X)_{\mathbf{A}}=\operatorname{Div}_{\infty}(X) \otimes \mathbf{A}$. Let $E_{1}, \cdots, E_{m}$ be the irreducible components of $\partial_{X} X_{0}$ (we will call them the prime divisors at infinity). Any element of $\operatorname{Div}_{\infty}(X)_{\mathbf{A}}$ is of the form $D=\sum_{i} a_{i}(D) E_{i}$ with $a_{i}(D) \in \mathbf{A}$. We will write $\operatorname{ord}_{E_{i}}(D)$ for $a_{i}(D)$ of $D$ at $E_{i}$. For a family $\left(D_{j}\right)_{j \in J}$ of elements of $\operatorname{Div}_{\infty}(X)$ the coefficients $a_{i}(D)$ are integers; so, using the natural order on $\mathbf{Z}$, we define the supremum $\bigvee_{j \in J} D_{j}$ and the infimum $\bigwedge_{j \in J} D_{j}$ by

$$
\begin{equation*}
\bigvee_{j} D_{j}=\sum_{i} \sup \left(\operatorname{ord}_{E_{i}}\left(D_{j}\right)\right) E_{i} \quad \text { and } \quad \bigwedge_{j} D_{j}=\sum_{i} \inf \left(\operatorname{ord}_{E_{i}}\left(D_{j}\right)\right) E_{i} \tag{3.8}
\end{equation*}
$$

It only exists if each $\left(\operatorname{ord}_{E_{i}}\left(D_{j}\right)\right)_{j \in J}$ is bounded respectively from above or from below. If $\bigwedge_{j} D_{j}$ (respectively $\bigvee_{j} D_{j}$ ) is well defined we say that the family $\left(D_{j}\right)$ is bounded from below (from above). Notice that we only define supremum and infimum for family of divisors with coefficients in $\mathbf{Z}$.

### 3.2.2 Morphisms between completions, Weil, Cartier divisors

Some notations If $\pi: Y \rightarrow X$ is a projective birational morphism between smooth projective surfaces and $D_{X}$ is a divisor on $X$, we will denote by $\pi^{*} D_{X}$ the pull-back of $D_{X}$ under $\pi$ and if $D_{X}$ is effective, then $\pi^{\prime}\left(D_{X}\right)$ will be the strict transform of $D_{X}$ under $\pi$. For any projective
surface $Z$, if $D_{Z}$ is a divisor on $Z$, we will denote by $O_{Z}\left(D_{Z}\right)$ the invertible sheaf on $Z$ associated to $D_{Z}$.

Let $X_{1}, X_{2}$ be two completions of $X_{0}$ with their embeddings $\mathfrak{1}_{1}, \mathfrak{1}_{2}$. There exists a unique birational map $\pi: X_{1} \rightarrow X_{2}$ such that the diagram

commutes. If $\pi$ is a morphism, we call it a morphism of completions. In that case we say that $X_{1}$ is above $X_{2}$. By Theorem 3.1.5, $\pi^{-1}$ is a composition of blow-ups; since $\pi$ is an isomorphism over $X_{0}$, the centers of these blowups are above $\partial_{X_{2}} X_{0}$. Conversely, let $X$ be a completion of $X_{0}$ with an embedding $\mathfrak{\imath}: X_{0} \hookrightarrow X$, let $\pi: Y \rightarrow X$ be the blowup of $X$ at a point $p \in \partial_{X} X_{0}$, then $Y$ with the embedding $\pi^{-1} \circ \mathfrak{l}: X_{0} \rightarrow Y$ is a completion of $X_{0}$ and $\pi$ is a morphism of completions. For a morphism of completions $\pi: Y \rightarrow X$, we will write $\operatorname{Exc}(\pi) \subset Y$ for the exceptional locus of $\pi$.

Lemma 3.2.1. The system of completions of $X_{0}$ is a projective system: For any two completions $X_{1}, X_{2}$ of $X_{0}$ there exists a completion $X_{3}$ above $X_{1}$ and $X_{2}$.

Proof. Let $X_{1}, X_{2}$ be two completions of $X_{0}$, let $\pi: X_{1} \rightarrow X_{2}$ be the birational map from Diagram 3.9. By Theorem 3.1.5, there exists a sequence of blow-ups $\pi_{1}: X_{3} \rightarrow X_{1}$ such that $g=\pi_{1} \circ \pi: X_{3} \rightarrow X_{2}$ is regular. It is clear that $\pi_{1}$ is a morphism of completions since by definition $\mathfrak{l}_{X_{3}}=: \mathfrak{l}_{3}=\mathfrak{l}_{1} \circ \boldsymbol{\pi}_{1}^{-1}$. The map $g$ is also a morphism of completion because by construction $g=\boldsymbol{\pi} \circ \boldsymbol{\pi}_{1}$ and $\mathfrak{l}_{2}=\boldsymbol{\pi} \circ \mathfrak{l}_{1}$, therefore $\mathfrak{l}_{3}=\boldsymbol{\pi}_{1}^{-1} \circ \mathfrak{l}_{1}=g^{-1} \circ \boldsymbol{\pi} \circ \mathfrak{l}_{1}=g^{-1} \circ \mathfrak{l}_{2}$

If $\pi: X_{1} \rightarrow X_{2}$ is a morphism of completions. We can define (see [Ful98], Section 1.4) the pushforward $\pi_{*}: \operatorname{Div}\left(X_{1}\right)_{\mathbf{A}} \rightarrow \operatorname{Div}\left(X_{2}\right)_{\mathbf{A}}$ and pullback $\pi^{*}: \operatorname{Div}\left(X_{2}\right)_{\mathbf{A}} \rightarrow \operatorname{Div}\left(X_{1}\right)_{\mathbf{A}}$ of divisors. They define group homomorphisms

$$
\begin{equation*}
\pi_{*}: \operatorname{Div}_{\infty}\left(X_{1}\right)_{\mathbf{A}} \rightarrow \operatorname{Div}_{\infty}\left(X_{2}\right)_{\mathbf{A}} \quad \text { and } \quad \pi^{*}: \operatorname{Div}_{\infty}\left(X_{2}\right)_{\mathbf{A}} \hookrightarrow \operatorname{Div}_{\infty}\left(X_{1}\right)_{\mathbf{A}} ; \tag{3.10}
\end{equation*}
$$

the map $\pi^{*}$ is often called the total transform. Recall that ([Har77] Proposition 3.2 p .386 )

$$
\begin{equation*}
\pi_{*} \pi^{*}=\operatorname{id}_{\operatorname{Div}\left(X_{2}\right)_{\mathbf{A}}} \tag{3.11}
\end{equation*}
$$

Let $X$ be a completion of $X_{0}$ and $P \in A$, then $\left(\mathfrak{l}_{X}^{-1}\right)^{*}(P) \in \mathbf{k}(X)$. We set $\left(\mathfrak{l}_{X}\right)_{*}:=\left(\mathfrak{l}_{X}^{-1}\right)^{*}$ and we denote by $\operatorname{div}_{X}(P):=\operatorname{div}\left(\left(\imath_{X}\right)_{*} P\right)$ the divisor of the rational function $P$ in $X$. In particular, if
$\pi: Y \rightarrow X$ is a morphism of completions above $X_{0}$, then by Diagram (3.9), one has $\mathfrak{l}_{Y}=\pi^{-1} \circ \mathfrak{l}_{X}$. Therefore $\operatorname{div}_{Y}(P)=\operatorname{div}\left(\left(\pi^{-1} \circ \mathfrak{l}_{X}\right)_{*}(P)\right)=\operatorname{div}\left(\pi^{*}\left(\left(\mathfrak{l}_{X}\right)_{*}(P)\right)\right)=\pi^{*} \operatorname{div}_{X}(P)$. We will write $\operatorname{div}_{\infty, X}(P) \in \operatorname{Div}_{\infty}(X)$ the divisor on $X$ supported at infinity such that

$$
\operatorname{div}_{X}(P)=D+\operatorname{div}_{\infty, X}(P)
$$

where $D$ is an effective divisor and no components of its support is in $\partial_{X} X_{0}$.
Example 3.2.2. Let $X_{0}=\mathbf{A}^{2}=\operatorname{Spec} \mathbf{k}[x, y]$ and let $P=x y$. Take the completion $\mathbf{P}^{2}$ of $\mathbf{A}^{2}$ with homogeneous coordinates $X, Y, Z$ such that $x=X / Y$ and $y=Y / Z$. Then,

$$
\begin{equation*}
\operatorname{div}_{\mathbf{P}^{2}}(P)=\{X=0\}+\{Y=0\}-2\{Z=0\} \tag{3.12}
\end{equation*}
$$

and $\operatorname{div}_{\infty, \mathbf{P}^{2}}(P)=-2\{Z=0\}$. Let $\pi: X \rightarrow \mathbf{P}^{2}$ be the blow-up of $[1: 0: 0]$, we can take $X$ to be the subscheme of $\mathbf{P}^{2} \times \mathbf{P}^{1}$ given by the equation

$$
\begin{equation*}
U Z=V Y \tag{3.13}
\end{equation*}
$$

where $U, V$ are the homogeneous coordinates of $\mathbf{P}^{1}$. Then $\pi$ is the projection onto the first factor. We take the affine chart $X=1$ in $\mathbf{P}^{2}$ with affine coordinates $y^{\prime}=Y / X$ and $z^{\prime}=Z / X$. Take the chart $U=1$ with affine coordinate $v$ in $\mathbf{P}^{1}$, then $X \cap\{X=1\} \times\{U=1\}$ is an affine chart of $X X$ with coordinates $v, y^{\prime}$ and we have the relation $z^{\prime}=v y^{\prime} ; y^{\prime}=0$ is a local equation of the exceptional divisor and $v=0$ is a local equation of the strict transform of $z^{\prime}=0$.

$$
\begin{equation*}
\pi^{*}(P)=\pi^{*}\left(\frac{y^{\prime}}{\left(z^{\prime}\right)^{2}}\right)=\frac{y^{\prime}}{v^{2}\left(y^{\prime}\right)^{2}}=\frac{1}{v^{2} y^{\prime}} \tag{3.14}
\end{equation*}
$$

Therefore,

$$
\begin{equation*}
\operatorname{div}_{X}(P)=\pi^{\prime}\{X=0\}+\pi^{\prime}\{Y=0\}-2 \pi^{\prime}\{Z=0\}-\widetilde{E}=\pi^{*}\left(\operatorname{div}_{\mathbf{P}^{2}}(P)\right) \tag{3.15}
\end{equation*}
$$

and

$$
\begin{equation*}
\operatorname{div}_{\infty, X}(P)=-2 \pi^{\prime}\{Z=0\}-\widetilde{E} \tag{3.16}
\end{equation*}
$$

The system of completions of $X_{0}$ is a projective system by Lemma 3.2.1. Consider the system of groups $\left(\operatorname{Div}_{\infty}(X)\right)_{\mathbf{A}}$ for $X$ a completion of $X_{0}$ with compatibility morphisms

$$
\begin{equation*}
\pi_{*}: \operatorname{Div}_{\infty}(X) \rightarrow \operatorname{Div}_{\infty}(Y) \tag{3.17}
\end{equation*}
$$

for any morphism of completions $\pi: X \rightarrow Y$. This is also a projective system of groups. We denote by Weil ${ }_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$ the projective limit of this system. Analogously, the same system of groups with $\pi^{*}$ as compatibility morphisms is an inductive system and we denote by $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$ the inductive limit. Concretely, an element $D \in$ Weil $_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$ is a collection $D=\left(D_{X}\right)$ such that $D_{X}$ is an element of $\operatorname{Div}_{\infty}(X)_{\mathbf{A}}$ for every completion $X$ of $X_{0}$ and such that for any morphism of completions $\pi: X \rightarrow Y, \pi_{*} D_{X}=D_{Y} ; D_{X}$ is called the incarnation of $D$ in $X$. An element of $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$ is the data of a completion $X$ and a divisor $D \in \operatorname{Div}_{\infty}(X)$ where two pairs $(X, D)$ and $\left(X^{\prime}, D^{\prime}\right)$ are equivalent if there exists a completion $Z$ above $X$ and $X^{\prime}$ with morphisms of completion $\pi: Z \rightarrow X, \pi^{\prime}: Z \rightarrow X^{\prime}$ such that $\pi^{*} D=\left(\pi^{\prime}\right)^{*} D^{\prime}$. We will say that $D \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$ is defined over a completion $X$ if $D$ is the equivalence class of $\left(X, D_{X}\right)$ for some $D_{X} \in \operatorname{Div}_{\infty}(X)_{\mathbf{A}}$. We have a natural inclusion

$$
\begin{equation*}
\varphi: \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}} \hookrightarrow \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}} \tag{3.18}
\end{equation*}
$$

defined as follows. If $(X, D) \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$, then we need to define the incarnation $\varphi(D)_{Y}$ for any completion $Y$. First of all, set $\varphi(D)_{X}=D$. Then, for any completion $Y$, by Lemma 3.2.1, there exists a completion $Z$ above $Y$ and $X$; denote by $\pi_{Y}: Z \rightarrow Y$ and $\pi_{Z}: Z \rightarrow X$ the respective morphism of completions. We define $\varphi(D)_{Y}:=\left(\pi_{Y}\right)_{*} \pi_{X}^{*} D$. This does not depend on the choice of $Z$ because of Equation (3.11). In the rest of the paper, we will drop the notation $\varphi(D)$ and denote by $D$ the image of $(X, D)$ in Weil $_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$. We equip Weil $\infty_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$ with the projective limit topology.

In the same manner we define $\operatorname{Cartier}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}:=\xrightarrow{\lim \operatorname{Div}(X)_{\mathbf{A}}}$ and $\operatorname{Weil}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}:=\underset{\longleftrightarrow}{\lim \operatorname{Div}(X)_{\mathbf{A}}}$ and we have the following commutative diagram

Remark 3.2.3. We have that $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}=\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right) \otimes \mathbf{A}$ but Weil $_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$ is strictly larger than $\operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right) \otimes \mathbf{A}$ when $\mathbf{A}=\mathbf{Q}, \mathbf{R}$. Indeed, let $W_{1}, \ldots, W_{r} \in \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right), \lambda_{1}, \ldots, \lambda_{r} \in \mathbf{A}$ and set $W:=\sum_{i} \lambda_{i} W_{i}$. Then, for every completion $X$ and for every prime divisor $E$ at infinity in $X$ we have

$$
\begin{equation*}
\operatorname{ord}_{E}\left(W_{X}\right)=\operatorname{ord}_{E}\left(\sum_{i} \lambda_{i} W_{i, X}\right)=\sum_{i} \lambda_{i} \operatorname{ord}_{E}\left(W_{i, X}\right) \in \mathbf{Z} \lambda_{1}+\cdots+\mathbf{Z} \lambda_{r} \tag{3.20}
\end{equation*}
$$

In particular, the group $G(W)$ generated by $\left(\operatorname{ord}_{E}\left(W_{X}\right)\right)_{(X, E)}$ for all completions $X$ and all prime divisor $E$ at infinity in $X$ is a finitely generated subgroup of $\mathbf{R}$. Now pick a completion $X_{1}$ and consider a sequence of blow ups $\pi_{n}: X_{n+1} \rightarrow X_{n}$ starting with $X_{1}$. Let $E_{n}$ be the exceptional divisor of $\pi_{n}$. We still denote by $E_{n}$ the strict transform of $E_{n}$ in every $X_{m}, m \geqslant n+1$. Define the Weil divisor $W \in \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$ such that its incarnation in $X_{n+1}$ is $W_{X_{n+1}}=\sum_{k=1}^{n} \frac{1}{k} E_{k}$. Then, $G(W)$ is not finitely generated, therefore $W \notin$ Weil $_{\infty}\left(\mathrm{X}_{0}\right) \otimes \mathbf{A}$.

An element $D$ of Weil $\infty_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$ with $\mathbf{A}=\mathbf{Z}, \mathbf{Q}, \mathbf{R}$ is called effective (denoted by $D \geqslant 0$ ) if its incarnation in every completion $X$ is effective; if $D$ belongs to $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{R}}$ this is equivalent to $D_{X} \geqslant 0$ for one completion $X$ where $D$ is defined. If $D_{1}, D_{2} \in \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$, we will write $W_{1} \geqslant W_{2}$ for $W_{1}-W_{2} \geqslant 0$.

### 3.2.3 A canonical basis

Let $X$ be a completion of $X_{0}$, we define $\mathcal{D}_{X}$ as follows. Elements of $\mathcal{D}_{X}$ are equivalence classes of prime divisors exceptional above $X$ at infinity in completions $\pi_{Y}: Y \rightarrow X$ above $X$ where two prime divisors $E$ and $E^{\prime}$ belonging respectively to $Y$ and $Y^{\prime}$ are equivalent if the birational map $\pi_{Y^{\prime}}^{-1} \circ \pi_{Y}: Y \rightarrow Y^{\prime}$ induces an isomorphism $\pi_{Y^{\prime}}^{-1} \circ \pi_{Y}: E \rightarrow E^{\prime}$. We call $\mathcal{D}_{X}$ the set of prime divisors above $X$. We also define $\mathcal{D}_{\infty}\left(X_{0}\right)$ as the set of equivalence classes of prime divisors at infinity modulo the same equivalence relation. We write $\mathbf{A}^{\mathcal{D}_{X}}$ for the set of functions $\mathcal{D}_{X} \rightarrow \mathbf{A}$ and $\mathbf{A}^{\left(\mathcal{D}_{X}\right)}$ for the subset of functions with finite support.

Proposition 3.2.4. If $X$ is a completion of $X_{0}$, then

$$
\begin{equation*}
\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}=\operatorname{Div}_{\infty}(X)_{\mathbf{A}} \oplus \mathbf{A}^{\left(\mathcal{D}_{X}\right)}, \quad \text { and } \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}=\operatorname{Div}_{\infty}(X)_{\mathbf{A}} \oplus \mathbf{A}^{\mathcal{D}_{X}} . \tag{3.21}
\end{equation*}
$$

This is a homeomorphism with respect to the product topology of $\mathbf{A}^{\mathcal{D}_{X}}$.
Proof. Following [BFJ08] Proposition 1.4, for any $E \in \mathcal{D}_{X}$ there exists a minimal completion $X_{E}$ above $X$ such that $E$ is a prime divisor in $X_{E}$. We denote by $\alpha_{E} \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$ the element $\alpha_{E}:=\left(X_{E}, E\right)$. Let $E_{1}, \ldots, E_{r}$ be the prime divisor at infinity in $X$, then

$$
\begin{equation*}
\left(E_{0}, \ldots, E_{r}\right) \cup\left\{\alpha_{E}: E \in \mathcal{D}_{X}\right\} \tag{3.22}
\end{equation*}
$$

is a $\mathbf{A}$-basis of $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$. In the same fashion we obtain the second homeomorphism.
Remark 3.2.5. Since for any completion $X$, one can find a good completion $Y$ above $X$ and the blow up of a good completion is still a good completion, the projective system of good
completions is cofinal in the projective system of completions, so in the rest of the paper any completion that we take will be a good completion.

If $f: X_{0} \rightarrow X_{0}$ is a dominant endomorphism, then we can define

$$
\begin{equation*}
f^{*}: \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}} \rightarrow \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}} \text { and } f_{*}: \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}} \rightarrow \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}} \tag{3.23}
\end{equation*}
$$

as follows. Let $D=\left(X, D_{X}\right) \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$. Let $Y$ be a completion of $X_{0}$ such that the lift $F: Y \rightarrow X$ of $f$ is regular, then we define

$$
\begin{equation*}
f^{*} D:=\left(Y, F^{*} D_{X}\right) \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}} . \tag{3.24}
\end{equation*}
$$

This does not depend on the choice of $Y$. If $D \in$ Weil $_{\infty}\left(\mathrm{X}_{0}\right)$, let $X, Y$ be completions of $X_{0}$ such that the lift $F: Y \rightarrow X$ is regular, then

$$
\begin{equation*}
\left(f_{*} D\right)_{X}:=F_{*} D_{Y} . \tag{3.25}
\end{equation*}
$$

Again, this does not depend on the choice of $Y$.

### 3.2.4 Local version of the canonical basis

Let $X$ be a completion and let $p \in X$ be a closed point at infinity i.e on $\partial_{X} X_{0}$. We denote by $\operatorname{Weil}(X, p)_{\mathbf{A}}$ the subspace of $\operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$ defined as follows: $D \in \operatorname{Weil}(X, p)_{\mathbf{A}}$ if and only if $D_{X}=0$ and for every completion $\pi: Y \rightarrow X$ above $X$ and every prime divisor $E$ at infinity in $Y$, one has $E \in \operatorname{Supp} D_{Y}$ if and only if $\pi(E)=p$. We define

$$
\begin{equation*}
\operatorname{Cartier}(X, p)_{\mathbf{A}}=\operatorname{Weil}(X, p)_{\mathbf{A}} \cap \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{A}} . \tag{3.26}
\end{equation*}
$$

We can define the set $\mathcal{D}_{X, p}$ of prime divisors above $p$ as follows. We will say that a completion $\pi: Y \rightarrow X$ is exceptional above $p$ if $\pi(\operatorname{Exc}(\pi))=p$. We will write $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, p)$ for such a completion. Elements of $\mathcal{D}_{X, p}$ are equivalence classes of prime divisors $E \in \operatorname{Exc}(\pi)$ for all completions $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, p)$.

Proposition 3.2.6. If $X$ is a completion of $X_{0}$, then $\mathcal{D}_{X}=\bigsqcup_{p \in \partial_{X} X_{0}} \mathcal{D}_{X, p}$ and

$$
\begin{align*}
\operatorname{Cartier}(X, p)_{\mathbf{A}} & =(\mathbf{A})^{\left(\mathcal{D}_{X, p}\right)}  \tag{3.27}\\
\operatorname{Weil}(X, p)_{\mathbf{A}} & =(\mathbf{A})^{\mathcal{D}_{X, p}} \tag{3.28}
\end{align*}
$$

### 3.2.5 Supremum and infimum of divisors

Let $\left(D_{i}\right)_{i \in I}$ be a family of elements of Weil $_{\infty}\left(\mathrm{X}_{0}\right)$ such that for all completions $X$, the family $\left(D_{i, X}\right)$ is bounded from below, we define $\bigwedge_{i \in I} D_{i}$ with its incarnation in $X$ being

$$
\begin{equation*}
\left(\bigwedge D_{i}\right)_{X}=\bigwedge_{i} D_{i, X} \tag{3.29}
\end{equation*}
$$

We have an analogous definition for $\bigvee_{i} D_{i}$ when each $\left(D_{i, X}\right)$ is bounded from above.
Lemma 3.2.7. If $D, D^{\prime} \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$, then $D \wedge D^{\prime}, D \vee D^{\prime} \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$.
Proof. It suffices to show that $D \wedge D^{\prime} \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$ because $D \vee D^{\prime}=-\left(-D \wedge-D^{\prime}\right)$. So take $D, D^{\prime} \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$, we have to show that $D \wedge D^{\prime}$ belongs to $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$.

Now, it suffices to show this for $D, D^{\prime}$ effective, indeed let $X$ be a completion such that $D$ and $D^{\prime}$ are defined over $X$. Then, there exists $D_{2} \in \operatorname{Div}_{\infty}(X)$ such that $D-D_{2}$ and $D^{\prime}-D_{2}$ are effective. Indeed, take $D_{2}$ as the Cartier class determined by $D \wedge D^{\prime}$ in $X$, Then

$$
\begin{equation*}
D \wedge D^{\prime}=\left(D-D_{2}\right) \wedge\left(D^{\prime}-D_{2}\right)+D_{2} . \tag{3.30}
\end{equation*}
$$

Therefore, suppose $D, D^{\prime}$ are effective. Then $\mathfrak{a}=O_{X}(-D)+O_{X}\left(-D^{\prime}\right)$ is a coherent sheaf of ideals such that $\mathfrak{a}_{\mid X_{0}}=O_{X_{0}}$, let $\pi: Y \rightarrow X$ be the blow-up along $\mathfrak{a}$. Since $\mathfrak{a}_{\mid X_{0}}$ is trivial, $\pi$ is an isomorphism over $X_{0}$, therefore $Y$ is a completion of $X_{0}$ with respect to the embedding $\mathfrak{l}_{Y}:=\pi^{-1} \circ \mathfrak{l}_{X}$ and $\pi$ is a morphism of completions. Then, $\mathfrak{b}:=\pi^{*} \mathfrak{a} \cdot O_{Y}$ is an invertible sheaf over $Y$ trivial over $X_{0}$, so there exists a divisor $D_{Y} \in \operatorname{Div}_{\infty}(Y)$ such that $\mathfrak{b}=O_{Y}\left(-D_{Y}\right)$.
Claim 3.2.8. The Cartier class in $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$ induced by $D_{Y}$ is $D \wedge D^{\prime}$.
We postpone the proof of this claim to the end of Section 3.3 .
Example 3.2.9. Let $X$ be a completion that contains two prime divisors $E, E^{\prime}$ at infinity in $X$ such that they intersect (transversely) at a point $p$. The sheaf of ideals $\mathfrak{a}=O_{X}(-E)+O_{X}\left(-E^{\prime}\right)$ is the ideal of regular functions vanishing at $p$. The blow up of $\mathfrak{a}$ is exactly the blow up $\pi: Y \rightarrow X$ at $p$ since by universal property of the blow-up $\pi^{*} \mathfrak{a}=O_{Y}(-\widetilde{E})$ where $\widetilde{E}$ is the exceptional divisor above $p$. If we still denote by $E, E^{\prime}, \widetilde{E}$ the elements they define in $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$, then $E \wedge E^{\prime}=\widetilde{E}$.

Let $X$ be a good completion of $X_{0}$. Let $D_{1}, D_{2} \in \operatorname{Div}_{\infty}(X)$. Let $E, F$ be two prime divisors at infinity that intersect. We say that $\left(D_{1}, D_{2}\right)$ is well ordered at $E \cap F$ if

$$
\begin{equation*}
\operatorname{ord}_{E}\left(D_{1}\right)<\operatorname{ord}_{E}\left(D_{2}\right) \Leftrightarrow \operatorname{ord}_{F}\left(D_{1}\right)<\operatorname{ord}_{F}\left(D_{2}\right) . \tag{3.31}
\end{equation*}
$$

We say that ( $D_{1}, D_{2}$ ) is a well ordered pair if it is well ordered at $E \cap F$ for every prime divisor $E, F$ at infinity that intersect.

Lemma 3.2.10. If $D_{1} \wedge D_{2}$ or $D_{1} \vee D_{2}$ is defined in $X$, then $\left(D_{1}, D_{2}\right)$ is a well ordered pair.
Proof. Suppose for example that $D_{1} \vee D_{2}$ is defined in $X$ and that $D_{1}, D_{2}$ is not a well ordered pair and let $E, F$ be two prime divisors at infinity that intersect such that at $E \cap F, D_{i}=\alpha_{i} E+\beta_{i} F$ with $\alpha_{1}<\alpha_{2}$ and $\beta_{1}>\beta_{2}$. Then, $D_{1} \vee D_{2}=\alpha_{2} E+\beta_{1} F$. Let $\widetilde{E}$ be the exceptional divisor above $E \cap F$, then we have $\operatorname{ord}_{\widetilde{E}}\left(D_{1} \vee D_{2}\right)=\alpha_{2}+\beta_{1}$. But

$$
\begin{equation*}
\operatorname{ord}_{\widetilde{E}} D_{i}=\alpha_{i}+\beta_{i}<\alpha_{2}+\beta_{1}=\operatorname{ord}_{\widetilde{E}}\left(D_{1} \vee D_{2}\right) \tag{3.32}
\end{equation*}
$$

This is a contradiction.

Remark 3.2.11. This is actually an equivalence, if $D_{1}, D_{2}$ is a well ordered pair, then $D_{1} \wedge D_{2}$ and $D_{1} \vee D_{2}$ is defined in $X$. This gives an algorithmic procedure by successive blow ups to find the minimum and maximum of two Cartier divisors.

Definition 3.2.12. Let $S_{\infty}\left(X_{0}\right)$ be the semigroup of $\operatorname{Weil}_{\infty}\left(X_{0}\right)$ of elements $D \in \operatorname{Weil}_{\infty}\left(X_{0}\right)$ such that there exists a (potentially uncountable) family $\left(D_{i}\right)_{i \in I} \subset \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$ such that

$$
\begin{equation*}
D=\bigvee_{I} D_{i} \tag{3.33}
\end{equation*}
$$

Proposition 3.2.13. 1. $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right) \subset \mathcal{S}_{\infty}\left(X_{0}\right)$.
2. For $a, b \geqslant 0$ and $D, D^{\prime} \in S_{\infty}\left(X_{0}\right)$, one has $a D+b D^{\prime} \in S_{\infty}\left(X_{0}\right)$.
3. If $D_{i} \in \mathcal{S}_{\infty}\left(X_{0}\right)$ for each $i \in I$ and $\left(D_{i}\right)$ is bounded from above then $\bigvee_{i \in I} D_{i} \in \mathcal{S}_{\infty}\left(X_{0}\right)$.
4. If $D, D^{\prime} \in S_{\infty}\left(X_{0}\right)$, then $D \wedge D^{\prime} \in \mathcal{S}_{\infty}\left(X_{0}\right)$.

Proof. The first assertion is trivial as for $D \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), D=\bigvee D$. For Property (2), let $X$ be a completion of $X_{0}$ then $\bigvee_{i} a D_{i, X}+\bigvee_{j} b D_{j, X}^{\prime}=\bigvee_{i, j}\left(a D_{i}+b D_{j}^{\prime}\right)_{X}$. For Property (3), if $D_{i}=\bigvee_{j} D_{i, j}$, then $\bigvee_{i} D_{i}=\bigvee_{(i, j)} D_{i, j}$. Finally, the fourth assertion is a corollary of Lemma 3.2.7.

Example 3.2.14. We have $S_{\infty}\left(X_{0}\right) \nsubseteq \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)$. Let $X_{0}=\mathbf{A}^{2}$ and $X=\mathbf{P}^{2}$. Let $E_{0}$ denote the line at infinity, a canonical divisor in $\mathbf{P}^{2}$ is given by $K_{\mathbf{P}^{2}}=-3 E_{0}$. We can define an element
$K \in \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)$ by taking for any completion $Y$ of $\mathbf{A}^{2}$ the canonical divisor supported at infinity. More precisely, let $Y$ is any completion of $\mathbf{A}^{2}$ above $\mathbf{P}^{2}$. We still denote by $E_{0}$ the strict transform of $E_{0}$ in $Y$. Then, $K_{Y}$ is of the form

$$
\begin{equation*}
K_{Y}=-3 E_{0}+\sum_{E \subset \partial_{X} X_{0}, E \neq E_{0}} E . \tag{3.34}
\end{equation*}
$$

Suppose that $K=\sup _{i}\left(D_{i}\right)$ for some $D_{i} \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$. Let $D \in\left(D_{i}\right)$ such that $D$ is defined over some completion $Y$ and for some prime divisor $E \neq E_{0}$ at infinity, $\operatorname{ord}_{E}(D)=1$. Then, we must have $K \geqslant D$ meaning that for any completion $Z, K_{Z} \geqslant D_{Z}$. Consider the following blow ups. Let $\pi_{1}: Y_{1} \rightarrow Y$ be the blow-up of a point $p$ of $E$ that does not belong to any other divisor at infinity. Let $\widetilde{E}$ be the exceptional divisor of $\pi$. Now let $\pi_{2}: Y_{2} \rightarrow Y_{1}$ be the blow-up at $\pi_{1}^{\prime} E \cap \widetilde{E}$ and let $\widetilde{F}$ be the exceptional divisor of $\pi_{2}$. Then, $\operatorname{ord}_{\widetilde{F}}\left(K_{Y_{2}}\right)=1$ but $\operatorname{ord}_{\widetilde{F}}\left(D_{Y_{2}}\right)=\operatorname{ord}_{\widetilde{F}}\left(\left(\pi_{2} \circ \pi_{1}\right)^{*} D\right)=2$ and this is a contradiction.

### 3.2.6 Picard-Manin Space at infinity and its completion

Let $X$ be a completion of $X_{0}$ and let $\operatorname{NS}(X)$ be the Néron-Severi group of $X$. We have a perfect pairing given by the intersection form

$$
\begin{equation*}
\mathrm{NS}(X)_{\mathbf{R}} \times \mathrm{NS}(X)_{\mathbf{R}} \rightarrow \mathbf{R} \tag{3.35}
\end{equation*}
$$

Recall the Hodge index theorem
Theorem 3.2.15 (Hodge Index Theorem, [Har77] Theorem 1.9 p.364). Let $X$ be a projective surface over a smooth projective surface over an algebraically closed field. Let $\alpha \in \operatorname{NS}(X)$ and let $H$ be an ample divisor on $X$. If $\alpha \cdot H=0$, then

$$
\begin{equation*}
\alpha^{2}<0 . \tag{3.36}
\end{equation*}
$$

In particular, the signature of the quadratic form induced by the intersection form is $(1, \rho-1)$ where $\rho$ is the rank of $\mathrm{NS}(X)$.

A class $\alpha \in \operatorname{NS}(X)$ is nef if for all irreducible curve $C \subset X, \alpha \cdot[C] \geqslant 0$. If $\pi: Y \rightarrow X$ is a morphism of completions we have two group homomorphisms

$$
\begin{equation*}
\pi_{*}: \mathrm{NS}(Y)_{\mathbf{A}} \rightarrow \mathrm{NS}(X)_{\mathbf{A}}, \pi^{*}: \mathrm{NS}(X)_{\mathbf{A}} \rightarrow \mathrm{NS}(Y)_{\mathbf{A}} \tag{3.37}
\end{equation*}
$$

with the following properties

1. $\pi_{*} \circ \pi^{*}=\operatorname{id}_{\mathrm{NS}(X)_{\mathbf{A}}}$
2. $\pi^{*} \alpha \cdot \pi^{*} \beta=\alpha \cdot \beta$
3. $\pi^{*} \alpha \cdot \beta=\alpha \cdot \pi_{*} \beta$ (Projection Formula)

Furthermore, if $\pi: Y \rightarrow X$ is the blow up of one point, let $\widetilde{E}$ be the exceptional divisor, then

$$
\begin{equation*}
[\widetilde{E}]^{2}=-1, \text { and } \operatorname{NS}(Y)_{\mathbf{A}}=\pi^{*} \operatorname{NS}(X)_{\mathbf{A}} \oplus \mathbf{A} \cdot[\widetilde{E}] \tag{3.38}
\end{equation*}
$$

Therefore, the system of groups $(\mathrm{NS}(X))$ with compatibility morphisms $\pi_{*}$ is a projective system of groups and $(\mathrm{NS}(X))$ with compatibility morphisms $\pi^{*}$ is an inductive system of groups.

Definition 3.2.16. The Picard-Manin spaces of $X_{0}$ are defined as

We equip Weil-NS $\left(\mathrm{X}_{0}\right)_{\mathbf{A}}$ with the topology of the projective limit. We have the same description as for $\operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)$ and $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$. An element of Weil-NS $\left(\mathrm{X}_{0}\right)$ is a family $\alpha=\left(\alpha_{X}\right)_{X}$ where $\alpha_{X} \in \mathrm{NS}(X)$ such that for all $\pi: Y \rightarrow X$, we have

$$
\pi_{*} \alpha_{Y}=\alpha_{X}
$$

We call $\alpha_{X}$ the incarnation of $\alpha$ in $X$.
An element of Cartier-NS $\left(\mathrm{X}_{0}\right)$ is the data of a completion $X$ of $X_{0}$ and a class $\alpha \in \operatorname{NS}(X)$ with the following equivalence relation: $(X, \alpha) \simeq(Y, \beta)$ if there exists a completion $Z$ with a morphism of completion

$$
\pi_{Y}: Z \rightarrow Y, \quad \pi_{X}: Z \rightarrow X
$$

such that $\pi_{Y}^{*} \beta=\pi_{X}^{*} \alpha$. We say that the Cartier class is defined (by $\alpha$ ) in $X$. We have a natural embedding

$$
\begin{equation*}
\text { Cartier-NS }\left(\mathrm{X}_{0}\right) \hookrightarrow \text { Weil-NS }\left(\mathrm{X}_{0}\right) \tag{3.40}
\end{equation*}
$$

We have a pairing

$$
\begin{equation*}
\text { Weil-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \times \text { Cartier-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \rightarrow \mathbf{R} \tag{3.41}
\end{equation*}
$$

given by the following: let $\alpha \in$ Weil-NS $\left(\mathrm{X}_{0}\right)_{\mathbf{R}}$ and $\beta \in$ Cartier-NS $\left(\mathrm{X}_{0}\right)_{\mathbf{R}}$; let $X$ be a completion where $\beta$ is defined i.e $\beta=\left(X, \beta_{X}\right)$; then

$$
\begin{equation*}
\alpha \cdot \beta:=\alpha_{X} \cdot \beta_{X} \tag{3.42}
\end{equation*}
$$

This is well defined because if $\pi: Y \rightarrow X$ then

$$
\begin{equation*}
\alpha_{Y} \cdot \beta_{Y}=\alpha_{Y} \cdot \pi^{*} \beta_{X}=\pi_{*} \alpha_{Y} \cdot \beta_{X}=\alpha_{X} \cdot \beta_{X} \tag{3.43}
\end{equation*}
$$

by the projection formula.
An element $\alpha \in$ Weil-NS $\left(\mathrm{X}_{0}\right)_{\mathbf{R}}$ is $n e f$ if for all completion $X, \alpha_{X}$ is nef.
Proposition 3.2.17 ([|BFJ08] Proposition 1.7). The intersection pairing

$$
\begin{equation*}
\text { Weil-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \times \text { Cartier-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \rightarrow \mathbf{R} \tag{3.44}
\end{equation*}
$$

is a perfect pairing and it induces a homeomorphism $\operatorname{Weil-NS}\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \simeq \operatorname{Cartier-NS}\left(\mathrm{X}_{0}\right)_{\mathbf{R}}^{*}$ endowed with the weak-* topology.

Using the canonical basis of divisors introduced in $\$ 3.2 .3$ we have a more explicit description of the Picard Manin spaces of $X_{0}$.

Proposition 3.2.18. Let $X$ be a completion of $X_{0}$, then

$$
\begin{equation*}
\text { Cartier-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{A}}=\operatorname{NS}(X)_{\mathbf{A}} \oplus \mathbf{A}^{\left(\mathcal{D}_{X}\right)}, \quad \text { Weil-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{A}}=\operatorname{NS}(X) \oplus \mathbf{A}^{\mathcal{D}_{X}} \tag{3.45}
\end{equation*}
$$

Moreover, the intersection product is negative definite over $\mathbf{A}^{\left(\mathcal{D}_{X}\right)}$ and $\left\{\alpha_{E}: E \in \mathcal{D}_{X}\right\}$ is an orthonormal basis for the quadratic form $\alpha \in \mathbf{A}^{\left(\mathcal{D}_{X}\right)} \mapsto-\alpha^{2}$.

Proof. The decomposition follows from Equation (3.38). The fact that the intersection form is negative definite follows from the existence of an ample divisor on $X$, the Hodge Index theorem and the projection formula. The fact that $\left\{\alpha_{E}: E \in \mathcal{D}_{X}\right\}$ is an orthonormal basis is again a consequence of the projection formula and Equation (3.38).

### 3.2.6.1 The local Picard-Manin space

Let $X$ be a completion of $X_{0}$ and let $p$ be a point at infinity. Then, by Proposition 3.2.18 we have the canonical embeddings

$$
\begin{equation*}
\operatorname{Cartier}(X, p)_{\mathbf{A}} \hookrightarrow \operatorname{Cartier-NS}\left(\mathrm{X}_{0}\right)_{\mathbf{A}}, \quad \text { Weil }(X, p)_{\mathbf{A}} \hookrightarrow \operatorname{Weil-NS}\left(\mathrm{X}_{0}\right) \tag{3.46}
\end{equation*}
$$

Proposition 3.2.19. If $\mathbf{A}=\mathbf{R}$, the space $\operatorname{Cartier}(X, p)_{\mathbf{R}}$ is an infinite dimensional $\mathbf{R}$-vector space and the intersection product defines a negative definite quadratic form over it. The set $\left\{\alpha_{E}: E \in \mathcal{D}_{X, p}\right\}$ is an orthonormal basis for the scalar product $\alpha \mapsto-\alpha^{2}$. Furthermore, the pairing

$$
\begin{equation*}
\operatorname{Weil}(X, p)_{\mathbf{R}} \times \operatorname{Cartier}(X, p)_{\mathbf{R}} \rightarrow \mathbf{R} \tag{3.47}
\end{equation*}
$$

is perfect.

### 3.2.6.2 The divisors supported at infinity

Fix a completion $X$ of $X_{0}$, we have a natural linear map $\tau: \operatorname{Div}_{\infty}(X)_{\mathbf{R}} \rightarrow \mathrm{NS}(X)_{\mathbf{R}}$.
Proposition 3.2.20. The intersection pairing restricted to $\tau\left(\operatorname{Div}_{\infty}(X)_{\mathbf{R}}\right)$ is non degenerate.

Proof. Let $D \in \tau\left(\operatorname{Div}_{\infty}(X)_{\mathbf{R}}\right)$, suppose that $D \cdot D^{\prime}=0$ for all $D^{\prime} \in \tau\left(\operatorname{Div}_{\infty}(X)_{\mathbf{R}}\right)$. Then, by Theorem 3.1.4, there exists $H \in \operatorname{Div}_{\infty}(X)$ ample. We have $D \cdot H=0$. By the Hodge index theorem, if $D$ is not numerically equivalent to zero, then $D^{2}<0$ and this is a contradiction.

Let $V \subset \mathrm{NS}(X)$ be the orthogonal subspace of $\tau\left(\operatorname{Div}_{\infty}(X)_{\mathbf{R}}\right)$. Then,

$$
\begin{equation*}
\mathrm{NS}(X)_{\mathbf{R}}=V \oplus \tau\left(\operatorname{Div}_{\infty}(X)_{\mathbf{R}}\right) \tag{3.48}
\end{equation*}
$$

For example if $X_{0}=\mathbf{A}^{2}$ and $X=\mathbf{P}^{2}$, then $V=0$. Since we only blow up at infinity we get
Proposition 3.2.21. Let $X_{0}$ be an affine surface, then

$$
\begin{equation*}
\text { Cartier-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}}=V \oplus \tau\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{R}}\right), \quad \text { Weil-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}}=V \oplus \tau\left(\operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{R}}\right) \tag{3.49}
\end{equation*}
$$

### 3.2.6.3 Functoriality

Let $f: X_{0} \rightarrow X_{0}$ be a dominant endomorphism of $X_{0}$. We define $f^{*}, f_{*}$ on the Picard-Manin spaces as follows. We first define

$$
\begin{equation*}
f^{*}: \text { Cartier-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \rightarrow \text { Cartier-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \tag{3.50}
\end{equation*}
$$

Let $\beta \in$ Cartier-NS $\left(\mathrm{X}_{0}\right)_{\mathbf{R}}$ and let $X$ be a completion where $\beta$ is defined. Let $Y$ be a completion of $X_{0}$ such that the lift $F: Y \rightarrow X$ is regular, then we define $f^{*} \beta$ as the Cartier class defined in $Y$ by

$$
\begin{equation*}
f^{*} \beta:=\left(Y, F^{*} \beta_{X}\right) \tag{3.51}
\end{equation*}
$$

this does not depend on the choice of $Y$. Indeed, if $Y^{\prime}$ is another completion such that $F^{\prime}: Y^{\prime} \rightarrow X$ is well defined, then there exists a completion $Z$ such that we have the following diagram.

Then, the lift of $f: Z \rightarrow X$ is $F \circ \pi_{Y}=F^{\prime} \circ \pi_{Y^{\prime}}$, hence we get

$$
\begin{equation*}
\pi_{Y}^{*} \circ F^{*}=\pi_{Y^{\prime}}^{*} \circ\left(F^{\prime}\right)^{*} \tag{3.53}
\end{equation*}
$$

and the pull back of Cartier classes is well defined.
Next, we define $f_{*}:$ Weil-NS $\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \rightarrow$ Weil-NS $\left(\mathrm{X}_{0}\right)_{\mathbf{R}}$. Let $\alpha \in$ Weil-NS $\left(\mathrm{X}_{0}\right)_{\mathbf{R}}$. Let $X, Y$ be completions of $X_{0}$ such that the lift $F: Y \rightarrow X$ is regular, then the incarnation of $f_{*} \alpha$ in $X$ is

$$
\begin{equation*}
\left(f_{*} \alpha\right)_{X}:=F_{*} \alpha_{Y} . \tag{3.54}
\end{equation*}
$$

Again, this does not depend on the choice of $Y$ by a similar argument as for the pullback. We have the following proposition

Proposition 3.2.22 ([][BFJ08] Section 2). We have the following properties.

- The operator $f^{*}$ extends to an operator

$$
\begin{equation*}
f^{*}: \text { Weil-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \rightarrow \text { Weil-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \tag{3.55}
\end{equation*}
$$

- the operator $f_{*}$ restricts to an operator

$$
\begin{equation*}
f_{*}: \text { Cartier-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \rightarrow \text { Cartier-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \tag{3.56}
\end{equation*}
$$

- Let $\alpha \in$ Weil-NS $\left(\mathrm{X}_{0}\right)$, let $X, Y$ be completions of $X_{0}$ such that the lift $f: X \rightarrow Y$ does not contract any curves, then

$$
\begin{equation*}
\left(f^{*} \alpha\right)_{X}=\left(f^{*} \alpha_{Y}\right)_{X} \tag{3.57}
\end{equation*}
$$

Remark 3.2.23. For a completion $X$, we can also define the restriction of $f^{*}$ and $f_{*}$ to $\operatorname{NS}(X)$. We denote them respectively by $f_{X}^{*}$ and $\left(f_{X}\right)_{* .}$. They are defined by

$$
\begin{equation*}
\forall \beta \in \operatorname{NS}(X), \quad f_{X}^{*} \beta=\left(f^{*} \beta\right)_{X}, \quad\left(f_{X}\right)_{*} \beta=\left(f_{*} \beta\right)_{X} \tag{3.58}
\end{equation*}
$$

### 3.2.6.4 Spectral property of the first dynamical degree

Consider a completion $X$ of $X_{0}$ and $\omega \in \mathrm{NS}(X)$ an ample class. By the Hodge index theorem, the intersection form on Cartier-NS $\left(\mathrm{X}_{0}\right) \times \operatorname{Cartier-NS}\left(\mathrm{X}_{0}\right)$ is negative definite on $\omega^{\perp}$. If $\alpha \in \operatorname{Cartier}-\mathrm{NS}\left(\mathrm{X}_{0}\right)$, the projection of $\alpha$ on $\omega^{\perp}$ is $\alpha-(\alpha \cdot \omega) \omega$. Consider the quadratic form on Cartier-NS ( $\mathrm{X}_{0}$ ) given by

$$
\begin{equation*}
\forall \alpha \in \operatorname{Cartier-NS}\left(\mathrm{X}_{0}\right),\|\alpha\|^{2}:=(\omega \cdot \alpha)^{2}-\frac{1}{\omega^{2}}(\alpha-(\alpha \cdot \omega) \omega)^{2} . \tag{3.59}
\end{equation*}
$$

This defines a norm on Cartier-NS $\left(\mathrm{X}_{0}\right)_{\mathbf{R}}$ and Cartier-NS $\left(\mathrm{X}_{0}\right)_{\mathbf{R}}$ is not complete for this norm. We denote by $L^{2}\left(X_{0}\right)$ the completion of Cartier-NS $\left(X_{0}\right)_{\mathbf{R}}$ with respect to this norm; Had we chosen a different ample class, we would have gotten an equivalent norm so the space $\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$ is independent of the choice of $\omega$. This is a Hilbert space and we have

Proposition 3.2.24 ([]BFJ08] Proposition 1.10). There is a continuous injection

$$
\begin{equation*}
\mathrm{L}^{2}\left(\mathrm{X}_{0}\right) \hookrightarrow \text { Weil-NS }\left(\mathrm{X}_{0}\right) \tag{3.60}
\end{equation*}
$$

and the topology on $\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$ induced by Weil-NS $\left(\mathrm{X}_{0}\right)$ coincides with its weak topology as a Hilbert space. If $\alpha \in$ Weil- $\mathrm{NS}\left(\mathrm{X}_{0}\right)$ then $\alpha$ belongs to $\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$ if and only if $\inf _{X}\left(\alpha_{\mathbf{X}}^{2}\right)>-\infty$, in which case $\alpha^{2}=\inf _{X}\left(\alpha_{X}^{2}\right)$. Furthermore, the intersection product • defines a continuous bilinear form on $\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$.

Remark 3.2.25. In particular, any nef class belongs to $L^{2}\left(X_{0}\right)$. Recall that $\alpha \in \operatorname{Weil-NS}\left(X_{0}\right)_{\mathbf{R}}$ is nef if for every completion $X, \alpha_{X}$ is nef. The cone theorem ([LLaz04] Theorem 1.4.23) states that $\alpha_{X}$ is a limit of ample classes in $\operatorname{NS}(X)_{\mathbf{R}}$, therefore $\left(\alpha_{X}\right)^{2} \geqslant 0$ and $\alpha \in \mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$.

Using the canonical basis of exceptional divisors we can have an explicit description of $\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$. Let $\alpha \in$ Cartier-NS $\left(\mathrm{X}_{0}\right)$ and let $\alpha_{X}$ be the incarnation of $\alpha$ in $X$. Then, since $\alpha$ is a Cartier class, we have for all but finitely many $E \in \mathcal{D}_{X}$ that $\alpha \cdot \alpha_{E}=0$ and

$$
\begin{equation*}
\alpha=\alpha_{X}+\sum_{E \in \mathcal{D}_{X}}\left(\alpha \cdot \alpha_{E}\right) \alpha_{E} . \tag{3.61}
\end{equation*}
$$

Therefore,

$$
\begin{equation*}
\|\boldsymbol{\alpha}\|^{2}=\left\|\alpha_{X}\right\|^{2}+\sum_{E \in \mathcal{D}_{X}}\left(\boldsymbol{\alpha} \cdot \boldsymbol{\alpha}_{E}\right)^{2}, \tag{3.62}
\end{equation*}
$$

and

$$
\begin{equation*}
\alpha^{2}=\alpha_{X}^{2}-\sum_{E \in \mathcal{D}_{X}}\left(\alpha \cdot \alpha_{E}\right)^{2} \tag{3.63}
\end{equation*}
$$

Therefore, $\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$ is isomorphic to the Hilbert space

$$
\begin{equation*}
\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)=\mathrm{NS}(X) \oplus \ell^{2}\left(\mathcal{D}_{X}\right) \tag{3.64}
\end{equation*}
$$

We also have the local version of this statement

Proposition 3.2.26. Let $X$ be a completion of $X_{0}$ and $p \in X$ be a point at infinity. Then,

$$
\begin{equation*}
\mathrm{L}^{2}\left(\mathrm{X}_{0}\right) \cap \operatorname{Weil}(X, p)=\ell^{2}\left(\mathcal{D}_{X, p}\right) \tag{3.65}
\end{equation*}
$$

and $\left\{\alpha_{E}: E \in \mathcal{D}_{X, p}\right\}$ is a Hilbert basis of this space.
Proposition 3.2.27 ([|][5J08]). Let $f$ be a dominant endomorphism of $X_{0}$. The linear maps

$$
\begin{equation*}
f^{*}, f_{*}: \text { Weil-NS }\left(\mathrm{X}_{0}\right) \rightarrow \text { Weil-NS }\left(\mathrm{X}_{0}\right) \tag{3.66}
\end{equation*}
$$

induce continuous operators

$$
\begin{equation*}
f^{*}, f_{*}: \mathrm{L}^{2}\left(\mathrm{X}_{0}\right) \rightarrow \mathrm{L}^{2}\left(\mathrm{X}_{0}\right) \tag{3.67}
\end{equation*}
$$

Furthermore, we have the following properties in $\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$.

1. $\left(f^{n}\right)^{*}=\left(f^{*}\right)^{n}$;
2. $\forall \alpha, \beta \in \mathrm{L}^{2}\left(\mathrm{X}_{0}\right), f^{*} \alpha \cdot \beta=\alpha \cdot f_{*} \beta$.
3. $\forall \alpha \in \mathrm{L}^{2}\left(\mathrm{X}_{0}\right), f^{*} \alpha \cdot f^{*} \alpha=e(f) \alpha \cdot \alpha$ where $e(f)$ is the topological degree of $f$.

In particular, if $f \in \operatorname{Aut}\left(X_{0}\right)$ then $f^{*}$ is an isometry of $\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$ viewed as an infinite dimensional hyperbolic space (see [CLC13]).

Theorem 3.2.28 ([]BFJ08, [DF21]). Suppose that $\lambda_{1}(f)^{2}>\lambda_{2}(f)$, then there exist nef classes $\theta^{*}, \theta_{*} \in \mathrm{~L}^{2}\left(\mathrm{X}_{0}\right)$ unique up to multiplication by a positive constant such that

1. $f^{*} \theta^{*}=\lambda_{1} \theta^{*}$.
2. $f_{*} \theta_{*}=\lambda_{1} \theta_{*}$.
3. For all $\alpha \in \mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$,

$$
\begin{align*}
& \frac{1}{\lambda_{1}^{n}}\left(f^{n}\right)^{*} \alpha=\left(\alpha \cdot \theta_{*}\right) \theta^{*}+1 O_{\alpha}\left(\left(\frac{\lambda_{2}}{\lambda_{1}^{2}}\right)^{n / 2}\right),  \tag{3.68}\\
& \frac{1}{\lambda_{1}^{n}}\left(f^{n}\right)_{*} \alpha=\left(\alpha \cdot \theta^{*}\right) \theta_{*}+O_{\alpha}\left(\left(\frac{\lambda_{2}}{\lambda_{1}^{2}}\right)^{n / 2}\right) . \tag{3.69}
\end{align*}
$$

1. $A=O_{\alpha}(B)$ means that there exists a constant $C(\alpha)>0$ such that $A \leqslant C(\alpha) B$.

In particular, for all $\alpha, \beta \in \mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$,

$$
\begin{equation*}
\lim _{n} \frac{1}{\lambda_{1}^{n}}\left(f^{n}\right)^{*} \alpha \cdot \beta=\left(\alpha \cdot \theta_{*}\right)\left(\beta \cdot \theta^{*}\right) \tag{3.70}
\end{equation*}
$$

Furthermore, $\theta^{*}$ and $\theta_{*}$ satisfy

$$
\begin{equation*}
\left(\theta^{*}\right)^{2}=0, \quad \theta_{*} \cdot \theta^{*}>0 \tag{3.71}
\end{equation*}
$$

We call $\theta^{*}$ and $\theta_{*}$ the eigenclasses of $f$.
Sketch of proof. We sketch here the proof for $\theta^{*}$. Let $X$ be a completion of $X_{0}$. The pull back $f^{*}$ induces a linear map $f_{X}^{*}: \mathrm{NS}(X) \rightarrow \mathrm{NS}(X)$. Let $\rho_{X}$ be the spectral radius of this map. We have for any ample class $w \in \operatorname{NS}(X)$ that $\rho_{X}=\lim _{n \rightarrow \infty}\left(\left(f_{X}^{*}\right)^{n} w \cdot w\right)^{1 / n}$. Now, $f_{X}^{*}$ the cone $C_{X}$ of nef classes in $\mathrm{NS}(X)_{\mathbf{R}}$. This is a closed convex cone with compact basis and non-empty interior. By a Perron-Frobenius type argument, there exists $\theta_{X} \in C_{X}$ such that $f_{X}^{*} \theta_{X}=\rho_{X} \theta_{X}$.

Now, Let $\left(X_{N}\right)$ be a sequence of completions of $X_{0}$ such that $X_{1}=X$ and $X_{N+1}$ is a composition of blowups of $X_{N}$ at infinity such that the lift of $f$ to $F_{N}: X_{N+1} \rightarrow X_{N}$ is regular, we denote by $\pi_{N}: X_{N+1} \rightarrow X_{N}$ the induced morphism of completions. Let $\rho_{N}:=\rho_{X_{N}}$ and $\theta_{N}:=\theta_{X_{N}}$. One can show that $\lim _{N} \rho_{N}=\lambda_{1}$. By construction, we have that for all $N \geqslant 1$, the element $f^{*} \theta_{N}-\rho_{N} \theta_{N} \in \operatorname{Weil-NS}\left(\mathrm{X}_{0}\right)_{\mathbf{R}}$ has incarnation zero in $X_{N}$, hence it tends to zero in Weil-NS $\left(\mathrm{X}_{0}\right)_{\mathbf{R}}$. We can normalize all $\theta_{N}$ such that $\theta_{N} \cdot w=1$ where $w$ is an ample class of $\operatorname{NS}(X)$. Now, the set $\left\{W \in \operatorname{Weil-NS}\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \mid W \cdot w=1\right\}$ is a compact subset of Weil-NS $\left(\mathrm{X}_{0}\right)$ so the sequence $\left(\theta_{N}\right)$ has an accumulation point $\theta^{*} \in$ Weil-NS $\left(X_{0}\right)$ that is nef, effective and we get $f^{*} \theta^{*}=\lambda_{1} \theta^{*}$.

### 3.3 Valuations

### 3.3.1 Valuations and completions

Our general reference for the theory of valuations is Vaq00]. Let $R$ be a commutative $\mathbf{k}$-algebra that is also an integral domain, a valuation on $R$ is a function $v: R \rightarrow \mathbf{R} \cup\{\infty\}$ such that
(i) $v\left(\mathbf{k}^{*}\right)=0$;
(ii) For all $P, Q \in R, v(P Q)=v(P)+v(Q)$;
(iii) For all $P, Q \in R, v(P+Q) \geqslant \min (v(P), v(Q))$;
(iv) $\mathbf{v}(0)=+\infty$.

If $I$ is an ideal of $R$, we set $v(I):=\min _{i \in I} v(i)$. If $S \subset I$ is a set of generators, then

$$
\begin{equation*}
v(I)=\min _{s \in S} v(s) . \tag{3.72}
\end{equation*}
$$

Remark 3.3.1. In Abh56] A valuation can take the value $+\infty$ only at 0 but we do not require such a property. Let $\mathfrak{p}_{v}=\{a \in R: v(a)=\infty\}$ then $\mathfrak{p}_{v}$ is a prime ideal of $R$ that we call the bad ideal of $v$. If $v$ is a valuation on $R$, it defines naturally a valuation in the sense of [Abh56] on the quotient field $R / \mathfrak{p}_{v}$. Furthermore $v$ can be naturally extended to a valuation on the ring $R_{\mathfrak{p}_{v}}$ via the formula $v(p / q)=v(p)-v(q)$. In particular, if $\mathfrak{p}_{v}=\{0\}$, then $v$ defines a valuation over Frac $R$.

Let $X$ be a completion of $X_{0}$ and let $v$ be a valuation over $B:=O_{X}\left(X_{0}\right)$. Let $\mathfrak{p}_{v}$ be the bad ideal of $v$. Consider $B_{\mathfrak{p}_{v}}$ the localization of $B$ at $\mathfrak{p}_{v}$. Set

$$
\begin{equation*}
O_{v}:=\left\{x \in B_{\mathfrak{p}_{v}}: v(x) \geqslant 0\right\} . \tag{3.73}
\end{equation*}
$$

This is a subring of $B_{\mathfrak{p}_{v}}$. If $\mathfrak{p}_{v}=\{0\}$, then this is the classical valuation ring of $v$.
Lemma 3.3.2. The subring $O_{v}$ is a local ring, its maximal ideal is

$$
\begin{equation*}
\mathfrak{m}_{v}:=\left\{x \in O_{v}: v(x)>0\right\} . \tag{3.74}
\end{equation*}
$$

Proof. It suffices to show that if $v(x)=0$, then $x$ is invertible in $O_{v}$ but this is obvious since $v\left(x^{-1}\right)=-v(x)=0$.

One defines naturally a valuation $v$ on $C:=B / \mathfrak{p}_{v}$, let $L$ be the fraction field of $C$ and $O$ be the valuation ring of $L$ with respect to $v$. Then, we have the natural isomorphisms

$$
\begin{equation*}
L \simeq B_{\mathfrak{p}_{v}} / \mathfrak{p}_{v} \text { and } O_{v} / \mathfrak{p}_{v} \simeq O \tag{3.75}
\end{equation*}
$$

Geometrically, the Zariski closure of $\mathfrak{p}_{v}$ inside $X$ defines an irreducible closed subscheme $Y$ of $X$ and $L$ is isomorphic to the field of rational functions on $Y$.

Two valuations $v_{1}, v_{2}$ are equivalent if there exists a real number $\lambda>0$ such that $v_{1}=\lambda \nu_{2}$. Let $R, R^{\prime}$ be two integral domains with a homomorphism of schemes $\varphi: \operatorname{Spec} R^{\prime} \rightarrow \operatorname{Spec} R$;
it induces a ring homomorphism $\varphi^{*}: R \rightarrow R^{\prime}$. If $v$ is a valuation on $R^{\prime}$ we define $\varphi_{*} v$ the pushforward by $\varphi$ of $v$ by

$$
\begin{equation*}
\forall P \in R, \varphi_{*} v(P)=v\left(\varphi^{*}(P)\right) . \tag{3.76}
\end{equation*}
$$

Let $X_{0}=\operatorname{Spec} A$ as in Section 3.2.2. Denote by $\mathcal{V}$ the set of valuations on $A$. We equip this space with the topology of weak convergence, that is the coarsest topology such that the evaluation map $v \in \mathcal{V} \mapsto \mathcal{V}(P)$ is continuous for all $P \in A$. If $f$ is an endomorphism of $X_{0}$, then $f$ induces a continuous map $f_{*}: \mathcal{V} \rightarrow \mathcal{V}$.

Via the natural isomorphism $\mathrm{t}_{X}^{*}: O_{X}\left(X_{0}\right) \rightarrow A$, every $v \in \mathcal{V}$ induces a valuation $\left(l_{X}\right)_{*} v$ on $O_{X}\left(X_{0}\right)$, namely

$$
\begin{equation*}
\forall P \in O_{X}\left(X_{0}\right), \quad\left(\mathfrak{l}_{X}\right)_{*} v(P):=v\left(\imath_{X}^{*} P\right) \tag{3.77}
\end{equation*}
$$

We will denote $\left(\mathrm{l}_{X}\right)_{*} v$ by $v_{X}$ for every valuation $v$ on $A$.
Remark 3.3.3. Take a morphism of completions $\pi: X_{1} \rightarrow X_{2}$ and $v$ a valuation on $A$. Then, $\left(\boldsymbol{l}_{X_{2}}\right)_{*} \nu=\left(\pi^{-1} \circ l_{X_{1}}\right)_{*} \nu$. In particular $\pi_{*} \nu_{X_{2}}=v_{X_{1}}$.

Remark 3.3.4. In the language of Berkovich theory, the set $\mathcal{V}$ is the Berkovich analytification of $X_{0}$ over $\mathbf{k}$ where we have endowed $\mathbf{k}$ with the trivial valuation (see [Ber12]).

Example 3.3.5 (Divisorial valuations). Let $X$ be a completion of $X_{0}$ and $E$ be a prime divisor of $X$. Let $\operatorname{ord}_{E}$ be the valuation on $\mathbf{k}(X)$ such that for any $f \in \mathbf{k}(X), \operatorname{ord}_{E}(f)$ is the order of vanishing of $f$ along $E$. Any valuation $v$ on $A$ such that $v_{X}$ is equivalent to $\operatorname{ord}_{E}$ for some prime divisor $E$ in some completion $X$ is called a divisorial valuation. In that case $\mathfrak{p}_{v}=\{0\}$ and $v$ extends uniquely to a valuation on Frac $A$. For example if $X_{0}=\mathbf{A}^{2}$ and $X=\mathbf{P}^{2}$, then let $L_{\infty}$ be the line at infinity, we have $\forall P \in \mathbf{k}[x, y], \operatorname{ord}_{L_{\infty}}(P)=-\operatorname{deg}(P)$. If instead we take the completion $P^{1} \times \mathbf{P}^{1}$, decompose $\mathbf{A}^{2}=\mathbf{A}^{1} \times \mathbf{A}^{1}$ and let $x, y$ be the affine coordinate of $\mathbf{A}^{2}$ each being an affine coordinate of $\mathbf{A}^{1}$. Let $L_{x}=\{\infty\} \times \mathbf{P}^{1}$ and $L_{y}=\mathbf{P}^{1} \times\{\infty\}$, then

$$
\begin{equation*}
\forall P \in \mathbf{k}[x, y], \operatorname{ord}_{L_{x}}(P)=-\operatorname{deg}_{x}(P), \quad \operatorname{ord}_{L_{y}}(P)=-\operatorname{deg}_{y}(P) \tag{3.78}
\end{equation*}
$$

where $\operatorname{deg}_{x}\left(\right.$ respectively $\left.\operatorname{deg}_{y}\right)$ is the degree with respect to the variable $x$ (respectively $y$ ).
Example 3.3.6 (Curve valuations). Let $X$ be a completion of $X_{0}$, let $p \in \partial_{X} X_{0} C$ be the germ of a (formal) curve at $p$. This means that $C$ is defined as $\varphi=0$ for $\varphi$ in the completion $\hat{O}_{X, p}$ of the local ring $O_{X, p}$ at $p$. If $\psi \in \widehat{O}_{X, p}$ is another germ of a formal curve at $p$, we define the intersection number at $p$ by

$$
\begin{equation*}
\{\varphi=0\} \cdot p\{\psi=0\}:=\operatorname{dim}_{\mathbf{k}} \hat{O}_{X, p} /\langle\varphi, \psi\rangle . \tag{3.79}
\end{equation*}
$$

This number is equal to $\infty$ exactly when one of the germs divides the other. We first define a valuation $v_{C, p}$ on $\widehat{O}_{X, p}$ by

$$
\begin{equation*}
v_{C, p}(\psi)=\{\psi=0\} \cdot{ }_{p} C \tag{3.80}
\end{equation*}
$$

Suppose $\varphi$ is not divisible by the local equation of any component of $\partial_{X} X_{0}$. For any $P \in O_{X}\left(X_{0}\right)$, $P$ can be written as $P=\psi_{1}^{\alpha_{1}} \cdots \psi_{r}^{\alpha_{r}}$ with $\psi_{i} \in \hat{O}_{X, p}$ irreducible and $\alpha_{i} \in \mathbf{Z}$. We define

$$
\begin{equation*}
v_{C, p}(P):=\sum_{i} \alpha_{i} v_{C, p}\left(\Psi_{i}\right) \in \mathbf{R} \cup\{\infty\} \tag{3.81}
\end{equation*}
$$

Then $v_{C, p}$ is a valuation on $O_{X}\left(X_{0}\right)$. Any valuation on $A$ such that $v_{X}$ is equivalent to $v_{C, p}$ is called a curve valuation. If $v$ is a valuation such that $\mathfrak{p}_{v} \neq\{0\}$, then $v$ is a curve valuation (see [FJ04] and Proposition 3.3.9 below). We will make the following distinction, if $C$ is defined by $\varphi \in O_{X, p}$ we will say that $v_{C, p}$ is an algebraic curve valuation. Otherwise, we will say that it is a formal curve valuation.

If $\varphi$ was divisible by the local equation of a component of $\partial_{X} X_{0}$, then $v_{C, p}$ would not define a valuation on $A$ as some regular functions $P \in A$ would have a pole along $C$ and $v(P)$ would be equal to $-\infty$.

### 3.3.2 Valuations over $\mathbf{k}[[x, y]]$

We recall some results about valuations from [FJ04] and [FJ07]. Let $R$ be a regular local ring with maximal ideal $\mathfrak{m}$. We say that a valuation on $R$ is centered if $v \geqslant 0$ and $v_{\mid \mathfrak{m}}>0$. Here we set $R:=\mathbf{k}[[x, y]]$ for our local ring. Its maximal ideal is $\mathfrak{m}:=(x, y)$ we will study the set of centered valuations on $R$.

Proposition 3.3.7 (Proposition 2.10 [FJ04], [Spi90]). Any valuation on $\mathbf{k}[x, y]$ centered at the origin extends uniquely to a centered valuation on $R$ as follows. Let $\varphi \in R$ and let $\varphi_{n}$ be the polynomial of degree $n$ such that $\varphi=\lim \varphi_{n}$. Then,

$$
\begin{equation*}
v(\varphi)=\lim _{n \rightarrow \infty} \min \left(v\left(\varphi_{n}\right), n\right) . \tag{3.82}
\end{equation*}
$$

Corollary 3.3.8. Let $R^{\prime}$ be regular local ring of dimension 2 over $\mathbf{k}$, then the $\mathfrak{m}_{R^{\prime}}$-adic completion $\hat{R}^{\prime}$ of $R^{\prime}$ is isomorphic to $R$. Any centered valuation on $R^{\prime}$ extends uniquely to a centered valuation on $\hat{R}^{\prime}$.

Proof. Let $(x, y)$ be a regular sequence of $R^{\prime}$, that is $\mathfrak{m}_{R^{\prime}}=(x, y)$. It exists because $R^{\prime}$ is a regular
local ring of dimension 2. Then, $\hat{R}^{\prime}$ is isomorphic to $\mathbf{k}[[x, y]]$. Let $v$ be a centered valuation on $R^{\prime}$. We have that $\mathbf{k}[x, y] \subset R^{\prime}$, so $v$ induces a valuation on $\mathbf{k}[x, y]$ that is centered at the origin and we can apply the previous proposition to conclude.

Let $p$ be a regular point on a surface $X$ and let $R=\widehat{O_{X, p}}$ we define 4 types of valuations over $R$.

### 3.3.2.1 Divisorial valuations

A valuation $v$ over $R$ is divisorial if there exists a sequence of blow-up $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, x)$ such that $v$ is equivalent to $\pi_{*} \operatorname{ord}_{E}$ for some prime divisor $E \subset \operatorname{Exc}(\pi)$.

### 3.3.2.2 Quasimonomial valuations

Let $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, x)$ be a sequence of blow-ups and let $q \in \operatorname{Exc}(\pi)$. A monomial valuation at $q$ is a valuation $v$ on $\widehat{O_{Y, q}}$ such that there exists $s, t>0$,

$$
\begin{equation*}
v\left(\sum_{i, j} a_{i j} x^{i} y^{j}\right)=\min \left\{s i+t j: a_{i j} \neq 0\right\} \tag{3.83}
\end{equation*}
$$

for some local coordinates at $q$. We write $v=v_{s, t}$.
A valuation over $\widehat{O_{X, p}}$ is called quasimonomial if there exists a sequence of blow-ups $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, p)$ such that $v=\pi_{*} v_{s, t}$. Quasimonomial valuations split into two categories: if $s / t \in \mathbf{Q}$, one can show actually that v is divisorial. Otherwise $s / t \in \mathbf{R} \backslash \mathbf{Q}, v$ is not divisorial and we say that it is irrational.

### 3.3.2.3 Curve valuations

Let $\varphi \in \widehat{\mathfrak{m}_{p}}$ be irreducible, we define $v_{\varphi}$ by

$$
\begin{equation*}
\forall \psi \in \widehat{O_{X, p}}, \quad v_{\varphi}(\psi)=\frac{\{\varphi=0\} \cdot\{\psi=0\}}{m(\varphi)} \tag{3.84}
\end{equation*}
$$

where $m(\varphi)$ is the order of vanishing of $\varphi$ at the origin. A curve valuation is a valuation equivalent to $v_{\varphi}$ for some $\varphi \in \widehat{\mathfrak{m}_{p}}$ irreducible.

### 3.3.2.4 Infinitely singular valuations

These are all the remaining valuations. They have a nice description in term of Puiseux series (see [FJ04] Section 4.1 for more details). Briefly, to any valuation $v$ of $\mathbf{k}[[x, y]]$, one can associated a generalized power series

$$
\begin{equation*}
\hat{\varphi}=\sum_{j} a_{j} x^{\beta_{j}} \tag{3.85}
\end{equation*}
$$

with $a_{j} \in \mathbf{k}$ and $\beta_{j} \in \mathbf{Q}$. The infinitely singular valuations are exactly the valuations such that $\lim _{j} \beta_{j} \neq+\infty$.

Proposition 3.3.9 ([[FJ04]). There are four types of centered valuations on $R$ : divisorial, irrational, curve valuations and infinitely singular valuations. The only type of valuation $v$ such that $\mathfrak{p}_{v}=\{v=+\infty\} \neq 0$ are curve valuations

Remark 3.3.10. Instead of looking at valuations over $R$ with values in $\mathbf{R}$, we can look at valuations with values in a totally ordered abelian group $\Gamma$, these are called Krull valuations (see [FJ04], section 1.3) and they have the advantage to always extend to Frac $R$. We can make any curve valuation into a Krull valuation by the following procedure (see [FJ04], section 1.5.5): Let $\varphi \in \mathfrak{m}$ and consider the curve valuation $\nu_{\varphi}$. Let $\Gamma=\mathbf{Z} \times \mathbf{Q}$ with the lexicographical order, we define $\widehat{v}_{\varphi}: R \rightarrow \Gamma$ as follows. For any $\psi \in R$, there exists an integer $k \in \mathbf{N}$ such that

$$
\begin{equation*}
\psi=\varphi^{k} \widehat{\psi} \tag{3.86}
\end{equation*}
$$

where $\hat{\psi}$ is not divisible by $\varphi$. Set

$$
\begin{equation*}
\widehat{v}(\psi):=\left(k, v_{\varphi}(\widehat{\psi})\right) \tag{3.87}
\end{equation*}
$$

Notice that $v_{\varphi}(\psi)=\infty \Leftrightarrow p_{1}\left(\widehat{v}_{\varphi}(\psi)\right)>0$ where $p_{1}: \Gamma \rightarrow \mathbf{Z}$ is the projection to the first coordinate and if $v_{\varphi}(\psi)<+\infty$, then $\widehat{v}_{\varphi}(\psi)=\left(0, \nu_{\varphi}(\psi)\right)$. We will not need Krull valuations in the rest of the text. But this argument comes in handy for the proof of Proposition 3.3.18 so we state it here.

### 3.3.3 The center of a valuation

Let $X$ be a completion of $X_{0}$ and let $v$ be a valuation on $O_{X}\left(X_{0}\right)$. A center of $v$ on $X$ is a schemetheoretic point $p \in X$ such that $O_{V}$ dominates the local ring $O_{X, p}$ (i.e $O_{X, p} \subset O_{V}$ and $\mathfrak{m}_{p} \subset \mathfrak{m}_{v}$ ).

## Chapter 3 - Valuations and Algebraic geometry

If such a $p$ exists then $v$ induces a centered valuation on $O_{X, p}(\mathrm{cf} 3.3 .2)$ and in particular for any open affine subset $U \subset X$ that contains $p, v$ induces a valuation on $O_{X}(U)$ via the inclusion $O_{X}(U) \subset O_{X, p}$.

Lemma 3.3.11. The center of $v$ on $X$ always exists and is unique.
Proof. Let $O_{v}$ be the subring of $\mathbf{k}(X)$ where $v$ is $\geqslant 0$; it contains $\mathbf{k}^{*}$. Let $L=B_{\mathfrak{p}_{v}} / \mathfrak{p}_{v}$ and $O=O_{v} / \mathfrak{p}_{v}$. If $p$ is a center of $v$ on $X$ then we have the following commutative diagram of ring homomorphism

$$
\begin{equation*}
O_{X, p} \longleftrightarrow O_{v} \longrightarrow O \longleftrightarrow L \longleftrightarrow<B_{\mathfrak{p}_{v}} \tag{3.88}
\end{equation*}
$$

inducing the following commutative diagram of scheme morphisms

Since $X$ is proper over $\mathbf{k}$ (it's a projective variety), the valuative criterion of properness ([Har77]) shows that if the center exists, then it is unique. For the existence, Let $x \in X$ be the image of the maximal ideal of $O$, then $x$ is the center of $v$ on $X$. Indeed, the image of $\operatorname{Spec} L$ is the prime ideal $\mathfrak{p}_{v}$ of $O_{X}\left(X_{0}\right)$ and $x$ belongs to its closure, therefore $O_{X, x} \subset B_{\mathfrak{p}_{v}}$ and the morphism of local rings $O_{X, x} \rightarrow O$ shows that $O_{V}$ dominates $O_{X, x}$.

The center of $v$ on $X$ is the center of $v_{X}$ we will denote it by $c_{X}(v)$.
Example 3.3.12. Let $v$ be a divisorial valuation over $A$ and let $X$ be a completion of $X_{0}$ such that $v_{X} \simeq \operatorname{ord}_{E}$ for some prime divisor $E$ of $X$, then the center of $v$ on $X$ is the generic point $x_{E}$ of $E$. Indeed, the ring of regular function at the generic point of $E$ is a discrete valuation ring since $E$ is of codimension 1 . In that case, we will identify the center with its closure and say that the center of $v$ on $X$ is the prime divisor $E$. In fact a valuation is divisorial if and only if its center on some completion of $X_{0}$ is a prime divisor because if $c_{X}(v)=x_{E}$, then $v$ and $\operatorname{ord}_{E}$ defines the same valuation ring which is a discrete valuation ring, therefore they are equivalent.

Example 3.3.13. If $v$ is a curve valuation and $X$ is a completion of $X_{0}$ such that $\left(v_{X}\right)_{*} \nu \simeq v_{C, p}$, then the center of $v$ on $X$ is the closed point $p$.

A valuation over $A=\mathbf{k}\left[X_{0}\right]$ is centered at infinity if there exists a completion $X$ such that $c_{X}(v) \notin X_{0}$.

Corollary 3.3.14. Let $X_{0}=\operatorname{Spec} A$ be a smooth affine surface, there are exactly four types of valuations centered at infinity over A: divisorial valuations, irrational valuations, curve valuations and infinitely singular valuations. If v is a valuation such that $\mathfrak{p}_{\mathrm{v}} \neq\{0\}$, then v is a curve valuation.

Proof. let $v$ be a valuation over $A$ and let $c_{X}(v)$ be its center on some completion $X$. If $c_{X}(v)$ is a prime divisor at infinity then $v$ is divisorial. Otherwise, $c_{X}(v)$ is a regular point at infinity and $v$ induces a centered valuation over $\widehat{O_{X, p}}$. The result follows from the classification of centered valuations over $\mathbf{k}[[x, y]]$ from Proposition 3.3.9.

Definition 3.3.15. - Let $X$ be a good completion of $X_{0}$ and $p \in \partial_{X} X_{0}$ a point at infinity. Following [FJ04], we say that $p$ is a free point if it belongs to a unique prime divisor at infinity and we say that it is a satellite point otherwise, i.e it is the intersection point of two prime divisors at infinity.

- Let $v$ be a valuation over $A$ centered at infinity. Let $p_{1}=c_{X}(v)$ be its center on $X$ and $X_{1}:=X$. We define the following sequence: If $p_{n}$ is a prime divisor, then the sequence stops, else $p_{n}$ is a closed point of $X_{n}$ and we define $X_{n+1}$ as the blow up of $p_{n}$, then define $p_{n+1}:=c_{X_{n+1}}(v)$. This is the sequence of centers of $v$ with respect to $X$.

We adopt the following convention: When we write "let $p \in E$ be a free point (at infinity)" this means that $E$ is the unique prime divisor at infinity on which $p$ lies. If we write "let $p=E \cap F$ be a satellite point", this means that $E$ and $F$ are the two prime divisors at infinity such that $p=E \cap F$ (Recall that we only work with good completions).

Proposition 3.3.16 ([[FJ04], Section 6.2 ). Let $\vee$ be a valuation centered at infinity. Let $X$ be a completion of $X_{0}$ and $\left(p_{n}\right)$ the sequence of centers (above $X$ ) associated to $v$. Then,

1. $v$ is divisorial if and only if the sequence $\left(p_{n}\right)$ is finite.
2. If V is irrational, then $\left(p_{n}\right)$ contains finitely many free points.
3. if v is a curve valuation, then $\left(p_{n}\right)$ contains finitely many satellite points.
4. If $v$ is infinitely singular, then $\left(p_{n}\right)$ contains infinitely many free points.

Proof. Assertion 1 is clear since the sequence $\left(p_{n}\right)$ stops if and only if $p_{n}$ is a prime divisor at infinity. Assertion 2 and 4 follows from [FJ04] Theorem 6.10 and Assertion 3 follows from [FJ04] Proposition 6.12.

### 3.3.4 Image of a valuation via an endomorphism

Let $f: X_{0} \rightarrow X_{0}$ be a endomorphism of $X_{0}$, it induces a map $f_{*}$ on the space of valuation $f_{*}: \mathcal{V} \rightarrow \mathcal{V}$ via the formula

$$
\begin{equation*}
\forall P \in A, \forall v \in \mathcal{V}, \quad f_{*} v(\varphi) \tag{3.90}
\end{equation*}
$$

We will denote by $f_{\bullet}$ the induced map $f_{\bullet}: \hat{\mathcal{V}} \rightarrow \hat{\mathcal{V}}$.
Proposition 3.3.17 (Proposition 2.4 of [FJ07]). Suppose that $f$ is dominant, the map $f_{*}$ preserves the sets of divisorial, of irrational and of infinitely singular valuations. If $v_{C}$ is a curve valuation such that $f$ does not contract $C$, then $f_{*} v_{C}$ is a curve valuation. If $f$ contracts $C$, then $f_{*} v_{C}$ is a divisorial valuation.

We will use this proposition in the following context. Let $X, Y$ be two completions of $X_{0}$ such that the lift $F: X \rightarrow Y$ of $f$ is regular. For any point $p \in X \backslash X_{0}$, we have a map $F_{*}: \mathcal{V}_{X}(p) \rightarrow \mathcal{V}_{Y}(F(p))$ that preserves the type of the valuations. The only curve that might be contracted by $F$ to $q$ are the divisors at infinity; but the curve valuation that they define do not define valuations on $A$.

Proposition 3.3.18. Let $f: X_{0} \rightarrow X_{0}$ be a dominant endomorphism of topological degree $\lambda_{2}$. Then, every valuation $v$ on $A$ has at most $\lambda_{2}$ preimages under $f_{*}$.

Proof. Suppose first that the valuation $v$ takes the value $+\infty$ only for 0 . Therefore, it extends to a valuation on $K=\operatorname{Frac} A$. The extension $f^{*} K \hookrightarrow K$ is a finite extension of degree $\lambda_{2}$. The valuation $v$ induces a valuation on $f^{*} K$ and every valuation $w$ such that $f_{*} w=v$ is an extension of $v_{\mid f^{*} K}$ to $K$. By [ZS60] Theorem 19 p .55 , there are at most $\lambda_{2}$ extension of $v_{\mid f f^{*} K}$.

If now $\mathfrak{p}_{v}=\{v=+\infty\} \neq 0$, then we know that $v$ is a curve valuation. By Remark 3.3.10, $v$ can be made into a Krull valuation $\hat{v}$. Since $\widehat{v}$ is a Krull valuation, it extends to a Krull valuation over $K$ and $f_{*} v$ extends to a Krull valuation over $f^{*} K$. The same argument as above still works as [ZS60] deals with Krull valuations.

### 3.4 Tree structure on the space of valuations

### 3.4.1 Trees

For this section, we refer to [FJ04] Section 3.1. Let $(\mathcal{T}, \leqslant)$ be a partially ordered set, a subset $\mathcal{S} \subset \mathcal{T}$ is full if for every $\sigma, \sigma^{\prime} \in \mathcal{S}, \tau \in \mathcal{T}, \sigma \leqslant \tau \leqslant \sigma^{\prime} \Rightarrow \tau \in \mathcal{S}$.

Definition 3.4.1. Let $\Lambda=\mathbf{N}, \mathbf{Q}, \mathbf{R}$. An interval in $\Lambda$ is a subset $I \subset \Lambda$ such that for all $x, y, z \in \Lambda$, if $x \leqslant y \leqslant z$ and $x, z \in I$, then $y \in I$. If $(\mathcal{T}, \leqslant)$ be a partially ordered set, then $(\mathcal{T}, \leqslant)$ is a rooted $\Lambda$-tree if

1. $\mathcal{T}$ has a unique minimal element $\tau_{0}$ called the root of $\mathcal{T}$.
2. If $\tau \in \mathcal{T}$, the set $\{\sigma \in \mathcal{T}: \sigma \leqslant \tau\}$ is ${ }^{2}$ isomorphic to an interval in $\Lambda$.
3. Every full, totally ordered subset of $\mathcal{T}$ is isomorphic to an interval in $\Lambda$.

A parametrized- $\Lambda$ tree is a rooted $\Lambda$-tree $\mathcal{T}$ with a map $\alpha: \mathcal{T} \rightarrow \Lambda \cup\{\infty\}$ such that the restriction of $\alpha$ to any full totally ordered subset of $\mathcal{T}$ induces a bijection with an interval in $\Lambda$. The map $\alpha$ is called the parametrisation.

A rooted $\mathbf{R}$-tree is called complete if every increasing sequence has an upper bound.
A subtree $\mathcal{S}$ of a $\Lambda$-tree $\mathcal{T}$ is a subset such that $(\mathcal{S}, \leqslant \mid S)$ is a $\Lambda$-tree. An inclusion of $\Lambda$-trees is an order preserving injection $\mathfrak{\imath}: \mathcal{S} \rightarrow \mathcal{T}$. In particular, $\mathfrak{l}(\mathcal{S})$ is a subtree of $\mathcal{T}$.

If $\mathcal{T}$ is an $\mathbf{R}$-tree and $\tau_{1}, \tau_{2} \in \mathcal{T}$, then the minimum $\tau_{1} \wedge \tau_{2} \in \mathcal{T}$ exists by completeness of $\mathbf{R}$. We define the set

$$
\begin{equation*}
\left[\tau_{1}, \tau_{2}\right]:=\left\{\tau \in \mathcal{T}: \tau_{1} \wedge \tau_{2} \leqslant \tau \leqslant \tau_{1} \text { or } \tau_{1} \wedge \tau_{2} \leqslant \tau \leqslant \tau_{2}\right\} \tag{3.91}
\end{equation*}
$$

and we call it a segment. The segments $\left[\tau_{1}, \tau_{2}\right),\left(\tau_{1}, \tau_{2}\right]$ and $\left(\tau_{1}, \tau_{2}\right)$ are defined similarly. A finite subtree of $\mathcal{T}$ is a subtree that consists of a finite union of segments in $\mathcal{T}$.

If $\mathcal{T}$ is an $\mathbf{R}$-tree, a tangent vector $\vec{v}$ at $\tau \in \mathcal{T}$ is an equivalence class where

$$
\begin{equation*}
\tau^{\prime} \sim \tau^{\prime \prime} \Leftrightarrow\left[\tau, \tau^{\prime}\right] \cap\left[\tau, \tau^{\prime \prime}\right] \neq \varnothing . \tag{3.92}
\end{equation*}
$$

We define the weak topology on $\mathcal{T}$ by the topology generated by the sets

$$
\begin{equation*}
U(\vec{v}):=\left\{\tau^{\prime} \in \mathcal{T}: \tau^{\prime} \text { represents } \vec{v}\right\} . \tag{3.93}
\end{equation*}
$$

Theorem 3.4.2 ([|FJ04] Proposition 3.12). We have the following

- Every rooted $\mathbf{R}$-tree $\mathcal{T}$ admits a completion $\overline{\mathcal{T}}$ that is a complete rooted $\mathbf{R}$-tree.
- Every rooted $\mathbf{Q}$-tree $\mathcal{T}_{\mathbf{Q}}$ admits a completion $\mathcal{T}_{\mathbf{R}}$ into a rooted $\mathbf{R}$-tree, i.e there exists an order preserving injection $\mathfrak{v}: \mathcal{T}_{\mathbf{Q}} \hookrightarrow \mathcal{T}_{\mathbf{R}}$ such that

[^3]1. If $\tau_{0}$ is the root of $\mathcal{T}_{\mathbf{Q}}, \mathbf{1}\left(\tau_{0}\right)$ is the root of $\mathcal{T}_{\mathbf{R}}$.
2. $\mathfrak{l}\left(\mathcal{T}_{\mathbf{Q}}\right)$ is weakly dense in $\mathcal{T}_{\mathbf{R}}$
3. $\mathcal{T}_{\mathbf{R}}$ is minimal for this property.

- If $\alpha_{\mathbf{Q}}: \mathcal{T}_{\mathbf{Q}} \rightarrow \mathbf{\mathbf { Q } _ { + }}$ is a parametrisation of $\mathcal{T}_{\mathbf{Q}}$, then there exists a unique parametrisation $\alpha_{\mathbf{R}}$ of $\mathcal{T}_{\mathbf{R}}$ such that $\alpha_{\mathbf{Q}}=\alpha_{\mathbf{R}} \circ \mathbf{v}$.

### 3.4.2 The local tree structure of the space of valuations

We denote by $\mathcal{V}_{0}$ the set of centered valuations on $R$ where $R=\mathbf{k}[[x, y]]$. Define the multiplicity valuation $\nu_{\mathfrak{m}}$ by $\nu_{\mathfrak{m}}(\varphi)=\max \left\{n \geqslant 0: \varphi \in \mathfrak{m}^{n}\right\}$. We will sometimes write $m(\varphi)$ instead of $\nu_{\mathfrak{m}}(\varphi)$. Let $\mathcal{V}_{\mathfrak{m}} \subset \mathcal{V}_{0}$ be the set of centered valuations on $R$ such that $v(\mathfrak{m})=1$ and consider the following order relation on $\mathcal{V}_{\mathfrak{m}}: v \leqslant w \Longleftrightarrow \forall \varphi \in R, v(\varphi) \leqslant w(\varphi)$. With this order relation $\mathcal{V}$ becomes a complete rooted $\mathbf{R}$-tree called the valuative tree ([FJ04] Theorem 3.14) rooted in $v_{\mathfrak{m}}$. The ends of $\mathcal{V}_{\mathfrak{m}}$ consist of the curve valuations and the infinitely singular ones. The interior points are all quasimonomial valuations, all divisorial valuations are branching points whereas all the irrational valuations are regular points (i.e admit only two tangent vectors). Define on $\mathcal{V}_{\mathfrak{m}}$ the following function

$$
\begin{equation*}
\alpha(v):=\sup \left\{\frac{v(\varphi)}{m(\varphi)}: \varphi \in \mathfrak{m}, v_{\varphi} \geqslant v\right\} . \tag{3.94}
\end{equation*}
$$

It is called the skewness function (see [FJ04] §3.3)
Proposition 3.4.3 (Proposition 3.25 of [FJ04]). The skewness function $\alpha: \mathcal{V}_{\mathfrak{m}} \rightarrow[1,+\infty]$ defines a parametrisation of $\mathcal{V}_{\mathfrak{m}}$. We have the following properties.

- $\alpha(v)=1 \Leftrightarrow v=v_{m}$.
- Let $\varphi \in \mathfrak{m}$ be irreducible and let $\mathcal{v} \in \mathcal{V}_{\mathfrak{m}}$, then

$$
\begin{equation*}
\forall \varphi \in \mathfrak{m}, v(\varphi)=\alpha\left(v \wedge v_{\varphi}\right) m(\varphi) \tag{3.95}
\end{equation*}
$$

- If v is divisorial, then $\alpha(\mathrm{v}) \in \mathbf{Q}$
- if $v$ is irrational, then $\alpha(v) \in \mathbf{R} \backslash \mathbf{Q}$.
- If $\mathcal{V}_{\mathfrak{m}, \text { div }}$ is the subset of $\mathcal{V}_{\mathfrak{m}}$ consisting of the divisorial valuations, then $\left(\mathcal{V}_{\mathfrak{m}, \text { div }}, \alpha\right)$ is a parametrized $\mathbf{Q}$-tree.

We can define two topologies over $\mathcal{V}_{\mathfrak{m}}$. The first one is the weak topology being the coarsest topology such that for all $\varphi \in R$, the evaluations map $v \in \mathcal{V}_{\mathfrak{m}} \mapsto v(\varphi)$ is continuous. The second is the weak topology given by the $\mathbf{R}$-tree structure on $\mathcal{V}_{\mathfrak{m}}$.

Proposition 3.4.4 ([[FJ04], Theorem 5.1). The weak topology over $\mathcal{V}_{\mathfrak{m}}$ given by the evaluation maps $v \in \mathcal{V}_{\mathfrak{m}} \mapsto v(\varphi)$ and the weak topology induced by the tree structure of $\mathcal{V}_{\mathfrak{m}}$ are the same.

Let $X$ be a good completion of $X_{0}=\operatorname{Spec} A$ and let $p$ be a smooth point of $X$. Take local coordinates $z, w$ at $p$, then the completion of the local ring $O_{X, p}$ with respect the maximal ideal $\mathfrak{m}_{p}$ is isomorphic to $\mathbf{k}[[z, w]]$. Let $V_{X}(p)$ be the set of valuations $v$ on $A$ centered at $p$. We will denote by $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ the subset of $\mathcal{V}_{X}(p)$ of valuations $v$ such that $v\left(\mathfrak{m}_{p}\right)=1$. The space $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ is an $\mathbf{R}$-tree isomorphic rooted in $\nu_{\mathfrak{m}_{p}}$. We make its structure precise.

Proposition 3.4.5. The $\mathbf{R}$-tree $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ is not complete.

1. If $p \in E$ is a free point then $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ is isomorphic to $\mathcal{V}_{\mathfrak{m}} \backslash\left\{v_{z}\right\}$ where $z$ is a local equation of $E$.
2. If $p=E \cap F$ is a satellite point, then $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ is isomorphic to $\mathcal{V}_{\mathfrak{m}} \backslash\left\{v_{z}, v_{w}\right\}$ where $z, w$ are local coordinates at $p$ with $z$ a local equation of $E$ and $w$ a local equation of $F$.

Proof. If $p \in E$ is a free point, let $z, w$ be local coordinates at $p$ such that $z$ is a local equation of $E$. Then, the completion of the local ring at $p$ is isomorphic to $\mathbf{k}[[z, w]]$ by Theorem 3.1.2. Every $P \in A$ is of the form $P=\frac{\varphi}{z^{a}}$ with $a \geqslant 0$ and $\varphi \in O_{X, p}$. Hence, a centered valuation on $\mathbf{k}[[z, w]]$ defines a valuation over $A$ if and only if it is not the curve valuation $v_{z}$. Hence we have an isomorphism $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right) \simeq \mathcal{V}_{\mathfrak{m}} \backslash\left\{v_{z}\right\}$.

If $p=E \cap F$ is a satellite point, then let $z, w$ be local coordinates at $p$ such that $z$ is a local equation of $E$ and $w$ is a local equation of $F$. Every $P \in A$ is of the form $P=\frac{\varphi}{z^{a} w^{b}}$ where $a, b \geqslant 0$ and $\varphi \in O_{X, p}$. Therefore a centered valuation on $\mathbf{k}[[z, w]]$ defines a valuation over $A$ if and only if it is not the curve valuation $v_{z}$ or $v_{w}$. Hence we have an isomorphism $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right) \rightarrow \mathcal{V}_{\mathfrak{m}} \backslash\left\{v_{z}, v_{w}\right\}$.

### 3.4.3 The relative tree with respect to a curve $z=0$

Let $R=\mathbf{k}[[x, y]]$ and let $\mathfrak{m}$ be the maximal ideal of $R$. Let $z \in \mathfrak{m}$ be irreducible such that $v_{\mathfrak{m}}(z)=1$. One can consider the set $\mathcal{V}_{z}$ of centered valuations on $R$ such that $v(z)=1$; we also add the valuation $\operatorname{ord}_{z}$ to $\mathcal{V}_{z}$ defined by $\operatorname{ord}_{z}(\varphi)=\max \left\{n \geqslant 0: z^{n} \mid \varphi\right\}$. (notice that $\operatorname{ord}_{z}$ is not centered, because for example if $x \neq z, \operatorname{ord}_{z}(x)=0$ ). This is also a tree rooted in $\operatorname{ord}_{z}$ called the
relative tree (see [FJ04] Proposition 3.61) with the order relation $v \leqslant_{z} \mu \Leftrightarrow \forall \varphi \in R, v(\varphi) \leqslant \mu(\varphi)$. We can define the weak topology on $\mathcal{V}_{z}$ being the coarsest topology such that the for all $\varphi \in R$, the evaluation map $v \in V_{z} \mapsto v(\varphi)$ is continuous. There is also the weak topology given by the tree structure of $\mathcal{V}_{z}$.

Proposition 3.4.6 (Relative version of 3.4.4. The weak topology over $\mathcal{V}_{z}$ given by the evaluation maps $v \in \mathcal{V}_{z} \mapsto v(\varphi)$ and the weak topology induced by the tree structure of $\mathcal{V}_{z}$ are the same.

Proposition 3.4.7 ([[]J04] Lemma 3.59). We have an onto map $N_{z}: \mathcal{V}_{0} \rightarrow \mathcal{V}_{z}$ defined by

$$
\begin{aligned}
N_{z}(v) & =v / v(z) \text { if } v \neq v_{z} \\
N_{z}\left(v_{z}\right) & =\operatorname{ord}_{z} .
\end{aligned}
$$

This map restricts to a homeomorphism $N_{z}: \mathcal{V}_{\mathfrak{m}} \rightarrow \mathcal{V}_{z}$ with respect to the weak topology. If $w \in \mathfrak{m}$ is irreducible, then the map $N_{z, w}:=N_{w} \circ N_{w}^{-1}: \mathcal{V}_{z} \rightarrow \mathcal{V}_{w}$ is a homeomorphism for the weak topology.

The tree $\mathcal{V}_{z}$ comes with a skewness function $\alpha_{z}: \mathcal{V}_{z} \rightarrow[0,+\infty]$ and a multiplicity function $m_{z}(\varphi)=v_{z}(\varphi)$. The skewness is defined by

$$
\begin{equation*}
\alpha_{z}(v):=\sup \left\{\left.\frac{v(\psi)}{m_{z}(\psi)} \right\rvert\, \psi \in \mathfrak{m}, \nu_{\psi} \geqslant v\right\} \tag{3.96}
\end{equation*}
$$

Proposition 3.4.8 (Relative version of Proposition 3.4.3). The function $\alpha_{z}: \mathcal{V}_{z} \rightarrow[0,+\infty]$ defines a parametrisation of the tree $\mathcal{V}_{z}$. We have the following properties.

- $\alpha_{z}(v)=0 \Leftrightarrow v=\operatorname{ord}_{z}$.
- Let $\varphi \in \mathfrak{m}$ be irreducible and let $v \in \mathcal{V}_{z}$, then

$$
\begin{equation*}
v(\varphi)=\alpha_{z}\left(v \wedge N\left(v_{\varphi}\right)\right) m_{z}(\varphi) . \tag{3.97}
\end{equation*}
$$

- If v is divisorial or $\mathrm{v}=\operatorname{ord}_{z}$, then $\alpha_{z}(\mathrm{v}) \in \mathbf{Q}$
- If v is irrational, then $\alpha_{z}(\mathrm{v}) \in \mathbf{R} \backslash \mathbf{Q}$.
- If $\mathcal{V}_{z, \text { div }}$ is the subset of $\mathcal{V}_{z}$ consisting of $\operatorname{ord}_{z}$ and divisorial valuations, then $\left(\mathcal{V}_{z, \text { div }}, \alpha_{z}\right)$ is a parametrised $\mathbf{Q}$-tree.

Proposition 3.4.9 ([[FJ04], Proposition 3.65). We have the following relation

$$
\begin{equation*}
\forall v \in \mathcal{V}_{0}, \quad v(z)^{2} \alpha_{z}\left(\frac{v}{v(z)}\right)=\min (v(x), v(y))^{2} \alpha\left(\frac{v}{\min (v(x), v(y))}\right) \tag{3.98}
\end{equation*}
$$

If $w \in \mathfrak{m}$ is another irreducible element with $m(w)=1$, then

$$
\begin{equation*}
\forall v \in \mathcal{V}_{0}, v(z)^{2} \alpha_{z}\left(\frac{v}{v(z)}\right)=v(w)^{2} \alpha_{w}\left(\frac{v}{v(w)}\right) \tag{3.99}
\end{equation*}
$$

Proposition 3.4.10 ([[FJ04], Lemma 3.60 and 6.47). The map $N: \mathcal{V}_{\mathfrak{m}} \rightarrow \mathcal{V}_{z}$ is not an isomerphism of trees. The two orders on $\mathcal{V}_{\mathfrak{m}}$ and $\mathcal{V}_{z}$ are compatible except on the segments $\left[v_{\mathfrak{m}}, v_{z}\right]$ and $\left[\operatorname{ord}_{z}, N\left(v_{\mathfrak{m}}\right)\right]$ where they are reversed. More precisely,

1. $\forall v, \mu \in\left[v_{\mathfrak{m}}, v_{z}\right] \subset \mathcal{V}_{\mathfrak{m}}, v \leqslant_{\mathfrak{m}} \mu \Leftrightarrow N(v) \geqslant_{z} N(\mu)$.
2. $\forall v_{1}, v_{2} \in \mathcal{V}_{z} \backslash\left\{\operatorname{ord}_{z}\right\}, v_{1} \leqslant_{z} v_{2} \Leftrightarrow\left[N^{-1}\left(v_{1}\right), v_{z}\right] \subset\left[N^{-1}\left(v_{2}\right), v_{x}\right]$.

The situation is summed up in Figure 3.1 where we have put arrows on the branches of the tree to indicate the order.

Figure 3.1: The homeomorphism between $\mathcal{V}_{\mathfrak{m}}$ and $\mathcal{V}_{z}$
We will use the relative tree in the following context. Let $E$ be a prime divisor at infinity
of some good completion $X$, let $p$ be a point of $E$ and let $z, w$ be local coordinates at $p$ such that $E=\{z=0\}$. The completion of the local ring at $p$ is isomorphic to $\mathbf{k}[[z, w]]$. We define $\mathcal{V}_{X}(p ; E)$ as follows; an element of $\mathcal{V}_{X}(p ; E)$ is either a valuation $v$ on $A$ centered at $p$ such that $v(z)=1$ or the divisorial valuation $\operatorname{ord}_{E}$. Notice that the definition of $\mathcal{V}_{X}(p ; E)$ does not depend on the local equation $z=0$ of $E$ because the quotient of two local equations is a regular invertible function.

Proposition 3.4.11. Let $X$ be a completion and let $p \in X$ be a closed point at infinity.

1. If $p \in E$ is a free point, then $\mathcal{V}_{X}(p ; E)$ is isomorphic to $\mathcal{V}_{z}$.
2. If $p=E \cap F$ is a satellite point. Let $z, w$ be local coordinates at $p$ such that $z$ is a local equation of $E$ and $w$ a local equation of $F$ then $\mathcal{V}_{X}(p ; E)$ is isomorphic to $\mathcal{V}_{z} \backslash\left\{v_{w}\right\}$ and $\mathcal{V}_{X}(p ; F)$ is isomorphic to $\mathcal{V}_{w} \backslash\left\{v_{z}\right\}$.

The map $N_{z}: \mathcal{V}_{\mathfrak{m}} \rightarrow \mathcal{V}_{z}$ induces a homeomorphism

$$
\begin{equation*}
N_{p, E}: \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right) \rightarrow \mathcal{V}_{X}(p ; E) \backslash\left\{\operatorname{ord}_{E}\right\} \tag{3.100}
\end{equation*}
$$

Furthermore, if $p=E \cap F$, then the map

$$
\begin{equation*}
N_{p, F} \circ N_{p, E}^{-1}: \mathcal{V}_{X}(p ; E) \backslash\left\{\operatorname{ord}_{E}\right\} \rightarrow \mathcal{V}_{X}(p ; F) \backslash\left\{\operatorname{ord}_{F}\right\} \tag{3.101}
\end{equation*}
$$

is a homeomorphism.
Proof. If $p \in E$ is a free point. Let $z, w$ be local coordinates at $p$ such that $z$ is a local equation of $E$. The completion of the local ring at $p$ is isomorphic to $\mathbf{k}[[z, w]]$ by Theorem 3.1.2. For every $P \in A, P$ is of the form $P=\frac{\varphi}{z^{a}}$ where $a \geqslant 0$ and $\varphi \in O_{X, p}$. Therefore, a centered valuation on $\mathbf{k}[[z, w]]$ defines a valuation over $A$ if and only if it is not the curve valuation $v_{z}$. Since $v_{z} \notin \mathcal{V}_{z}$ we have that $\mathcal{V}_{X}(p ; E) \simeq \mathcal{V}_{z}$. Call $\sigma: \mathcal{V}_{X}(p ; E) \rightarrow \mathcal{V}_{z}$ the isomorphism. We define $N_{p, E}$ as follows. Recall by Proposition 3.4.7 that there is a homeomorphism $N: \mathcal{V}_{\mathfrak{m}} \rightarrow \mathcal{V}_{z}$ where in particular $N\left(v_{z}\right)=\operatorname{ord}_{z}$. Here we have that $\operatorname{ord}_{z}$ is canonically identified with $\operatorname{ord}_{E}$ and $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ is isomorphic to $\mathcal{V}_{\mathfrak{m}} \backslash\left\{v_{z}\right\}$, call $\mathfrak{:}: \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right) \rightarrow \mathcal{V}_{\mathfrak{m}} \backslash\left\{v_{z}\right\}$ the isomorphism. Define

$$
\begin{equation*}
N_{p, E}:=\sigma^{-1} \circ N \circ \tau: \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right) \rightarrow \mathcal{V}_{X}(p ; E) \backslash\left\{\operatorname{ord}_{E}\right\} \tag{3.102}
\end{equation*}
$$

it is a homeomorphism.

If $p=E \cap F$ is a satellite point. Let $(z, w)$ be local coordinates at $p$ such that $z$ is a local equation of $E$ and $w$ is a local equation of $F$. The completion of the local ring at $p$ is isomorphic to $\mathbf{k}[[z, w]]$ by Theorem 3.1.2. Every $P \in A$ is of the form $P=\frac{\varphi}{z^{a} w^{b}}$ where $a, b \geqslant 0$ and $\varphi \in O_{X, p}$. Therefore a centered valuation on $\mathbf{k}[[z, w]]$ defines a valuation over $A$ if and only if it is not the curve valuation associated to $z$ or $w$. Or $v_{z}$ does not belong to $\mathcal{V}_{z}$ but $v_{w}$ does. Therefore, $\mathcal{V}_{X}(p ; E)$ is isomorphic to $\mathcal{V}_{z} \backslash\left\{v_{w}\right\}$. If $N_{z}: \mathcal{V}_{\mathfrak{m}} \rightarrow \mathcal{V}_{z}$ is the map from Proposition 3.4.7, then $N\left(v_{z}\right)=\operatorname{ord}_{z}$ and $N\left(v_{w}\right)=v_{w}$. Therefore, $N_{w} \circ N_{z}^{-1}: \mathcal{V}_{z} \rightarrow \mathcal{V}_{w}$ is a homeomorphism that sends ord $\operatorname{org}_{z}$ 帾 and $v_{w}$ to $\operatorname{ord}_{w}$. Fix an isomorphism $\tau_{E}: \mathcal{V}_{X}(p ; E) \rightarrow \mathcal{V}_{z}\left\{v_{w}\right\}$ and $\tau_{F}: \mathcal{V}_{X}(p ; F) \rightarrow \mathcal{V}_{w} \backslash \mathcal{V}_{z}$. We have that the map

$$
\begin{equation*}
N_{p, F} \circ N_{p, E}^{-1}=\tau_{F}^{-1} \circ N_{w} \circ N_{z}^{-1} \circ \tau_{E}: \mathcal{V}_{X}(p ; E) \backslash\left\{\operatorname{ord}_{E}\right\} \rightarrow \mathcal{V}_{X}(p ; F) \backslash\left\{\operatorname{ord}_{F}\right\} \tag{3.103}
\end{equation*}
$$

is a homeomorphism.

Proposition 3.4.12. Let $X$ be a completion of $X_{0}$ and let $E$ be a prime divisor at infinity. If $p_{1}, p_{2} \in E$ are closed points with $p_{1} \neq p_{2}$, then $\mathcal{V}_{X}\left(p_{1} ; E\right) \cap \mathcal{V}_{X}\left(p_{2} ; E\right)=\left\{\operatorname{ord}_{E}\right\}$. Define the set $\mathcal{V}_{X}(E ; E)$ of valuations $v$ such that $c_{X}(v) \in E$ and $v(z)=1$ where $z$ is a local equation of $E$ at $c_{X}(v)$. Then

$$
\begin{equation*}
\mathcal{V}_{X}(E ; E)=\bigcup_{p \in E} \mathcal{V}_{X}(p ; E) \tag{3.104}
\end{equation*}
$$

and it has a natural structure of a rooted $\mathbf{R}$-tree rooted in $\operatorname{ord}_{E}$. The skewness functions $\alpha_{E}$ glue together to give $\mathcal{V}_{X}(E ; E)$ the structure of a parametrized rooted tree. Every point $p \in E$ defines a tangent vector at $\operatorname{ord}_{E}$ given by $\mathcal{V}_{X}(p ; E) \backslash\left\{\operatorname{ord}_{E}\right\}$.

Furthermore, Let $Y$ be a completion of $X_{0}$ and $q \in Y$ a closed point at infinity. Let $\pi: Z \rightarrow Y$ be the blow up of $q$ and let $\widetilde{E}$ be the exceptional divisor of $\pi$. Then, for every $\widetilde{q} \in \widetilde{E}$, the map $\pi_{\bullet}: \mathcal{V}_{Z}(\widetilde{q} ; \widetilde{E}) \rightarrow \mathcal{V}_{Y}\left(q ; \mathfrak{m}_{q}\right)$ is actually equal to $\pi_{*}$ and they glue together to give a map

$$
\begin{equation*}
\pi_{*}: \mathcal{V}_{Z}(\widetilde{E} ; \widetilde{E}) \rightarrow \mathcal{V}_{Y}\left(q ; \mathfrak{m}_{q}\right) \tag{3.105}
\end{equation*}
$$

which is an isomorphism of trees. We have the relation $\alpha_{\mathfrak{m}_{q}} \circ \pi_{*}=1+\alpha_{E}$ and $b_{\mathfrak{m}_{q}} \circ \pi_{*}=b_{E}$.

We postpone the proof to the next section. If $E \simeq \mathbf{P}^{1}$, this tree is isomorphic to the tree of normalized valuations centered at infinity over $\mathbf{A}^{2}$ constructed in [FJ07], Appendix.

### 3.4.4 The monomial valuations centered at an intersection point at infinity

Let $X$ be a good completion of $X_{0}$ and let $E, F$ be two divisors at infinity that intersect at a point $p$. Let $(x, y)$ be local coordinates at $p$ such that $E=\{x=0\}$ and $F=\{y=0\}$. There are three spaces to consider: $\mathcal{V}_{X}\left(p, \mathfrak{m}_{p}\right), \mathcal{V}_{X}(p ; E)$ and $\mathcal{V}_{X}(p ; F)$. We explain here how they are related. For $(s, t) \in[0,+\infty]^{2} \backslash\{(0,0),(\infty, \infty)\}$, we denote by $v_{s, t}$ the monomial valuation defined by

$$
\begin{equation*}
v_{s, t}\left(\sum a_{i j} x^{i} y^{j}\right)=\min \left\{s i+t j \mid a_{i j} \neq 0\right\} \tag{3.106}
\end{equation*}
$$

Notice that $v_{0,1}=\operatorname{ord}_{F}, v_{1,0}=\operatorname{ord}_{E}, v_{1, \infty}=v_{y}, v_{\infty, 1}=v_{x}$. We will denote the set of such valuation by $\left[\operatorname{ord}_{E}, \operatorname{ord}_{F}\right]$. We use this notation because of the following: $\left[\operatorname{ord}_{E}, \operatorname{ord}_{F}\right] \cap V_{X}(p ; E)$ consists of the valuations $\mathrm{v}_{1, t}$ for $t \in[0,+\infty]$ and $\left[\operatorname{ord}_{E}, \operatorname{ord}_{F}\right] \cap \mathcal{V}_{X}(p ; F)$ consists of the valuations $\mathrm{v}_{s, 1}$ for $s \in[0,+\infty]$. So they define segments in the respective trees. In particular we have

$$
\begin{equation*}
N_{p, F} \circ N_{p, E}^{-1}\left(v_{1, t}\right)=v_{1 / t, 1}, \quad \forall t \in[0,+\infty] \tag{3.107}
\end{equation*}
$$

One can show with the definition of the level function $\alpha$ that $\alpha_{E}\left(v_{1, t}\right)=t$. Therefore we show

Lemma 3.4.13. Let $\vee$ be a monomial valuation centered at $p=E \cap F$. One has

$$
\begin{aligned}
& \alpha_{E}\left(\frac{v}{v(x)}\right)=\frac{v(y)}{v(x)}=\frac{s}{t} \text { if } v=v_{s, t} \\
& \alpha_{F}\left(\frac{v}{v(y)}\right)=\frac{v(x)}{v(y)}=\frac{t}{s} \text { if } v=v_{s, t}
\end{aligned}
$$

In particular we have that $\alpha_{E}\left(\frac{v}{v(x)}\right)=\alpha_{F}\left(\frac{v}{v(y)}\right)^{-1}$ on $] \operatorname{ord}_{E}, \operatorname{ord}_{F}[$.

### 3.4.5 Geometric interpretations of the valuative tree

Let $X$ be a completion of $X_{0}$ and let $p \in X$ be a closed point at infinity. We consider in this section only completions above $X$ that are exceptional above $p$. If $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, p)$ is such a completion, then we call $\Gamma_{\pi}$ the dual graph which vertices consist of the exceptional divisors of $\pi$. Two exceptional divisors are linked by an edge if they intersect. The graph $\Gamma_{\pi}$ is connected without cycles, it is therefore an $\mathbf{N}$-tree. We set the root of $\Gamma_{\pi}$ to be the exceptional divisor $\widetilde{E}$ that appears after blowing up $p$.

If $E$ is a prime divisor at infinity of $X$ such that $p \in E$. We define the dual graph

$$
\begin{equation*}
\Gamma_{\pi, E}:=\Gamma_{\pi} \cup\{E\} \tag{3.108}
\end{equation*}
$$

It is also a $\mathbf{N}$-tree. We set the root of $\Gamma_{\pi, E}$ to be $E$.
Lemma 3.4.14 ([|FJ04], Proposition 6.2). Let $\pi: Y \rightarrow(X, p)$ be a completion exceptional above p. if $\tau: Z \rightarrow Y$ is the blow up of a point in the exceptional locus of $\pi$, then there are natural inclusions of $\mathbf{N}$-trees

$$
\begin{equation*}
\Gamma_{\pi} \hookrightarrow \Gamma_{\pi \circ \tau}, \quad \Gamma_{\pi, E} \hookrightarrow \Gamma_{\pi \circ \tau, E} . \tag{3.109}
\end{equation*}
$$

Therefore, the direct limits $\Gamma:=\underset{\longrightarrow}{\lim _{\pi}} \Gamma_{\pi}, \Gamma_{E}:=\underset{\longrightarrow}{\lim _{\pi, E}} \Gamma_{\pi,}$ are well defined. The points of $\Gamma$ are in bijection with $\mathcal{D}_{X, p}$ and $\Gamma_{E}=\Gamma \cup\{E\}$ and they have a structure of $\mathbf{Q}$-trees.

Lemma 3.4.15 ([|FJ04] Theorem 6.9). We have a map $\pi_{\bullet}: \Gamma_{\pi} \hookrightarrow \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)_{\text {div }}$ defined by

$$
\begin{equation*}
\pi_{\bullet}(F)=v_{F} \tag{3.110}
\end{equation*}
$$

where $v_{F}$ is the valuation equivalent to $\pi_{*} \operatorname{ord}_{F}$ that belongs to $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$. These maps are compatible with the direct limit and give a map $\Gamma \hookrightarrow \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$.

Lemma 3.4.16. We have a map $\pi_{\mathbf{\bullet}}: \Gamma_{\pi, E} \hookrightarrow \mathcal{V}_{E, \text { div }}$ defined by

$$
\begin{equation*}
\pi_{\bullet}(F)=v_{F} \tag{3.111}
\end{equation*}
$$

where $\nu_{F}$ is the valuation equivalent to $\pi_{*} \operatorname{ord}_{F}$ that belongs to $\mathcal{V}_{X}(p ; E)$. These maps are compatible with the direct limit and give a map $\Gamma_{E} \hookrightarrow \mathcal{V}_{X}(p ; E)$.

Proposition 3.4.17 ([|FJ04], Lemma 6.28). Let $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, p)$ be a completion exceptional above $p$. Let $q \in Y$ be a closed point that belongs to the exceptional component of $\pi$. Let $\widetilde{F}$ be the exceptional divisor above $q$.

1. If $q \in F$ with $F \in \Gamma_{\pi}$, then $v_{\widetilde{F}}>v_{F}$.
2. If $q=F_{1} \cap F_{2}$ with $F_{1}, F_{2} \in \Gamma_{\pi}$, suppose that $\nu_{F_{1}}<\nu_{F_{2}}$, then $\nu_{F_{1}}<\vee_{\tilde{F}}<\nu_{F_{2}}$.

Proposition 3.4.18 (Relative version of Proposition 3.4.17). Let $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, p)$ be a completion exceptional above $p$. Let $q \in \operatorname{Exc}(\pi)$. Let $\widetilde{F}$ be the exceptional divisor above $q$.

1. If $q \in F$ is a free point with $F \in \Gamma_{\pi, E}$, then $\vee_{\widetilde{F}}>\nu_{F}$.
2. If $q=F_{1} \cap F_{2}$ is a satellite point with $F_{1}, F_{2} \in \Gamma_{\pi, E}$, if $v_{F_{1}}<\nu_{F_{2}}$, then $v_{F_{1}}<v_{\widetilde{F}}<\nu_{F_{2}}$.
3. In particular, if $q=E \cap F$, then $\operatorname{ord}_{E}<\vee_{\tilde{F}}<\mathrm{v}_{F}$.

Theorem 3.4.19 ([[FJ04], Theorem 6.22). We have an isomorphism of $\mathbf{Q}$-trees

$$
\begin{equation*}
\Gamma \simeq \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)_{\mathrm{div}}, \quad \Gamma_{E} \simeq \mathcal{V}_{X}(p ; E)_{\mathrm{div}} \tag{3.112}
\end{equation*}
$$

given by $F \simeq \boldsymbol{v}_{F}$. We can take the completion of the $\mathbf{Q}$-trees to get the isomorphism

$$
\begin{equation*}
\bar{\Gamma} \simeq \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right), \quad \bar{\Gamma}_{E} \simeq \mathcal{V}_{X}(p ; E) \tag{3.113}
\end{equation*}
$$

Proposition 3.4.20. Let $X$ be a completion of $X_{0}$ and let $p \in X$ be a closed point at infinity. Let $\mathcal{V}_{*}$ be either $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ or $\mathcal{V}_{X}(p ; E)$ for some prime divisor $E$ at infinity such that $p \in E$. Let $\Gamma_{*}$ be either $\Gamma$ or $\Gamma_{E}$. Let $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, p)$ be a completion exceptional above $p$. Let $q \in \operatorname{Exc}(\pi)$ be a closed point. The map $\pi$ induces a map $\pi_{*}: \mathcal{V}_{Y}(q) \rightarrow \mathcal{V}_{X}(p)$.

1. If $q \in E_{q}$ is a free point with $E_{q} \in \Gamma_{*}$, then we have an inclusion map $\pi_{\bullet}: \mathcal{V}_{Y}\left(q ; E_{q}\right) \hookrightarrow \mathcal{V}_{*}$. The order relation in $\mathcal{V}_{Y}\left(q ; E_{q}\right)$ and $\mathcal{V}_{*}$ are compatible and $\pi_{0}$ is an inclusion of trees.
2. If $q=E_{q} \cap F_{q}$ is a satellite point with $E_{q}, F_{q} \in \Gamma_{*}$, then, if $\nu_{E_{q}}<_{*} \nu_{F_{q}}$, the order relations on $\mathcal{V}_{*}$ and $\mathcal{V}_{Y}\left(q ; E_{q}\right)$ are compatible and $\pi_{\bullet}: \mathcal{V}_{Y}\left(q ; E_{q}\right) \hookrightarrow \mathcal{V}_{*}$ is an inclusion of trees.

Proof. We only need to show that the orders are compatible on the divisorial valuations of $\mathcal{V}_{Y}\left(q ; E_{q}\right)$. Therefore we show the following,

Claim 3.4.21. For every completion $\tau:(Z, \operatorname{Exc}(\tau)) \rightarrow(Y, q)$ exceptional above $q$, we have the following

1. For all $F_{1}, F_{2} \in \Gamma_{\tau, E_{q}}$,

$$
\begin{equation*}
\nu_{F_{1}}<* v_{F_{2}} \Leftrightarrow v_{F_{1}}<E_{q} \nu_{F_{2}} \tag{3.114}
\end{equation*}
$$

2. If $F \in \Gamma_{\tau, E_{q}}$ satisfies $F \cap F_{q} \neq \varnothing$, then

$$
\begin{equation*}
v_{F}<v_{F_{q}} \tag{3.115}
\end{equation*}
$$

Here there is a slight abuse of notation as we denote by $\nu_{F_{i}}$ the image of $F_{i}$ both in $\mathcal{V}_{Y}\left(q ; E_{q}\right)$ and $\mathcal{V}_{*}$. This is done to lighten notations, we believe that it does not provide any confusion.

We prove this by induction on the number of blow ups above $q$. If $\tau=\mathrm{id}$, then $\operatorname{ord}_{E_{q}}$ is the root of $\mathcal{V}_{Y}\left(q ; E_{q}\right)$ and $v_{E_{q}}<v_{F_{q}}$ by assumption so there is nothing to do.

Let $\tau:(Z, \operatorname{Exc}(\tau)) \rightarrow(Y, q)$ be a completion exceptional above $q$ such that Claim (3.4.21) is true. Let $q^{\prime} \in \operatorname{Exc}(\tau)$ be a closed point, let $\tau^{\prime}: Z^{\prime} \rightarrow Z$ be the blow up of $q^{\prime}$ and let $\widetilde{F}$ be the exceptional divisor above $q^{\prime}$.

- If $q^{\prime} \in F$ is a free point with $F \in \Gamma_{\tau, E_{q}}$, then by Proposition 3.4.18 we have

$$
\begin{equation*}
v_{F}<E_{q} v_{\widetilde{F}} \tag{3.116}
\end{equation*}
$$

Now we have two possibilities.

- If $q^{\prime}$ is also a free point with respect to $\Gamma_{*}$, then by Proposition 3.4.17 and 3.4.18 we also get

$$
\begin{equation*}
v_{F}<_{*} v_{\widetilde{F}} . \tag{3.117}
\end{equation*}
$$

Since $\widetilde{F} \cap F_{q}=\varnothing$, Claim 3.4.21 is shown for $\Gamma_{\tau \circ \tau^{\prime}, E_{q}}$.

- If $q^{\prime}$ is the satellite point $F \cap F_{q}$, then by induction hypothesis we have $\nu_{F}<_{*} \nu_{F_{q}}$ and therefore $\widetilde{F} \cap F_{q} \neq \varnothing$ and by Proposition 3.4.17 and 3.4.18 we get

$$
\begin{equation*}
v_{F}<* v_{\tilde{F}}<* v_{F_{q}} \tag{3.118}
\end{equation*}
$$

So Claim 3.4.21 is shown for $\Gamma_{\tau \circ \tau^{\prime}, E_{q}}$.

- If $q^{\prime}$ is a satellite point. Let $F_{1}, F_{2} \in \Gamma_{\tau, E_{q}}$ such that $q=F_{1} \cap F_{2}$. Suppose without loss of generality that $v_{F_{1}}<_{E_{q}} \nu_{F_{2}}$, then by the induction hypothesis we have $\nu_{F_{1}}<_{*} \nu_{F_{2}}$ and by Proposition 3.4.17 and 3.4.18, we get

$$
\begin{equation*}
v_{F_{1}}<E_{q} v_{\widetilde{F}}<E_{q} v_{F_{2}} \text { and } v_{F_{1}}<_{*} v_{\widetilde{F}}<_{*} v_{F_{2}} . \tag{3.119}
\end{equation*}
$$

Since $\widetilde{F} \cap F_{q}=\varnothing$ we have proven Claim 3.4.21 for $\Gamma_{\text {} \circ \tau^{\prime}, E_{q}}$.

Proof of Proposition 3.4.12 Let $Y$ be a completion of $X_{0}$ and let $q \in Y$ be a closed point at infinity. Let $\pi: Z \rightarrow Y$ be the blow up of $q$. Let $\widetilde{E}$ be the exceptional divisor and let $\widetilde{q} \in \widetilde{E}$ be a closed point. Apply Proposition 3.4 .20 with $\mathcal{V}_{*}=\mathcal{V}_{Y}\left(q ; \mathfrak{m}_{q}\right)$. The map $\pi_{\bullet}: \mathcal{V}_{Z}(\widetilde{q} ; \widetilde{E}) \rightarrow \mathcal{V}_{Y}\left(q ; \mathfrak{m}_{q}\right)$ is an
inclusion of trees. There exists local coordinates $z, w$ at $q$ and $x, y$ at $p$ such that $\pi(z, w)=(z, z w)$ where $z$ is a local equation of $\widetilde{E}$. We therefore get

$$
\begin{equation*}
v(z)=1 \Leftrightarrow \min \left(\pi_{*} v(x), \pi_{*} v(y)\right)=1 \tag{3.120}
\end{equation*}
$$

Hence, $\pi_{\bullet}=\pi_{*}$ and $\pi_{*}\left(\operatorname{ord}_{\tilde{E}}\right)=v_{\mathfrak{m}_{q}}$. Therefore we can glue these maps to obtain an isomorphism of trees

$$
\begin{equation*}
\pi_{*}: \mathcal{V}_{Z}(\widetilde{E} ; \widetilde{E}) \rightarrow \mathcal{V}_{Y}\left(q ; \mathfrak{m}_{q}\right) \tag{3.121}
\end{equation*}
$$

We get the relation on the skewness functions by Proposition 3.4 .28 which will be proven in the next section.

### 3.4.6 Properties of skewness

We have two valuative tree structures. We describe some properties of the skewness function for these two structures and how they behave after blowing up. Fix a completion $X$, let $p \in X$ be a closed point at infinity and let $E$ be a prime divisor at infinity in $X$ such that $p \in E$. In accordance with the notations of the previous section, set $\Gamma=\mathcal{D}_{X, p}$ and $\Gamma_{E}=\mathcal{D}_{X, p} \cup\{E\}$.

Definition 3.4.22. If $F \in \Gamma$ is a prime divisor above $p$, we define the generic multiplicity $b(F)$ inductively as follows.

- $b(\widetilde{E})=1$ where $\widetilde{E}$ is the exceptional divisor above $p$.
- If $q \in F$ is a free point with $F \in \Gamma$, then $b(\widetilde{F})=b(F)$ where $\widetilde{F}$ is the exceptional divisor above $q$.
- If $q=F_{1} \cap F_{2}$ is a satellite point with $F_{1}, F_{2} \in \Gamma$, then $b(\widetilde{F})=b\left(F_{1}\right)+b\left(F_{2}\right)$.

If $v \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ is divisorial then we define $b(v):=b(E)$ where $E$ is the center of $v$ in some completion above $X$.

Definition 3.4.23. If $F \in \Gamma_{E}$, we define the relative generic multiplicity $b_{E}(F)$ inductively as follows.

- $b_{E}(E)=1$.
- If $q \in F$ is a free point with $F \in \Gamma_{E}$, then $b_{E}(\widetilde{F})=b_{E}(F)$.
- If $q=F_{1} \cap F_{2}$ is a satellite point with $F_{1}, F_{2} \in \Gamma_{E}$, then $b_{E}(\widetilde{F})=b_{E}\left(F_{1}\right)+b_{E}\left(F_{2}\right)$.

If $v \in \mathcal{V}_{X}\left(p ; E_{z}\right)$ is divisorial, then we set $b_{E}(v):=b_{E}(F)$ where $F$ is the center of $v$ in some completion above $X$.

Figure 3.2 sums up the definition of the generic multiplicity.

Figure 3.2: Algorithm for computing the generic multiplicity

The term generic multiplicity is justified by the following proposition.
Proposition 3.4.24 ([FJ04] Proposition 6.26). Let $\mathcal{v} \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ be divisorial, let $E \in \Gamma$ be the center of $v$ over some completion $\pi: Y \rightarrow X$ above $X$. Then,

$$
\begin{equation*}
\pi_{*} \operatorname{ord}_{E}\left(\mathfrak{m}_{p}\right)=b(v) \tag{3.122}
\end{equation*}
$$

Proposition 3.4.25 (Relative version of Proposition 3.4.24. If $v \in \mathcal{V}_{X}(p ; E)$ is divisorial, let $F$ be the center of $v$ over some completion $\pi: Y \rightarrow X$ above $X$. Then,

$$
\begin{equation*}
\pi_{*} \operatorname{ord}_{F}(z)=b_{E}(F) \tag{3.123}
\end{equation*}
$$

where $z \in O_{X, p}$ is a local equation of $E$. This means that $\operatorname{ord}_{F}\left(\pi^{*} E\right)=b_{E}(F)$.

From now on we write $\mathcal{V}_{*}$ for either $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ and $\mathcal{V}_{X}(p ; E)$ and we write $\alpha_{*}, b_{*}$ for the skewness function and the generic multiplicity function associated to the tree structure.

For a valuation $v \in \mathcal{V}_{*}$, we define the approximating sequence of $v$ as follows, set $v_{0}=v_{*}$ the root of $\mathcal{V}_{*}$ and let $p_{n}$ be the sequence of centers above $X$ associated to $v$. Let $E_{n}$ be the exceptional divisor above $p_{n}$. Set $v_{n}=\frac{1}{b_{*}\left(E_{n}\right)} \operatorname{ord}_{E_{n}}$, if $v$ is quasimonomial $\left(v_{n}\right)$ is the approximating sequence of $v$. If $v$ is a curve valuation or infinitely singular we define the approximating sequence of $v$ as the subsequence of $v_{n}$ where $c_{X_{n}}(v)$ is a free point (at infinity).

Proposition 3.4.26 ([][504] Theorem 6.9, Theorem 6.10 and Lemma 3.32). Let $\boldsymbol{v} \in \mathcal{V}_{*}$ and let $v_{n}$ be its approximating sequence

- the sequence $v_{n}:=\frac{1}{b_{n}} \operatorname{ord}_{E_{n}}$ converges weakly towards $\nu$.
- $\alpha_{*}(v)=\lim _{n} \alpha_{*}\left(v_{n}\right)$.

We will say that two divisorial valuations $v, v^{\prime}$ are adjacent if there exists a completion $Y$ above $X$ such that the centers of $v$ and $v^{\prime}$ are both prime divisors and they intersect.

Proposition 3.4.27 ([[FJ04], Corollary 6.39). Let $\mathrm{v}, \mathrm{v}^{\prime} \in \mathcal{V}_{*}$. Assume $v<\mathrm{v}^{\prime}$ and that they are adjacent, then

$$
\begin{equation*}
\alpha_{*}\left(v^{\prime}\right)-\alpha_{*}(v)=\frac{1}{b_{*}(v) b_{*}\left(v^{\prime}\right)} \tag{3.124}
\end{equation*}
$$

Proposition 3.4.28 ([FJ04], Theorem 6.51). Let $\pi: Y \rightarrow X$ be a completion above $X$ and let $q \in E_{q}$ be a free point of $Y$ such that $\pi\left(E_{q}\right)=p$. By Proposition 3.4.20, $\pi_{\bullet}: \mathcal{V}_{Y}\left(q ; E_{q}\right) \rightarrow \mathcal{V}_{*}$ is an inclusion of trees.

1. The normalization of $\pi_{*} \operatorname{ord}_{E_{q}}$ (to get a valuation in $\mathcal{V}_{*}$ ) is

$$
\begin{equation*}
v_{E_{q}}=\frac{1}{b_{*}\left(E_{q}\right)} \pi_{*} \operatorname{ord}_{E_{q}} . \tag{3.125}
\end{equation*}
$$

2. 

$$
\begin{array}{ll}
\forall v \in \mathcal{V}_{Y}(p ; E), & \alpha_{*}\left(\pi_{\bullet} v\right)=\alpha_{*}\left(v_{E_{q}}\right)+\frac{1}{b_{*}\left(E_{q}\right)^{2}} \alpha_{E_{q}}(v) \\
& b_{*}\left(\pi_{\bullet} v\right)=b_{*}\left(E_{q}\right) b_{E_{1}}(v) \tag{3.127}
\end{array}
$$

Proof. It suffices to show this formula for every divisorial valuation $v \in \mathcal{V}_{Y}\left(q ; E_{q}\right)$ by Proposition 3.4.26. We prove the result by induction on the number of blow-ups above $q$. Namely we show the following

Claim 3.4.29. For every completion $\tau:(Z, \operatorname{Exc}(\tau)) \rightarrow(Y, q)$ exceptional above q, for every $F \in \Gamma_{\tau, E_{q}}$,

$$
\begin{align*}
b_{*}(F) & =b_{E_{q}}(F) b_{*}\left(E_{q}\right)  \tag{3.128}\\
\alpha_{*}\left(v_{F}\right) & =\alpha_{*}\left(v_{E_{q}}\right)+\frac{1}{b_{*}\left(E_{q}\right)} \alpha_{E_{q}}\left(v_{F}\right) \tag{3.129}
\end{align*}
$$

If $\tau=$ id $: Y \rightarrow Y$, then $\Gamma_{\tau, E_{q}}=\left\{E_{q}\right\}$. We have by definition that $b_{E_{q}}\left(E_{q}\right)=1, \alpha_{E_{q}}\left(\operatorname{ord}_{E_{q}}\right)=0$. Therefore Equations (3.128) and 3.129 holds.

Suppose the claim to be true for a completion $\tau:(Z, \operatorname{Exc}(\tau)) \rightarrow(Y, q)$ exceptional above $q$. Let $\tau^{\prime}: Z^{\prime} \rightarrow Z$ be the blow up of a closed point $q^{\prime} \in \operatorname{Exc}(\tau)$. Let $\widetilde{E}$ be the exceptional divisor above $q^{\prime}$.

If $q^{\prime} \in F$ is a free point with $F \in \Gamma_{\tau, E}$, then $q^{\prime}$ is also a free point with respect to $\Gamma_{*, \pi \circ \tau}$ because $q \in Y$ is a free point. Therefore by definition

$$
\begin{equation*}
b_{*}(\widetilde{E})=b_{*}(F), \quad b_{E_{q}}(\widetilde{E})=b_{E_{q}}(F) \tag{3.130}
\end{equation*}
$$

So Equation (3.128) is true for $\widetilde{E}$ by induction. Now, by Proposition 3.4.27

$$
\begin{equation*}
\alpha_{*}\left(v_{\widetilde{E}}\right)=\alpha_{*}\left(v_{F}\right)+\frac{1}{b_{*}(F) b_{*}\left(E_{q}\right)}, \quad \alpha_{E_{q}}\left(v_{\widetilde{E}}\right)=\alpha_{E_{q}}\left(v_{F}\right)+\frac{1}{b_{E_{q}}(\widetilde{E}) b_{E_{q}}(F)} \tag{3.131}
\end{equation*}
$$

By induction, Equation (3.129) is true for $\widetilde{E}$.
If $q^{\prime}=F_{1} \cap F_{2}$ is a satellite point with $F_{1}, F_{2} \in \Gamma_{\tau, E_{q}}$, then

$$
\begin{equation*}
b_{*}(\widetilde{E})=b_{*}\left(F_{1}\right)+b_{*}\left(F_{2}\right), \quad b_{E_{q}}(\widetilde{E})=b_{E_{q}}\left(F_{1}\right)+b_{E_{q}}\left(F_{2}\right) \tag{3.132}
\end{equation*}
$$

So by induction Equation (3.128) holds for $\widetilde{E}$. Suppose without loss of generality that $v_{F_{1}}<v_{F_{2}}$ both in $\mathcal{V}_{*}$ and $\mathcal{V}_{Y}\left(q ; E_{q}\right)$. This is possible by Proposition 3.4.20. By Proposition 3.4.27

$$
\begin{equation*}
\alpha_{*}\left(v_{\widetilde{E}}\right)=\alpha_{*}\left(v_{F_{1}}\right)+\frac{1}{b_{*}\left(F_{1}\right) b_{*}(\widetilde{E})}, \quad \alpha_{E_{q}}\left(v_{\widetilde{E}}\right)=\alpha_{E_{q}}\left(v_{F_{1}}\right)+\frac{1}{b_{E_{q}}\left(F_{1}\right) b_{E_{q}}(\widetilde{E})} . \tag{3.133}
\end{equation*}
$$

Therefore, Equation (3.129) holds for $\widetilde{E}$. And the claim is shown by induction.
Proposition 3.4.30. Let $v$ be a valuation over $A$ centered at infinity. Let $X$ be a completion of $X_{0}$ and let $E$ be a prime divisor of $X$ at infinity such that $\widetilde{v} \in \mathcal{V}_{X}(E ; E)$ for some valuation $\widetilde{v}$ equivalent to $v$. If $\alpha_{E}(\widetilde{v})<+\infty$, then for every completion $Y$ of $X_{0}$ if $\widetilde{v} \in \mathcal{V}_{Y}(F, F)$ for some
prime divisor $F$ at infinity in $Y$, then $\alpha_{F}(\widetilde{v})<+\infty$.
Proof. If $v$ is quasimonomial, this is immediate as for any prime divisor $E$ at infinity and any closed point $p \in E$, we have that $\alpha_{E}(v)<+\infty$ for $v=\operatorname{ord}_{E}$ or $v$ quasimonomial centered at $p$. If $v$ is a curve valuation, then $\alpha_{E}(v)=+\infty$ for any prime divisor $E$ of any completion $X$ such that $c_{X}(v) \in E$. So it remains to show the result for $v$ an infinitely singular valuation.

We show that if $\pi: Y \rightarrow X$ is a completion above $X$, then $\alpha_{E^{\prime}}(v)<+\infty \Leftrightarrow \alpha_{E}(v)<+\infty$ where $E^{\prime}$ is a prime divisor of $Y$ at infinity such that some multiple of $v$ belongs to $\mathcal{V}_{Y}\left(E^{\prime}, E^{\prime}\right)$. Let $p=c_{X}(v)$ and $q=c_{Y}(v)$. Since $v$ is infinitely singular, by Proposition 3.3.16 there exists a completion $\tau:(Z, \operatorname{Exc}(\tau)) \rightarrow(Y, q)$ exceptional above $q$ such that $c_{Z}(v)$ is a free point $q^{\prime}$ lying over a unique prime divisor $F$ at infinity. We apply Proposition 3.4.28. We have that

$$
\begin{align*}
\alpha_{E}(v) & =\alpha_{E}\left(v_{F}\right)+\frac{1}{b_{E}(F)^{2}} \alpha_{F}(v)  \tag{3.134}\\
\alpha_{E^{\prime}}(v) & =\alpha_{E^{\prime}}\left(v_{F}\right)+\frac{1}{b_{E^{\prime}}(F)^{2}} \alpha_{F}(v) \tag{3.135}
\end{align*}
$$

Thus $\alpha_{E}(v)<+\infty \Leftrightarrow \alpha_{F}(v)<+\infty \Leftrightarrow \alpha_{E^{\prime}}(v)<+\infty$.
Proposition 3.4.31 ([]J04] Proposition 6.35). Let $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, p)$ be a completion exceptional above $p$. Let $q=E \cap F \in \operatorname{Exc}(\pi)$ be a satellite point with $E, F \in \Gamma_{*, \pi}$. Define $\nu_{E}=\frac{1}{b_{*}(E)} \pi_{*} \operatorname{ord}_{E}$ and $v_{F}=\frac{1}{b_{*}(F)} \pi_{*} \operatorname{ord}_{F}$. Let $z, w$ be local coordinates at $q$ associated to $(E, F)$. Let $v_{s, t}$ be the monomial valuation centered at $q$ such that $v(z)=s$ and $v(w)=t$. Then, the map $\pi_{*}$ induces a homeomorphism from the set $\left\{\mathrm{v}_{s, t} \mid s, t \geqslant 0, s b_{*}(E)+t b_{*}(F)=1\right\}$ and $\left[v_{E}, \nu_{F}\right] \subset \mathcal{V}_{*}$ for the weak topology.

Furthermore, the skewness function is given by

$$
\begin{equation*}
\alpha_{*}\left(\pi_{*} v_{s, t}\right)=\alpha\left(v_{E}\right)+\frac{t}{b(E)} \tag{3.136}
\end{equation*}
$$

### 3.5 Different topologies over the space of valuations

### 3.5.1 The weak topology

Let $X_{0}$ be an affine surface and let $\mathcal{V}_{\infty}$ be the space of valuations centered at infinity. We define $\widehat{\mathcal{V}_{\infty}}$ to be the space of valuations centered at infinity modulo equivalence and $\eta: \mathcal{V}_{\infty} \rightarrow \widehat{\mathcal{V}_{\infty}}$ the quotient map. We define the weak topology over $\mathcal{V}_{\infty}$ as follows. A basis for the topology is given by

$$
\begin{equation*}
\left\{v \in \mathcal{V}_{\infty}: t<v(P)<t^{\prime}\right\} \tag{3.137}
\end{equation*}
$$

for some $t, t^{\prime} \in \mathbf{R}, P \in A$. A sequence $v_{n}$ of $\mathcal{V}_{\infty}$ converges towards $v$ if and only if for every $P \in A$, the sequence $v_{n}(P)$ converges towards $v(P)$. We define the weak topology over $\widehat{\mathcal{V}_{\infty}}$ to be the thinnest topology such that $\eta: \mathcal{V}_{\infty} \rightarrow \widehat{\mathcal{V}_{\infty}}$ is continuous with respect to the weak topology.

Proposition 3.5.1. Let $X$ be a completion of $X_{0}$. Let $v \in \mathcal{V}_{\infty}$ and $\left(v_{n}\right)$ a sequence of elements of $\mathcal{V}_{\infty}$. Suppose that $\mathrm{v}_{n} \rightarrow \mathrm{v}$ with respect to the weak topology. Then,

- If $c_{X}(v)=p$ is a closed point at infinity, then for all $n$ large enough $c_{X}\left(v_{n}\right)=p$.
- If $c_{X}(v)=E$ is a prime divisor at infinity, then for all $n$ large enough $c_{X}\left(v_{n}\right) \in E$.

Proof. Suppose first that $c_{X}(v)=p$ is a closed point at infinity. Let $(x, y)$ be local coordinates at $p$. By definition of the center we have $v(x), v(y)>0$. We can find $P_{1}, P_{2}, Q_{1}, Q_{2} \in O_{X}\left(X_{0}\right)$ such that $x=P_{1} / Q_{1}, y=P_{2} / Q_{2}$ and such that $v\left(Q_{1}\right), \mathrm{v}\left(Q_{2}\right) \neq \infty$. Indeed by Lemma 3.3.11, $O_{X, p}$ is a subring of $O_{X}\left(X_{0}\right)_{\mathfrak{p}_{v}}$ where $\mathfrak{p}_{v}=\{v=+\infty\}$. Now, we have that $v_{n}\left(P_{i}\right) \rightarrow v\left(P_{i}\right)$ and $v_{n}\left(Q_{i}\right) \rightarrow v\left(Q_{i}\right)$ as $n \rightarrow \infty$, therefore for all n large enough

$$
\begin{equation*}
v_{n}(x), v_{n}(y)>0 . \tag{3.138}
\end{equation*}
$$

Thus, for all $n$ large enough $c_{X}\left(v_{n}\right)=p$.
If $c_{X}(v)=E$, then $v=\lambda \operatorname{ord}_{E}$ for some $\lambda>0$. Let $U$ be an open affine subset of $X$ such that $U \cap E \neq \varnothing$. Let $z$ be a local equation of $E$ over $U$. Similarly, we can write $z=P / Q$ with $v(Q) \neq \infty$. Since $v_{n}(P) \rightarrow v(Q)$ and $v_{n}(Q) \rightarrow v(Q)$, we get that $v_{n}(z) \rightarrow v(z)>0$. Therefore for $n$ large enough, $v_{n}(z)>0$ and therefore $c_{X}\left(v_{n}\right) \in E$.

Proposition 3.5.2. Let $X$ be a completion and let $p \in X$ be a closed point at infinity. Let $v \in \mathcal{V}_{X}(p)$ and $v_{n} \in \mathcal{V}_{X}(p)$. Then, $v_{n} \rightarrow v$ weakly if and only iffor every $\varphi \in O_{X, p}, v_{n}(\varphi) \rightarrow v(\varphi)$.

Proof. Indeed, every $\varphi \in O_{X, p}$ can be written as $\varphi=\frac{P}{Q}$ with $v(Q) \neq \infty$. This shows one implication. Conversely, every $P \in A$ is of the form $\frac{\varphi}{\psi}$ where $\varphi, \psi \in O_{X, p}$. Furthermore, if $p \in E$ is a free point then $\psi=u^{a}$ where $a \in \mathbf{Z}_{\geqslant 0}$ and $u$ is a local equation of $E$. If $p=E \cap F$ is a satellite point, then $\psi=u^{a} v^{b}$ where $u v$ is a local equation of $E \cup F$. Now since $v_{n}$ and $v$ are valuations over $A$, they cannot be the curve valuations associated to a prime divisor at infinity. Therefore, for all $n, v_{n}(\psi) \neq \infty$ and $v(\psi) \neq \infty$. This shows the other implication.

Proposition 3.5.3. Let $X$ be a completion of $X_{0}$ and let $p \in X$ be a closed point. Let $E$ be a prime divisor at infinity in $X$ such that $p \in X$. Let $\eta_{p}: \mathcal{V}_{X}(p) \rightarrow \mathcal{V}_{X}(p ; E)$ be the natural map defined by $\eta_{p}(v)=\frac{v}{v(z)}$ where $z \in O_{X, p}$ is a local equation of $E$. Let $\left(v_{n}\right)$ be a sequence of $\mathcal{V}_{X}(p)$ and let $v \in \mathcal{V}_{X}(p)$. If $v_{n} \rightarrow v$ for the weak topology of $\mathcal{V}_{\infty}$, then $\eta_{p}\left(v_{n}\right) \rightarrow \eta_{p}(v)$ for the weak topology of $\mathcal{V}_{X}(p ; E)$.

Proof. If $v_{n} \rightarrow v$ for the weak topology, then, $v_{n}(z) \rightarrow v(z)$ by Proposition 3.5.2. Therefore $\eta_{p}\left(v_{n}\right) \rightarrow \eta_{p}(v)$, again by Proposition 3.5.2. This shows the first implication.
Theorem 3.5.4. Let $X$ be a completion of $X_{0}$. The weak topology on $\widehat{\mathcal{V}_{\infty}}$ is the topology induced by the open subsets $\mathcal{V}_{X}(E ; E)$ for all prime divisor $E$ at infinity.

Proof. Let $X$ be a completion at infinity and let $E$ be a prime divisor at infinity. Let $\mathcal{V}_{X}(E)$ be the set of valuations $v$ over $A$ such that $c_{X}(v) \in E$ (this includes $c_{X}(v)=E$, i.e $v=\operatorname{ord}_{E}$ ). We have that

$$
\begin{equation*}
\mathcal{V}_{X}(E)=\left\{\operatorname{ord}_{E}\right\} \cup \bigcup_{p \in E} \mathcal{V}_{X}(p) . \tag{3.139}
\end{equation*}
$$

Let $U_{1}, \cdots, U_{r}$ be a finite open affine cover of $E$ such that for every $i=1, \cdots, r$ there exists $z_{i} \in O_{X}\left(U_{i}\right)$ a local equation of $E$. Then, every $z_{i}$ is of the form $z_{i}=P_{i} / Q_{i}$ with $P_{i}, Q_{i} \in A$. Then,

$$
\begin{equation*}
\mathcal{V}_{X}(E)=\bigcup_{i}\left\{v\left(Q_{i}\right)<+\infty, v\left(P_{i}\right)-v\left(Q_{i}\right)>0\right\} \tag{3.140}
\end{equation*}
$$

and, it follows that $\mathcal{V}_{X}(E)$ is an open subset of $\mathcal{V}_{\infty}$. Set $\widehat{\mathcal{V}_{\infty}}(p):=\eta\left(\mathcal{V}_{X}(p)\right)$. Define a map $\sigma_{p}: \widehat{\mathcal{V}_{\infty}}(p) \rightarrow \mathcal{V}_{X}(p ; E) \backslash\left\{\operatorname{ord}_{E}\right\} \subset \mathcal{V}_{X}(p)$ by

$$
\begin{equation*}
\sigma_{p}([v])=\eta_{p}(v) \tag{3.141}
\end{equation*}
$$

where $\eta_{p}$ is the map from Proposition 3.5 .3 and $[v]$ is the class of $v$ in $\widehat{\mathcal{V}_{\infty}}$. By Proposition 3.5.3. $\sigma_{p}$ is a continuous section of $\eta_{\mid \mathcal{V}_{X}(p)}: \mathcal{V}_{X}(p) \rightarrow \widehat{\mathcal{V}_{\infty}}(p)$. Still by Proposition 3.5.3, the map $\sigma_{p}:\left[\operatorname{ord}_{E}\right] \cup \widehat{\mathcal{V}_{\infty}}(p) \rightarrow \mathcal{V}_{X}(p ; E)$ extended by $\sigma_{p}\left(\left[\operatorname{ord}_{E}\right]\right)=\operatorname{ord}_{E}$ is also a continuous
section of $\eta:\left\{\lambda \operatorname{ord}_{E}: \lambda>0\right\} \cup \mathcal{V}_{X}(p) \rightarrow\left\{\left[\operatorname{ord}_{E}\right]\right\} \cup \widehat{\mathcal{V}_{\infty}}(p)$. These maps $\sigma_{p}$ glue together to give a continuous section $\sigma_{E}: \widehat{\mathcal{V}_{\infty}}(E) \rightarrow \mathcal{V}_{X}(E ; E) \subset \mathcal{V}_{X}(E)$ of $\eta: \mathcal{V}_{X}(E) \rightarrow \widehat{\mathcal{V}_{\infty}}(E)$.

To finish the proof we need to understand the behaviour of $\sigma_{F}, \sigma_{E}$ on

$$
\begin{equation*}
\widehat{\mathcal{V}_{\infty}}(E) \cap \widehat{\mathcal{V}_{\infty}}(F)=\widehat{\mathcal{V}_{\infty}}(p) \tag{3.142}
\end{equation*}
$$

for $p=E \cap F$ where $E, F$ are two prime divisors at infinity. By Proposition 3.4.11, we have that the map $N_{p, F} \circ N_{p, E}^{-1}: \mathcal{V}_{X}(p ; E) \backslash\left\{\operatorname{ord}_{E}\right\} \rightarrow \mathcal{V}_{X}(p ; F) \backslash\left\{\operatorname{ord}_{F}\right\}$ is a homeomorphism and we have

$$
\begin{equation*}
\left(\sigma_{F}\right)_{\mid \widehat{\mathcal{V}_{\infty}}(p)}=\left(N_{p, F} \circ N_{p, E}^{-1}\right) \circ\left(\sigma_{E}\right)_{\mid \widehat{\mathcal{V}_{\infty}}(p)} \tag{3.143}
\end{equation*}
$$

### 3.5.2 The strong topology

Let $R=\mathbf{k}[[x, y]]$ and let $\mathfrak{m}=(x, y)$. Let $\mathcal{V}_{*}$ be the valuative tree with either the normalization by $\mathfrak{m}$ or with respect to a curve $z$. We will write $\alpha_{*}$ for the skewness function over $\mathcal{V}_{*}$. We consider a stronger topology on $\mathcal{V}_{*}$. Let $\mathcal{V}_{*}^{q m}$ be the subset of quasimonomial valuations. We define the following distance

$$
\begin{equation*}
d\left(v_{1}, v_{2}\right)=\alpha\left(v_{1}\right)-\alpha\left(v_{1} \wedge v_{2}\right)+\alpha\left(v_{2}\right)-\alpha\left(v_{1} \wedge v_{2}\right) . \tag{3.144}
\end{equation*}
$$

The topology induced by this distance is called the strong topology.
Proposition 3.5.5 ([[FJ04] Proposition 5.12). We have the following

- The strong topology is stronger than the weak topology.
- The closure of $\mathcal{V}_{*}^{q m}$ with respect to the strong topology is the subspace of $\mathcal{V}_{*}$ consisting of valuations of finite skewness.

Proposition 3.5.6. Let $R=\mathbf{k}[[z, w]]$ and let $\mathcal{V}_{\mathfrak{m}}, \mathcal{V}_{z}, \mathcal{V}_{w}$ be the three valuation trees. Let $\mathcal{V}_{\mathfrak{m}}^{\prime}, \mathcal{V}_{z}^{\prime}, \mathcal{V}_{w}^{\prime}$ be the three subtrees of valuations of finite skewness. Then, the maps

$$
\begin{equation*}
N_{z}: \mathcal{V}_{\mathfrak{m}}^{\prime} \rightarrow \mathcal{V}_{z}^{\prime} \backslash\left\{\operatorname{ord}_{z}\right\}, \quad N_{w} \circ N_{z}^{-1}: \mathcal{V}_{z}^{\prime} \rightarrow \mathcal{V}_{w}^{\prime} \tag{3.145}
\end{equation*}
$$

are homeomorphisms with respect to the strong topology.

This follows from Proposition 3.4.9.
Let $\mathcal{V}_{\infty}^{\prime \prime}$ be the subset of $\mathcal{V}_{\infty}$ of valuations of finite skewness, this set is well defined thanks to Proposition 3.4.30. We define the strong topology on $\mathcal{V}_{\infty}^{\prime}$ as follows. First define the strong topology on $\widehat{\mathcal{V}}_{\infty}^{\prime}:=\eta\left(\mathcal{V}_{\infty}^{\prime}\right)$ using the notations from the proof of Theorem 3.5.4 Consider the map $\sigma_{E}: \widehat{\mathcal{V}}_{\infty}^{\prime} \cap \widehat{\mathcal{V}_{\infty}}(E) \rightarrow \mathcal{V}_{X}(E ; E)^{\prime}$. We define the strong topology on $\widehat{\mathcal{V}}_{\infty}^{\prime} \cap \widehat{\mathcal{V}}_{\infty}(E)$ as the coarsest topology such that $\sigma_{E}$ is continuous for the strong topology on $\mathcal{V}_{X}(E ; E)^{\prime}$. This defines a topology on $\widehat{\mathcal{V}}_{\infty}{ }^{\prime}$ thanks to Proposition 3.5.6.

Corollary 3.5.7. Let $v$ be a valuation centered at infinity, let $X$ be a completion of $X_{0}$ and let $\left(v_{n}\right)$ be the approximating sequence of $v$ from Proposition 3.4.26 If $v \in \mathcal{V}_{\infty}^{\prime}$, then $\eta\left(v_{n}\right)$ converges towards $\eta(v)$ with respect to the strong topology.

Proof. Let $p=c_{X}(v)$ and we can suppose that $v_{n}, v \in \mathcal{V}_{X}(p ; E)$ for some prime divisor $E$ at infinity with $p \in E$. Then, we have $v_{n} \leqslant v$ for all $n$ and $\alpha\left(v_{n}\right) \rightarrow \alpha(v)$. Therefore

$$
\begin{equation*}
d\left(v_{n}, v\right)=\alpha(v)-\alpha\left(v_{n}\right) \xrightarrow[n \rightarrow \infty]{\longrightarrow} 0 \tag{3.146}
\end{equation*}
$$

### 3.6 Valuations as Linear forms

As done in [JM12], we can view valuations on $X_{0}$ as

- linear forms with values in $\mathbf{R}$ over the space of integral Cartier Divisors over $X$ supported at infinity
- as real-valued functions over the set of coherent fractional ideal sheaves of $X$ co-supported at infinity.

We recall how to do so. For a divisor $D$, we denote by $H^{0}\left(X, O_{X}(D)\right)$ the set of global sections of the line bundle $O_{X}(D)$ and

$$
\begin{equation*}
\Gamma\left(X, O_{X}(D)\right)=\left\{h \in \mathbf{k}(X)^{\times}: D+\operatorname{div}(h) \geqslant 0\right\} . \tag{3.147}
\end{equation*}
$$

### 3.6.1 Valuations as linear forms over $\operatorname{Div}_{\infty}(X)$

Lemma 3.6.1. Let $D \in \operatorname{Div}(X)$ such that the negative part (if any) of $D$ is supported in $\partial_{X} X_{0}$. For any point $p \in X$, there exists an open neighbourhood $U$ of $p$ such that a local equation of $D$ on $U$ is of the form $\varphi=P \cdot \psi$ with $P \in O_{X}\left(X_{0}\right)$ and $\psi \in O_{X}(U)$.

Proof. Let $\varphi \in \mathbf{k}\left(U^{\prime}\right)^{*}=\mathbf{k}(X)^{*}$ be a local equation of $D$ where $U^{\prime}$ is an open subset of $X$ containing $p$.

Let $H$ be an effective divisor such that the linear system $|H|$ is base point free and such that $\operatorname{Supp}(H)=\partial_{X} X_{0}$. There exists an integer $n \geqslant 1$ such that $D+n H \geqslant 0$. Pick $P$ general in $\Gamma\left(X, O_{X}(n H)\right) \subset O_{X}\left(X_{0}\right)$, then $\operatorname{div} P=Z_{P}-n H$ with $Z_{P} \geqslant 0$ and $p \notin \operatorname{Supp} Z_{P}$ because we chose $P$ general and $|n H|$ is basepoint free, in particular $P$ restricts to a regular function over $X_{0}$. Set $\psi:=\varphi / P$, one has

$$
\begin{equation*}
\operatorname{div}\left(\Psi_{\mid U}\right)=D_{\mid U}+n H_{\mid U}-Z_{P \mid U} . \tag{3.148}
\end{equation*}
$$

Set $U=U^{\prime} \backslash \operatorname{Supp} Z_{P}$, then $\operatorname{div}(\psi)_{\mid U^{\prime}} \geqslant 0$, i.e $\psi \in O_{X}(U)$ and we are done.
Corollary 3.6.2. If $D$ is a divisor such that the negative part (if any) of $D$ is at infinity and $v$ is a valuation on $A$, then for all small enough affine open subsets $U \subset X$ containing $c_{X}(v)$,

$$
\begin{equation*}
\Gamma\left(U, O_{X}(-D)\right) \subset O_{X}\left(X_{0}\right)_{\mathfrak{p}_{V_{X}}} \tag{3.149}
\end{equation*}
$$

and $v_{X}$ can be extended to $\Gamma\left(U, O_{X}(-D)\right)$.

Proof. If $U$ is small enough, then $\Gamma\left(U, O_{X}(-D)\right)$ is the $O_{X}(U)$-module generated by $\varphi$ where $\varphi$ is a local equation of $D$. Now, by Lemma 3.6.1, $\varphi$ is of the form $\varphi=P \cdot \psi$ where $P \in O_{X}\left(X_{0}\right)$ and $\psi \in O_{X}(U)$. By definition we have $O_{X}\left(X_{0}\right) \subset O_{X}\left(X_{0}\right)_{\mathfrak{p}_{X}}$ and for all affine open neighbourhood $U$ of $c_{X}(v), O_{X}(U) \subset O_{X}\left(X_{0}\right)_{\mathfrak{p}_{w_{X}}}$ by the proof of Lemma 3.3.11.

Let $D$ be divisor of $X$ supported at infinity and let $\varphi \in \mathbf{k}(X)$ be a local equation of $D$ at $c_{X}(v)$. Then we set

$$
\begin{equation*}
L_{v, X}(D):=v_{X}(\varphi) . \tag{3.150}
\end{equation*}
$$

This is well defined because by Corollary 3.6.2 because by definition there exists an open affine neighbourhood $U$ of $c_{X}(v)$ such that $\varphi \in \Gamma\left(U, O_{X}(-D)\right)$. This does not depend on the choice of the local equation because if $\psi$ is another local equation of $D$, then $\frac{\varphi}{\psi}$ is a regular invertible function near $c_{X}(v)$ and $v_{X}(\varphi / \psi)=0$.

Lemma 3.6.3. Let $\vee$ be a valuation over $A$ and let $X$ be a completion of $X_{0}$, then for all $D \in \operatorname{Div}_{\infty}(X)_{\mathbf{R}}, L_{v, X}(D)<\infty$.

Proof. It suffices to show Lemma 3.6 .3 for $D$ an integral divisor supported at infinity in $X$. We can apply corollary 3.6 .2 to $D$ and $-D$, therefore if $\varphi$ is a local equation of $D$, we have that both $\mathrm{t}_{X}^{*}(\varphi)$ and $\mathrm{t}_{X}^{*}(1 / \varphi)$ belong to $A_{\mathfrak{p}_{\mathrm{v}}}$ and this means that $\nu_{X}(\varphi)<\infty$.

Remark 3.6.4. We can in fact define $L_{v, X}$ at any divisor $D$ on $X$ such that the negative part of $D$ is supported at infinity but it could happen that $L_{v, X}(D)$ is infinite. For example, let $X_{0}=\mathbf{A}^{2}, X=\mathbf{P}^{2}$. Let $v$ be the curve valuation centered at $[1: 0: 0]$ associated to the curve $y=0$, then

$$
\begin{equation*}
L_{v, \mathbf{P}^{2}}(\{Y=0\}-\{Z=0\})=v(Y / Z)=+\infty . \tag{3.151}
\end{equation*}
$$

Example 3.6.5. If $X$ is a completion of $X_{0}$, let $E$ be a prime divisor at infinity. Let $D \in \operatorname{Div}_{\infty}(X)$. Recall that we have defined in Section 3.2 .1 that $\operatorname{ord}_{E}(D)$ is the weight of $D$ along $E$, then

$$
\begin{equation*}
L_{\text {ord }_{E}}(D)=\operatorname{ord}_{E}(D) \tag{3.152}
\end{equation*}
$$

Indeed, at the generic point of $E$, a local equation of $D$ is $z^{\operatorname{ord}_{E}(D)} \varphi$ where $z$ is a local equation of $E$ and $\varphi$ is regular not divisible by $z$.

Proposition 3.6.6. If $\vee$ is a valuation over $A$, and $X$ is a completion of $X_{0}$ then

1. $L_{v, X}\left(0_{\operatorname{Div}_{\infty}(X)}\right)=0$.
2. For any $D, D^{\prime} \in \operatorname{Div}_{\infty}(X), L_{v, X}\left(D+D^{\prime}\right)=L_{v, X}(D)+L_{v, X}\left(D^{\prime}\right)$, and $L_{v, X}(m D)=m L_{v, X}(D)$ for all $m \in \mathbf{Z}$.
3. If $D \geqslant 0$, then $L_{v, X}(D) \geqslant 0$ and $L_{v, X}(D)>0 \Leftrightarrow c_{X}(v) \in \operatorname{Supp} D$. In particular, if $v$ is not centered at infinity then $L_{v}=0$.
4. If $P \in O_{X}\left(X_{0}\right)$, then $v_{X}(P)=L_{v, X}(\operatorname{div} P)$.
5. If $Y$ is another completion of $X_{0}$ above $X$, and $\pi: Y \rightarrow X$ is the morphism of completions over $X_{0}$, then $L_{v, X}(D)=L_{v, Y}\left(\pi^{*} D\right)$.

Thus, we can extend $L_{v, X}$ to $\operatorname{Div}_{\infty}(X)_{\mathbf{R}}$ by linearity:

$$
\begin{equation*}
L_{v, X}: \operatorname{Div}_{\infty}(X)_{\mathbf{R}} \rightarrow \mathbf{R} . \tag{3.153}
\end{equation*}
$$

Proof. The first assertion is trivial as 1 is a local equation of the trivial divisor. The second assertion follows from the fact that if $\varphi, \psi$ are local equations of $D$ and $D^{\prime}$ respectively, then $\varphi \psi$ is a local equation of $D+D^{\prime}$ and $1 / \varphi$ is a local equation of $-D$. For the third one, suppose $D$ is an integral divisor. If $D$ is effective and $f$ is a local equation at $c_{X}(v)$, then $f$ is regular at $p$ and by definition of the center $v(f) \geqslant 0$, now if $c_{X}(v)$ belongs to $\operatorname{Supp} D$, then $f$ vanishes at $c_{X}(v)$; thus, $v(f)>0$. If on the other hand $c_{X}(v) \notin \operatorname{Supp} D$, then $f$ is invertible at the center of $v_{X}$ and $v_{X}(f)=0$. The fourth assertion follows from $f$ being a local equation of $\operatorname{div}(f)$ and the fact that $f$ has no pole over $X_{0}$. Finally, if $f \in \mathbf{k}(X)$ is a local equation of $D$ at $c_{X}(v)$, then $\pi^{*} f$ is a local equation of $\pi^{*} D$ at $c_{Y}(v)$ and by Remark 3.3.3, one has $v_{X}(f)=v_{Y}\left(\pi^{*} f\right)$.

Proposition 3.6.7. Let $f: X_{0} \rightarrow X_{0}$ be a dominant endomorphism of $X_{0}$. Let $Y, X$ be two completions of $X_{0}$ such that the lift $F: Y \rightarrow X$ of $f$ is regular. Then,

$$
\begin{equation*}
F\left(c_{Y}(v)\right)=c_{X}\left(f_{*} v\right) \text { and } \forall D \in \operatorname{Div}_{\infty}(X), L_{f_{*}, X}(D)=L_{v, Y}\left(F^{*} D\right) \tag{3.154}
\end{equation*}
$$

Proof. Let $p=c_{Y}(v)$ and $q=c_{X}\left(f_{*} v\right)$. Then, $F$ induces a local ring homomorphism

$$
F^{*}: O_{X, q} \rightarrow O_{Y, p}
$$

Now, for any $\varphi \in O_{X, q}$, there exists $P, Q \in A$ such that $\varphi=\frac{P}{Q}$. Therefore,

$$
F^{*} \varphi=\frac{f^{*} P}{f^{*} Q}
$$

and therefore $f_{*} v(\varphi)=v\left(F^{*} \varphi\right)>0$. Therefore, $q=c_{X}\left(f_{*} \nu\right)$.
Now, to show the second result. If $g$ is a local equation of $D$ at the center of $v_{X}$, then $F^{*} g$ is a local equation of $F^{*} D$ at the center of $\nu_{Y}$. Since $\pi_{*} v_{Y}=v_{X}$, one has

$$
\begin{equation*}
v_{Y}\left(F^{*} g\right)=v_{X}\left(\left(F \circ \pi^{-1}\right)^{*} g\right)=v_{X}\left(f^{*} g\right)=\left(f_{*} v\right)_{X}(g) \tag{3.155}
\end{equation*}
$$

and this shows the result.

### 3.6.2 Valuations as real-valued functions over the set of fractional ideals co-supported at infinity in $X$

An ideal of $X$ is a sheaf of ideals of $O_{X}$ and a fractional ideal is a coherent sub- $O_{X}$-module of the constant sheaf $\mathbf{k}(X)$. Let $\mathfrak{a}$ be a fractional ideal of $X$, we say that $\mathfrak{a}$ is co-supported at infinity if $\mathfrak{a}_{\mid X_{0}}=O_{X_{0}}$. For example, for any divisor $D \in \operatorname{Div}(X), O_{X}(D)$ is a fractional ideal of $X$ and if $D \in \operatorname{Div}_{\infty}(X)$ then $O_{X}(D)$ is co-supported at infinity.

Proposition 3.6.8. Let $\mathfrak{a}$ be a fractional ideal of $X$ co-supported at infinity and let $p \in X$, for any finite system $\left(f_{1}, \cdots, f_{r}\right)$ of local generators of $\mathfrak{a}$ at $p$ there exists an open neighbourhood $U$ of $p$ such that $f_{i \mid U}$ is of the form

$$
\begin{equation*}
f_{i}=F_{i} g_{i} \tag{3.156}
\end{equation*}
$$

with $F_{i} \in O_{X}\left(X_{0}\right)$ and $g_{i} \in O_{X}(U)$.
Proof. Pick $U^{\prime}$ an open neighbourhood containing $p$. Since $f_{i}$ is regular over $X_{0}$, we have $\operatorname{div} f_{i}=D^{+}-D_{1}^{-}-D_{2}^{-}$where $D^{+}, D_{1}^{-}$and $D_{2}^{-}$are effective divisors such that $\operatorname{Supp} D_{1}^{-} \subset \partial_{X} X_{0}$ and $D_{2}^{-}{ }_{\mid U^{\prime}}=0$. By Lemma 3.6.1 there exists an open neighbourhood $U_{i} \subset U^{\prime}$ of $p$ such that $\left(D^{+}-D_{1}^{-}\right)_{\mid U_{i}}=\operatorname{div} F_{i} g_{i}^{\prime}$ with $F_{i} \in O_{X}\left(X_{0}\right)$ and $g_{i}^{\prime} \in O_{X}\left(U_{i}\right)$. Therefore, there exists $g_{i}^{\prime \prime} \in O_{X}\left(U_{i}\right)$ such that $f_{i}=F_{i} g_{i}^{\prime} g_{i}^{\prime \prime}$. Set $U=\cap U_{i}$ and $g_{i}=g_{i}^{\prime} g_{i}^{\prime \prime}$.

Corollary 3.6.9. Let $\mathfrak{a}$ be a fractional ideal co-supported at infinity and let $v$ be a valuation over $A$, then for all affine open neighbourhood of $c_{X}(v), \Gamma(U, \mathfrak{a}) \subset O_{X}\left(X_{0}\right)_{\mathfrak{p}_{X}}$ and $v_{X}$ is defined $\operatorname{over} \Gamma(U, \mathfrak{a})$.

If $v$ is a valuation over $A$, then we define $L_{v, X}(\mathfrak{a})$ as

$$
\begin{equation*}
L_{v, X}(\mathfrak{a}):=\min _{f} v_{X}(f) . \tag{3.157}
\end{equation*}
$$

where the $f$ runs over the germs of sections of $\mathfrak{a}$ at $c_{X}(v)$. This makes sense by Corollary 3.6.9.
Proposition 3.6.10. If $v$ is a valuation over $A$, then

1. $L_{v, X}\left(O_{X}\right)=0$.
2. If $\mathfrak{a}, \mathfrak{b}$ are two fractional ideals of $X$ co-supported at infinity, then

$$
\begin{equation*}
L_{v, X}(\mathfrak{a} \cdot \mathfrak{b})=L_{v, X}(\mathfrak{a})+L_{v, X}(\mathfrak{b}) \text { and } L_{v, X}(\mathfrak{a}+\mathfrak{b})=\min \left(L_{v, X}(\mathfrak{a}), L_{v, X}(\mathfrak{b})\right) \tag{3.158}
\end{equation*}
$$

3. If $f_{1}, \cdots, f_{r} \in \mathbf{k}(X)$ is a set of local generators of $\mathfrak{a}$ at $c_{X}(v)$, then

$$
\begin{equation*}
L_{v, X}(\mathfrak{a})=\min \left(v_{X}\left(f_{1}\right), \cdots, v_{X}\left(f_{r}\right)\right) . \tag{3.159}
\end{equation*}
$$

4. If $D \in \operatorname{Div}(X)$ is a divisor, then $L_{v, X}(D)=L_{v, X}\left(O_{X}(-D)\right)$.
5. If $Y$ is another completion of $X_{0}$ above $X$, and $\pi: Y \rightarrow X$ is the morphism of completions over $\mathbf{X}_{0}$, then $\tilde{\mathfrak{a}}:=\pi^{*} \mathfrak{a} \cdot O_{Y}$ is a fractional ideal over $Y$ and $L_{v, X}(\mathfrak{a})=L_{v, Y}(\tilde{\mathfrak{a}})$.

Proof. The first assertion is trivial since 1 is a local generator of the trivial sheaf. For Assertion (2), notice that if $\left(f_{1}, \ldots, f_{r}\right)$ are local generators of $\mathfrak{a}$ at $c_{X}(v)$ and $\left(g_{1}, \ldots, g_{s}\right)$ local generators of $\mathfrak{b}$ at $c_{X}(v)$ then $\left(f_{i} g_{j}\right)_{i, j}$ is a set of local generators of $\mathfrak{a} \cdot \mathfrak{b}$ at $c_{X}(v)$ and $\left(f_{1}, \ldots, f_{r}, g_{1}, \ldots, g_{s}\right)$ is a set of local generators of $\mathfrak{a}+\mathfrak{b}$ at $c_{X}(v)$, so Assertion (2) follows from Assertion (3). To show Assertion (3), let $f_{1}, \cdots, f_{r}$ be local generators of $\mathfrak{a}$ at $c_{X}(v)$. This implies that $\mathfrak{a}_{c_{X}(v)}=f_{1} O_{c_{X}(v)}+f_{2} O_{c_{X}(v)}+\cdots+f_{r} O_{c_{X}(v)}$. Since $v$ is nonnegative on $O_{c_{X}(v)}$ by definition of the center, the assertion follows. For assertion 5, if $f_{1}, \cdots, f_{r}$ are local generators of $\mathfrak{a}$, then $\pi^{*} f_{1}, \cdots, \pi^{*} f_{r}$ are local generators of $\tilde{\mathfrak{a}}$ at $c_{Y}(\mathrm{v})$ and the result follows since $\pi_{*} v_{Y}=v_{X}$. Assertion (4) follows from the fact $O_{X}(-D)$ is locally generated by an equation of $D$ and Assertion (5) follows from the fact that if $\left(f_{1}, \cdots, f_{r}\right)$ are local generators of $\mathfrak{a}$ at $c_{X}(v)$ then $\left(\pi^{*} f_{1}, \cdots, \pi^{*} f_{r}\right)$ are local generators of $\tilde{\mathfrak{a}}$ at $c_{Y}(v)$.

Proposition 3.6.11. If $\vee$ is a valuation over $A$ and $\mathfrak{a}$ is a fractional ideal co-supported at infinity, then $L_{v, X}(\mathfrak{a})<\infty$.

Proof. Take $f_{1}, \cdots, f_{r}$ local generators of $\mathfrak{a}$ at $p$ the center of $v$ on $X$. The proof of Lemma 3.6.1 shows that there exists an affine open neighbourhood $U$ of $p$ such that $f_{i \mid U}=h_{i} g_{i}$ with $h_{i} \in A$ and $g_{i} \in O_{X}(U)$ and such that $f_{i}^{-1}$ can be put into the same form. This shows that for all $i, v\left(f_{i}\right)<\infty$.

Remark 3.6.12. The same definition would allow one to define $L_{v, X}(\mathfrak{a})$ for any fractional ideal such that $\mathfrak{a}$ is a sheaf of ideals of $X_{0}$ but we have to allow infinite values. In particular, $L_{v, X}(\mathfrak{a})$ is defined for any sheaf of ideals over $X$.

### 3.6.3 Valuations centered at infinity

Recall that a valuation $v$ over $A$ is centered at infinity, if $v$ does not admit a center on $X_{0}$. We denote by $\mathcal{V}_{\infty}$ the set of valuations over $A$ centered at infinity.

Lemma 3.6.13. Let $\vee$ be valuation over A. The following assertions are equivalent.

1. $v$ is centered at infinity.
2. There exists $P \in A$ such that $v(P)<0$.
3. For any completion $X$ of $X_{0}$ and any effective divisor $H$ in $X$ such that $\operatorname{Supp} H=\partial_{X} X_{0}$, one has $L_{v, X}(H)>0$.
4. There exists a completion $X$ of $X_{0}$ and an effective divisor $H \in X$ with $\operatorname{Supp} H=\partial_{X} X_{0}$ such that $L_{v, X}(H)>0$.

Proof. We will show the following implications $2 \Rightarrow 1 \Rightarrow 3 \Rightarrow 4$. Then, we will show that $1 \Rightarrow 2$ and finally that $4 \Rightarrow 2$.
$2 \Rightarrow 1 \Rightarrow 3 \Rightarrow 4 \quad$ If there exists a regular function $P$ over $X_{0}$ such that $v(P)<0$ then the center of $v$ cannot be a point of $X_{0}$ because $P$ is regular at every point of $X_{0}$. This shows $2 \Rightarrow 1$, then if $v$ is centered at infinity, take a completion $X$ of $X_{0}$, let $E$ be a prime divisor at infinity in $X$ such that $c_{X}(v) \in E$. Then, since $H$ is effective and $E \in \operatorname{Supp} H, L_{v, X}(H) \geqslant v(E)>0$ by Proposition 3.6.6(1). This shows $1 \Rightarrow 3$ and $3 \Rightarrow 4$ is clear.
$1 \Rightarrow 2$ Conversely, suppose $v$ is centered at infinity and fix a closed embedding $X_{0} \hookrightarrow \mathbf{A}^{N}$ for some integer $N$. Let $X$ be the Zariski closure of $X_{0}$ in $\mathbf{P}^{N}$ with homogeneous coordinates $x_{0}, \cdots, x_{N}$ such that $\left\{x_{0}=0\right\}$ is the hyperplane at infinity. The surface $X$ might not be smooth so it is not necessarily a completion of $X_{0}$ but it still is proper and the center $p$ of $v$ on $X$ belongs to $\left\{x_{0}=0\right\} \cap X$. Let $1 \leqslant i \leqslant N$ be an integer such that $p$ belongs to the open subset $\left\{x_{i} \neq 0\right\}$. Then, the rational function $P:=\frac{x_{i}}{x_{0}}$ is a regular function on $X_{0}$ and $1 / P$ vanishes at $p$. Therefore, $v(P)<0$.
$4 \Rightarrow 1 \quad$ Suppose that $v$ is not centered at infinity, i.e the center of $v$ belongs to $X_{0}$. Then, for any completion $X$ and for any divisor $D \in \operatorname{Div}_{\infty}(X)$, one has $L_{v, X}(D)=0$ by Proposition 3.6.6 (1) since $c_{X}(v) \notin \operatorname{Supp} D$.

This lemma shows that being centered at infinity is a property that can be tested on only one completion $X_{0}$.

Corollary 3.6.14. The space $\mathcal{V}_{\infty}$ is an open subset of $\mathcal{V}$.

Proof. We have by Lemma 3.6.13 that

$$
\begin{equation*}
\mathcal{V}_{\infty}=\bigcup_{P \in A}\{v(P)<0\} . \tag{3.160}
\end{equation*}
$$

Therefore, it is a union of open subsets.

### 3.6.3.1 Topologies over the set of valuations centered at infinity

Let $X$ be a completion of $X_{0}$. Call $\sigma$ the coarsest topology such that the evaluation maps $\varphi_{f}: \boldsymbol{v} \in \mathcal{V}_{\infty} \mapsto \mathrm{v}(f)$ are continuous for all $f \in A$ and $\tau$ the coarsest topology such that the evaluation maps $\psi_{\mathbf{A}}: v \in \mathcal{V}_{\infty} \mapsto L_{V}(\mathbf{A})$ are continuous for all fractional ideals $\mathbf{A}$ of $X$ such that $\mathbf{A}_{\mid X_{0}}$ is a sheaf of ideals over $X_{0}$. Recall that we allow in both cases infinite values.

Proposition 3.6.15. [JM12] These two topologies on $\mathcal{V}$ are the same.

Proof. First if $f \in A$, then $v(f)=L_{v}((f))$ where $(f)$ is the fractional ideal generated by $f$. So $\sigma$ is finer than $\tau$. For the other way, Let $H$ be an ample divisor supported at infinity and let $\mathbf{A}$ be a fractional ideal co-supported at infinity. There exists an integer $n>0$ such that $\mathbf{A} \otimes O_{X}(n H)$ and $O_{X}(n H)$ are generated by global sections $\left(f_{1}, \cdots, f_{r}\right)$ and $\left(g_{1}, \cdots, g_{s}\right)$ respectively. Notice that for all $i, j$, the rational functions $f_{i}, g_{j}$ belong to $O_{X}\left(X_{0}\right)$. Now, we have that $L_{v}(\mathbf{A})=L_{v}\left(\mathbf{A} \otimes O_{X}(n H) \otimes O_{X}(-n H)\right)$, therefore

$$
L_{v}(\mathbf{A})=\min _{i, j}\left(v\left(\frac{f_{i}}{g_{j}}\right)\right)=\min _{i, j}\left(v\left(f_{i}\right)-v\left(g_{j}\right)\right)
$$

Therefore, $\tau$ is finer than $\sigma$ and the result is shown.

### 3.6.3.2 Valuations centered at infinity as linear forms over $\operatorname{Cartier}_{\infty}\left(X_{0}\right)$

Definition 3.6.16. Let $v$ be a valuation over $A$. Let $D \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$ and $X$ be a completion of $X_{0}$ such that $D$ is defined by $D_{X}$. We define

$$
\begin{equation*}
L_{v}(D):=L_{v, X}\left(D_{X}\right) \tag{3.161}
\end{equation*}
$$

This does not depend on the choice $X$ and defines a linear map on $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$ by Proposition 3.6 .6 and $L_{v}(D)<+\infty$ by Lemma 3.6.3. Notice that $L_{v}=0$ if and only if $v$ is not centered at infinity.

Proposition 3.6.17. If $v$ is a valuation on $A$ centered at infinity then $L_{v}$ is a linear form $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right) \rightarrow \mathbf{R}$ and satisfies

1. If $D \geqslant 0$, then $L_{v}(D) \geqslant 0$.
2. For $D, D^{\prime} \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), L_{v}\left(D \wedge D^{\prime}\right)=\min \left(L_{v}(D), L_{v}\left(D^{\prime}\right)\right)$.

We will say that an element of $\operatorname{Hom}\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \mathbf{R}\right)$ that satisfies these 2 properties satisfies property (+).

Proof. Assertion 1 follows from Proposition 3.6.6(3). We show the second assertion. Take $D, D^{\prime} \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$ and $X$ a completion of $X_{0}$ such that $D, D^{\prime}$ are defined by their incarnation $D_{X}, D_{X}^{\prime}$. By Claim 3.2.8 (that we prove in the next section), we know that there exists a completion $Y$ along with a morphism of completions $\pi: Y \rightarrow X$ such that $D \wedge D^{\prime}$ is the Cartier class determined by some divisor $D_{Y}$ in $Y$ such that $\pi^{*}\left(O_{X}\left(-D_{X}\right)+O_{X}\left(-D_{X}^{\prime}\right)\right) \cdot O_{Y}=O_{Y}\left(-D_{Y}\right)$. Using Proposition 3.6.10, it follows that

$$
\begin{aligned}
L_{v}\left(D \wedge D^{\prime}\right) & =L_{v, Y}\left(D_{Y}\right) \\
& =L_{v, Y}\left(O_{Y}\left(-D_{Y}\right)\right) \quad 3.6 .10(4) \\
& =L_{v, X}\left(O_{X}\left(-D_{X}\right)+O_{X}\left(-D_{X}^{\prime}\right)\right) \quad 3.2 .8 \\
& =\min \left(L_{v, X}\left(O_{X}\left(-D_{X}\right)\right), L_{v, X}\left(O_{X}\left(-D_{X}^{\prime}\right)\right)\right) \quad 3.6 .10(2) \\
& =\min \left(L_{v}(D), L_{v}\left(D^{\prime}\right)\right) \quad 3.6 .10
\end{aligned}
$$

For the third assertion, let $X$ be a completion of $X_{0}$, by Theorem 3.1.4 there exists an ample divisor $H \in \operatorname{Div}_{\infty}(X)$ such that $H \geqslant 0$ and $\operatorname{Supp} H=\partial_{X} X_{0}$. We get that $c_{X}(v) \in \operatorname{Supp} H$ (whether
it is a prime divisor or a closed point) and therefore by Proposition 3.6.6 item (3), we get $L_{v}(H)>0$.

Proposition 3.6.18. Let $\vee$ be a valuation over $A$ and $f: X_{0} \rightarrow X_{0}$ a dominant endomorphism, then for all $D \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$,

$$
\begin{equation*}
L_{f_{*}}(D)=L_{v}\left(f^{*} D\right)=\left(f_{*} L_{v}\right)(D) \tag{3.162}
\end{equation*}
$$

Proof. Let $X$ be a completion of $X_{0}$ where $D$ is defined, then $f$ induces a dominant rational map $f: X \rightarrow X$. Let $\pi: Y \rightarrow X$ be a projective birational morphism such that the lift $F: Y \rightarrow X$ is regular. Since $f$ is an endomorphism of $X_{0}$ we can suppose that $\pi$ is the identity over $X_{0}$, hence $Y$ is a completion of $X_{0}$ and $\pi$ is a morphism of completions. Now, if $\varphi$ is a local equation of $D$ near the center of $v_{X}$, then $F^{*} \varphi$ is a local equation of $F^{*} D$ near the center of $v_{Y}$. Since $\pi_{*} v_{Y}=v_{X}$, one has

$$
\begin{equation*}
v_{Y}\left(F^{*} g\right)=v_{X}\left(\left(F \circ \pi^{-1}\right)^{*} g\right)=v_{X}\left(f^{*} g\right)=\left(f_{*} v\right)_{X}(g) \tag{3.163}
\end{equation*}
$$

We equip $\operatorname{Hom}\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \mathbf{R}\right)$ with the weak- $\star$ topology, that is the coarsest topology such that the map $L \in \operatorname{Hom}\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \mathbf{R}\right) \mapsto L(D)$ is continuous for all $D \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$. We extend $L_{v}$ to $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{R}}$ by linearity.

Proposition 3.6.19. The map $v \in \mathcal{V}_{\infty} \mapsto L_{v} \in \operatorname{Hom}\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \mathbf{R}\right)$ is a continuous embedding.

Proof. For the injectivity, let $v, \omega \in \mathcal{V}_{\infty}$ such that $v \neq \omega$. First, if $w=t v$ with $t>0$, then since $L_{v} \neq 0$, we have $L_{v} \neq L_{w}$. Otherwise, there exists a completion $X$ such that $c_{X}(v) \neq c_{X}(\omega)$. If the centers are both prime divisors at infinity then it is clear that $L_{v} \neq L_{W}$. If $c_{X}(v)$ is a point, let $\widetilde{E}$ be the exceptional divisor above it. Then, by Proposition 3.6.6, $L_{v}(\widetilde{E})>0$, but $L_{w}(\widetilde{E})=0$.

By definition, to show continuity we have to show that for all $D \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$, the map $v \in \mathcal{V}_{\infty} \mapsto L_{v}(D)$ is continuous. Let $X$ be a completion where $D$ is defined, then by Proposition 3.6.6 $L_{v}(D)=L_{v}\left(O_{X}(-D)\right)$ and by Proposition 3.6.15 the map $v \in \mathcal{V}_{\infty} \mapsto L_{v}\left(O_{X}(-D)\right)$ is continuous.

Proposition 3.6.20. Let $X$ be a completion of $X_{0}$ and $p \in X$ a closed point at infinity. Let $v \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$. If $E$ is a prime divisor of $X$ at infinity such that $p \in E$, then

$$
\begin{equation*}
1 \leqslant L_{v}(E) \leqslant \alpha(v) \tag{3.164}
\end{equation*}
$$

Proof. Let $z \in O_{X, p}$ be a local equation of $E, z$ is irreducible and we have $L_{v}(E)=v(z)$. We have that $z \in \mathfrak{m}_{p}$, therefore $v(z) \geqslant v\left(\mathfrak{m}_{p}\right)=1$. This shows the first inequality. For the second one, let $v_{z}$ be the curve valuation associated to $z$. It does not define a valuation over $\mathbf{k}\left[X_{0}\right]$ but it defines a valuation over $O_{X, p}$ by Proposition 3.4.3, we get

$$
\begin{equation*}
v(z)=\alpha\left(v_{z} \wedge v\right) \leqslant \alpha(v) \tag{3.165}
\end{equation*}
$$

### 3.6.3.3 Special look at divisorial valuations centered at infinity

Lemma 3.6.21. Let $X$ be a completion of $X_{0}$ and let $E$ be a prime divisor at infinity. One has $L_{\text {ord }_{E}}(E)=1$ and for any prime divisor $F \neq E$ in $X, L_{\text {ord }_{E}}(F)=0$.

Furthermore, if $\pi: Y \rightarrow X$ is some blow-up of $X$, and $\pi^{\prime}(E)$ the strict transform of $E$ by $\pi$, then

$$
\begin{equation*}
\pi_{*} \operatorname{ord}_{\pi^{\prime}(E)}=\operatorname{ord}_{E} \tag{3.166}
\end{equation*}
$$

Proof. The first assertion follows from Proposition 3.6.6(3). We show the second assertion. It suffices to show it when $\pi$ is the blow-up of one point of $X$. Let $D=a E+\sum_{F \neq E} \operatorname{ord}_{F}(D) F$, then $\pi^{*} D$ is of the form

$$
\begin{equation*}
\pi^{*} D=a \pi^{\prime}(E)+b \widetilde{E}+\sum_{F \neq E} a_{F}(D) \pi^{\prime}(F) \tag{3.167}
\end{equation*}
$$

where $\widetilde{E}$ is the exceptional divisor of $\pi$. Therefore $\operatorname{ord}_{\pi^{\prime}(E)}\left(\pi^{*}(D)\right)=a=\operatorname{ord}_{E}(D)$.
Proposition 3.6.22. Let $\vee$ be a divisorial valuation, then $L_{v}$ can be extended naturally to Weil $\omega_{\infty}\left(\mathrm{X}_{0}\right)$ in a compatible way with the definition of $L_{v}$ over $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$.

Proof. Take $W \in \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)$. Since $v$ is divisorial, there exists a completion $X$ of $X_{0}$ that contains a prime divisor $E$ at infinity such that $\left(\imath_{X}\right)_{*} \nu=\lambda \operatorname{ord}_{E}$. We set

$$
\begin{equation*}
L_{v}(W):=L_{v, X}\left(W_{X}\right) \tag{3.168}
\end{equation*}
$$

This does not depend on the completion $X$. To show this, it suffices to show that we get the same result if we blow up one point of $X$. So, let $\pi: Y \rightarrow X$ be the blow up of one point of $X_{0}$ at infinity. Then, by Lemma 3.6.21, $v_{Y}=\lambda \operatorname{ord}_{\pi^{\prime}(E)}$ and $\operatorname{ord}_{\pi^{\prime}(E)}\left(W_{Y}\right)=\operatorname{ord}_{E}\left(\pi_{*} W_{Y}\right)=\operatorname{ord}_{E}\left(W_{X}\right)$.

If $D \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$, then this is compatible with the previous definition of $L_{v}(D)$ because if $D$ is defined over $X$, there exists a completion $\pi: Y \rightarrow X$ such that the center of $v$ on $Y$ is a prime divisor at infinity and by Proposition 3.6.6 (5) $L_{v, Y}\left(\pi^{*} D\right)=L_{v, X}(D)$.

Remark 3.6.23. Recall that we have defined in Section 3.2.1 the set $\mathcal{D}_{\infty}\left(X_{0}\right)$ as the set of equivalence classes of prime divisors at infinity modulo the following equivalence relations : $\left(X_{1}, E_{1}\right) \sim\left(X_{2}, E_{2}\right)$ if $\pi=\mathfrak{l}_{2} \circ \mathfrak{l}_{1}^{-1}: X_{1} \rightarrow X_{2}$ satisfies $\pi\left(E_{1}\right)=E_{2}$. Lemma 3.6.21 shows that it makes sense to define $\operatorname{ord}_{E}$ for $E \in \mathcal{D}_{\infty}\left(X_{0}\right)$ and that $\operatorname{ord}_{E}$ is defined over Weil ${ }_{\infty}\left(\mathrm{X}_{0}\right)$.

Proposition 3.6.24. Let $W, W^{\prime} \in \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)$, then $W^{\prime \prime}=W \wedge W^{\prime}$ if and only if for any divisorial valuation $E \in \mathcal{D}_{\infty}\left(X_{0}\right)$,

$$
\begin{equation*}
\operatorname{ord}_{E}\left(W^{\prime \prime}\right)=\min \left(\operatorname{ord}_{E}(W), \operatorname{ord}_{E}\left(W^{\prime}\right)\right) \tag{3.169}
\end{equation*}
$$

Proof. This is immediate as for any completion $X$,

$$
\begin{equation*}
W_{X}=\sum_{E \in \partial_{X} X_{0}} \operatorname{ord}_{E}(W) \cdot E . \tag{3.170}
\end{equation*}
$$

We can now show that the minimum of two Cartier divisors is still a Cartier divisor.
Proposition 3.6.25. Let $X$ be a completion of $X_{0}$, let $D, D^{\prime} \in \operatorname{Div}_{\infty}(X)$ be two effective divisor and let $\mathfrak{a}$ be the sheaf of ideals $\mathfrak{a}=O_{X}(-D)+O_{X}\left(-D^{\prime}\right)$. Then, $D \wedge D^{\prime}$ is the Cartier divisor defined by $\pi^{*} \mathfrak{a}$ where $\pi$ is the blow up of $\mathfrak{a}$.

Notice that $\mathfrak{a}$ is not locally principle only at satellite points, so $\pi$ is a sequence of blow-ups of satellite points. This shows the Claim 3.2.8.

Proof of Claim 3.2.8. Define the sheaf of ideals $\mathfrak{a}=O_{X}(-D)+O_{X}\left(-D^{\prime}\right)$ and let $\pi: Y \rightarrow X$ be the blow up of $\mathfrak{a}$. There exists a Cartier divisor $D_{Y}$ on $Y$ such that $\mathfrak{b}=O_{Y}\left(-D_{Y}\right)=\pi^{*} \mathfrak{a} \cdot O_{Y}$. We show that $D_{Y}=D \wedge D^{\prime}$ in $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$. By Proposition 3.6.24, we only need to show that for any divisorial valuation $\mathrm{v}, L_{v, Y}\left(D_{Y}\right)=\min \left(L_{v, X}(D), L_{v, X}\left(D^{\prime}\right)\right)$, but by Proposition 3.6.10 we have the following equalities

$$
\begin{equation*}
L_{v, Y}\left(D_{Y}\right)=L_{v, Y}(\mathfrak{b})=L_{v, X}(\mathfrak{a})=\min \left(L_{v, X}(D), L_{v, X}\left(D^{\prime}\right)\right) \tag{3.171}
\end{equation*}
$$

### 3.6.4 Local divisor associated to a valuation

Let $X$ be a completion of $X_{0}$ and let $p \in X$ be a closed point at infinity. Let $v$ be a valuation centered at $p$. We know by Section 3.6.3.2 that $v$ induces a linear form $L_{v}$ on $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{R}}$. By restriction, it induces a linear form $L_{v, X, p}$ on $\operatorname{Cartier}(X, p)_{\mathbf{R}}$. Now by Proposition 3.2.19, the pairing

$$
\begin{equation*}
\operatorname{Weil}(X, p)_{\mathbf{R}} \times \operatorname{Cartier}(X, p)_{\mathbf{R}} \rightarrow \mathbf{R} \tag{3.172}
\end{equation*}
$$

induced by the intersection product is perfect. Thus, there is a unique $Z_{v, X, p} \in \operatorname{Weil}(X, p)_{\mathbf{R}}$ such that

$$
\begin{equation*}
\forall D \in \operatorname{Cartier}(X, p)_{\mathbf{R}}, \quad Z_{v, X, p} \cdot D=L_{v, X, p}(D) \tag{3.173}
\end{equation*}
$$

Example 3.6.26. If $\widetilde{E}$ is the exceptional divisor above $p$, then $Z_{\text {ord }_{\tilde{E}}, X, p}=-\widetilde{E}$.
Proposition 3.6.27. For any valuation $v \in \mathcal{V}_{X}(p)$, we have $Z_{v, X, p} \in \operatorname{Cartier}(X, p)$ if and only if $v$ is divisorial. Furthermore, $Z_{v, X, p}$ is defined over any completion such that the center of $v$ is a prime divisor at infinity. Furthermore, for any $E \in \mathcal{D}(X, p), Z_{\mathrm{ord}_{E}, X, p} \in \operatorname{Cartier}(X, p)_{\mathbf{Q}}$.

Proof. Let $E \in \mathcal{D}_{X, p}$, for every $W \in \operatorname{Weil}(X, p), \operatorname{ord}_{E}(W)=\operatorname{ord}_{E}\left(W_{Y}\right)$ where $Y$ is a completion exceptional above $p$ by Proposition 3.6.22. Let $E, E_{1}, \cdots, E_{r}$ be the component of $\partial_{Y} X_{0}$ that are exceptional above $p$. The intersection form is non degenerate on

$$
\begin{equation*}
V:=\mathbf{Q} E \oplus\left(\bigoplus_{i} \mathbf{Q} E_{i}\right) . \tag{3.174}
\end{equation*}
$$

Let $L$ be the restriction of $\operatorname{ord}_{E}$ to $V$, by duality there exists a unique $Z \in V$ such that for all $W \in V, W \cdot Z=L(W)=\operatorname{ord}_{E}(W)$. This implies that $Z=Z_{\operatorname{ord}_{E}, X, p}$. Conversely, if $v$ is a valuation such that $Z_{v, X, p} \in \operatorname{Cartier}(X, p)$ then let $Y$ be a completion where $Z_{v, X, p}$ is defined. If $c_{Y}(v)$ is a point at infinity, then let $\widetilde{E}$ be the exceptional divisor above $c_{Y}(v)$. Then, we must have $Z_{v, X, p} \cdot \widetilde{E}>0$ but it is equal to 0 , this is a contradiction.

Proposition 3.6.28. The embedding $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right) \hookrightarrow \mathrm{Weil}(X, p)_{\mathbf{R}}$ is continuous with respect to the weak topology.

Proof. This is a direct consequence of Proposition 3.6.19 and Proposition 3.5.2.
Thus, For all completion $\pi: Y \rightarrow X$, for all $E \in \Gamma_{\pi}$, we can consider $Z_{\text {ord }_{E}, X, p}$ as an element of $\operatorname{Div}_{\infty}(Y)_{\mathbf{R}}$.

Proposition 3.6.29. Let $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, p)$ be a completion exceptional above $p$. Let $\vee$ be a valuation such that $c_{X}(v)=p$. Suppose that $c_{Y}(v)$ is a point at infinity. Consider $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ with its generic multiplicity function $b$.

1. If $c_{Y}(v) \in E$ is a free point with $E \in \Gamma_{\pi}$, then the incarnation of $Z_{v, X, p}$ in $Y$ is

$$
\begin{equation*}
\left(Z_{v, X, p}\right)_{Y}=L_{v}(E) Z_{\operatorname{ord}_{E}, X, p} \tag{3.175}
\end{equation*}
$$

Moreover if $v \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$, then $L_{v}(E)=\frac{1}{b(E)}$.
2. If $c_{Y}(v)=E \cap F$ is a satellite point with $E, F \in \Gamma_{\pi}$, then

$$
\begin{equation*}
\left(Z_{V, X, p}\right)_{Y}=L_{v}(E) Z_{\operatorname{ord}_{E}, v, p}+L_{v}(F) Z_{\operatorname{ord}_{F}, X, p} \tag{3.176}
\end{equation*}
$$

Moreover if $v \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$, then $L_{v}(E) b(E)+L_{v}(F) b(F)=1$.

Furthermore, if $q \neq c_{Y}(v)$ and $\tau: Z \rightarrow Y$ is the blow up of $q$ then

$$
\begin{equation*}
\left(Z_{v, X, p}\right)_{Z}=\tau^{*}\left(Z_{v, X, p}\right)_{Y} \tag{3.177}
\end{equation*}
$$

Proof. For any prime divisor $E$ at infinity of $Y, L_{v}(E)>0 \Leftrightarrow c_{Y}(v) \in E$ by item (3) ofProposition 3.6.6. Therefore, if $c_{Y}(v) \in E$ is a free point with $E \in \Gamma_{\pi}$, then for $F \in \Gamma_{\pi}, L_{v}(F) \neq 0 \Leftrightarrow F=E$, hence

$$
\begin{equation*}
\left(L_{V}\right)_{\mid \operatorname{Div}_{\infty}(Y)_{\mathbf{R}}}=\left(L_{V}(E)\right)\left(L_{\operatorname{ord}_{E}}\right)_{\mid \operatorname{Div}_{\infty}(Y)_{\mathbf{R}}} . \tag{3.178}
\end{equation*}
$$

by definition (see Equation 3.152)). This shows the result if $c_{Y}(v)$ is a free point. Now, if $c_{Y}(v)=E \cap F$ is a satellite point with $E, F \in \Gamma_{\pi}$, then for all prime divisors $F^{\prime}$ of $Y$ at infinity $L_{v}\left(F^{\prime}\right)>0 \Leftrightarrow F^{\prime}=E$ or $F^{\prime}=F$. We therefore have

$$
\begin{equation*}
\left(L_{V}\right)_{\mid \operatorname{Div}_{\infty}(Y)_{\mathbf{R}}}=\left(L_{V} \cdot E\right)\left(L_{\operatorname{ord}_{E}}\right)_{\mid \operatorname{Div}_{\infty}(Y)_{\mathbf{R}}}+\left.\left(L_{V} \cdot F\right)\left(L_{\operatorname{ord}_{F}}\right)\right|_{\mid \operatorname{Div}_{\infty}(Y)_{\mathbf{R}}} . \tag{3.179}
\end{equation*}
$$

This shows the result in the satellite case.
If $v \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$. Let $\tau: Z \rightarrow X$ be the blow up of $p$. We know then that $L_{V}(\widetilde{E})=1$ where $\widetilde{E}$ is the exceptional divisor above $p$ by Proposition 3.4.12. Let $b_{\widetilde{E}}$ be the generic multiplicity function of the tree $\mathcal{V}_{Z}(\widetilde{E} ; \widetilde{E})$. We have for every prime divisor $F$ exceptional above $p$ that $\operatorname{ord}_{F}(\widetilde{E})=b_{\widetilde{E}}(F)$ again by Proposition 3.4.12. In the free point case, we get
$1=L_{v}(\widetilde{E})=L_{v}\left(b_{\widetilde{E}}(E) E\right)$ by Proposition 3.6.6 (3) and (5). In the satellite point case, we get

$$
\begin{equation*}
1=L_{v}(\widetilde{E})=L_{v}\left(b_{\widetilde{E}}(E) E+b_{\widetilde{E}}(F) F\right) \tag{3.180}
\end{equation*}
$$

again by Proposition 3.6.6 (3) and (5).
For the last assertion, if $\widetilde{F}$ is the exceptional divisor above $q$, we have

$$
\begin{equation*}
\left(Z_{v, X, p}\right)_{Z}=\tau^{*}\left(Z_{v, X, p}\right)_{Y}-\left(Z_{v, X, p} \cdot \widetilde{F}\right) \widetilde{F} \tag{3.181}
\end{equation*}
$$

Since $c_{Z}(v) \notin \widetilde{F}$, we have $L_{v}(\widetilde{F})=0$ by Proposition 3.6.6 (3).

From now on let $b$ be the generic multiplicity function of $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ and for any prime divisor $E \in \mathcal{D}_{X, p}=\Gamma$, set $\nu_{E}=\frac{1}{b(E)} \operatorname{ord}_{E}$.

Proposition 3.6.30. Let $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, p)$ be a completion exceptional above $p$. Let $q \in \operatorname{Exc}(\pi)$ be a closed point. Let $\tau: Z \rightarrow Y$ be the blow up of $q$ and let $\widetilde{E}$ be the exceptional divisor above $q$.

1. If $q \in E$ is a free point with $E \in \Gamma_{\pi}$, then

$$
\begin{equation*}
Z_{v_{\widetilde{E}}, X, p}=\tau^{*}\left(Z_{v_{E}, X, p}\right)-\frac{1}{b(\widetilde{E})} \widetilde{E} \in \operatorname{Div}_{\infty}(Z)_{\mathbf{Q}} \tag{3.182}
\end{equation*}
$$

2. If $q=E \cap F$ is a satellite point with $E, F \in \Gamma_{\pi}$, then

$$
\begin{equation*}
Z_{v_{\tilde{E}}, X, p}=\frac{b(E)}{b(E)+b(F)} \tau^{*} Z_{v_{E}, X, p}+\frac{b(F)}{b(E)+b(F)} \tau^{*} Z_{v_{F}, X, p}-\frac{1}{b(\widetilde{E})} \widetilde{E} \in \operatorname{Div}_{\infty}(Z)_{\mathbf{Q}} \tag{3.183}
\end{equation*}
$$

Proof. If $q \in E$ is a free point with $E \in \Gamma_{\pi}$, we have by Proposition 3.6 .29 that the incarnation of $Z_{\operatorname{orr}_{\tilde{E}}, X, p}$ in $Y$ is

$$
\begin{equation*}
\tau_{*}\left(Z_{\operatorname{ord}_{\tilde{E}}, X, p}\right)=Z_{\operatorname{ord}_{E}, X, p} \tag{3.184}
\end{equation*}
$$

because $\operatorname{ord}_{\tilde{E}}(E)=1$. Therefore

$$
\begin{equation*}
Z_{\operatorname{ord}_{\tilde{E}}, X, p} \tau^{*} Z_{\text {ord }_{E}, X, p}+\lambda \widetilde{E} \tag{3.185}
\end{equation*}
$$

with $\lambda \in \mathbf{R}$. Since $Z_{\operatorname{ord}_{\tilde{E}}, X, p} \cdot \widetilde{E}=1$, we get $\lambda=-1$. Now, by the definition of the generic
multiplicity, we have $b(\widetilde{E})=b(E)$. Therefore,

$$
\begin{equation*}
Z_{v_{\tilde{E}}, X, p}=\tau^{*} Z_{v_{E}, X, p}-\frac{1}{b(\widetilde{E})} \widetilde{E} \tag{3.186}
\end{equation*}
$$

If $q=E \cap F$ is a satellite point with $E, F \in \Gamma_{\pi}$, then $b(\widetilde{E})=b(E)+b(F)$. Note that $\operatorname{ord}_{\tilde{E}}(E)=\operatorname{ord}_{\widetilde{E}}(F)=1$. We have by Proposition 3.6.29

$$
\begin{equation*}
\tau_{*} Z_{\operatorname{ord}_{\tilde{E}}, X, p}=Z_{\operatorname{ord}_{E}, X, p}+Z_{\operatorname{ord}_{F}, X, p} \tag{3.187}
\end{equation*}
$$

and since $\operatorname{ord}_{\widetilde{E}}(\widetilde{E})=1$, we get

$$
\begin{equation*}
Z_{\operatorname{ord}_{\tilde{E}}, X, p}=\tau^{*} Z_{\operatorname{ord}_{E}, X, p}+\tau^{*} Z_{\operatorname{ord}_{F}, X, p}-\widetilde{E} . \tag{3.188}
\end{equation*}
$$

Therefore,

$$
\begin{equation*}
Z_{v_{\tilde{E}}, X, p}=\frac{b(E)}{b(E)+b(F)} \tau^{*} Z_{\mathrm{ord}_{E}, X, p}+\frac{b(F)}{b(E)+b(F)} \tau^{*} Z_{\mathrm{ord}_{F}, X, p}-\frac{1}{b(\widetilde{E}))} \widetilde{E} . \tag{3.189}
\end{equation*}
$$

Theorem 3.6.31. Let $\mathrm{v}, \mathfrak{v}^{\prime} \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$, then

$$
\begin{equation*}
Z_{v, X, p} \cdot Z_{v^{\prime}, X, p}=-\alpha\left(v \wedge v^{\prime}\right) \tag{3.190}
\end{equation*}
$$

Proof. We show by induction the
Claim 3.6.32. For every completion $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, p)$ exceptional above $p$, for all $E \in \Gamma_{\pi}$, for all $v \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$,

$$
\begin{equation*}
Z_{v_{E}, X, p} \cdot Z_{v, X, p}=-\alpha\left(v_{E} \wedge v\right) \tag{3.191}
\end{equation*}
$$

First if $\pi: Y \rightarrow X$ is the blow up of $p$ with exceptional divisor $\widetilde{E}$. Recall that $\pi_{*} \operatorname{ord}_{\widetilde{E}}=v_{\mathfrak{m}_{p}}$ then $Z_{\text {ord }_{\tilde{E}}, X, p}=-E$ and

$$
\begin{equation*}
Z_{\operatorname{ord}_{\widetilde{E}}, X, p} \cdot Z_{v, X, p}=Z_{v, X, p} \cdot(-\widetilde{E})=L_{v}(-\widetilde{E}) . \tag{3.192}
\end{equation*}
$$

By definition, $v\left(\mathfrak{m}_{p}\right)=1$ and $\pi^{*} \mathfrak{m}_{p}=O_{Y}(-\widetilde{E})$. Therefore, by Proposition 3.6.10, we get $Z_{\operatorname{ord}_{\widetilde{E}}, X, p} \cdot Z_{v, X, p}=-1=-\alpha\left(v_{\mathfrak{m}_{p}} \wedge v\right)$.

Suppose that $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, p)$ is a completion exceptional above $p$ for which the
claim holds. Let $q \in Y$ be a closed point at infinity, let $\tau: Z \rightarrow Y$ be the blow up of $q$ and let $\widetilde{E}$ be the exceptional divisor. Let $v \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$, we show that $Z_{v, X, p} \cdot Z_{v_{\tilde{E}}, X, p}=-\alpha\left(v \wedge v_{\tilde{E}}\right)$. We divide the proof in 2 different cases.

Case 1: $q \in E$ is a free point with $E \in \Gamma_{\pi}$ In that case $v_{\tilde{E}}>v_{E}$ by Proposition 3.4.17. We also have $b(\widetilde{E})=b(E)$ and $Z_{v_{\widetilde{E}}, X, p}=Z_{v_{E}, X, p}-\frac{1}{b(\widetilde{E})} \widetilde{E}$ by Proposition 3.6.30. If $c_{Y}(v) \neq(q)$ (this includes the case where $c_{Y}(v)$ is a prime divisor at infinity. Then, $v \wedge \nu_{\widetilde{E}}=v \wedge v_{E}$. We have by Proposition 3.6.30 that $Z_{v_{\tilde{E}}, X, p}=\tau^{*}\left(Z_{v_{E}, X, p}\right)-\frac{1}{b(\widetilde{E})} \widetilde{E}$. Since $Z_{v, X, p} \cdot \widetilde{E}=0$, we get

$$
\begin{equation*}
Z_{v, X, p} \cdot Z_{v_{\tilde{E}}, X, p}=Z_{v, X, p} \cdot Z_{v_{E}, X, p} \tag{3.193}
\end{equation*}
$$

This is equal to $-\alpha\left(v \wedge v_{E}\right)$ by induction and therefore it is equal to $-\alpha\left(v \wedge v_{\widetilde{E}}\right)$.
If $c_{Y}(v)=q$, then $c_{Z}(v) \in \widetilde{E}$. We either have $v_{\widetilde{E}} \leqslant v$ or $v_{E}<v \wedge v_{\widetilde{E}}<v_{\widetilde{E}}$.

1. If $v \geqslant v_{\widetilde{E}}$, then $v \wedge v_{\widetilde{E}}=v_{\widetilde{E}}$ and $c_{Z}(v)$ is either $\widetilde{E}$ or a free point on $\widetilde{E}$. In both cases by Proposition 3.6.29, the incarnation of $Z_{v, X, p}$ in $Z$ is $Z_{v_{\tilde{E}}, X, p}$. Therefore

$$
\begin{equation*}
Z_{v, X, p} \cdot Z_{v_{\widetilde{E}, X, p}}=\left(Z_{v_{\widetilde{E}}, X, p}\right)^{2}=\left(Z_{v_{E}, X, p}\right)^{2}-\frac{1}{b(\widetilde{E})^{2}} \tag{3.194}
\end{equation*}
$$

By induction $\left(Z_{v_{E}, X, p}\right)^{2}=-\alpha\left(v_{E}\right)$ and $\alpha\left(v_{\widetilde{E}}\right)=\alpha\left(v_{E}\right)+\frac{1}{b(\tilde{E})^{2}}$ by Proposition 3.4.27, so the claim is shown in that case.
2. If $v_{E}<\nu \wedge \nu_{\tilde{E}}<v_{\tilde{E}}$. Then, $v \wedge \nu_{E}$ is a monomial valuation centered at $E \cap \widetilde{E}$ (we still denote by $E$ the strict transform of $E$ in $Z$ ). Therefore, by Proposition 3.4.31 there exists $s, t>0$ such that $s b(E)+t b(\widetilde{E})=1$ and $\nu \wedge v_{\tilde{E}}=v_{s, t}$ is the monomial valuation with weight $s, t$ with respect to local coordinates associated to $E$ and $\widetilde{E}$ respectively. By Proposition 3.6.29, we have

$$
\begin{equation*}
\left(Z_{v, X, p}\right)_{Z}=s Z_{\operatorname{ord}_{E}, X, p}+t Z_{\operatorname{ord}_{\tilde{E}}, X, p}=s b_{E} Z_{v_{E}, X, p}+t b_{\tilde{E}} Z_{v_{\tilde{E}}, X, p} . \tag{3.195}
\end{equation*}
$$

Therefore,

$$
\begin{equation*}
Z_{v, X, p} \cdot Z_{v_{\tilde{E}}, X, p}=s b(E) Z_{v_{E}, X, p} \cdot Z_{v_{\tilde{E}}, X, p}+t b(\widetilde{E})\left(Z_{{ }_{\widetilde{E}}, X, p}\right)^{2} . \tag{3.196}
\end{equation*}
$$

By induction and the previous case this is equal to $-b(E)\left(s \alpha\left(v_{E}\right)+t \alpha\left(v_{\tilde{E}}\right)\right)$. By Propo-
sition 3.4.27. we have $\alpha\left(v_{\tilde{E}}\right)=\alpha\left(v_{E}\right)+\frac{1}{b(E)^{2}}$. Therefore, we get

$$
\begin{equation*}
-b(E)\left(s \alpha\left(v_{E}\right)+t \alpha\left(v_{\tilde{E}}\right)\right)=-\alpha\left(v_{E}\right)-\frac{t}{b(E)} \tag{3.197}
\end{equation*}
$$

and this is equal to $-\alpha\left(\pi_{*} v_{s, t}\right)$ by Proposition 3.4.31.

Case 2: $q=E_{1} \cap E_{2}$ is a satellite point We can suppose without loss of generality that $\nu_{E_{1}}<\nu_{E_{2}}$. In that case we get $\nu_{E_{1}}<\nu_{\tilde{E}}<\nu_{E_{2}}, b(\widetilde{E})=b\left(E_{1}\right)+b\left(E_{2}\right)$ and

$$
\begin{equation*}
Z_{v_{\widetilde{E}}, X, p}=\frac{b\left(E_{1}\right)}{b\left(E_{1}\right)+b\left(E_{2}\right)} Z_{V_{E_{1}}, X, p}+\frac{b\left(E_{2}\right)}{b\left(E_{1}\right)+b\left(E_{2}\right)} Z_{v_{E_{2}}, X, p}-\frac{1}{b(\widetilde{E})} \widetilde{E} \tag{3.198}
\end{equation*}
$$

by Proposition 3.6.30.
If $c_{Y}(v) \neq q$, then $v \wedge v_{\tilde{E}} \leqslant v_{E_{1}}$ or $v \wedge v_{\tilde{E}} \geqslant v_{E_{2}}$ and we get

$$
\begin{equation*}
Z_{v, X, p} \cdot Z_{v_{\tilde{E}}, X, p}=\frac{b\left(E_{1}\right)}{b\left(E_{1}\right)+b\left(E_{2}\right)}\left(Z_{v, X, p} \cdot Z_{v_{E_{1}}, X, p}\right)+\frac{b\left(E_{2}\right)}{b\left(E_{1}\right)+b\left(E_{2}\right)}\left(Z_{v, X, p} \cdot Z_{V_{E_{2}}, X, p}\right) . \tag{3.199}
\end{equation*}
$$

By induction, this is equal to $-\frac{b\left(E_{1}\right)}{b\left(E_{1}\right)+b\left(E_{2}\right)} \alpha\left(v_{E_{1}} \wedge v\right)-\frac{b\left(E_{2}\right)}{b\left(E_{1}\right)+b\left(E_{2}\right)} \alpha\left(v_{E_{2}} \wedge v\right)$.
If $v \wedge v_{\tilde{E}} \leqslant v_{E_{1}}$, then $v \wedge v_{E_{2}}=v \wedge v_{\tilde{E}} \nu \wedge \nu_{E_{1}}$ and the quantity in Equation (3.199) is equal to $-\alpha\left(v \wedge v_{\widetilde{E}}\right)$.

If $\nu \wedge \nu_{\widetilde{E}} \geqslant \nu_{E_{2}}$, then $\nu>\nu_{\widetilde{E}}$ and $\nu \wedge \nu_{\widetilde{E}}=\nu_{\tilde{E}}$. In that case $\nu \wedge \nu_{E_{1}}=\nu_{E_{1}}$ and $\nu \wedge \nu_{E_{2}} \nu_{E_{2}}$. Therefore, the quantity in Equation (3.199) is equal to

$$
\begin{equation*}
-\frac{b\left(E_{1}\right)}{b\left(E_{1}\right)+b\left(E_{2}\right)} \alpha\left(v_{E_{1}}\right)-\frac{b\left(E_{2}\right)}{b\left(E_{1}\right)+b\left(E_{2}\right)} \alpha\left(v_{E_{2}}\right) . \tag{3.200}
\end{equation*}
$$

By Proposition 3.4.27, $\alpha\left(v_{E_{2}}\right)=\alpha\left(v_{E_{1}}\right)+\frac{1}{b\left(E_{1}\right) b\left(E_{2}\right)}$, so we get

$$
\begin{equation*}
Z_{v, X, p} \cdot Z_{v_{\tilde{E}}, X, p}=-\alpha\left(v_{E_{1}}\right)-\frac{1}{b\left(E_{1}\right)\left(b\left(E_{1}\right)+b\left(E_{2}\right)\right)}=-\alpha\left(v_{E_{1}}\right)-\frac{1}{b\left(E_{1}\right) b(\widetilde{E})} \tag{3.201}
\end{equation*}
$$

and this is equal to $-\alpha\left(v_{\tilde{E}}\right)$ again by Proposition 3.4.27.
If $c_{Y}(v)=q$, then $c_{Z}(v) \in \widetilde{E}$. We have that $v_{E_{1}}<v \wedge v_{\widetilde{E}}<\nu_{E_{2}}$. Therefore either $v=v_{\widetilde{E}}$ or $c_{Z}(v) \mathfrak{n} \widetilde{E}$ is a free point and $v \wedge v_{\tilde{E}}$ is a monomial valuation centered at $E_{1} \cap \widetilde{E}$ or $E_{2} \cap \widetilde{E}$. We show again the claim by induction in an analogous way as in Case 1. We have thus shown the claim by induction.

To show the Proposition, let $v, v^{\prime} \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$. If $v \neq \boldsymbol{v}^{\prime}$, then there exists a completion $\pi:(Y, \operatorname{Exc}(p i)) \rightarrow(X, p)$ exceptional above $p$ such that $c_{Y}(v) \neq c_{Y}\left(v^{\prime}\right)$. Then, we have that

$$
\begin{equation*}
Z_{\vee, X, p} \cdot Z_{{v^{\prime}}^{\prime}, X, p}=\left(Z_{v, X, p}\right)_{Y} \cdot\left(Z_{\mathcal{V}^{\prime}, X, p}\right)_{Y} \tag{3.202}
\end{equation*}
$$

If $v^{\prime}$ is infinitely singular or a curve valuation, we can suppose that $c_{Y}\left(v^{\prime}\right)$ is a free point lying over a unique prime divisor $E$ at infinity. Then, $v^{\prime}>v_{E}$ and $v^{\prime} \wedge v=v^{\prime} \wedge v_{E}$. Furthermore, the incarnation of $Z_{v, X, p}$ in $Y$ is exactly $Z_{v_{E}, X, p}$ by Proposition 3.6.29. Therefore,

$$
\begin{equation*}
Z_{V, X, p} \cdot Z_{V^{\prime}, X, p}=Z_{V, X, p} \cdot Z_{V_{E}, X, p} \tag{3.203}
\end{equation*}
$$

This is equal to $-\alpha\left(v \wedge v_{E}\right)=-\alpha\left(v \wedge v^{\prime}\right)$ by the Claim.
If $\mathrm{v}^{\prime}$ is irrational, then we can suppose that $c_{Y}\left(\mathrm{v}^{\prime}\right)=E_{1} \cap E_{2}$ for $E_{1}, E_{2}$ two prime divisors at infinity. Suppose without loss of generality that $v_{E_{1}}<v_{E_{2}}$. By Proposition 3.4.31, we have that $v^{\prime}=\pi_{*} v_{s, t}$ for some $s, t>0$ such that $s b\left(E_{1}\right)+t b\left(E_{2}\right)=1$ and $\alpha\left(v^{\prime}\right)=\alpha\left(v_{E_{1}}\right)+\frac{t}{b\left(E_{1}\right)}$. Furthermore, by Proposition 3.6.29, the incarnation of $Z_{v^{\prime}, X, p}$ in $Y$ is

$$
\begin{equation*}
\left(Z_{\mathcal{V}^{\prime}, X, p}\right)_{Y}=\operatorname{sb}\left(E_{1}\right) Z_{v_{E_{1}}, X, p}+t b\left(E_{2}\right) Z_{v_{E_{2}}, X, p} \tag{3.204}
\end{equation*}
$$

And we have

$$
\begin{equation*}
Z_{v, X, p} \cdot Z_{v^{\prime}, X, p}=\operatorname{sb}\left(E_{1}\right)\left(Z_{v, X, p} \cdot Z_{v_{E_{1}}, X, p}\right)+t b\left(E_{2}\right)\left(Z_{v, X, p} \cdot Z_{V_{E_{2}}, X, p}\right) \tag{3.205}
\end{equation*}
$$

Either $v \wedge v^{\prime}=v \wedge v_{E_{1}}$ or $v \wedge v^{\prime}=v^{\prime}$. If $v \wedge v^{\prime}=v \wedge v_{E_{1}}$, then we also have $v \wedge v_{E_{2}}=v \wedge v_{E_{1}}$. The quantity in Equation (3.205) is then equal to

$$
\begin{equation*}
-s b\left(E_{1}\right) \alpha\left(v \wedge v_{E_{1}}\right)-t b\left(E_{2}\right) \alpha\left(v \wedge v_{E_{2}}\right)=\alpha\left(v \wedge v_{E_{1}}\right)=-\alpha\left(v \wedge v^{\prime}\right) \tag{3.206}
\end{equation*}
$$

If $v \wedge v^{\prime}=v^{\prime}$, then $v \wedge v_{E_{1}}=v_{E_{1}}$ and $v \wedge v_{E_{2}}=v_{E_{2}}$. The quantity in Equation 3.205) is then equal to

$$
\begin{equation*}
-s b\left(E_{1}\right) \alpha\left(v_{E_{1}}\right)-t b\left(E_{2}\right) \alpha\left(v_{E_{2}}\right)=-\alpha\left(v_{E_{1}}\right)-\frac{t}{b\left(E_{1}\right)}=-\alpha\left(v^{\prime}\right) . \tag{3.207}
\end{equation*}
$$

To get the last two equalities we use Proposition 3.4.27 and 3.4.31.
Finally, if $v=v^{\prime}$, we need to show that $\left(Z_{v, X, p}\right)^{2}=-\alpha(v)$. We know the result if $v$ is divisorial. We use approximating sequence to conclude in general. If $v$ is infinitely singular or
a curve valuation. Let $\left(X_{n}, p_{n}\right)$ be the sequence of infinitely near points associated to $v$. The approximating sequence of $v$ (Proposition 3.4.26 is the subsequence $v_{n}=\frac{1}{b\left(E_{n}\right)} \operatorname{ord}_{E_{n}}$ where $p_{n}$ is a free point lying over a unique prime divisor $E_{n}$ at infinity. We have that $\alpha\left(v_{n}\right) \rightarrow \alpha(v)$ and the incarnation of $Z_{v, X, p}$ in $X_{n}$ is $Z_{v_{n}, X, p}$. Therefore,

$$
\begin{equation*}
\left(Z_{v, X, p}\right)^{2}=\lim _{n}\left(Z_{v_{n}, X, p}\right)^{2}=-\lim _{n} \alpha\left(v_{n}\right)=-\alpha(v) \tag{3.208}
\end{equation*}
$$

If $v$ is irrational, then let $\left(X_{n}, p_{n}\right)$ be the sequence of infinitely near points associated to $v$. For every $n$ large enough, $p_{n}=E_{n} \cap F_{n}$ for $E_{n}, F_{n}$ two prime divisors at infinity. Suppose that for all $n, v_{E_{n}}<v_{F_{n}}$. Then, we have $v_{E_{n}}<v<v_{F_{n}}, \alpha\left(v_{E_{n}}\right) \rightarrow \alpha(v), \alpha\left(v_{F_{n}}\right) \rightarrow \alpha(v)$ and $b\left(E_{n}\right) \rightarrow+\infty, b\left(F_{n}\right) \rightarrow+\infty$. We have by Proposition 3.6.29 that the incarnation of $Z_{v, X, p}$ in $X_{n}$ is

$$
\begin{equation*}
s_{n} b\left(E_{n}\right) Z_{v_{E_{n}}, X, p}+t_{n} b\left(F_{n}\right) Z_{V_{F_{n}}, X, p} \tag{3.209}
\end{equation*}
$$

for some $s_{n}, t_{n}>0$ such that $s_{n} b\left(E_{n}\right)+t_{n} b\left(F_{n}\right)=1$. We have

$$
\begin{align*}
\left(Z_{v, X, p}\right)^{2} & =\lim _{n}\left(s_{n} b\left(E_{n}\right) Z_{v_{n}, X, p}+t_{n} b\left(F_{n}\right) Z_{v_{F_{n}, X, p}}\right)^{2}  \tag{3.210}\\
& =\lim _{n}-s_{n}^{2} b\left(E_{n}\right)^{2} \alpha\left(v_{E_{n}}\right)-2 s_{n} t_{n} b\left(E_{n}\right) b\left(F_{n}\right) \alpha\left(v_{E_{n}}\right)-t_{n}^{2} b\left(F_{n}\right)^{2} \alpha\left(v_{F_{n}}\right) \tag{3.211}
\end{align*}
$$

Therefore we get

$$
\begin{equation*}
\lim _{n}-\alpha\left(v_{E_{n}}\right) \leqslant\left(Z_{v, X, p}\right)^{2} \leqslant \lim _{n}-\alpha\left(v_{F_{n}}\right) \tag{3.212}
\end{equation*}
$$

Hence $\left(Z_{v, X, p}\right)^{2}=-\alpha(v)$.
Corollary 3.6.33. If $v \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$, then $Z_{v, X, p} \notin \operatorname{Weil}(X, p)_{\mathbf{Q}}$ if and only if $v$ is irrational.
Proof. If $v$ is divisorial, let $E \in \mathcal{D}_{X, p}$ such that $v$ is equivalent to $\operatorname{ord}_{E}$. Then,

$$
\begin{equation*}
Z_{v, X, p}=\frac{1}{b(E)} Z_{\operatorname{ord}_{E}, X, p} \in \operatorname{Weil}(X, p)_{\mathbf{Q}} \tag{3.213}
\end{equation*}
$$

by Proposition 3.6.27. If $v$ is infinitely singular or a curve valuation, let $\mu$ be any divisorial valuation. We have that $\mu \wedge \nu$ must be a divisorial valuation, therefore by Theorem 3.6.31 we have

$$
\begin{equation*}
Z_{\mu} \cdot Z_{v}=-\alpha(v \wedge \mu) \in \mathbf{Q} \tag{3.214}
\end{equation*}
$$

Hence $Z_{v, X, p} \in \operatorname{Weil}(X, p)_{\mathbf{Q}}$.
If $v$ is irrational, then for all $\mu \geqslant v$ divisorial we have $\alpha(\mu \wedge v)=\alpha(v) \in \mathbf{R} \backslash \mathbf{Q}$. Therefore, $Z_{V, X, p} \notin \operatorname{Weil}(X, p)$.

Proposition 3.6.34. Let $X$ be a completion, let $p \in X$ be a closed point at infinity. If $\left(v_{n}\right)$ is a sequence of $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ such that $\alpha\left(v_{n}\right)<+\infty$ for all $n$ and $v \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$, then $v_{n} \rightarrow v$ for the strong topology if and only if $Z_{v_{n}, X, p} \rightarrow Z_{v, X, p}$ for the strong topology of $\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$.

Proof. This all comes from Theorem 3.6.31 as

$$
\begin{align*}
\left|\left(Z_{v, X, p}-Z_{v_{n}, X, p}\right)^{2}\right| & =\left|-\alpha(v)+2 \alpha\left(v \wedge v_{n}\right)-\alpha\left(v_{n}\right)\right|  \tag{3.215}\\
& =\left|\alpha(v)-\alpha\left(v \wedge v_{n}\right)+\alpha\left(v_{n}\right)-\alpha\left(v \wedge v_{n}\right)\right| . \tag{3.216}
\end{align*}
$$

### 3.7 From linear forms to valuations

Suppose now that we have an element $L$ of $\operatorname{Hom}\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \mathbf{R}\right)$ satisfying property ( + ), we want to construct a valuation $v_{L}: A \rightarrow \mathbf{R} \cup\{\infty\}$ centered at infinity such that $L_{v_{L}}=L$.

First we extend $L$ to $S_{\infty}\left(X_{0}\right)$ (see Definition 3.2.12) by setting

$$
\begin{equation*}
\text { If } D=\bigvee_{i} D_{i} \text { with } D_{i} \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \quad L(D):=\sup _{i} L\left(D_{i}\right) . \tag{3.217}
\end{equation*}
$$

Proposition 3.7.1. This definition does not depend on the representation of $D$ as a supremum $D=\bigvee_{i} D_{i}$ with $D_{i} \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$.

Proof. If $D=\bigvee_{i \in I} D_{i}=\bigvee_{j \in J} D_{j}^{\prime}$. Let $j \in J$ be an index and $X$ a completion such that $D_{j}^{\prime}$ is defined on $X$. Let $\varepsilon>0$ and let $H$ be an effective divisor such that $\operatorname{Supp}(H)=\partial_{X} X_{0}$. There exists an index $i \in I$ such that $D_{i}+\varepsilon H \geqslant D_{j}^{\prime}$, since otherwise we would get $D+\varepsilon H \leqslant D_{j}^{\prime} \leqslant D$. Therefore we have by property $(+)$ item (1)

$$
\begin{equation*}
L\left(D_{j}^{\prime}\right) \leqslant L\left(D_{i}\right)+\varepsilon L(H) \leqslant \sup _{k} L\left(D_{k}\right)+\varepsilon L(H) . \tag{3.218}
\end{equation*}
$$

Letting $\varepsilon$ go to 0 , we get $\sup _{j} L\left(D_{j}^{\prime}\right) \leqslant \sup _{k} L\left(D_{k}\right)$ and the result holds by symmetry.
Proposition 3.7.2. We have the following properties: for $D, D^{\prime} \in \mathcal{S}_{\infty}\left(X_{0}\right)$

1. $L\left(D+D^{\prime}\right)=L(D)+L\left(D^{\prime}\right)$.
2. $L\left(D \wedge D^{\prime}\right)=\min \left(L(D), L\left(D^{\prime}\right)\right)$.
3. If $D \geqslant 0$, then $L(D) \geqslant 0$.

Proof. For (1), write

$$
\begin{aligned}
L\left(D+D^{\prime}\right) & =\sup _{(i, j) \in I \times J} L\left(D_{i}+D_{j}^{\prime}\right) \\
& =\sup _{i \in I} L\left(D_{i}\right)+\sup _{j \in J} L\left(D_{j}^{\prime}\right)=L(D)+L\left(D^{\prime}\right)
\end{aligned}
$$

For (2), let $D=\bigvee_{i} D_{i}$ and $D^{\prime}=\bigvee_{j} D_{j}^{\prime}$ be two elements of $\mathcal{S}_{\infty}\left(X_{0}\right)$. Then,

$$
\begin{equation*}
D \wedge D^{\prime}=\bigvee_{i, j} D_{i} \wedge D_{j}^{\prime} \tag{3.219}
\end{equation*}
$$

and

$$
\begin{align*}
& L\left(D \wedge D^{\prime}\right)=\sup _{i, j} \min \left(L\left(D_{i}\right), L\left(D_{j}^{\prime}\right)\right)  \tag{3.220}\\
&=\min _{\left(\sup _{i} L\left(D_{i}\right), \sup _{j} L\left(D_{j}^{\prime}\right)\right)}  \tag{3.221}\\
&=\min \left(L(D), L\left(D^{\prime}\right)\right) . \tag{3.222}
\end{align*}
$$

For (3), if $D=0$, then $L(D)=0$. Otherwise, $D>0$ and there exists a Cartier divisor $D_{i}$ defined in some completion $X$ of $X_{0}$ such that $D_{X} \geqslant D_{i} \geqslant 0$ and therefore

$$
\begin{equation*}
L(D) \geqslant L\left(D_{i}\right) \geqslant 0 \tag{3.223}
\end{equation*}
$$

Recall the notations of Section 3.2.2, Define

$$
\begin{equation*}
w(P):=\left(\operatorname{div}_{\infty, X}(P)\right)_{X} \tag{3.224}
\end{equation*}
$$

Proposition 3.7.3. For $P \in A, w(P)$ defines an element of $\mathrm{Weil}_{\infty}\left(\mathrm{X}_{0}\right)$, moreover if one identifies for any completion $X$ the divisor $\operatorname{div}_{\infty, X}(P) \in \operatorname{Div}_{\infty}(X)$ with its image in $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$, then

$$
\begin{equation*}
w(P)=\bigvee_{X} \operatorname{div}_{\infty, X}(P) \tag{3.225}
\end{equation*}
$$

Thus, $w(P)$ defines an element of $\mathcal{S}_{\infty}\left(X_{0}\right)$.
Proof. To prove both assertions it suffices to show that if $X$ is a completion of $X_{0}$ and $Y$ is the blow up of some point at infinity, then $\pi_{*} \operatorname{div}_{\infty, Y}(P)=\operatorname{div}_{\infty, X}(P)$ and $\pi^{*} \operatorname{div}_{\infty, X}(P) \leqslant \operatorname{div}_{\infty_{\infty}, Y}(P)$. Let $\widetilde{E}$ be the exceptional divisor of $\pi$ and let $E_{1}, \ldots, E_{r}$ be the prime divisors in $\partial_{X} X_{0}$. Since $P$ is regular over $X_{0}, \operatorname{div}_{X}(P)$ is of the form

$$
\begin{equation*}
\operatorname{div}_{X}(P)=D+\sum_{i=1}^{r} a_{i} E_{i} \tag{3.226}
\end{equation*}
$$

where $D$ is an effective divisor such that no irreducible component of its support is one of the $E_{i}$ 's; by definition $\operatorname{div}_{\infty, X}(P)=\sum_{i=1}^{r} a_{i} E_{i}$. Then, $\operatorname{div}_{Y}(P)$ is of the form

$$
\begin{equation*}
\operatorname{div}_{Y}(P)=\operatorname{div}_{Y}(P \circ \pi)=\pi^{*} \operatorname{div}_{X}(P)=\pi^{\prime}(D)+b \widetilde{E}+\sum_{i=1}^{r} a_{i} \pi^{\prime}\left(E_{i}\right) \tag{3.227}
\end{equation*}
$$

for some $b \in \mathbf{Z}$. So $\operatorname{div}_{\infty, Y}(P)=b \widetilde{E}+\sum_{i=1}^{r} a_{i} \pi^{\prime}\left(E_{i}\right)$ and we get $\pi_{*}\left(\operatorname{div}_{\infty, Y}(P)\right)=\operatorname{div}_{\infty, X}(P)$ as $\pi_{*}(\widetilde{E})=0$, This shows that $w(P)$ is an element of $\operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)$.

To show that $\pi^{*} \operatorname{div}_{\infty, X}(P) \leqslant \operatorname{div}_{\infty, Y}(P)$ we have to be more precise about the coefficient $b$. We can write $b=c+d$, where $\pi^{*} D=\pi^{\prime}(D)+d \widetilde{E}$ and $\pi^{*} \operatorname{div}_{\infty, X}(P)=c \widetilde{E}+\sum_{i} a_{i} \pi^{\prime}\left(E_{i}\right)$. Since, $D$ is effective, we have $d \geqslant 0$ and the result follows.

We define

$$
\begin{equation*}
v_{L}(P):=L(w(P)) \tag{3.228}
\end{equation*}
$$

Remark 3.7.4. The class $w(P)$ is not in general a Cartier class. Indeed, take $X_{0}=\mathbf{A}^{2}, X=\mathbf{P}^{2}$ with homogeneous coordinates $[x: y: z]$ such that $\{z=0\}$ is the line at infinity. Consider $P=y / z \in \mathbf{k}\left(\mathbf{P}^{2}\right)$. Define a sequence of blow ups $X_{i}$ by $X_{0}=\mathbf{P}^{2}, E_{0}=\{z=0\}$ and $\pi_{i+1}: X_{i+1} \rightarrow X_{i}$ the blow up of the intersection point of the strict transform of $\{y=0\}$ in $X_{i}$ and $E_{i}$, where $E_{i}$ is the exceptional divisor in $X_{i}$. Let $C_{y}$ be the strict transform of $\{y=0\}$ in any the $X_{i}$. We still denote by $E_{i}$ its strict transform in every $X_{j}, j \geqslant i$. Then,

$$
\begin{aligned}
\operatorname{div}_{\mathbf{P}^{2}}(P) & =C_{y}-E_{0} \\
\operatorname{div}_{X_{1}}(P) & =C_{y}-E_{0} \\
\operatorname{div}_{X_{2}}(P) & =C_{y}+E_{2}-E_{0} \\
\operatorname{div}_{X_{3}}(P) & =C_{y}+2 E_{3}+E_{2}-E_{0}
\end{aligned}
$$

and by induction, we get for all $k \geqslant 2$

$$
\begin{equation*}
\operatorname{div}_{X_{k}}(P)=C_{y}+\sum_{j=2}^{k}(j-1) E_{j}-E_{0} \tag{3.229}
\end{equation*}
$$

Therefore, for all $k \geqslant 2$

$$
\begin{aligned}
\pi_{k+1}^{*} \operatorname{div}_{\infty, X_{k}}(P) & =(k-1) E_{k+1}+\sum_{j=2}^{k}(j-1) E_{j}-E_{0} \\
& \neq k E_{k+1}+\sum_{j=2}^{k}(j-1) E_{j}-E_{0}=\operatorname{div}_{\infty, X_{k+1}}(P)
\end{aligned}
$$

Thus, $w(P)$ is not a Cartier class.
Proposition 3.7.5. The function $\nu_{L}$ is a valuation on $A$ centered at infinity.
Proof. We first show that $v_{L}$ is in fact a valuation

1. For any $\lambda \in \mathbf{k}^{*}$ and for any completion $X$ of $X_{0}, \operatorname{div}_{X}(\lambda)=0$ so $v_{L}(\lambda)=0$.
2. If $f, g \in A$, then $\operatorname{div}_{X}(f g)=\operatorname{div}_{X}(f)+\operatorname{div}_{X}(g)$. So, $w(f g)=w(f)+w(g)$ and by Proposition 3.7.2 $\mathrm{v}_{L}(f g)=\mathrm{v}_{L}(f)+\mathrm{v}_{L}(g)$.
3. Let $f, g \in A, f \neq-g$, then $\operatorname{div}_{X}(f+g) \geqslant \operatorname{div}_{X}(f) \wedge \operatorname{div}_{X}(g)$, therefore

$$
\begin{equation*}
w(f+g) \geqslant w(f) \wedge w(g) \tag{3.230}
\end{equation*}
$$

and by Proposition 3.7.2 $v_{L}(f+g) \geqslant \min \left(v_{L}(f), v_{L}(g)\right)$.
If $L \neq 0$, there exists a completion $X$ and a prime divisor $E$ at infinity such that $L(E)>0$. By Theorem 3.1.4 there exists $H \in \operatorname{Div}_{\infty}(X)$ ample such that $H \geqslant 0, \operatorname{Supp} H=\partial_{X} X_{0}$. We have by item (1) of $(+)$ that $L(H) \geqslant L(E)>0$. To show that $v_{L}$ is centered at infinity, it suffices to show that $L_{v_{L}}(H)>0$. Up to replacing $H$ by one of its multiples (which does not change the hypothesis $L(H)>0$ ), we can suppose that $H$ is very ample and that it induces an embedding $\tau: X \hookrightarrow \mathbf{P}^{N}$ such that $\tau(H)$ is the intersection of $\tau(X)$ with the hyperplane $\left\{x_{0}=0\right\}$. By Bertini's theorem, we can find a hyperplane $M=\left\{\sum_{i} \lambda_{i} x_{i}=0\right\} \neq\left\{x_{0}=0\right\}$ such that $M \cap \tau(X)$ is a smooth irreducible subvariety $C$ in $X$ satisfying

1. The intersection of $C$ with any divisor at infinity of $X$ is transverse.
2. If $v_{L}$ is not divisorial, the center of $v_{L}$ is not contained in $C$.

Indeed, by Bertini theorem, the set $U_{X}$ of hyperplanes $H$ such that $H \cap X$ is a smooth irreducible curve is an open dense subset. Let $E_{1}, \cdots, E_{n}$ be the primes at infinity in $X$. Applying Bertini
theorem to $E_{i}$ yields an open subset $U_{i}$ of hyperplanes that meet $E_{i}$ transversally. Finally, if the center of $\mathrm{v}_{L}$ is a subvariety $Y$ of codimension $\geqslant 2$, then the set of hyperplanes that contain $Y$ is a closed nowhere dense subset of $\mathbf{P}\left(\Gamma\left(\mathbf{P}^{n}, O(1)\right)\right)$ because $|H|$ is base point free, so its complementary is a non-empty open subset $U_{Y}$. Now, $U_{1} \cap \cdots \cap U_{n} \cap U_{Y}$ is an open subset that intersects $U_{X}$ since it is dense, we then choose $M$ in the intersection. Define

$$
\begin{equation*}
P=\sum_{i=0}^{N} \lambda_{i} \frac{x_{i}}{x_{0}} \tag{3.231}
\end{equation*}
$$

Then, $P$ is a regular function over $X_{0}$ such that $\operatorname{div}_{X}(P)=C-H$ and $1 / P$ is a local equation of $H$ at the center of $v_{L}$ (even if $v_{L}$ is divisorial). Hence,

$$
\begin{equation*}
L_{v_{L}}(H)=v_{L}(1 / P)=\sup _{Y}\left(L\left(\operatorname{div}_{\infty, Y}(1 / P)\right) \geqslant L(H)>0 .\right. \tag{3.232}
\end{equation*}
$$

In Section 3.6, we have constructed a map

$$
\begin{equation*}
L: \mathcal{V}_{\infty} \rightarrow \operatorname{Hom}\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \mathbf{R}\right)_{(+)} \tag{3.233}
\end{equation*}
$$

here, we have constructed a map

$$
\begin{equation*}
v: \operatorname{Hom}\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \mathbf{R}\right)_{(+)} \rightarrow \mathcal{V}_{\infty} \tag{3.234}
\end{equation*}
$$

where $\operatorname{Hom}\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \mathbf{R}\right)_{(+)}$are the linear forms over $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$ that satisfy property $(+)$. We shall prove that they are mutual inverse in Section 3.8 (this result is not needed in this memoir).

### 3.8 Proof that $v$ and $L$ are mutual inverses

Set $\mathcal{M}:=\operatorname{Hom}\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \mathbf{R}\right)_{(+)}$. In Section 3.6, we have defined $L: v \in \mathcal{V}_{\infty} \mapsto L_{v} \in \mathscr{M}$ and $v: L \in \mathcal{M} \mapsto v_{L} \in \mathcal{V}_{\infty}$. The goal is to show that these two maps are inverse of each other.

Proposition 3.8.1. For all valuation $\boldsymbol{v} \in \mathcal{V}_{\infty}$ and for all $P \in O_{X}\left(X_{0}\right), v(P)=L_{v}(w(P))$.
Proof. Let $X$ be a completion of $X_{0}$. We have seen that $\operatorname{div}_{\infty, X}(P)=\operatorname{div}_{X}(P)-D$ where $D$ is an effective divisor not supported in $\partial_{X} X_{0}$. Therefore,

$$
\begin{equation*}
L_{v, X}\left(\operatorname{div}_{\infty, X}(P)\right)=v(P)-L_{v, X}(D) \leqslant v(P) \tag{3.235}
\end{equation*}
$$

Taking the supremum over $X$, we get $L_{v}(w(P)) \leqslant v(P)$.
To show the other inequality, take a valuation $v$ centered at infinity and let $X$ be a completion of $X_{0}$. Up to further blow ups of point at infinity, we can suppose that $D:=\operatorname{div}_{X}(P)$ is a divisor in $X$ with simple normal crossing on $\partial_{X} X_{0}$. Let $E_{1}, \cdots, E_{r}$ be the prime divisors at infinity of $X$. Then, $D$ is of the form

$$
\begin{equation*}
D=\sum_{i=1}^{r} a_{i} E_{i}+\sum_{j \in J} b_{j} F_{j} \tag{3.236}
\end{equation*}
$$

for some prime divisors $F_{j}$ not supported at infinity. Let $p$ be the center of $v$ on $X$, there are two cases.

1. For all $j \in J, p \notin F_{j}$, in that case for all $j \in J, L_{v, X}\left(F_{j}\right)=0$ and $v(P)=L_{v, X}\left(\operatorname{div}_{\infty, X}(P)\right)$. Therefore, $v(P) \leqslant L_{v}(w(P))$ and they are equal.
2. There exist a unique $j \in J$ and a unique $i$ such that $p=E_{i} \cap F_{j}$. The uniqueness comes from the fact that $D$ is a divisor with simple normal crossing. We denote them respectively by $E$ and $F$. Then, we construct a sequence of blow up of points $\pi_{i}: \overline{X_{i+1}} \rightarrow \overline{X_{i}}$ such that $\pi_{i}$ is the blow-up of the center of $v$ in $X_{i}$ and $X_{0}=X$. We still denote by $F$ the strict transform of $F$ in any of these blow-ups. There are two possibilities:
(a) Either there exists a number $k$ such that the center of $v$ in $X_{k}$ does not belong to $F$ (This includes the case where $v$ is divisorial, in that case the center becomes a prime divisor and there are no more blow-ups to be done). In that case, we are back in case 1 and $v(P)=v_{X_{k}}\left(\operatorname{div}_{\infty, X_{k}}(P)\right) \leqslant L_{v}(w(P))$ and we get the desired equality.
(b) Or for all $k \geqslant 0$, the center of $v$ in $X_{k}$ belongs to $F$, in that case $v$ is the curve valuation associated to $F$ at $p$ and $v(P)=+\infty$. We show that $v_{X_{k}}\left(\operatorname{div}_{\infty, X_{k}}(P)\right) \rightarrow+\infty$ using the following result.

Lemma 3.8.2. In case 2.(b), set $E_{0}=E$ and for $k \geqslant 1, \widetilde{E}_{k}$ the exceptional divisor in $X_{k}$ above $c_{X_{k-1}}(v)$, then $L_{v, X_{0}}(E)=L_{v, X_{k}}\left(E_{k}\right)$ for all $k$ and the divisor $\operatorname{div}_{X_{k}}(P)$ is of the form

$$
\begin{equation*}
\operatorname{div}_{X_{k}}(P)=(a+k b) \widetilde{E}_{k}+b F+D_{k}^{\prime} \tag{3.237}
\end{equation*}
$$

where $a=\operatorname{ord}_{E}(P)>0, b=\operatorname{ord}_{F}(P)>0$ and $c_{X_{k+1}}(v)$ does not belong to the support of $D_{k}^{\prime}$.

Proof. First, since we are in case 2 b and we have supposed that $\operatorname{Suppdiv}_{X}(P)$ is with simple normal crossings, we have that for all $k \geqslant 0$ the center of $v$ in $X_{k}$ is the intersection point $p_{k}:=\widetilde{E}_{k} \cap F$.

We proceed by induction on $k$. If $k=0$ then the result is true as $X_{0}=X$ and $c_{X}(v)=E \cap F$. Suppose the result true for a given index $k \geqslant 0$, then when we blow up $p_{k}, p_{k+1}$ is the intersection point of $\widetilde{E}_{k+1}$ and $F$ so it does not belong to $\pi_{k}^{\prime}\left(\widetilde{E}_{k}\right)$ therefore $L_{v, X_{k+1}}\left(\pi_{k}^{\prime}\left(\widetilde{E}_{k}\right)\right)=0$. By induction we have $v_{X_{k}}\left(\widetilde{E}_{k}\right)=L_{v, X_{0}}(E)$, and we know that

$$
\begin{equation*}
L_{v, X_{k}}\left(\widetilde{E}_{k}\right)=L_{v, X_{k+1}}\left(\pi_{k}^{*} \widetilde{E}_{k}\right)=L_{v, X_{k+1}}\left(\pi_{k}^{\prime}\left(\widetilde{E}_{k}\right)+\widetilde{E}_{k+1}\right)=L_{v, X_{k+1}}\left(\widetilde{E}_{k+1}\right) \tag{3.238}
\end{equation*}
$$

so this shows the first assertion. Now, by induction $\operatorname{div}_{X_{k}}(P)$ is of the form

$$
\begin{equation*}
\operatorname{div}_{X_{k}}(P)=(a+k b) \widetilde{E}_{k}+b F+D_{k}^{\prime} \tag{3.239}
\end{equation*}
$$

Now, since $p_{k}=\widetilde{E}_{k} \cap F$ and $p_{k} \notin \operatorname{Supp} D_{k}^{\prime}$, one has

$$
\begin{equation*}
\operatorname{div}_{X_{k+1}(P)}=\pi_{k}^{*} \operatorname{div}_{X_{k}}(P)=(a+(k+1) b) \widetilde{E}_{k+1}+b F+(a+k b) \pi_{k}^{\prime}\left(\widetilde{E}_{k}\right)+\pi_{k}^{\prime}\left(D_{k}^{\prime}\right) \tag{3.240}
\end{equation*}
$$

Since $p_{k+1} \notin \pi_{k}^{\prime}\left(\widetilde{E}_{k}\right)$, the support of the divisor $D_{k+1}^{\prime}:=\pi_{k}^{\prime}\left(D_{k}^{\prime}\right)+(a+k b) \pi_{k}^{\prime}\left(\widetilde{E}_{k}\right)$ does not contain $p_{k+1}$ and we are done.

Using this lemma we see that

$$
\begin{equation*}
L_{v, X_{k}}\left(\operatorname{div}_{\infty, X_{k}}(P)\right)=(a+k b) L_{v, X_{0}}(E) \underset{k \rightarrow \infty}{\longrightarrow}+\infty \tag{3.241}
\end{equation*}
$$

Therefore $L_{v}(w(P))=+\infty$ and since $v(P) \geqslant L_{v}(w(P))$ we have that $v(P)=+\infty$

To show that $L \circ v=\mathrm{id}_{\mathcal{M}}$ we need some technical lemmas.
Proposition 3.8.3. Let $L \in \mathcal{M}$ and $X$ be a completion of $X_{0}$. If there exists two divisors $E, E^{\prime}$ at infinity in $X$ such that $L(E), L\left(E^{\prime}\right)>0$, then $E$ and $E^{\prime}$ must intersect.

Proof. Suppose that $E$ and $E^{\prime}$ do not intersect, then the sheaf of ideals $\mathfrak{a}=O_{X}(-E) \oplus O_{X}\left(-E^{\prime}\right)$ is trivial, $\mathfrak{a}=O_{X}$. From Proposition 3.6.25, we get $E \wedge E^{\prime}=0$. Thus $L\left(E \wedge E^{\prime}\right)=0$. But $L\left(E \wedge E^{\prime}\right)=\min \left(L(E), L\left(E^{\prime}\right)\right)>0$ and this is a contradiction.

Corollary 3.8.4. Let $X$ be a completion of $X_{0}$, suppose there exists two prime divisors at infinity $E, F$ such that $L(E), L(F)>0$. Then, let $\widetilde{E}$ be the exceptional divisor above $p=E \cap F$, one has $L(\widetilde{E})>0$.
Proof. Let $\pi: Y \rightarrow X$ be the blow up of $p$ and suppose that $L(\widetilde{E})=0$. Since $\pi^{*} E=\pi^{\prime}(E)+\widetilde{E}$ and $\pi^{*} F=\pi^{\prime}(F)+\widetilde{E}$, one has $L\left(\pi^{\prime}(E)\right)>0$ and $L\left(\pi^{\prime}(F)\right)>0$ but the two divisors no longer meet and this is a contradiction.

Proposition 3.8.5. Let $X$ be a completion of $X_{0}$, there are two possibilities

1. There exist a unique closed point $p$ in $X$ at infinity such that if $\widetilde{E}$ is the exceptional divisor above $p$, one has $L(\widetilde{E})>0$. We call this point the center of $L$ in $X$.
2. If no point satisfy this property, then there exists a unique divisor at infinity $E$ in $X$ such that $L(E)>0$. In that case we call $E$ the center of $L$ in $X$.
and we have the following properties
(a) Let $E$ be a prime divisor at infinity in $X$. If the center of $L$ on $X$ is a point $p$, then $p \in E \Leftrightarrow L(E)>0$.
(b) If $Y$ is a completion of $X_{0}$ above $X$, then the center of $L$ in $Y$ belongs to the inverse image of the center of $X$.

Proof. Suppose there are two points $p_{1}, p_{2}$ satisfying this property on $X$. Let $\pi_{i}$ be the blow up of $p_{i}$ in $X$, we have commutative diagram

where on the left side we first blow up $p_{1}$ then we blow up the strict transform of $p_{2}$ and the other way around on the right. Now let $\widetilde{E}_{1}, \widetilde{E}_{2}$ be the exceptional divisors above $p_{1}$ and $p_{2}$ respectively in $X_{1}$ and in $X_{2}$ and suppose that $L\left(\widetilde{E}_{1}\right), L\left(\widetilde{E}_{2}\right)>0$. Then, since $p_{1}$ does not belong to $\widetilde{E}_{2}$ and $p_{2}$ does not belong to $\widetilde{E}_{1}$, we have that $L\left(\widetilde{E}_{1}\right)=L\left(\tau_{1}^{*} \widetilde{E}_{1}\right)=L\left(\tau_{1}^{\prime}\left(\widetilde{E}_{1}\right)\right)>0$ and $L\left(\tau_{2}^{\prime}\left(\widetilde{E}_{2}\right)\right)>0$. But in $Y$ the prime divisors $\tau_{1}^{\prime}\left(\widetilde{E}_{1}\right)$ and $\tau_{2}^{\prime}\left(\widetilde{E}_{2}\right)$ do not intersect and that contradicts Proposition 3.8.3.

Now, if $E, F$ are two divisors at infinity such that $L(E), L(F)>0$, Lemma 3.8.4 shows that $E \cap F$ must be the center of $L$ on $X$. Hence if no point of $X$ is the center of $L$ there is only one prime divisor at infinity $E$ such that $L(E)>0$.

To show assertion (a), suppose that the center of $L$ on $X$ is a point $p$ and let $\pi$ be the blow up of $p$. If $p \in E$, then $\pi^{*}(E)=\pi^{\prime}(E)+\widetilde{E}$ and $L(E)=L\left(\pi^{*} E\right) \geqslant L(\widetilde{E})>0$. If $L(E)>0$ then $p$ must belong to $E$ otherwise $\widetilde{E}$ and $E$ would not intersect and this contradicts Proposition 3.8.3.

We now assertion (b), we only need to show it for the blow up of a point $\pi: Y \rightarrow X$. Suppose first that the center of $L$ on $X$ is a (closed) point $p$. If we blow up another point than $p$, then it is clear that the center of $L$ on $Y$ is the point $\pi^{-1} p$ as the order of the blow ups does not matter in that case.

Suppose now that we blow up $p$, then the exceptional divisor $\widetilde{E}$ verifies $L(\widetilde{E})>0$, if the center of $L$ on $Y$ is a prime divisor then it must be $\widetilde{E}$. If it is a point then it must belong to $\widetilde{E}$ by assertion (a).

If the center of $L$ on $X$ is a prime divisor $E$, then for any blow up $\pi: Y \rightarrow X$ of a point of $X$, we show that the center of $L$ on $Y$ is $\pi^{\prime}(E)$. The exceptional divisor $\widetilde{E}$ verifies $L(\widetilde{E})=0$ and $\pi^{\prime}(E)$ is the only prime divisor of $Y$ such that $L\left(\pi^{\prime}(E)\right)>0$. Thus, if the center of $L$ on $Y$ is not a point, it must be $\pi^{\prime}(E)$. If the center of $L$ on $Y$ is a point $q$, then it must belong to $\pi^{\prime}(E)$ by assertion (a). If $q$ is not the intersection point $\pi^{\prime}(E) \cap \widetilde{E}$, then it is the strict transform of a point $p \in E$ and in that case $p$ was the center of $L$ in $X$ this is a contradiction. If $q=\widetilde{E} \cap \pi^{\prime}(E)$, then $L(\widetilde{E})>0$ by assertion (a) and this is also a contradiction. Therefore, the center of $L$ on $Y$ cannot be a point, it is $\pi^{\prime}(E)$.

We say that $L$ is divisorial if there exists a completion $X$ of $X_{0}$ such that the center of $L$ on $X$ is a prime divisor at infinity.

Proposition 3.8.6. The map $v$ sends divisorial valuations to divisorial elements of $\mathcal{M}$ and the map L sends divisorial functions to divisorial valuations.

Proof. The fact that divisorial valuations induce divisorial functions on Cartier divisors is clear. Suppose that $L$ is a divisorial function and let $X$ be a completion such that the center of $L$ in
$X$ is a prime divisor $E$ at infinity. Then, for all completion $\pi: Y \rightarrow X$ above $X$, the center of $L$ on $Y$ is the strict transform of $E$ by Proposition 3.8.5 and $L(E)=L\left(\pi^{\prime}(E)\right)$. Therefore, let $v$ be the divisorial valuation on $A$ such that $v_{X}=\operatorname{ord}_{E}$ and let $P \in O_{X_{0}}\left(X_{0}\right)$, then for all completion $Y$ above $X$, we have by Proposition 3.8.5

$$
\begin{equation*}
L\left(\operatorname{div}_{\infty, Y}(P)\right)=L\left(\pi^{\prime}(E)\right) \operatorname{ord}_{E}\left(\operatorname{div}_{Y}(P)\right)=L(E) v(P) \tag{3.242}
\end{equation*}
$$

Therefore $\nu_{L}(P)=L(E) v(P)$ and it is a divisorial valuation.
Proposition 3.8.7. One has $L \circ \mathrm{~V}=\mathrm{id}_{\mathcal{M}}$.
Proof. We can assume that $L$ and $\nu_{L}$ are not divisorial. Let $X$ be a completion of $X_{0}$, we will show first that if $H \in \operatorname{Div}_{\infty}(X)$ is an effective divisor such that $|H|$ is base point free and $\operatorname{Supp} H=\partial_{X} X_{0}$, then $v_{L}(H)=L(H)$. Pick $f$ generic in $H^{0}\left(X, O_{X}(H)\right)$. We have that $\operatorname{div} f=Z_{f}-H$ with $Z_{f}$ effective, $\operatorname{Supp} Z_{f}$ does not contain any divisor at infinity and the center of $v_{L}$ and the center of $L$ do not belong to $\operatorname{Supp} Z_{f}$. Thus, $f$ defines a regular function over $X_{0}$, $1 / f$ is a local equation of $H$ at the center of $v_{L}$ and we have

$$
\begin{equation*}
\nu_{L}(f)=\sup _{Y} L\left(\operatorname{div}_{\infty, Y}(f)\right) \tag{3.243}
\end{equation*}
$$

Now, by our assumptions on $f$ we have
Lemma 3.8.8. For all $Y$ above $X, \operatorname{div}_{Y}(f)$ is of the form $Z_{f, Y}+\operatorname{div}_{\infty, Y}(f)$ where $Z_{f, Y}$ is effective, supported on $X_{0}$ and $\operatorname{Supp} Z_{f, Y}$ does not contain the center of $L$. Furthermore, we have $L\left(\operatorname{div}_{\infty, Y}(f)\right)=L\left(\operatorname{div}_{\infty, X}(f)\right)$.

Proof. This is true for $Y=X$. We proceed by induction. Let $Y$ be a completion above $Y$ where the lemma is true and let $\pi: Y_{1} \rightarrow Y$ be a blow up of $Y$ at a point $p$. If $p$ is not the center of $L$ then the lemma is clearly true over $Y_{1}$, if $p$ is the center of $L$ over $Y$ then since $p$ does not belong to $\operatorname{Supp} Z_{f, Y}$ we have

$$
\begin{equation*}
\operatorname{div}_{f, Y_{1}}=\pi^{\prime}\left(Z_{f, Y}\right)+\pi^{*}\left(\operatorname{div}_{\infty, Y}(f)\right) \tag{3.244}
\end{equation*}
$$

and the lemma is true since $Z_{f, Y_{1}}=\pi^{\prime}\left(Z_{f, Y}\right)$ and $\operatorname{div}_{\infty, Y_{1}}(f)=\pi^{*}\left(\operatorname{div}_{\infty, Y}(f)\right)$.

Using this lemma we conclude that $v_{L}(f)=L\left(\operatorname{div}_{\infty, X}(f)\right)=-L(H)$. Therefore,

$$
\begin{equation*}
v_{L}(H)=v_{L}(1 / f)=L(H) \tag{3.245}
\end{equation*}
$$

Now take any divisor $D \in \operatorname{Div}_{\infty}(X)$. There exists an integer $n \geqslant 1$ such that $D+n H$ is effective and $|D+n H|$ is base-point free. Therefore,

$$
\begin{equation*}
v_{L}(D)=v_{L}(D+n H)-v_{L}(n H)=L(D+n H)-L(n H)=L(D) . \tag{3.246}
\end{equation*}
$$

## Eigenvaluations And dynamics at <br> INFINITY

### 4.1 Dynamics when $A^{\times}=\mathbf{k}^{\times}$and $\operatorname{Pic}^{0}\left(X_{0}\right)=0$

### 4.1.1 The structure of the Picard-Manin space of $X_{0}$

From Section 3.2.6 we have linear maps

$$
\begin{equation*}
\tau: \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \rightarrow \text { Cartier-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}}, \quad \tau: \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \rightarrow \text { Weil-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \tag{4.1}
\end{equation*}
$$

For this section we suppose that $X_{0}=\operatorname{Spec} A$ is a normal affine surface over an algebraically closed field $\mathbf{k}$ such that

1. $A^{\times}=\mathbf{k}^{\times}$;
2. For all completion $X$ of $X_{0}, \operatorname{Pic}^{0}(X)=0$.

It suffices to test the second condition on one completion of $X_{0}$ as the Albanese variety of a projective variety is a birational invariant. We will make an abuse of notations and write $\operatorname{Pic}^{0}\left(X_{0}\right)=0$ for the second hypothesis.

If these two conditions are satisfied, the finite dimensional subspace $\operatorname{Div}_{\infty}(X)$ embeds into $\mathrm{NS}(X)$. Indeed, consider the composition

$$
\begin{equation*}
\operatorname{Div}_{\infty}(X) \rightarrow \operatorname{Pic}(X) \rightarrow \mathrm{NS}(X), \tag{4.2}
\end{equation*}
$$

the first map is injective since $A^{\times}=\mathbf{k}^{\times}$and the second is an isomorphism because $\operatorname{Pic}^{0}(X)=0$. Therefore the maps $\tau$ are injective and we have the orthogonal decomposition

$$
\begin{equation*}
\text { Weil-NS }\left(\mathrm{X}_{0}\right)_{\mathbf{R}}=\operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \oplus V \tag{4.3}
\end{equation*}
$$

## Chapter 4 - Eigenvaluations and dynamics at infinity

where $V$ is a finite-dimensional vector space(this decomposition also holds over $\mathbf{Q}$ ); in fact let $X$ be a completion of $X_{0}$, then $V$ is the orthogonal of $\operatorname{Div}_{\infty}(X)$ in $\operatorname{NS}(X)$.

### 4.1.1.1 The intersection form at infinity

Proposition 4.1.1. Let $X$ be a completion of $X_{0}$, then

- $\operatorname{Div}_{\infty}(X)$ embeds into $\operatorname{NS}(X)$ and the intersection form is non degenerate on $\operatorname{Div}_{\infty}(X)$.
- The perfect pairing Cartier- $\mathrm{NS}\left(\mathrm{X}_{0}\right) \times$ Weil-NS $\left(\mathrm{X}_{0}\right) \rightarrow \mathbf{R}$ induces a pairing

$$
\begin{equation*}
\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right) \times \text { Weil }_{\infty}\left(\mathrm{X}_{0}\right) \rightarrow \mathbf{R} \tag{4.4}
\end{equation*}
$$

that is also perfect.

- Weil $\omega_{\infty}\left(\mathrm{X}_{0}\right)$ is isomorphic, as a linear topological vector space, to $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)^{*}$ endowed with the weak-* topology.

Proof. Everything follows from Propositions 3.2.20 and 3.2.17 and that $\tau: \operatorname{Div}_{\infty}(X) \hookrightarrow \operatorname{NS}(X)$ is injective.

Corollary 4.1.2. The subspace $\operatorname{Hom}\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \mathbf{R}\right)_{(+)}$is a closed subspace of Weil ${ }_{\infty}\left(\mathrm{X}_{0}\right)$ with the weak-ᄎ topology.

Proof. All the conditions that elements of $\operatorname{Hom}\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \mathbf{R}\right)_{(+)}$have to satisfy are closed conditions. Indeed, we have

$$
\begin{equation*}
\operatorname{Hom}\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \mathbf{R}\right)_{(+)}=C_{1} \cap C_{2} \tag{4.5}
\end{equation*}
$$

where

$$
\begin{align*}
& C_{1}=\bigcap_{D \geqslant 0}\{L(D) \geqslant 0\}  \tag{4.6}\\
& C_{2}=\bigcap_{D, D^{\prime} \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)}\left\{L\left(D \wedge D^{\prime}\right)=\min \left(L(D), L\left(D^{\prime}\right)\right)\right\} . \tag{4.7}
\end{align*}
$$

### 4.1.1.2 A continuous embedding of $\mathcal{V}_{\infty}$ into $\mathrm{Weil}_{\infty}\left(\mathrm{X}_{0}\right)$

From Proposition 4.1.1, we get the immediate corollary.
Corollary 4.1.3. For any valuation $v$ centered at infinity, there exists a unique $Z_{v} \in \operatorname{Weil}_{\infty}\left(X_{0}\right)$ such that for all $D \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), L_{v}(D)=Z_{v} \cdot D$.

Corollary 4.1.4. A valuation $v$ is divisorial if and only if $Z_{v}$ belongs to $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$. In particular, for any prime divisor $E$ at infinity, $Z_{\text {ord }_{E}} \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{Q}}$. The embedding

$$
\begin{equation*}
v \in \mathcal{V}_{\infty} \mapsto Z_{v} \in \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right) \tag{4.8}
\end{equation*}
$$

is a continuous map for the weak topology.
Proof. If $v$ is divisorial, then there exists a completion $X$ such that the center of $v$ is a prime divisor $E$ at infinity. For every $W \in \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right), L_{\text {ord }_{E}}(W)=L_{\text {ord }_{E}, X}\left(W_{X}\right)$, by Proposition 3.6.22, By non-degeneracy of the intersection pairing on $\operatorname{Div}_{\infty}(X)_{\mathbf{Q}}$, there exists $Z \in \operatorname{Div}_{\infty}(X)_{\mathbf{Q}}$ such that for all $D \in \operatorname{Div}_{\infty}(X)_{\mathbf{Q}}, L_{\text {ord }_{E}, X}(D)=Z \cdot D$. It follows that $Z_{\text {ord }_{E}}$ is the Cartier class defined by $Z$, hence it is an element of $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{Q}}$.

Conversely, if $Z_{v} \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$, let $X$ be a completion where $Z_{v}$ is defined. The center of $v$ over $X$ cannot be a closed point $p$; otherwise let $\widetilde{E}$ be the exceptional divisor above $p$, we would have $L_{v}(\widetilde{E})>0$, but $Z_{v} \cdot \widetilde{E}=0$.

Now to show the continuity of the map of the Corollary, it suffices by Proposition 4.1.1 to show that for any $D \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$, the map $v \in \mathcal{V}_{\infty} \mapsto Z_{\nu} \cdot D$ is continuous, but this follows immediately from $Z_{v} \cdot D=L_{v}(D)$ and Proposition 3.6.19.

Proposition 4.1.5. Let $v$ be a valuation centered at infinity and $X$ a completion of $X_{0}$ such that $c_{X}(v) \in E$ is a free point. Then, the incarnation of $Z_{v}$ in $X$ is

$$
\begin{equation*}
Z_{\mathrm{V}, X}=\left(Z_{\mathrm{V}} \cdot E\right) Z_{\mathrm{ord}_{E}} . \tag{4.9}
\end{equation*}
$$

If $c_{X}(\mathrm{v})=E \cap F$ is a satellite point, then

$$
\begin{equation*}
Z_{v, X}=\left(Z_{v} \cdot E\right) Z_{\operatorname{ord}_{E}}+\left(Z_{v} \cdot F\right) Z_{\operatorname{ord}_{F}} \tag{4.10}
\end{equation*}
$$

Furthermore, if $\pi: Y \rightarrow X$ is the blow up of a point at infinity $p \neq c_{X}(v)$, then

$$
\begin{equation*}
Z_{v, Y}=\pi^{*} Z_{v, X} \tag{4.11}
\end{equation*}
$$

Proof. If $c_{X}(v) \in E$ is a free point. For any $D \in \operatorname{Div}_{\infty}(X)$, one has $D=\sum_{F} L_{\text {ord }_{F}}(D) F$, therefore by Proposition 3.6.6 (2) and (3) $L_{v}(D)=L_{\text {ord }_{E}}(D) L_{v}(E)$. Since $\left(Z_{v} \cdot E\right)=L_{V}(E)$, we get the result. The proof is similar for the case $c_{X}(v)=E \cap F$.

For the last assertion, if $\widetilde{E}$ is the exceptional divisor of $\pi: Y \rightarrow X$, then by definition

$$
\begin{equation*}
Z_{v, Y}=\pi^{*} Z_{v, X}-\left(Z_{v} \cdot \widetilde{E}\right) \widetilde{E} \tag{4.12}
\end{equation*}
$$

However, since $c_{X}(v) \neq p$, we have that $c_{Y}(v) \notin \widetilde{E}$ and therefore $Z_{v} \cdot \widetilde{E}=0$ by Proposition 3.6.6.

Recall that in $\S 3.6 .4$, we have defined for a point $p$ at infinity in a completion $X$ the local divisor $Z_{v, X, p}$ for every valuation $v$ centered at $p$. The divisor is defined by duality via the following property

$$
\begin{equation*}
\forall D \in \operatorname{Cartier}(X, p), \quad L_{v}(D)=Z_{v, p, X} \cdot D \tag{4.13}
\end{equation*}
$$

Corollary 4.1.6. Let $X$ be a completion of $X_{0}$ and let v be a valuation centered at infinity.

- If $p:=c_{X}(v) \in E$, then

$$
\begin{equation*}
Z_{v}=\left(Z_{v} \cdot E\right) Z_{\text {ord }_{E}}+Z_{v, X, p} \tag{4.14}
\end{equation*}
$$

- If $p:=c_{X}(v)=E \cap F$ is a satellite point, then

$$
\begin{equation*}
Z_{v}=\left(Z_{v} \cdot E\right) Z_{\operatorname{ord}_{E}}+\left(Z_{v} \cdot Z_{\operatorname{ord}_{F}}\right) Z_{\operatorname{ord}_{F}}+Z_{v, X, p} \tag{4.15}
\end{equation*}
$$

In particular, $Z_{v} \in \mathrm{~L}^{2}\left(\mathrm{X}_{0}\right)$ if and only if v is quasimonomial or there exists a completion $X$ and a closed point $p \in X$ at infinity such that $c_{X}(v)=p$ and $\alpha(\widetilde{v})<+\infty$ where $\widetilde{v}$ is the valuation equivalent to $v$ such that $\widetilde{v} \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$.

Proof. We have that

$$
\begin{equation*}
Z_{v}=Z_{v, X}+Z^{\prime} \tag{4.16}
\end{equation*}
$$

where $Z^{\prime} \in$ Weil $_{\infty}\left(\mathrm{X}_{0}\right)$ is exceptional above $X$. Now, for every divisor $D$ exceptional above $X$, we have

$$
\begin{equation*}
L_{v}(D)=Z_{v} \cdot D=Z^{\prime} \cdot D . \tag{4.17}
\end{equation*}
$$

If $D$ is exceptional above a point $q \neq p$, then $L_{v}(D)=0$ by Proposition 3.6.6 as $q \neq c_{X}(v)$. Therefore, we get that $Z^{\prime}=Z_{v, X, p}$.

Now, we have $Z_{v} \in \mathrm{~L}^{2}\left(\mathrm{X}_{0}\right) \Leftrightarrow\left(Z_{v}\right)^{2}<-\infty$. Replace $v$ by the equivalent valuation such that $v \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$, then by Theorem 3.6.31 $\left(Z_{v, X, p}\right)^{2}=-\alpha(v)$ and therefore

$$
\begin{equation*}
\left(Z_{v}\right)^{2}=\left(Z_{v, X}\right)^{2}-\alpha(v) \tag{4.18}
\end{equation*}
$$

This shows the result.

Corollary 4.1.7. Let $\mathrm{v} \in \mathcal{V}_{\infty}$, then up to normalisation $Z_{v} \in \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{Q}}$ if and only v is not irrational.

Proof. First, if $v$ is divisorial, the result follows from Corollary 4.1.4. Then, if $v$ is infinitely singular or a curve valuation. Then, there exists a completion $X$ such that $c_{X}(v)$ is a free point $p \in E$. Then, replace $v$ by its equivalent valuation such that $v \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$. Let $(z, w)$ be local coordinates at $p$ such that $z=0$ is a local equation of $E$. Then, $Z_{v}(E)=v(z)=\alpha\left(v \wedge v_{z}\right) \in \mathbf{Q}$ because $v \wedge v_{z}$ has to be a divisorial valuation. Therefore, by Corollary 3.6.33 and Proposition 4.1.5, we get that $Z_{v} \in \operatorname{Weil}_{\infty}\left(X_{0}\right)_{\mathbf{Q}}$.

Finally, if $v$ is irrational then let $X$ be a completion such that $c_{X}(v)=E \cap F$ is a satellite point. Then, $Z_{v, X}=s Z_{\text {ord }_{E}}+t Z_{\text {ord }_{F}}$ with $s / t \notin \mathbf{Q}$ by Proposition4.1.5. It is clear that no multiple of $Z_{v, X}$ can be in $\operatorname{Div}_{\infty}(X)_{\mathbf{Q}}$.

Corollary 4.1.8. Let $\mathcal{V}_{\infty}^{\prime}$ be the subspace of $\mathcal{V}_{\infty}$ consisting of $\mathcal{v} \in \mathcal{V}_{\infty}$ such that $Z_{v} \in \mathrm{~L}^{2}\left(\mathrm{X}_{0}\right)$, then

$$
\begin{equation*}
\mathcal{V}_{\infty}^{\prime} \hookrightarrow \mathrm{L}^{2}\left(\mathrm{X}_{0}\right) \tag{4.19}
\end{equation*}
$$

is a continuous embedding for the strong topology. Furthermore, it is a homeomorphism onto its image.

Proof. Let $X$ be a completion of $X_{0}$. Let $v_{n}$ be a sequence of $\mathcal{V}_{\infty}^{\prime}$ converging towards $v \in \mathcal{V}_{\infty}^{\prime}$ for the strong topology. We treat two cases, whether $v$ is associated to a prime divisor of $X$ or $v$ is centered at a closed point $p \in X$ at infinity.

If $v$ is centered at a closed point $p$ at infinity, then since $v_{n}$ converges strongly towards $v$ then it converges also weakly, therefore for $n$ big enough, $v_{n}$ is centered at $p$ by Proposition 3.5.1. We can replace each $v_{n}$ and $v$ by their representative such that $v_{n}, v \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$. Then

- If $p \in E$ is a free point,

$$
\begin{equation*}
Z_{v_{n}}=\left(Z_{v_{n}} \cdot E\right) Z_{\text {ord }_{E}}+Z_{v_{n}, X, p} \tag{4.20}
\end{equation*}
$$

- If $p=E \cap F$ is a satellite point, then

$$
\begin{equation*}
Z_{v_{n}}=\left(Z_{v_{n}} \cdot E\right) Z_{\text {ord }_{E}}+\left(Z_{v_{n}} \cdot F\right) Z_{\text {ord }_{F}}+Z_{v_{n}, X, p} \tag{4.21}
\end{equation*}
$$

and we have similar formulas for $Z_{v}$. Now the incarnation of $Z_{v_{n}}$ in $X$ converges towards the incarnation of $Z_{v}$ in $X$ in both the free and the satellite case by weak convergence. Let $\|\cdot\|$ be any norm over $\operatorname{NS}(X)_{\mathbf{R}}$, then

$$
\begin{equation*}
\left\|Z_{v}-Z_{v_{n}}\right\|_{L^{2}\left(X_{0}\right)}^{2}=\left\|Z_{v, X}-Z_{v_{n}, X}\right\|^{2}-\left(Z_{v, X, p}-Z_{v_{n}, X, p}\right)^{2} \tag{4.22}
\end{equation*}
$$

where $f=g$ means that there exists constants $A, B>0$ such that $A g \leqslant f \leqslant B g$. By Proposition 3.6.34, we have that $\left\|Z_{v}-Z_{v_{n}}\right\|_{L^{2}\left(\mathrm{X}_{0}\right)}^{2} \rightarrow 0$.

If $v \simeq \operatorname{ord}_{E}$ for some prime divisor $E$ at infinity in $X$, then for all $n$ large enough, $c_{X}\left(v_{n}\right) \in E$. We can suppose that $v=\operatorname{ord}_{E}$ and for all $\mathrm{n} v_{n}(E)>0$, i.e $\mathrm{v}, \nu_{n} \in \mathcal{V}_{X}(E)$ and $Z_{v_{n}} \cdot E \rightarrow 1$ as $n \rightarrow \infty$. We show that

$$
\begin{equation*}
\frac{Z_{v_{n}}}{Z_{v_{n}} \cdot E} \xrightarrow[n \rightarrow+\infty]{ } Z_{\text {ord }_{E}} \tag{4.23}
\end{equation*}
$$

in $\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$. We can replace $\mathrm{v}_{n}$ by its equivalent valuation such that $\mathrm{v}_{n} \in \mathcal{V}_{X}\left(p_{n}, \mathfrak{m}_{p_{n}}\right)$ where $p_{n}=c_{X}\left(v_{n}\right)$. Then, we have that $Z_{v_{n}, X} / Z_{v_{n}} \cdot E$ converges towards $Z_{\text {ord }_{E}}$ in $\operatorname{NS}(X)_{\mathbf{R}}$ by weak convergence. It suffices to show

$$
\begin{equation*}
\frac{\left(Z_{v_{n}, X, p}\right)^{2}}{\left(Z_{V_{n}} \cdot E\right)^{2}} \rightarrow 0 \tag{4.24}
\end{equation*}
$$

but this is equal to

$$
\begin{equation*}
-\frac{\alpha_{\mathfrak{m}_{p_{n}}}\left(v_{n}\right)}{v_{n}(E)^{2}}=-\frac{\alpha_{E}\left(v_{n}\right)}{v(E)^{2}} \xrightarrow[n \rightarrow+\infty]{ } 0 \tag{4.25}
\end{equation*}
$$

by Theorem 3.6.31 and Proposition 3.4.9 so we are done.
Finally, to show the homeomorphism, we have to show that if $Z_{v_{n}} \rightarrow Z_{v}$ in $L^{2}\left(X_{0}\right)$, then $v_{n}$ converges strongly towards $v$. Let $X$ be a completion of $X_{0}$. Suppose first that $c_{X}(v)$ is a point at infinity. Let $\widetilde{E}$ be the exceptional divisor above $c_{X}(v)$, we have $Z_{v} \cdot \widetilde{E}>0$, therefore for all n large enough $Z_{v_{n}} \cdot \widetilde{E}>0$ and $c_{X}\left(v_{n}\right)=c_{X}(v)=: p$. Now, we can suppose that $v_{n}, v \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$, it suffices to show that $v_{n} \rightarrow v$ for the strong topology of $V_{X}\left(p ; \mathfrak{m}_{p}\right)$ and this is a direct consequence of Proposition 3.6.34.

If $c_{X}(v)=E$ a prime divisor at infinity, then for all $n$ large enough, $Z_{v_{n}} \cdot E>0$. Suppose that $v=\operatorname{ord}_{E}$ and $v_{n} \in \mathcal{V}_{X}(E)$. We have that $Z_{v_{n}, X} / Z_{v} \cdot E \rightarrow Z_{\operatorname{ord}_{E}}$ in $\operatorname{NS}(X)_{\mathbf{R}}$. We need to show that $\alpha_{E}\left(\frac{v_{n}}{v_{n}(E)}\right) \rightarrow 0$. We can suppose that $v_{n} \in \mathcal{V}_{X}\left(p_{n}, \mathfrak{m}_{p_{n}}\right)$ where $p_{n}=c_{X}\left(v_{n}\right)$, then by Proposition
3.4.9

$$
\begin{equation*}
\alpha_{E}\left(\frac{v_{n}}{v_{n}(E)}\right)=\frac{\alpha_{\mathfrak{m}_{p_{n}}}\left(v_{n}\right)}{v_{n}(E)^{2}} . \tag{4.26}
\end{equation*}
$$

Thus, by Proposition 3.4.9 and Theorem 3.6.31

$$
\begin{equation*}
\alpha_{E}\left(\frac{v_{n}}{v_{n}(E)}\right)=\left|\frac{Z_{v_{n}, X, p_{n}}^{2}}{\left(Z_{v_{n}} \cdot E\right)^{2}}\right| \xrightarrow[n \rightarrow+\infty]{ } 0 \tag{4.27}
\end{equation*}
$$

Corollary 4.1.9. If $v$ is a curve valuation, then $Z_{v}$ is a Weil class satisfying $Z_{v}^{2}=-\infty$.
Proof. Let $X$ be a completion of $X_{0}$, let $p=c_{X}(v)$ and replace $v$ by the valuation equivalent to $v$ such that $v \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$. We have by Corollary 4.1.6 that

$$
\begin{equation*}
Z_{v}=Z_{v, X}+Z_{v, X, p} \tag{4.28}
\end{equation*}
$$

Therefore, by Theorem 3.6.31

$$
\begin{equation*}
\left(Z_{v}\right)^{2}=Z_{v, X}^{2}+\left(Z_{v, X, p}\right)^{2}=Z_{v, X}^{2}-\alpha(v)=-\infty \tag{4.29}
\end{equation*}
$$

because $\alpha(v)=-\infty$ for any curve valuation $v$ (see [FJ04] Lemma 3.32).

### 4.1.2 Endomorphisms

Proposition 4.1.10. Let $f$ be an endomorphism of $X_{0}$ and let $X, Y$ be completions of $X_{0}$ such that the lift $F: X \rightarrow Y$ of $f$ is regular. Let $p \in X$ be a closed point and $q:=F(p) \in Y$. Then,

- $f_{*} \mathcal{V}_{X}(p) \subset \mathcal{V}_{Y}(q)$.
- $f_{*}$ preserves the set of divisorial, irrational and infinitely singular valuations.
- If $v_{C}$ is a curve valuation centered at infinity and such that $f_{*} v_{C}$ is still centered at infinity, then $f_{*} v_{C}$ is also a curve valuation.
Proof. The map $F$ induces a local ring homomorphism $F^{*}: \widehat{O_{Y}(q)} \rightarrow \widehat{O_{X}(p)}$. Let $v$ be a valuation centered at $p$. For $\varphi \in O_{Y}(q), f_{*} v(\varphi)=v\left(F^{*} \varphi\right) \geqslant 0$ and for $\psi \in \mathfrak{m}_{Y, q}, f_{*} v(\psi)=v\left(F^{*} \psi\right)>0$. Therefore $f_{*} v$ is centered at $q$. The fact that $f_{*}$ preserves the type of valuations is shown in Proposition 3.3.17. It only remains to show the statement for curve valuations. Let $p=c_{X}\left(v_{C}\right)$
and $q=c_{Y}\left(f_{*} v_{C}\right)$. We have that $F(p)=q$. By Proposition 3.3.17 $f_{*} \vee_{C}$ is not a curve valuation only if it is contracted by $F$. But the only germ of holomorphic curve at $p$ that can be contracted by $F$ is the germ of a prime divisor $E$ at infinity on which $p$ lies, and the curve valuation associated to $E$ does not define a valuation on $A$. So, $f_{*} v_{C}$ is a curve valuation.

Example 4.1.11. It might happen that $f_{*} v$ is not centered at infinity even though $v$ is; if this is the case then $f$ is not proper. For example, let $X_{0}=\mathbf{A}^{2}$ with affine coordinates $(x, y)$ and consider the completion $\mathbf{P}^{2}$ with homogeneous coordinates $[X: Y: Z$ ]. We have the relation $x=X / Z, y=Y / Z$. Consider the chart $X \neq 0$ with affine coordinates $y^{\prime}=Y / X$ and $z^{\prime}=Z / X$. Define $v_{t}$ to be the monomial valuation centered at $[1: 0: 0]$ such that $v_{t}\left(y^{\prime}\right)=1$ and $v_{t}\left(z^{\prime}\right)=t$ with $t>0$. Let $P=\sum_{i, j} a_{i j} x^{i} y^{j} \in \mathbf{k}[x, y]$, we have that $v_{t}(P)=\min \left\{j+(j-i) t \mid a_{i j} \neq 0\right\}$. Now take the map $f:(x, y) \in \mathbf{A}^{2} \mapsto(x y, y), f$ contracts the curve $\{y=0\}$ to the point $(0,0)$ in $\mathbf{A}^{2}$, hence it is not proper. For any polynomial $P=\sum_{i, j} a_{i j} x^{i} y^{j}, f^{*} P=\sum_{i, j} a_{i j} x^{i} y^{i+j}$. We get

$$
\begin{equation*}
v_{1, t}\left(f^{*} P\right)=\min _{i, j}\left\{i+j(t+1) \mid a_{i j} \neq 0\right\} . \tag{4.30}
\end{equation*}
$$

The center of $f_{*} v_{t}$ is $[0: 0: 1]$ and $f_{*} v_{t}$ is the monomial valuation centered at $[0: 0: 1]$ such that $v_{t}(x)=1, v_{t}(y)=t+1$.

Lemma 4.1.12 (Proposition 3.2 of [[JJ07]). Let $f: X_{0} \rightarrow X_{0}$ be a dominant endomorphism and let $X, Y$ be completions of $X_{0}$. Let $F: X \rightarrow Y$ be the lift of $f$, let $p$ be a closed point of $X$ at infinity and $\mathcal{V}_{X}(p)$ be the set of valuations on $A$ centered at $p$. Then, $F$ is defined at $p$ if and only if $f_{*} \mathcal{V}_{X}(p)$ does not contain any divisorial valuation associated to a prime divisor (not necessarily at infinity) of $Y$. If $F$ is defined at $p$, then $F(p)$ is the unique point $q$ such that $f_{*} \mathcal{V}_{X}(p) \subset \mathcal{V}_{Y}(q)$.

Proof. If $\widehat{f}$ is defined at $p$, then let $q=\widehat{f}(p)$, we have that $f_{*} \mathcal{V}_{X}(p) \subset \mathcal{V}_{Y}(q)$ by Proposition 4.1.10

Conversely, If $p$ is an indeterminacy point of $\widehat{f}$. Let $\pi: Z \rightarrow X$ be a completion above $X$ such that the lift $F: Z \rightarrow Y$ is regular. Then, $F\left(\pi^{-1}(p)\right)$ contains a prime divisor $E^{\prime}$ of $Y$. Let $E$ be a prime divisor at infinity in $Z$ above $p$ such that $F(E)=E^{\prime}$, then $F_{*} \operatorname{ord}_{E}=f_{*}\left(\pi_{*} \operatorname{ord}_{E}\right)=\lambda \operatorname{ord}_{E^{\prime}}$ for some constant $\lambda>0$ and $\operatorname{ord}_{E^{\prime}} \in f_{*} \mathcal{V}_{X}(p)$.

Proposition 4.1.13. Let $\vee$ be a valuation over $A$ and let $f: X_{0} \rightarrow X_{0}$ be a dominant endomorphism, then

- $f_{*} Z_{v}=Z_{f_{*} v} \bmod \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)^{\perp}$.
- If f is proper then $f_{*}$ preserves $\operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)$ and $f_{*} Z_{v}=Z_{f_{*} v}$.

Proof. Indeed, let $D \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$, then

$$
\begin{equation*}
f_{*} Z_{v} \cdot D=Z_{v} \cdot f^{*} D=L_{v}\left(f^{*} D\right)=L_{f_{*}}(D)=Z_{f_{*} v} \cdot D . \tag{4.31}
\end{equation*}
$$

Therefore, we get that $Z_{f_{*} v}-f_{*} Z_{v}$ belongs to $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)^{\perp}$. If $f$ is proper, then Weil ${ }_{\infty}\left(\mathrm{X}_{0}\right)$ is $f_{*}$-stable and $f_{*} Z_{v} \in \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)$, thus $Z_{f_{*} v}=f_{*} Z_{v}$.

Example 4.1.14. Suppose that $P(x)$ and $Q(x)$ are two rational fractions of degree two and $E$ in $\mathbf{P}^{1} \times \mathbf{P}^{1}$ defined by the equation

$$
\begin{equation*}
y^{2}-P(x) y+Q(x)=0 . \tag{4.32}
\end{equation*}
$$

if $P, Q$ are general, then $E$ is smooth and irreducible and it is an elliptic curve in $\mathbf{P}^{2}$. Let $X=\mathbf{P}^{1} \times \mathbf{P}^{1}$ and $X_{0}=X \backslash E$. We have $\operatorname{Pic}^{0}\left(X_{0}\right)=0$ because it is a rational surface and $A^{\times}=\mathbf{k}^{\times}$ because $X \backslash X_{0}$ consists of a single irreducible curve. We have $Z_{\text {ord }_{E}}=\frac{1}{8} E$. Consider the projection $\mathrm{pr}_{1}: X \rightarrow \mathbf{P}^{1}$ to the first coordinates. Each fiber of $\pi_{1}$ is isomorphic to $\mathbf{P}^{1}$ and generically it has two intersection points with $E$. Let $x_{0}, x_{1}, x_{2}, x_{3}$ be the four roots of the discriminant $\delta=P(x)^{2}-4 Q(x)$. Then, $\mathrm{pr}_{1}^{-1}\left(x_{i}\right)$ has only one intersection point with $E$. Consider the following selfmap of $X_{0}$

$$
\begin{equation*}
f(x, y)=\left(x, \frac{y^{2}-Q(x)}{2 y-P(x)}\right) . \tag{4.33}
\end{equation*}
$$

It preserves the fibers of $\mathrm{pr}_{1}$ and it acts as $z \mapsto z^{2}$ in each fiber where the points 0 and $\infty$ of $\mathbf{P}^{1}$ are the intersection point of the fiber with $E$. See Figure 4.1. There are exactly 4 indeterminacy points on $X$, they are the points $\left(x_{i}, y_{i}\right)$ where $x_{i}$ is one of the roots of $\Delta$ and $y_{i} \in \mathbf{P}^{1}$ is such that $\left(x_{i}, y_{i}\right) \in E$.

Let $C_{0}=\left\{x_{0}\right\} \times \mathbf{P}^{1}$. Then, $\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)^{\perp}=\mathbf{R} \cdot\left(4 C_{0}-E\right)$ because $C_{0} \cdot E=2$ and $E^{2}=8$ and $\rho(X)=2$.

The endomorphism $f$ is not proper, indeed we have in $\operatorname{NS}(X), f_{*} E=E+4 C_{0}$. Since $f^{*} E$ is of the form $f^{*} E=2 E+\ldots$, we have $f_{*} \operatorname{ord}_{E}=2 \operatorname{ord}_{E}$. And we get

$$
\begin{align*}
f_{*} Z_{\mathrm{ord}_{E}}=\frac{1}{8} E+\frac{1}{2} C_{0} &  \tag{4.34}\\
& =\frac{1}{8} E+\frac{1}{8}\left(4 C_{0}-E\right)+\frac{1}{8} E  \tag{4.35}\\
& =2 Z_{\mathrm{ord}_{E}}+\frac{1}{8}\left(4 C_{0}-E\right) \tag{4.36}
\end{align*}
$$

Figure 4.1: The endomorphism $f$ on $X_{0}$

### 4.1.3 Existence of Eigenvaluations

Recall from Theorem 3.2.28 that there exists unique nef classes $\theta^{*}, \theta_{*} \in \mathrm{~L}^{2}\left(\mathrm{X}_{0}\right)$ up to normalization such that $f^{*} \theta^{*}=\lambda_{1} \theta^{*}$ and $f_{*} \theta_{*}=\lambda_{1} \theta^{*}$.

Proposition 4.1.15. If $A^{\times}=\mathbf{k}^{\times}$and $\operatorname{Pic}^{0}\left(X_{0}\right)=0$, then $\theta^{*} \in \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right) \cap \mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$ and is effective.

Proof. We have that Weil-NS $\left(\mathrm{X}_{0}\right)=V \oplus$ Weil $_{\infty}\left(\mathrm{X}_{0}\right)$ where $V$ is a finite dimensional vector space. Furthermore, Weil $\omega_{\infty}\left(\mathrm{X}_{0}\right)$ is $f^{*}$-invariant as $f$ is an endomorphism of $X_{0}$. In the proof of Theorem 3.2.28, for every completion $X$ we can consider the cone $C_{X}^{\prime} \subset \operatorname{Div}_{\infty}(X)_{\mathbf{R}}$ of nef, effective divisors supported at infinity. By Theorem 3.1.4, there exists an ample effective divisor $H \in \operatorname{Div}_{\infty}(X)$ such that $\operatorname{Supp} H=\partial_{X} X_{0}$. Therefore, $C_{X}^{\prime}$ is a closed convex cone with compact basis and non-empty interior, the Perron-Frobenius type argument shows that there exists $\theta_{X} \in C_{X}^{\prime}$ such that $f_{X}^{*} \theta_{X}^{*}=\rho_{X} \theta_{X}$ and the rest of the proof is unchanged.

Theorem 4.1.16. Let $X_{0}=\operatorname{Spec} A$ be an irreducible normal affine surface such that $A^{\times}=\mathbf{k}^{\times}$ and $\operatorname{Pic}^{0}\left(X_{0}\right)=0$. Let $f$ be a dominant endomorphism such that $\lambda_{1}(f)^{2}>\lambda_{2}(f)$, then there
exists a unique valuation $v_{*}$ centered at infinity up to equivalence satisfying

$$
\begin{align*}
\forall P \in A, v_{*}(P) & \leqslant 0  \tag{4.37}\\
f_{*} v_{*} & =\lambda_{1}(f) v_{*}  \tag{4.38}\\
Z_{v_{*}}^{2} & >-\infty \tag{4.39}
\end{align*}
$$

In particular, there exists $w \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)^{\perp}$ such that $\theta_{*}=w+Z_{\nu_{*} .}$. Furthermore, $\mathrm{v}_{*}$ is not a curve valuation.

We call $v_{*}$ the eigenvaluation of $f$.

Proof. By Theorem 3.2.28, there exists nef classes $\theta_{*}, \theta^{*} \in \mathrm{~L}^{2}\left(\mathrm{X}_{0}\right)$ that satisfy

1. $f^{*} \theta^{*}=\lambda_{1} \theta^{*}$
2. $f_{*} \theta_{*}=\lambda_{1} \theta_{*}$
3. $\forall \alpha \in \mathrm{L}^{2}\left(\mathrm{X}_{0}\right), \frac{1}{\lambda_{1}^{n}}\left(f^{n}\right)^{*} \alpha \rightarrow\left(\theta_{*} \cdot \alpha\right) \theta^{*}$

Let $X$ be a completion of $X_{0}$. Write the decomposition $\theta_{*}=w+Z$ with $w \in \operatorname{Div}_{\infty}(X)^{\perp}$ and $Z \in$ Weil $_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{R}} \cap \mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$. Let $E$ be a prime divisor at infinity in $X$ such that $Z_{\text {ord }_{E}} \cdot \theta^{*}>0$, it exists because $\theta^{*}$ is effective and nef. Then, Item (3) and the continuity of the intersection product in $\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$ imply that for all $D \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$,

$$
\begin{equation*}
Z_{\mathrm{ord}_{E}} \cdot\left(\frac{1}{\lambda_{1}^{n}}\left(f^{n}\right)^{*} D\right) \rightarrow\left(Z_{\mathrm{ord}_{E}} \cdot \theta^{*}\right)\left(\theta_{*} \cdot D\right)=\left(Z_{\mathrm{ord}_{E}} \cdot \theta^{*}\right)(Z \cdot D) \tag{4.40}
\end{equation*}
$$

Now, set $v_{n}:=\frac{1}{\lambda_{1}^{n}}\left(f^{n}\right)_{*} \operatorname{ord}_{E}$. Equation (4.40) shows that $Z_{v_{n}}$ converges towards $Z$ in Weil $\infty_{\infty}\left(X_{0}\right)$. But, for all $n, Z_{v_{n}}$ belongs to $\operatorname{Hom}\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \mathbf{R}\right)_{(+)}$which is a closed set of $\operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)$ by Corollary 4.1.2. Therefore, $Z \in \operatorname{Hom}\left(\operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right), \mathbf{R}\right)_{(+)}$and it defines a valuation $\mathbf{v}_{*}$ by Proposition 3.7.5. From the relation $f_{*} \theta_{*}=\lambda_{1} \theta_{*}$ we get that $f_{*} \nu_{*}=\lambda_{1} \nu_{*}$.

Using the decomposition $\theta_{*}=w+Z_{v_{*}}$ we have

$$
\begin{equation*}
0 \leqslant \theta_{*}^{2}=\omega^{2}+Z_{v_{*}}^{2} \tag{4.41}
\end{equation*}
$$

Therefore we get $Z_{v_{*}}^{2} \neq-\infty$ and by Corollary 4.1.9, $v_{*}$ is not a curve valuation.

Now to show the uniqueness of $v_{*}$, if $v$ is another valuation satisfying Equations 4.37, (4.38), (4.39), then for all $D \in \operatorname{Cartier}_{\infty}\left(\mathrm{X}_{0}\right)$, Item (3) implies

$$
\begin{equation*}
Z_{v} \cdot D=\frac{1}{\lambda_{1}^{n}} Z_{v} \cdot\left(f^{n}\right)^{*} D \underset{n \rightarrow \infty}{\longrightarrow}\left(Z_{v} \cdot \theta^{*}\right)\left(\theta_{*} \cdot D\right) \tag{4.42}
\end{equation*}
$$

Since $v \neq 0$, we get $Z_{v} \cdot \theta^{*}>0$. And then $v=v_{*}$ up to a scalar factor.
Corollary 4.1.17. With the hypothesis of Theorem 4.1.16. The dynamical degree $\lambda_{1}(f)$ is an algebraic integer of degree $\leqslant 2$. More precisely,

- If $\boldsymbol{v}_{*}$ is divisorial or infinitely singular, then $\lambda_{1} \in \mathbf{Z}_{>1}$.
- If $\boldsymbol{v}_{*}$ is irrational, then $\lambda_{1}$ is an algebraic integer of degree 2 , in particular $\lambda_{1} \notin \mathbf{Q}$.

Proof. By Theorem 4.1.16 $f$ admits an eigenvaluation $v_{*}$ satisfying Equations (4.37), (4.38), (4.39). We know that $v_{*}$ cannot be a curve valuation, so there are three cases. It can either be a divisorial valuation, an irrational one or an infinitely singular one. Hence, $v_{*}(P)=\infty \Leftrightarrow P=0$ and it defines a valuation over $K=\operatorname{Frac} A$. Let $G=v\left(K^{\times}\right)$be the value group of $v_{*}$. The value group of $f_{*} \nu_{*}$ is a subgroup of $G$, hence $f_{*}$ induces a $Z$-linear map $f_{*}: G \rightarrow G$.

1. If $v_{*}$ is divisorial, then $G$ is isomorphic to $\mathbf{Z}$. Since $f_{*} \nu_{*}=\lambda_{1} v_{*}$ we get that $\lambda_{1}$ is an integer.
2. If $\nu_{*}$ is irrational, then $G$ is isomorphic to $\mathbf{Z}^{2}$. Since $f_{*} \nu_{*}=\lambda_{1} \nu_{*}, \lambda_{1}$ is an eigenvalue of a $2 \times 2$ matrix with integer coefficients. Therefore, it is a quadratic integer.
3. If $v_{*}$ is infinitely singular. We will show in Proposition 4.2.3 below, the following.

Claim 4.1.18. There exists a completion $X$ of $X_{0}$ such that $p:=c_{X}(v) \in E$ is a free point at infinity, the lift $f: X \rightarrow X$ is defined at $p, f(p)=p$ and $f$ contracts $E$ to $p$.

Suppose the claim is true. Let $(z, w)$ be local coordinates at $p$ such that $z=0$ is a local equation of $E, f^{*} z$ is of the form $z^{a} \Phi(z, w)$ where $\Phi$ is a unit. Then,

$$
\begin{equation*}
\lambda_{1} L_{v_{*}}(E)=L_{f_{*} v_{*}}(E)=L_{v_{*}}\left(f^{*} E\right)=a L_{v_{*}}(E) . \tag{4.43}
\end{equation*}
$$

Since $L_{\nu_{*}}(E)>0$ we get $\lambda_{1}=a$ and it is an integer.

### 4.2 Local normal forms

From now on we suppose chark $=0$ and that $X_{0}$ is an affine surface. Since everything is defined over a finitely generated field over $\mathbf{Q}$, we can suppose that $\mathbf{k}$ is a subfield of $\mathbf{C}_{v}$, which is a complete algebraically closed field. We show that the existence of this eigenvaluation allows one to find an attracting fixed point at infinity and a local normal form at this fixed point.

Theorem 4.2.1. Let $X_{0}=\operatorname{Spec} A$ be an irreducible normal affine surface over a complete algebraically closed field $\mathbf{C}_{v}$. Let $f$ be a dominant endomorphism of $X_{0}$ such that $\lambda_{1}^{2}>\lambda_{2}$. Suppose that $\operatorname{Pic}^{0}\left(X_{0}\right)=0$ and $A^{\times}=\mathbf{k}^{\times}$then

1. If $v_{*}$ is infinitely singular or irrational, there exists a completion $X$ such that the lift $f: X \rightarrow X$ is defined at $c_{X}\left(\boldsymbol{v}_{*}\right), f\left(c_{X}\left(\boldsymbol{v}_{*}\right)\right)=c_{X}\left(\boldsymbol{v}_{*}\right)$ and $f$ defines a rigid contracting germ of holomorphic function at $c_{X}\left(v_{*}\right)$ with no $f$-invariant germ of curves at $c_{X}\left(v_{*}\right)$. Furthermore, there exists an open (euclidian) f-invariant neighbourhood $U^{*}$ of $c_{X}\left(v_{*}\right)$ such that $f\left(U^{*}\right) \Subset U^{*}$. We have the following local normal form:
(a) If $v_{*}$ is infinitely singular, $c_{X}\left(v_{*}\right) \in E$ is a free point and $f$ has the local normal form (3.3) and (3.2) if $\mathbf{C}_{v}=\mathbf{C}$ with $\{x=0\}$ a local equation of $E \lambda_{1}=a \in \mathbf{Z}_{\geqslant 2}$.
(b) If $v_{*}$ is irrational, $c_{X}\left(v_{*}\right)=E \cap F$ is a satellite point. The local normal form is pseudomonomial (3.5) with $(x, y)$ associated to $(E, F)$. If $\mathbf{C}_{v}=\mathbf{C}$ it is monomial (3.4) The dynamical degree $\lambda_{1}$ is the spectral radius of the matrix $\left(a_{i j}\right)$. It is an algebraic integer of degree 2 ; in particular $\lambda_{1} \notin \mathbf{Q}$.
2. If $\mathrm{v}_{*}$ is divisorial, then there exists a completion such that $c_{X}\left(\boldsymbol{v}_{*}\right)$ is a prime divisor $E$ at infinity. In that case, $E$ is $f$-invariant and $\lambda_{1} \in \mathbf{Z}_{\geqslant 2}$ is such that $f_{X}^{*} E=\lambda_{1} E+D$ where $D \in \operatorname{Div}_{\infty}(X)$ and $E \notin \operatorname{Supp} D$.
(a) Up to replacing $f$ by some iterate, there exists a noncritical fixed point $p \in E$ of $f_{\mid E}$, $p=E \cap E_{0}$ is a satellite point, $f: X \rightarrow X$ is defined at $p, f(p)=p$ and $f$ is a rigid germ (not necessarily contracting) at $p$ with $E$ the only $f$-invariant germ of curves at $p$. The local normal form of $f$ at $p$ is (3.6) with $(x, y)$ associated to $\left(E, E_{0}\right)$ and $\lambda_{1}=a$.
(b) The curve $E$ is an elliptic curve and $f_{\mid E}$ is a translation by a non-torsion element.

In particular, the dynamical degree of $f$ is an algebraic number of degree $\leqslant 2$, and if it is not an integer then the eigenvaluation $v_{*}$ of $f$ is irrational and the normal form is monomial.

We will call $2 b$ the elliptic case. The rest of this section is devoted to the proof of Theorem 4.2 .1 , we will prove the Theorem page 163 .

To prove the theorem we need to understand the dynamics of $f_{*}$ on the space of valuations.
Proposition 4.2.2. Let $v \in \mathcal{V}_{\infty}$ such that $Z_{v} \in \mathrm{~L}^{2}\left(\mathrm{X}_{0}\right)$. If $Z_{v} \cdot \theta^{*}>0$, then $\frac{1}{\lambda_{1}^{n}} f_{*}^{n} v$ strongly converges towards $\left(Z_{v} \cdot \theta^{*}\right) \nu_{*}$.

Proof. This is a direct consequence of Equation (3.69) and Corollary 4.1.8.
We will use this to show that $f$ admits a fixed point at infinity on some completion and that $f$ contracts a divisor at infinity there.

For the rest of Section 4.2, we suppose that we are in the conditions of Theorem 4.1.16,

### 4.2.1 Attractingness of $v_{*}$, the infinitely singular case

In this section we show the following
Proposition 4.2.3. Let $\mathbf{k}$ be an algebraically closed field (of any characteristic). If the eigenvaluation $v_{*}$ is infinitely singular, then there exists a completion $X$ of $X_{0}$ such that

1. $p:=c_{X}\left(v_{*}\right) \in E$ is a free point at infinity.
2. $f_{*} \mathcal{V}_{X}(p) \subset \mathcal{V}_{X}(p)$;
3. f contracts $E$ to $p$.
4. Let $f_{\bullet}: \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right) \rightarrow \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$, then for all $\boldsymbol{v} \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right), f_{\bullet}^{n} v \rightarrow \boldsymbol{v}_{*}$.

Furthermore, the set of completions $Y$ above $X$ that satisfy these 3 properties is cofinal in the set of all completions above $X$.

Let $X$ be a completion of $X_{0}$ such that $c_{X}\left(v_{*}\right)$ is a free point $p_{X} \in E_{X}$. Such a completion $X$ exists and there are infinitely many of them above $X$ by Proposition 3.3.16. Let $Y$ be a completion above $X$ such that $c_{Y}\left(v_{*}\right)$ on $Y$ is a free point $p_{Y} \in E_{Y}$ such that the diagram

commutes, where $F$ is regular and $F\left(p_{Y}\right)=p_{X}$, such a completion $Y$ exists by Proposition 3.3.16. Let $x, y$ be coordinates at $p_{X}$ such that $x=0$ is a local equation of $E_{X}$ and $z, w$ be coordinates at $p_{Y}$ such that $z=0$ is a local equation for $E_{Y}$. We use the notations of Section 3.4. We have that $f_{*} \mathcal{V}_{Y}\left(p_{Y}\right) \subset \mathcal{V}_{X}\left(p_{X}\right)$ by Lemma 4.1.12. We define $F_{\bullet}: \mathcal{V}_{Y}\left(p_{Y} ; E_{Y}\right) \mapsto \mathcal{V}_{X}\left(p_{X}, \mathfrak{m}_{p_{X}}\right)$ as follows:

$$
\begin{equation*}
\forall v \in \mathcal{V}_{Y}\left(p_{Y} ; E_{Y}\right), \quad F_{\bullet}(v):=\frac{F_{*} v}{\min \left(v\left(F^{*} x\right), v\left(F^{*} y\right)\right)} \tag{4.44}
\end{equation*}
$$

Similarly, we define

$$
\begin{equation*}
\forall v \in \mathcal{V}_{Y}\left(p_{Y} ; E_{Y}\right), \quad \pi_{\bullet}(v):=\frac{\pi_{*} v}{\min \left(v\left(\pi^{*} x\right), v\left(\pi^{*} y\right)\right)} \tag{4.45}
\end{equation*}
$$

By Proposition 3.4.20 item (1), the map $\pi_{\bullet}: \mathcal{V}_{Y}\left(p_{Y} ; E_{Y}\right) \rightarrow \mathcal{V}_{X}\left(p_{X} ; \mathfrak{m}_{p_{X}}\right)$ is an inclusion of trees and allows one to view $\mathcal{V}_{Y}\left(p_{Y} ; E_{Y}\right)$ as a subtree of $\mathcal{V}_{X}\left(p_{X} ; \mathfrak{m}_{p_{X}}\right)$.

See Figure 4.2. The tree $\mathcal{V}_{X}\left(p_{X}, \mathfrak{m}_{p_{X}}\right)$ is in black with its root $v_{\mathfrak{m}_{p_{X}}}$ in blue, the tree $\mathcal{V}_{Y}\left(p_{Y} ; E_{Y}\right)$ is in orange with its root $\operatorname{ord}_{E_{Y}}$ in red. One can see how $\pi_{0}$ maps homeomorphically $\mathcal{V}_{Y}\left(p_{Y} ; E_{Y}\right)$ to a subtree of $\mathcal{V}_{X}\left(p_{X}, \mathfrak{m}_{p_{X}}\right)$.

Figure 4.2: The embedding $\pi$ 。

Remark 4.2.4. Since the orders $\leqslant_{\mathfrak{m}_{p_{X}}}$ and $\leqslant_{E_{Y}}$ are compatible on $\mathcal{V}_{Y}\left(p_{Y} ; E_{Y}\right)$ and $\pi_{\bullet} \mathcal{V}_{Y}\left(p_{Y} ; E_{Y}\right)$ we will not write $\pi_{\bullet}$ or $\leqslant_{E_{Y}}$ when no confusion is possible to avoid heavy notations.

By Proposition 3.4.28, we have the following relation

$$
\begin{equation*}
\alpha_{\mathfrak{m}_{p_{X}}}\left(\pi_{\bullet} \mu\right)=\alpha_{\mathfrak{m}_{p_{X}}}\left(\pi_{\bullet} \operatorname{ord}_{E_{Y}}\right)+b\left(E_{Y}\right)^{-2} \alpha_{E_{Y}}(\mu) \tag{4.46}
\end{equation*}
$$

where $b$ is the generic multiplicity function of the tree $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ and $\alpha$ is the skewness function defined in $\$ 3.4$. Indeed, with the notation of Proposition 3.4.28, $v_{E_{Y}}=\pi_{\bullet} \operatorname{ord}_{E_{Y}}$.

Lemma 4.2.5. There exists $v \in \mathcal{V}_{Y}\left(p_{Y} ; E_{Y}\right)$ such that $v<\nu_{*}$ and for all $\mu \geqslant v$,

$$
\begin{equation*}
\min \left(\mu\left(F^{*} x\right), \mu\left(F^{*} y\right)\right)=\lambda_{1} . \tag{4.47}
\end{equation*}
$$

I.e set $U=\{\mu \geqslant v\}$, we have $F_{\bullet}=\frac{F_{*}}{\lambda_{1}}$ over $U$. In particular, $F_{\bullet}$ is order preserving over $U$ and $F_{\bullet}\left(\left[\mathrm{v}, \mathrm{v}_{*}\right]\right) \subset\left[\mathrm{v}_{\mathfrak{m}_{p_{X}}}, \mathrm{v}_{*}\right]$.
Proof. Using Proposition 3.4.3, we see that the map $v \mapsto \min \left(v\left(f^{*} x, f^{*} y\right)\right)$ is locally constant outside a finite subtree of $\mathcal{V}_{Y}\left(p_{Y} ; E_{p_{Y}}\right)$. Indeed, one has $f^{*} x=\prod_{i} \psi_{i}$ with $\psi_{i}$ irreducible and therefore

$$
\begin{align*}
v\left(f^{*} x\right) & =\sum_{i} v\left(\psi_{i}\right)  \tag{4.48}\\
& =\sum_{i} \alpha_{E_{Y}}\left(v \wedge v_{\psi_{i}}\right) m_{E_{Y}}\left(\Psi_{i}\right) \quad \text { by Proposition 3.4.3. } \tag{4.49}
\end{align*}
$$

Let $S_{x}$ be the finite subtree consisting of the segments $\left[\operatorname{ord}_{E_{Y}}, \nu_{\Psi_{i}}\right.$ ], then the map $\left.\mu \mapsto \mu\left(f^{*} x\right)\right)$ is locally constant outside of $S_{x}$. Let $S$ be the maximal finite subtree of $\mathcal{V}_{Y}\left(p_{Y} ; E_{p_{Y}}\right)$ such that the evaluation maps on $f^{*} x, f^{*} y$ and $z$ are locally constant outside of $S$. Since $v_{*}$ is an infinitely singular valuation it does not belong to $S$ and these three evaluation maps are constant on the open connected component $V$ of $\mathcal{V}_{Y}\left(p_{Y} ; E_{p_{Y}}\right) \backslash S$ containing $\nu_{*}$. Since $f_{*} \nu_{*}=\lambda_{1} \nu_{*}$, we have $f_{\bullet} \left\lvert\, V=\frac{f_{*}}{\lambda_{1}}\right.$ and the map $F_{\bullet}$ is order preserving on $V$. Following Remark 4.2.4, the two orders $\leqslant_{\mathfrak{m}_{p_{X}}}$ and $\leqslant_{E_{Y}}$ agree on $V$. Let $v \in\left[\operatorname{ord}_{E_{Y}}, v_{*}\right] \cap V$ be a divisorial valuation, $F_{\bullet}$ sends the segment $\left[v, v_{*}\right] \subset \mathcal{V}_{Y}\left(p_{Y} ; E_{Y}\right)$ inside the segment $\left[v_{\mathfrak{m}_{p_{X}}}, v_{*}\right] \subset \mathcal{V}_{X}\left(p_{X} ; \mathfrak{m}_{p_{X}}\right)$. Notice that $U:=\{\mu \geqslant \nu\} \subset V$ so the valuation $\nu$ satisfies Lemma 4.2.5.

Proposition 4.2.6 ([FJ07], Theorem 3.1). Let v be as in Lemma 4.2.5 For $t \in\left[\alpha_{E_{Y}}(v), \alpha_{E_{Y}}\left(v_{*}\right)\right]$, let $\mathrm{v}_{t}$ be the unique valuation in $\left[\mathrm{v}, \mathrm{v}_{*}\right]$ such that $\alpha_{E_{Y}}\left(\mathrm{v}_{t}\right)=t$. Then, there exists a divisorial valuation $\mathrm{v}^{\prime} \in\left[\mathrm{v}, \mathrm{v}_{*}\right]$ such that the map

$$
\begin{equation*}
t \in\left[\alpha_{E_{Y}}\left(v^{\prime}\right), \alpha_{E_{Y}}\left(v_{*}\right)\right] \mapsto \alpha_{m_{p_{X}}}\left(F_{\bullet} v_{t}\right) \tag{4.50}
\end{equation*}
$$

is an affine function of $t$ with nonnegative coefficients.
Proof. Let $v_{1}, v_{2} \in \mathcal{V}_{Y}\left(p_{Y} ; E_{Y}\right)$ be such that $v<v_{1}<v_{2}<\nu_{*}$. Since $F_{\bullet}$ is order preserving on $U=\{\mu \geqslant v\}$ one has that $F_{\bullet}$ maps $\left[v_{1}, v_{2}\right]$ homeomorphically to $\left[F_{\bullet} v_{1}, F_{\bullet} v_{2}\right]$. Let $\psi \in \widehat{O_{X, p_{X}}}$ be irreducible such that $v_{\psi}>F_{\bullet} v_{2}$, then by Proposition 3.4.3, for all $\mu \in\left[v_{1}, v_{2}\right]$ one has

$$
\begin{equation*}
\alpha_{\mathfrak{m}_{p_{X}}}\left(F_{\bullet} \mu\right)=\frac{F_{\bullet} \mu(\psi)}{m_{p_{X}}(\psi)}=\frac{\mu\left(f^{*} \psi\right)}{m_{p_{X}}(\psi) \lambda_{1}} \tag{4.51}
\end{equation*}
$$

Now let $\psi_{1}, \cdots, \psi_{r} \in \widehat{O_{Y, p_{Y}}}$ be irreducible (not necessarily distinct) such that $f^{*} \psi=\psi_{1} \cdots \psi_{r}$. One has,

$$
\begin{equation*}
\mu\left(f^{*} \psi\right)=\sum_{i} \mu\left(\psi_{i}\right)=\sum_{i} \alpha_{E_{Y}}\left(\mu \wedge v_{\psi_{i}}\right) m_{E_{Y}}\left(\psi_{i}\right) . \tag{4.52}
\end{equation*}
$$

Take one of the $\psi_{i}$ and call it $\psi_{0}$, we shall study the map $\mu \in\left[v_{1}, \nu_{2}\right] \mapsto \alpha_{E_{Y}}\left(\mu \wedge \nu_{\psi_{0}}\right)$. Let $\mu_{0}=v_{2} \wedge v_{\psi_{0}}$, this map is equal to $\alpha_{E_{Y}}$ on $\left[v_{1}, \mu_{0}\right]$ and constant equal to $\alpha_{E_{Y}}\left(\mu_{0}\right)$ on $\left[\mu_{0}, v_{2}\right]$. Therefore, the map $\mu \in\left[v_{1}, v_{2}\right] \mapsto \mu\left(f^{*} \Psi\right)$ is a piecewise affine function with nonnegative coefficients of $\alpha_{E_{Y}}(\mu)$. The points on $\left[v_{1}, v_{2}\right]$ where this map is not smooth are exactly the valuations $\nu_{*} \wedge v_{\psi_{i}}$ and there are at most $\lambda_{2}$ of them by Proposition 3.3.18. Therefore the map $\mu \mapsto v\left(f^{*} \psi\right)$ is an affine function of $\alpha_{E_{Y}}$ with nonnegative coefficients on the segment $\left[\mu^{\prime}, \nu_{*}\right]$ for any $\mu^{\prime}<\nu_{*}$ close enough to $v_{*}$.

As a corollary of the proof, we get the following proposition.
Proposition 4.2.7. Let $\mathrm{v} \in \mathcal{V}_{Y}\left(p_{Y} ; E_{Y}\right)$ be as in Proposition 4.2.6. let $\mathrm{v}_{0} \in\left[\mathrm{v}, \mathrm{v}_{*}\right]$ and let $\psi \in \widehat{O}_{X, p}$ be irreducible such that $v_{\psi}>f_{\bullet} v_{0}$. Then, for all $\varphi \in \widehat{O_{Y, p_{Y}}}$ such that $f_{\bullet} v_{\varphi}=v_{\psi}$, one has two possibilities:

1. Either $v_{\varphi}>v_{0}$.
2. or $\nu_{0} \wedge \nu_{\varphi}=\nu_{*} \wedge \nu_{\varphi} \leqslant \nu$.
I.e the configuration of Figure 4.3 cannot occur.

Proof. The map $\mu \in\left[v, v_{0}\right] \mapsto \alpha_{m_{p_{X}}}\left(F_{\bullet} \mu\right)$ is a smooth affine function of $\alpha_{E_{Y}}(\mu)$. If (1) and (2) were not satisfied, then we would get $v_{\varphi} \wedge v_{*} \in\left[v, v_{*}\right]$ and this would contradict the smoothness of the map $\mu \in\left[v, v_{*}\right] \mapsto \alpha_{m_{p_{X}}}\left(F_{\bullet} \mu\right)$

Figure 4.3: Configuration which is not possible

Lemma 4.2.8. Let $v$ be as in Proposition 4.2.6. If $\mu \in\left[v, v_{*}\right]$ is sufficiently close to $v_{*}$, then $F_{\bullet} \mu>\mu$ and $F_{\bullet}\left(\left\{\mu^{\prime} \geqslant \mu\right\}\right) \Subset U(\vec{v})$ where $\vec{v}$ is the tangent vector at $\mu$ defined by $v_{*}$ and $U(\vec{v})$ is its associated open subset.

We sum up Lemma 4.2.8 in Figure 4.4
Proof. Let $U=\{\mu \geqslant v\}$. Recall that $F_{\bullet}$ is order preserving over $U$. We first notice that if every $\mu \in\left[v, v_{*}\right]$ close enough to $v_{*}$ satisfies $F_{\bullet} \mu>\mu$, it is clear that $F_{\bullet}\left\{\mu^{\prime} \geqslant \mu\right\} \Subset U(\vec{v})$. Indeed, let $\mu^{\prime} \geqslant \mu$ and set $\mu_{0}:=\mu^{\prime} \wedge v_{*} \geqslant \mu$. Then, $F_{\bullet} \mu^{\prime} \geqslant F_{0} \mu_{0}>\mu_{0}$. In particular, $F_{0} \mu^{\prime} \wedge v_{*}>\mu^{\prime} \wedge v_{*} \geqslant \mu$.

Secondly, by Proposition 4.2.6, the map $t \in\left[\alpha_{E_{Y}}(v), \alpha_{E_{Y}}\left(v_{*}\right)\right] \mapsto \alpha_{m_{p_{X}}}\left(v_{t}\right)$ is affine and we know that it is non decreasing.

Lemma 4.2.9. Let $a: \mathbf{R} \rightarrow \mathbf{R}$ be a non-decreasing non constant affine function that admits a fixed point $t_{0}$. If there exists $s<t_{0}, a(s)>s$ then the slope of $a$ is $<1$ and for all $t<t_{0}, a(t)>t$. Proof of Lemma 4.2.9. We can suppose that $t_{0}=0$ by a linear change of coordinate. Then, $a(t)$ is of the form

$$
\begin{equation*}
a(t)=\alpha t \tag{4.53}
\end{equation*}
$$

with $\alpha>0$. Now, if $s<0$ satisfies $a(s)>s$, this means that $0<\alpha<1$ and therefore for all $t<0$, $a(t)>t$.

We show that there exists $\mu \in\left[v, v_{*}\right]$ such that $F_{\mathbf{\bullet}} \mu>\mu$. If not, then for all $\mu \in\left[v, v_{*}\left[, F_{\mathbf{\bullet}} \mu \leqslant \mu\right.\right.$. Under such an assumption, we show the following

Claim For all $\mu^{\prime} \geqslant v$ we have $F_{\bullet} \mu^{\prime} \wedge \nu_{*} \leqslant \mu^{\prime} \wedge \nu_{*}$.
Suppose that the claim is false and let $\mu^{\prime}$ be a valuation that contradicts this statement. It is clear that $\mu^{\prime}$ does not belong to $\left[v, v_{*}\right]$. Pick $v_{0} \in\left[v, v_{*}\right]$ such that $v \leqslant \mu^{\prime} \wedge v_{*}<v_{0}<F_{\bullet} \mu^{\prime} \wedge \nu_{*}$.

Figure 4.4: An $f_{\bullet}$-invariant open subset of $\mathcal{V}_{\infty}$, infinitely singular case
Let $\varphi \in \hat{O}_{Y, p_{Y}}$ be such that $v_{\varphi}>\mu^{\prime}$ and let $\psi \in \widehat{O}_{X, p}$ be such that $f_{\bullet} \nu_{\varphi}=v_{\psi}$. Since $f$ is order preserving we get that $v_{\psi}>F_{0} \mu^{\prime} \geqslant F_{0} \mu^{\prime} \wedge v_{*}>v_{0}$, therefore $v_{\psi}>F_{\mathbf{\bullet}} v_{0}$. But then $\varphi$ contradicts Proposition 4.2.7 since $v_{\varphi} \wedge v_{0}=\mu^{\prime} \wedge v_{0} \in\left[v, v_{0}\right]$. So the claim is shown.

Now, pick $\omega$ divisorial such that $Z_{\omega} \cdot \theta^{*}>0$ by Proposition 4.2 .2 the sequence $\frac{1}{\lambda_{1}^{n}} f_{*}^{n} \omega$ converges towards $\left(Z_{\omega} \cdot \theta^{*}\right) \nu_{*}$. Hence, there exists an integer $N_{0}>0$ such that for all $N \geqslant N_{0}$, $f_{*}^{N} v \in \mathcal{V}_{Y}\left(p_{Y}\right)$, replace $\omega$ by $f_{*}^{N_{0}} \omega$ and normalize it such that $\omega \in \mathcal{V}_{Y}\left(p_{Y}, E_{Y}\right)$. We can suppose up to choosing a larger $N_{0}$ that $\omega>v$. In that case $F_{0}^{N} \omega$ converges towards $\nu_{*}$ but by the claim, $\forall N \geqslant 0, F_{0}^{N} \omega \wedge \nu_{*} \leqslant \omega \wedge \nu_{*}$ which is a contradiction.

Therefore, there exists a valuation $\mu \in\left[v, v_{*}\left[\right.\right.$ such that $F_{\bullet} \mu>\mu$.

Proposition 4.2.10. With the notations from Lemma 4.2.8, we have $F_{\bullet}(U(\vec{v})) \Subset U(\vec{v})$ and for all $\mu^{\prime} \in U(\vec{v})$,

$$
\begin{equation*}
F_{\bullet}^{n} \mu^{\prime} \xrightarrow[n \rightarrow+\infty]{ } v_{*} \tag{4.54}
\end{equation*}
$$

for the weak topology.
Proof. For every $\mu^{\prime}$ in $U(\vec{v})$, write $\tilde{\mu^{\prime}}=\mu^{\prime} \wedge v_{*}$. By the proof of Lemma 4.2.8, $F_{\bullet}^{n}\left(\mu^{\prime}\right) \rightarrow v_{*}$ for the strong topology. Therefore, $F_{\bullet}^{n} \mu^{\prime} \wedge \nu_{*} \geqslant F_{\bullet}^{n}\left(\tilde{\mu^{\prime}}\right) \rightarrow v_{*}$ and $F_{\bullet}^{n} \mu^{\prime}$ converges weakly towards $\nu_{*}$ because for all $\varphi \in O_{Y, p}$ irreducible, we have

$$
\begin{equation*}
F_{\bullet}^{n}\left(\mu^{\prime}\right)(\varphi)=\alpha_{E_{Y}}\left(F_{\bullet}^{n} \mu^{\prime} \wedge v_{\varphi}\right) m_{E_{Y}}(\varphi) . \tag{4.55}
\end{equation*}
$$

For $n$ large enough we have $F_{\bullet}^{n} \mu^{\prime} \wedge v_{*} \geqslant v_{*} \wedge v_{\varphi}$, hence $F_{\bullet}^{n} \mu^{\prime} \wedge v_{\varphi}=v_{*} \wedge v_{\varphi}$ and

$$
\begin{equation*}
F_{\bullet}^{n}\left(\mu^{\prime}\right)(\varphi)=\alpha_{E_{Y}}\left(v_{*} \wedge v_{\varphi}\right) m_{E_{Y}}(\varphi)=v_{*}(\varphi) \tag{4.56}
\end{equation*}
$$

Proof of Proposition 4.2.3. Let $v$ be as in Proposition 4.2.6. Let $v_{n}$ be the approximating sequence of $v_{*}$ (see Proposition 3.4.26). We have for $n$ large enough $v_{n} \in\left[v, v_{*}\right]$ and $v_{n}$ satisfies Lemma 4.2.8. Set $\mu=v_{n}$ for some $n$ large enough and let $Z$ be a completion such that $c_{Z}(\mu)=E$ and $c_{Z}\left(v_{*}\right)=: p \in E$ is a free point. The open subset $U(\vec{v})$ associated to the tangent vector at $\mu$ defined by $v_{*}$ is exactly the image of $\mathcal{V}_{Z}(p)$ in $\mathcal{V}_{Y}\left(p_{Y} ; E_{Y}\right)$. By Proposition 4.2.10, $F_{\bullet} U(\vec{v}) \Subset U(\vec{v})$, this means that $f_{*} \mathcal{V}_{Y}(p) \subset \mathcal{V}_{Y}(p)$. By Lemma 4.1.12, $f$ is defined at $p, f(p)=p$ and since $F_{\bullet} \mu>\mu$, we get $f$ contracts $E$ to $p$. We have that for every $\mu \in \mathcal{V}_{Z}\left(p ; \mathfrak{m}_{p}\right), f_{\bullet}^{n} \mu \rightarrow \boldsymbol{v}_{*}$ also by Proposition 4.2.10.

The statement about cofinalness follows from the fact that the sequence of infinitely near points associated to $v_{*}$ contains infinitely many free points, so for every completion $X$ of $X_{0}$, there exists a completion above it where the center of $v_{*}$ is a free point at infinity.

### 4.2.2 Attractingness of $v_{*}$, the irrational case

Suppose now that char $\mathbf{k}=0$, this is necessary as we will use Theorem 3.1.9 in this paragraph. Suppose now that $\mathrm{v}_{*}$ is an irrational valuation. There exists a completion $X$ such that the center of $v_{*}$ on $X$ and on any completion above $X$ is the intersection of two divisors at infinity $E, F$. We still write $f: X \rightarrow X$ for the lift of $f$.

Let $X_{1}=X$ and for all $n \geqslant 1$, let $X_{n+1}$ be the blow up of $X_{n}$ at $c_{X_{n}}\left(v_{*}\right)$. (The center of $v_{*}$ is always a point since $v_{*}$ is not divisorial). Let $p_{n}=c_{X_{n}}\left(v_{*}\right)$ and $E_{n}, F_{n}$ be the divisors at infinity in $X_{n}$ such that $p_{n}=E_{n} \cap F_{n}$. A consequence of Theorem 3.1.9 is

Proposition 4.2.11. There exist integers $N \geqslant M$ such that the lift $\hat{f}: X_{N} \rightarrow X_{M}$ is regular at $p_{N}:=c_{X_{N}}\left(v_{*}\right)$ and such that $\hat{f}$ is monomial at $p_{N}$ in the coordinates that have $E_{N}, F_{N}$ and $E_{M}, F_{M}$ for axis respectively.

Proof. Apply Theorem 3.1.9 to $f: X \rightarrow X$. There exist completions $Y, Z$ above $X$ such that the lift $F: Y \rightarrow Z$ of $f$ is regular and monomial at every point. Let $N_{Y}=\max \left\{N: Y\right.$ is above $\left.X_{N}\right\}$ and define $N_{Z}$ in the same way. By construction, the morphism of completions $\pi: Y \rightarrow X_{N_{Y}}$ consists of blow up of points that are not $p_{N_{Y}}$. The same holds for $\tau: Z \rightarrow X_{N_{Z}}$. This shows that the lift $f: X_{N_{Y}} \rightarrow X_{N_{Z}}$ is defined at $p_{N_{Y}}$. We therefore have that $f\left(p_{N_{Y}}\right)=p_{N_{Z}}$ because $f_{*}\left(v_{*}\right)=\lambda_{1} v_{*}$ and $f$ is monomial at $p_{N_{Y}}$ in the coordinates that have $E_{N_{Y}, F_{M_{Y}}}$ and $E_{N_{Z}}, F_{N_{Z}}$ for axis respectively by Theorem 3.1.9. We set $M=N_{Z}$. If $N_{Y}<M$, we keep blowing up $p_{N_{Y}}$ until $N_{Y} \geqslant M$. This does not change the result because in local coordinates the blow up is given by a monomial map $\pi(u, v)=(u v, v)$ where $u$ and $v$ are local equation of the prime divisors at infinity to which the center of $v_{*}$ belong.

Using this we show
Proposition 4.2.12. There exists a completion $Y$ such that

1. The lift $\hat{f}: Y \rightarrow Y$ is defined at $p=c_{Y}\left(\boldsymbol{v}_{*}\right)$;
2. $\widehat{f}(p)=p$;
3. If $E, F$ are the two divisors at infinity such that $p=E \cap F$, then $E$ and $F$ are both contracted to $p$ by $\widehat{f}$.
4. Define $f_{\bullet}: \mathcal{V}_{Y}\left(p ; \mathfrak{m}_{p}\right) \rightarrow \mathcal{V}_{Y}\left(p ; \mathfrak{m}_{p}\right)$. For all $\mu \in \mathcal{V}_{Y}\left(p ; \mathfrak{m}_{p}\right), f_{\bullet}^{n} m u \rightarrow v_{*}$ for the weak topology of $\mathcal{V}_{Y}\left(p ; \mathfrak{m}_{p}\right)$.

Furthermore, If $Z$ is a completion above $Y$, then (1)-(4) remain true.
Proof. Let $N \geqslant M$ given by Proposition 4.2.11. We still write $f: X_{N} \rightarrow X_{M}$ for the lift of $f$ and $\pi: X_{N} \rightarrow X_{M}$ for the composition of blow ups. Let $x, y$ be local coordinates at $p_{N}$ such that $E_{N}=\{x=0\}$ and $F_{N}=\{y=0\}$ and let $z, w$ be local coordinates at $p_{M}$ such that $E_{M}=\{z=0\}$ and $F_{M}=\{w=0\}$. Both maps $f$ and $\pi$ are monomial at $p_{N}$ with respect to these coordinates. Write

$$
\begin{equation*}
f(x, y)=\left(x^{a} y^{b}, x^{c} y^{d}\right) \tag{4.57}
\end{equation*}
$$

Consider the tree $\mathcal{V}_{X_{M}}\left(p_{M} ; E_{M}\right)$ with its order $<_{M}$, its skewness function $\alpha_{M}$ and the generic multiplicity function $b_{M}$. This tree is rooted in $\operatorname{ord}_{E_{M}}$ and $F_{M}$ defines the end $v_{w}$ that we denote
by $v_{F_{M}}$. Let $v_{E_{N}}=\frac{1}{b_{M}\left(E_{N}\right)} \operatorname{ord}_{E_{N}}, v_{F_{N}}=\frac{1}{b_{M}\left(F_{N}\right)} \operatorname{ord}_{F_{N}}$. Suppose without loss of generality that $\nu_{E_{N}}<_{M} \nu_{F_{N}}$. Consider the tree $\mathcal{V}_{X_{N}}\left(p_{N} ; E_{N}\right)$ with its order $<_{N}$ and skewness function $\alpha_{N}$. We have by Proposition 3.4.20 item (2) that the map $\pi_{\bullet}: \mathcal{V}_{X_{N}}\left(p_{N} ; E_{N}\right) \rightarrow \mathcal{V}_{X_{M}}\left(p_{M} ; E_{M}\right)$ is an inclusion of trees. Hence, the orders $<_{M},<_{N}$ are compatible and $\mathcal{V}_{X_{N}}\left(p_{N} ; E_{N}\right)$ is naturally a subtree of $\mathcal{V}_{X_{M}}\left(p_{M} ; E_{M}\right)$ via the map $\pi_{\bullet}$. We also have the map $f_{\bullet}: \mathcal{V}_{X_{N}}\left(p_{N} ; E_{N}\right) \rightarrow \mathcal{V}_{X_{M}}\left(p_{M} ; E_{M}\right)$. The root of $\mathcal{V}_{X_{N}}\left(p_{N} ; E_{N}\right)$ is $\operatorname{ord}_{E_{N}}$ and $F_{N}$ defines the end $v_{y}$ in $\mathcal{V}_{X_{N}}\left(p_{N} ; E_{N}\right)$ that we also denote by $v_{F_{N}}$. We have that ord $E_{E_{N}}<_{N} \nu_{*}<_{N} \nu_{F_{N}}$. Using Equation (4.57), we can write

$$
\begin{equation*}
\forall v \in \mathcal{V}_{X_{N}}\left(p_{N} ; E_{N}\right), \quad f_{\bullet}(v)=\frac{f_{*} v}{a+b v(y)} \tag{4.58}
\end{equation*}
$$

Now, both maps $f_{\bullet}$ and $\pi_{\bullet}$ send the segment $\left[\operatorname{ord} E_{N}, \nu_{F_{N}}\right]$ into the segment $\left[\operatorname{ord}_{E_{M}}, v_{F_{M}}\right]$ via a Möbius transformation. Indeed, if $v_{1, t} \in \mathcal{V}_{X_{N}}\left(p_{N} ; E_{N}\right)$ is a monomial valuation at $p_{N}$, then $f_{*} \mathrm{v}_{1, t}=\mathrm{v}_{a+b t, c+t d}$ and one has by Lemma 3.4.13 and Equation (4.58)

$$
\begin{equation*}
\alpha_{M}\left(f_{\bullet} v_{1, t}\right)=\alpha_{M}\left(v_{1, \frac{c+t d}{a+t b}}\right)=\frac{c+\alpha_{N}\left(v_{1, t}\right) d}{a+\alpha_{N}\left(v_{1, t}\right) b}=M_{f}\left(\alpha_{N}\left(v_{1, t}\right)\right) \tag{4.59}
\end{equation*}
$$

Where $M_{f}$ is the Möbius transformation associated to the matrix $\left(\begin{array}{ll}d & c \\ b & a\end{array}\right)$. We can do the same process with the map $\pi_{\bullet}$ to get a Möbius transformation represented by a matrix $M_{\pi}$. Set $M$ to be the Möbius transformation $M_{f} \circ M_{\pi}^{-1}$.

Lemma 4.2.13. The Möbius map $M$ is loxodromic with an attracting fixed point $t_{*}=\alpha_{M}\left(\pi_{\bullet} v_{*}\right)$ and the multiplier of $M$ at $t_{*}$ is $\leqslant \sqrt{\frac{\lambda_{2}}{\lambda_{1}^{2}}}<1$.

In particular, for every $\mathrm{v}_{1}, \mathrm{v}_{2} \in \mathcal{V}_{X_{N}}\left(p_{N} ; E_{N}\right)$ close enough to $\mathrm{v}_{*}$ such that $\mathrm{v}_{1}<\mathrm{v}_{*}<\mathrm{v}_{2}$, $f_{\bullet}\left(\left[v_{1}, v_{2}\right]\right) \Subset\left[\pi_{\bullet} v_{1}, \pi_{\bullet} v_{2}\right]$.

Proof of Lemma 4.2.13. First of all, $M$ cannot be of finite order. Indeed, for every $v \in\left[v_{E_{N}}, v_{E_{M}}\right]$ sufficiently close to $v_{*}$, we have $Z_{v} \cdot \theta^{*}>0$ since $\theta^{*} \cdot \theta_{*}=1$. So $f_{\bullet}^{n} v \rightarrow v_{*}$ by Proposition4.2.2.

We know that $M\left(t_{*}\right)=t_{*}$ and we want to show that $\left|M^{\prime}\left(t_{*}\right)\right|<1$. The only way that the proposition is not true is if $t_{*}$ is a parabolic fixed point of $M$. This means up to reversing the orientation that $t_{*}$ is attracting for $t<t_{*}$ sufficiently close to $t_{*}$ and $t_{*}$ is repelling for $t>t_{*}$ sufficiently close to $t$. In particular, there exists $t^{\prime}$ such that the segment $\left[t^{\prime}, t_{*}\right]$ is sent strictly into itself, so we can iterate $M$ on it, and there exist two constant $c_{1}, c_{2}>0$ such that $\frac{c_{1}}{n} \leqslant\left|M^{n}(s)-t_{*}\right| \leqslant \frac{c_{2}}{n}$. We will show that we have actually an exponential speed of convergence and this leads to a contradiction. Let $v$ be the valuation centered at $p_{N}$ such that $\alpha_{M}\left(\pi_{\bullet} v\right)=t^{\prime}$,
we can suppose that $v$ is divisorial up to shrinking $\left[t^{\prime}, t_{*}\right]$. Since $f_{\bullet}^{n} v \rightarrow v_{*}$, we have $Z_{v} \cdot \theta^{*}>0$. We have by Equation (3.68)

$$
\begin{align*}
& \frac{1}{\lambda_{1}^{k}}\left(f_{*}^{k} Z_{v}\right) \cdot E_{M}=\left(\theta_{*} \cdot E_{M}\right)\left(Z_{v} \cdot \theta^{*}\right)+O\left(\left(\frac{\lambda_{2}}{\lambda_{1}^{2}}\right)^{k / 2}\right)  \tag{4.60}\\
& \frac{1}{\lambda_{1}^{k}}\left(f_{*}^{k} Z_{v}\right) \cdot F_{M}=\left(\theta_{*} \cdot F_{M}\right)\left(Z_{v} \cdot \theta^{*}\right)+O\left(\left(\frac{\lambda_{2}}{\lambda_{1}^{2}}\right)^{k / 2}\right) . \tag{4.61}
\end{align*}
$$

Using Lemma 3.4.13 we get that

$$
\begin{equation*}
\left|M^{k}\left(\alpha_{M}\left(\pi_{\bullet} v\right)\right)-t_{*}\right|=\left|\frac{f_{*}^{k} Z_{v} \cdot F_{M}}{f_{*}^{k} Z_{v} \cdot E_{M}}-\frac{\theta_{*}\left(F_{M}\right)}{\theta_{*}\left(E_{M}\right)}\right|=O\left(\left(\frac{\lambda_{2}}{\lambda_{1}^{2}}\right)^{k / 2}\right) . \tag{4.62}
\end{equation*}
$$

Therefore the speed of convergence is exponential and this shows that $\left|M^{\prime}\left(t_{*}\right)\right|<1$.

End of Proof of Proposition 4.2.12. By Lemma 4.2.13, pick $v_{1}, v_{2} \in \mathcal{V}_{X_{N}}\left(p_{N} ; E_{N}\right)$ divisorial sufficiently close to $v_{*}$ such that

$$
\begin{equation*}
\operatorname{ord}_{E_{N}}<_{N} v_{1}<_{N} v_{*}<_{N} v_{2}<_{N} v_{F_{N}} \tag{4.63}
\end{equation*}
$$

and

$$
\begin{equation*}
f_{\bullet}\left(\left[v_{1}, v_{2}\right]\right) \Subset\left[\pi_{\bullet} v_{1}, \pi_{\bullet} v_{2}\right] \tag{4.64}
\end{equation*}
$$

Let $U_{N}=\left\{v: v_{1}<v \wedge v_{F_{N}}<v_{2}\right\} \subset \mathcal{V}_{X_{N}}\left(p_{N} ; E_{N}\right)$. It is clear that $v_{F_{N}} \notin U_{N}$. Let $\psi \in \widehat{O_{X_{M}, p_{M}}}$ be such that $v_{\psi}>_{M} f_{\bullet}\left(\left[v_{1}, v_{2}\right]\right)$. Let $\psi_{1}, \cdots, \psi_{r} \in \widehat{O_{X_{N}, p_{N}}}$ be irreducible such that $f^{*} \psi=\psi_{1} \cdots \psi_{r}$. We can shrink the segment $\left[v_{1}, v_{2}\right]$ to make sure that none of the $\psi_{i}$ belong to $U_{N}$ (see Figure 4.5). If this is the case, then for all $\mu \in U_{N}$, set $\widetilde{\mu}=\mu \wedge v_{2}$, then for all i

$$
\begin{equation*}
\mu \wedge v_{\psi_{i}}=\tilde{\mu} \wedge v_{\psi_{i}} \tag{4.65}
\end{equation*}
$$

and

$$
\begin{equation*}
\mu \wedge v_{F_{N}}=\tilde{\mu} \wedge v_{F_{N}} \tag{4.66}
\end{equation*}
$$

Now, for all $\mu \in U_{N}$, by Equation (4.58) and Proposition 3.4.3

$$
\begin{equation*}
\left(f_{\bullet} \mu\right)(\psi)=\frac{\mu\left(f^{*} \psi\right)}{a+b \mu(y)}=\frac{\sum_{k} \alpha_{N}\left(\mu \wedge \nu_{\psi_{k}} m\left(\psi_{k}\right)\right)}{a+b \mu(y)} . \tag{4.67}
\end{equation*}
$$

## Chapter 4 - Eigenvaluations and dynamics at infinity

By Equations (4.65) and (4.66), we get

$$
\begin{equation*}
\left(f_{\bullet} \mu\right)(\psi)=\left(f_{\bullet} \widetilde{\mu}\right)(\psi) . \tag{4.68}
\end{equation*}
$$

This means that

$$
\begin{equation*}
\forall \mu \in U_{N}, \quad \alpha_{M}\left(\left(f_{\bullet} \mu\right) \wedge v_{\psi}\right)=\alpha_{M}\left(\left(f_{\bullet} \widetilde{\mu}\right) \wedge v_{\psi}\right) \tag{4.69}
\end{equation*}
$$

In particular, $f_{\bullet}\left(U_{N}\right) \Subset \pi_{\bullet}\left(U_{N}\right)$. So we can iterate $f_{\bullet}$ on $U_{N}$.

Figure 4.5: An $f_{\bullet}$-invariant open subset of $\mathcal{V}_{\infty}$, irrational case

Proposition 4.2.14. For every $\mu \in U_{N}, f_{\bullet}^{n} \mu \rightarrow v_{*}$ for the weak topology.
Proof. Let $\mu \in U_{N}$ and let $\widetilde{\mu}:=\mu \wedge \nu_{2}$. We have $f_{\bullet}^{n} \widetilde{\mu} \rightarrow v_{*}$ for the strong topology by Lemma 4.2.13. By equation (4.66), we have $f_{\bullet}^{n} \mu \wedge v_{2}=f_{\bullet}^{n} \widetilde{\mu} \wedge v_{2}$. Therefore for $\varphi \in O_{X_{N}, p_{N}}$ irreducible and for $n$ large enough, $\mathcal{F}_{\bullet}^{n} \mu \wedge v_{\varphi}=f_{\bullet}^{n} \tilde{\mu} \wedge v_{\varphi}$. Therefore,

$$
\begin{align*}
f_{\bullet}^{n} \mu(\varphi) & =\alpha_{N}\left(f_{\bullet}^{n} \mu \wedge v_{\varphi}\right) m_{N}(\varphi)  \tag{4.70}\\
& =\alpha_{N}\left(f_{\bullet} \tilde{\mu} \wedge v_{\varphi}\right) m_{N}(\varphi)  \tag{4.71}\\
& =f_{\bullet}^{n} \widetilde{\mu}(\varphi) \xrightarrow[n \rightarrow+\infty]{ } v_{*}(\varphi) . \tag{4.72}
\end{align*}
$$

Now pick a completion $X$ above $X_{N}$ such that for $i=1,2$, the center of $v_{i}$ is a prime divisor $E_{i}$ at infinity such that $E_{1}$ and $E_{2}$ intersect at a unique point $p$. We have $c_{X}\left(v_{*}\right)=p$. The open set $U_{N} \in \mathcal{V}_{X_{n}}\left(p_{N}, E_{N}\right)$ is the image of $V_{X}(p)$. Since $f_{\bullet} U_{N} \Subset \pi_{\bullet}\left(U_{N}\right)$, this shows that $f_{*} \mathcal{V}_{X}(p) \subset \mathcal{V}_{X}(p)$. Therefore by Lemma 4.1.12 the lift $f: X \rightarrow X$ is defined at $p, f(p)=p$ and since $f_{\bullet}$ contracts the segment $\left[v_{1}, v_{2}\right]$ we have that $f$ contracts $E_{1}$ and $E_{2}$ to $p$. We have for every $\mu \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right), f_{\bullet}^{n} \mu \rightarrow \mathrm{v}_{*}$ by Proposition 4.2.14.

If $Y$ is a completion above $X$, then $c_{Y}\left(v_{*}\right)=F_{1} \cap F_{2}$ where $F_{i}$ is a prime divisor at infinity because $v_{*}$ is irrational. The segment $\left[v_{F_{1}}, v_{F_{2}}\right]$ is a subsegment of $\left[v_{E_{1}}, v_{E_{2}}\right]$ and the same proof applies. This shows that $Y$ satisfies also Proposition 4.2.12.

### 4.2.3 Attractingness of $v_{*}$, the divisorial case

Suppose that $v_{*}$ is divisorial and let $X$ be a completion such that the center of $v_{*}$ on $X$ is a prime divisor $E$ at infinity. Since $f_{*} \operatorname{ord}_{E}=\lambda_{1} \operatorname{ord}_{E}$ we have that $f$ induces a rational selfmap of $E$.

Lemma 4.2.15. Either there exists an integer $N>0$ such that $f^{N}$ admits a noncritical fixed point on $E$, or $E$ is an elliptic curve and $f_{\mid E}$ is a translation by a non-torsion element of $E$.

Proof. The rational transformation $f$ induces a rational selfmap on $E$. If $E$ is rational, then $E \simeq \mathbf{P}^{1}$ and it admits a noncritical fixed point. If $E$ is of general type, then some iterate of $f$ induces the identity on $E$. Finally, if $E$ is an elliptic curve, then $E$ is isomorphic to $\mathbf{C} / \Lambda$ for some lattice $\Lambda, f$ lifts to a map $F: z \in \mathbf{C} \mapsto a z+b$. If $a=1$, then $F$ is a translation. Otherwise $F$ and hence $f_{\mid E}$ admits a noncritical fixed point.

Suppose char $\mathbf{k}=0$ and $\mathbf{k}=\mathbf{C}$. In the case where $f_{\mid E}$ is not a translation by a non-torsion element on an elliptic curve, $f$ defines a holomorphic fixed point germ at $p$ and we can proceed as in [FJ07] §5.2 to show that there exists a completion $X$ that contains a prime divisor $E_{0}$ at infinity such that $p=E \cap E_{0}$ and $f_{\bullet}$ maps the segment of monomial valuations $\left[\nu_{E}, \nu_{E_{0}}\right]$ strictly into itself. Here is how to proceed.

Set $X_{0}=X, p_{0}=p$. Define the sequence of completions $\left(X_{n}\right)$ as follows: $\pi_{n}: X_{n+1} \rightarrow X_{n}$ is the blow up of $X_{n}$ at $p_{n}$ and $p_{n+1}$ is the intersection point of the strict transform of $E$ with the exceptional divisor of $\pi_{n+1}$. We still denote by $E$ its strict transform in every $X_{n}$. For every $n$, we have $f_{\mid E}\left(p_{n}\right)=p_{n}$ and if $f: X_{n} \rightarrow X$ is defined at $p_{n}$, we have $f\left(p_{n}\right)=p$. We apply Theorem 3.1.9 to get

Proposition 4.2.16. There exists integers $N \geqslant M$ such that the lift $f: X_{N} \rightarrow X_{M}$ is defined at $p_{N}, f\left(p_{N}\right)=p_{M}$. Furthermore, there exists local coordinates $(x, y),(z, w)$ respectively at
$p_{N}, p_{M}$ such that $x=0$ and $z=0$ are local equations of the strict transform of $E$ in $X_{N}$ and $X_{M}$ respectively and $f$ is monomial in these coordinates.

The proof is the same as in Proposition 4.2.11.
Proposition 4.2.17. If $v_{*}$ is divisorial, there exists a completion $X$ such that

1. $c_{X}\left(v_{*}\right)$ is a prime divisor $E$ at infinity.
2. E intersects another prime divisor $E_{0}$ at infinity.
3. Up to replacing $f$ by an iterate, $f: X \rightarrow X$ is defined at $p, f(p)=p$.
4. $p$ is a noncritical fixed point of $f_{\mid E}$.
5. f leaves $E$ invariant and contracts $E_{0}$ to $p$.
6. Define $f_{\bullet}: V_{X}(p ; E) \rightarrow \mathcal{V}_{X}(p ; E)$, then for all $\mu \in c V_{X}(p ; E), f_{\bullet}^{n} \mu \rightarrow \operatorname{ord}_{E}$ for the weak topology.

If $\pi:(Y, \operatorname{Exc}(\pi)) \rightarrow(X, p)$ is a completion exceptional above $p$, then all the item above remain true in $Y$.

Proof. Let $N \geqslant M$ be as in Proposition 4.2.16. Let $F: X_{N} \rightarrow X_{M}$ be the lift of $f$. We can suppose that $N \geqslant M$ and denote by $\pi: X_{N} \rightarrow X_{M}$ the morphism of completions. We therefore have a map $f_{\bullet}: \mathcal{V}_{Y}\left(p_{N}, E\right) \rightarrow \mathcal{V}_{X}\left(p_{M}, E\right)$. Again, the tree $\mathcal{V}_{Y}\left(p_{N}, E\right)$ is a subtree via the map $\pi_{\bullet}$ and they are both rooted at the divisorial valuation $\operatorname{ord}_{E}$.

Let $(x, y),(z, w)$ be the local coordinates at $p_{N}$ and $p_{M}$ respectively given by Proposition 4.2.16. We have that $x=0$ is a local equation of $E$ in $X_{N}$ and $z=0$ is a local equation of $E$ in $X_{M}$.

$$
\begin{equation*}
f(x, y)=\left(x^{a} y^{b}, x^{c} y^{d}\right) . \tag{4.73}
\end{equation*}
$$

Since we know that $E$ is not contracted by $f$ we actually have $c=0$. We can therefore write

$$
\begin{equation*}
\forall v \in \mathcal{V}_{X_{N}}\left(p_{N} ; E\right), \quad f_{\bullet}(v)=\frac{f_{*} v}{a+b v(y)} \tag{4.74}
\end{equation*}
$$

(Recall from $\S 3.4$ that $\mathcal{V}_{X_{N}}\left(p_{n} ; E\right)$ is defined by the normalization $v(E)=1$ ). We have

$$
\begin{equation*}
f_{\bullet}\left[\operatorname{ord}_{E}, \mathrm{v}_{y}\right] \subset\left[\operatorname{ord}_{E}, \mathrm{v}_{w}\right] \tag{4.75}
\end{equation*}
$$

and the map is given by the following formula

$$
\begin{equation*}
f_{\bullet} v_{1, s}=v_{1, \frac{s d}{a+s b}} . \tag{4.76}
\end{equation*}
$$

As in the irrational case, we can consider the matrix $M_{f}$ and $M_{\pi}$ and study the type of the Möbius transformation induced by $M_{\pi}^{-1} \circ M_{f}$. Since $\operatorname{ord}_{E}$ is a fixed point, we show that it is not repelling on the segment $\left[\operatorname{ord}_{E}, v_{y}\right]$.

Let $v_{0} \in\left[\operatorname{ord}_{E}, v_{w}\right]$ be a divisorial valuation. We have $f_{\bullet}\left(\left[\operatorname{ord}_{E}, v_{0}\right]\right) \subset\left[\operatorname{ord}_{E}, v_{w}\right]$. Let $U_{N}=\left\{\mu: \operatorname{ord}_{E} \leqslant \mu \wedge v_{y}<v_{0}\right\} \subset \mathcal{V}_{X_{N}}\left(p_{N} ; E\right)$. It is clear that $v_{y} \notin U_{N}$. Let $\psi \in \widehat{O_{X_{M}, p_{M}}}$ be irreducible such that $v_{\psi}>f_{\bullet}\left(\left[\operatorname{ord}_{E}, v_{0}\right]\right)$. Let $\psi_{1}, \cdots, \psi_{r}, \in \widehat{O}_{X_{N}, p_{N}}$ be irreducible such that $f^{*} \psi=\psi_{1} \cdots \psi_{r}$. Up to shrinking the segment $\left[\operatorname{ord}_{E}, v_{0}\right]$ we can suppose that none of the $\nu_{\psi_{i}}$ belong to $U_{N}$ (See Figure 4.6). If this is the case, then for all $\mu \in U_{N}$, set $\tilde{\mu}=\mu \wedge v_{0}$, then for all i

$$
\begin{equation*}
\mu \wedge v_{\psi_{i}}=\widetilde{\mu} \wedge v_{\psi_{i}}, \quad \mu \wedge v_{y}=\widetilde{\mu} \wedge v_{y} \tag{4.77}
\end{equation*}
$$

Now, for all $\mu \in U_{N}$, by Equation (4.74) and Proposition 3.4.3

$$
\begin{equation*}
\left(f_{\bullet} \mu\right)(\psi)=\frac{\mu\left(f^{*} \psi\right)}{a+b \mu(y)}=\frac{\sum_{k} \alpha_{N}\left(\mu \wedge \nu_{\psi_{k}}\right) m\left(\psi_{k}\right)}{a+b \mu(y)} . \tag{4.78}
\end{equation*}
$$

By Equation 4.77, we get

$$
\begin{equation*}
\left(f_{\bullet} \mu\right)(\psi)=\left(f_{\bullet} \widetilde{\mu}\right)(\psi) . \tag{4.79}
\end{equation*}
$$

This means that

$$
\begin{equation*}
\forall \mu \in U_{N}, \quad \alpha_{M}\left(\left(f_{\bullet} \mu\right) \wedge v_{\psi}\right)=\alpha_{M}\left(\left(f_{\bullet} \widetilde{\mu}\right) \wedge v_{\psi}\right) \tag{4.80}
\end{equation*}
$$

If $v \in \mathcal{V}_{\infty}$ is divisorial such that $Z_{v} \cdot \theta^{*}>0$, then $\frac{1}{\lambda_{1}^{n}} f_{*}^{n} v \rightarrow v_{*}$ by Proposition 4.2.2. Then, there exists $N_{0} \geqslant 1$ such that for $n \geqslant N_{0}, \frac{1}{\lambda_{1}^{n}} f_{*}^{n} v \in U_{N}$. Replace $v$ by $\frac{1}{\lambda_{1}^{N_{0}}} f_{*}^{N_{0}}(v)$. If $\operatorname{ord}_{E}$ was a repelling fixed point, then we could not have $f_{\bullet}^{n} v \rightarrow v_{*}$ by Equation (4.77) and (4.80). Therefore, we can pick $v_{0}$ such that $f_{\bullet}\left[\operatorname{ord}_{E}, v_{0}\right] \Subset \pi_{\bullet}\left[\operatorname{ord}_{E}, v_{0}\right]$. In that case $f_{\bullet}\left(U_{N}\right) \Subset \pi_{\bullet}\left(U_{N}\right)$. So we can iterate $f_{\bullet}$ on $U_{N}$.

Proposition 4.2.18. For all $\mu \in U_{N}, f_{\bullet}^{n} \mu \rightarrow \operatorname{ord}_{E}$ for the weak topology.

Proof. The proof is similar to the proof of Proposition 4.2.14. Let $\mu \in U_{N}$ and set $\widetilde{\mu}=\mu \wedge v_{0}$. Since $\operatorname{ord}_{E}$ is an attracting fixed point for $f_{\bullet}$ and $f_{\bullet}\left[\operatorname{ord}_{E}, v_{0}\right] \Subset\left[\operatorname{ord}_{E}, v_{0}\right]$, we have $f_{\bullet} \widetilde{\mu} \rightarrow \operatorname{ord}_{E}$ for the strong topology. Then, by Equation (4.80), $f_{\bullet}^{n} \mu \wedge v_{0}=f_{\bullet}^{n} \widetilde{\mu}$. Let $\varphi \in O_{X_{N}, p_{N}}$ be irreducible

Figure 4.6: An $f_{\bullet}$-invariant open subset of $\mathcal{V}_{\infty}$, divisorial case
such that $\varphi$ is not a local equation of $E$, then for $n$ large enough

$$
\begin{align*}
f_{\bullet}^{n} \mu(\varphi) & =\alpha_{E}\left(f_{\bullet}^{n} \mu \wedge v_{\varphi}\right) m_{E}(\varphi)  \tag{4.81}\\
& =\alpha_{E}\left(f_{\bullet}^{n} \widetilde{\mu} \wedge v_{\varphi}\right) m_{E}(\varphi)  \tag{4.82}\\
& =\alpha_{E}\left(f_{\bullet}^{n} \widetilde{\mu}\right) m_{E}(\varphi) \xrightarrow[n \rightarrow+\infty]{ } 0 \tag{4.83}
\end{align*}
$$

Let $E_{0}$ be the divisor associated to the divisorial valuation $v_{0}$ and let $Z$ be a completion such that $c_{Z}\left(v_{0}\right)$ is the divisor $E_{0}$ and such that $E_{0} \cap E$ is a point $p$. Then, the open subset $U_{N}$ corresponds to $\mathcal{V}_{Z}(p)$ and we have $f_{*} \mathcal{V}_{Z}(p) \subset \mathcal{V}_{Z}(p)$. By Lemma 4.1.12, we have that the lift $\widehat{f}: Z \rightarrow Z$ is regular at $p, \widehat{f}(p)=p$ and since we know that $f_{\bullet} v_{0}<v_{0}$ and $f_{*} \operatorname{ord}_{E}=\lambda_{1}(f) \operatorname{ord}_{E}$ we have that $\hat{f}$ contracts $E_{0}$ at $p, E$ is $f$-invariant and for all $\mu \in \mathcal{V}_{Z}(p ; E), f_{\bullet}^{n} \mu \rightarrow v_{*}$ by Proposition 4.2.18,

If $\pi:\left(Z^{\prime}, \operatorname{Exc}(\pi)\right) \rightarrow(Z, p)$ is a completion exceptional above $p$, then $\operatorname{Exc}(\pi)$ is a tree of rational curves, let $E_{0}^{\prime}$ be the irreducible component of $\operatorname{Exc}(\pi)$ that intersect the strict transform of $E$. Then $E_{0}^{\prime}$ corresponds to a divisorial valuation $v_{0}^{\prime}$ such that $\operatorname{ord}_{E}=v_{*}<v_{0}^{\prime}<v_{0}$ and all the proofs above apply so Proposition 4.2 .17 holds also for $Z^{\prime}$.

Lemma 4.2.19. When $v_{*}$ is divisorial, $\lambda_{1} \leqslant \lambda_{2}$, with equality if and only if $f_{\mid E}: E \rightarrow E$ has degree 1 .

Proof. Let $X$ be a completion such that the center of $v_{*}$ is a prime divisor $E$ at infinity. Since
$f_{*} \nu_{*}=\lambda_{1} \nabla_{*}$, we have that $f^{*} E=\lambda_{1} E+R$ where $R$ denotes an effective divisor supported at infinity. Now, we also have $f_{*} E=d E+R^{\prime}$. From the equality $f_{*} \circ f^{*}=\lambda_{2}$ id, we get that $\lambda_{1} d \leqslant \lambda_{2}$. In particular, $\lambda_{1} \leqslant \lambda_{2}$.

### 4.2.4 Local normal form of $f$

We are now ready to proof Theorem 4.2.1.

Proof of Theorem 4.2.1 Suppose $v_{*}$ is infinitely singular. From Proposition 4.2.3, there exists a completion $X$ such that $c_{X}\left(v_{*}\right)=: p \in E$ is a free point, $f: X \rightarrow X$ is defined at $p$ and $f_{*}\left(\mathcal{V}_{X}(p)\right) \Subset \mathcal{V}_{X}(p)$. We need to show that the germ of holomorphic functions induced by $f$ at $p$ is contracting and rigid. It is clear that $E \in \operatorname{Crit}(f)$ (Recall the notations from §3.1.5). If $\operatorname{Crit}(f)$ admits another irreducible component, it induces a curve valuation in $\mathcal{V}_{X}(p)$, we can blow up $p$ to get another completion above $X$ satisfying Proposition 4.2.3 such that $\operatorname{Crit}(f)$ does not admit any other component than $E$. Thus, $f$ is rigid at $p$ it remains to show that it is contracting. Let $(x, y)$ be local coordinates at $p$ such that $x=0$ is a local equation of $E$. Since $\nu_{*}(E)>0$ and $f_{*} \nu_{*}=\lambda_{1} \nu_{*}$ we get that $f^{*} x=x^{\lambda_{1}} \varphi$ with $\varphi \in O_{X, p}^{\times}$and $\lambda_{1} \geqslant 2$. Now, since $E$ is contracted by $f$, we get that $f^{*} y=x \psi$ with $\psi \in O_{X, p}$ but since $f$ is dominant we have $\psi \in \mathfrak{m}_{p}$. Hence, we get that

$$
\begin{equation*}
f(x, y)=\left(x^{\lambda_{1}} \varphi, x \psi\right) \tag{4.84}
\end{equation*}
$$

with $\varphi \in O_{X, p}^{\times}$and $\psi \in \mathfrak{m}_{p}$. Consider the norm $\|(x, y)\|=\max (|x|,|y|)$ associated to the coordinates $x, y$ and let $U^{*}$ be the ball of center $p$ and radius $\varepsilon>0$. If $\varepsilon>0$ is small enough, then $U^{*}$ is $f$-invariant and $f\left(U^{*}\right) \Subset U^{*}$, so $f$ is contracting at $p$. Finally, there are no $f$-invariant germ of curves at $p$. Indeed, if $\varphi \in \widehat{O_{X, p}}$ is $f$-invariant, then $f_{\bullet} \nu_{\varphi}=\nu_{\varphi}$. But we have by Proposition 4.2 .3 that $f_{\bullet}^{n} \mathrm{v}_{\varphi} \rightarrow \mathrm{v}_{*}$ and this is a contradiction. Thus, we get that $f$ has the local normal form of (3.3) with $a=\lambda_{1}$. If $\mathbf{k}=\mathbf{C}$, Looking at the classification of the rigid contracting germs in dimension 2, we see that $f$ is in Class 4 of Table 1 in [Fav00] hence of type (3.2) thus there exists local analytic coordinates $(z, w)$ at $p$

$$
\begin{equation*}
\widehat{f}(z, w)=\left(z^{a}, \lambda z^{c} w+P(z)\right) \tag{4.85}
\end{equation*}
$$

where $a \geqslant 2, c \geqslant 1, \lambda \in \mathbf{C}^{\times}$and $P$ is a polynomial such that $P(0)=0$. Since $E$ is the only germ of curve contracted by $f$ (all the other germs of analytic curves are contained in $X_{0}$ they cannot be contracted to $p$ by $f$ since $f$ is an endomorphism of $X_{0}$ ), we have that $z=0$ is a local equation
of $E$. We infer $v_{*}(z)=v_{*}(E)>0$ and therefore

$$
\begin{equation*}
\lambda_{1} v_{*}(z)=f_{*} v_{*}(z)=v_{*}\left(z^{a}\right)=a \cdot v_{*}(z) ; \tag{4.86}
\end{equation*}
$$

thus $\lambda_{1}=a \in \mathbf{Z}_{\geqslant 0}$. Furthermore, since $f$ does not have any invariant germ of analytic curve, we get that $P \not \equiv 0$.

Suppose now that $\mathrm{v}_{*}$ is irrational, by Proposition 4.2.12, there exists a completion $X$ of $X_{0}$ such that the lift $f: X \rightarrow X$ is defined at $p=c_{X}\left(v_{*}\right), X$ contains two divisors at infinity $E, F$ such that $p=E \cap F$ and $\hat{f}$ contracts both $E$ and $F$ at $p$. It remains to show that $f$ is contracting and rigid at $p$. First we can suppose up to further blow ups that $\operatorname{Crit}(f) \cap X_{0}=\varnothing$. Therefore $f$ is rigid, now since both $E, F$ are contracted to $p, f$ is contracting. Finally, there are no $f$-invariant germs of curves at $p$ since for all $\mu \in \mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right), f_{\bullet}^{n} \mu \rightarrow \mathrm{v}_{*}$ by Proposition 4.2.12. Let $(z, w)$ be local coordinates at $p$ associated to $(E, F)$. We have that $f$ is of the pseudomonomial form

$$
\begin{equation*}
f(z, w)=\left(z^{a} w^{b} \varphi, z^{c} w^{d} \psi\right) \tag{4.87}
\end{equation*}
$$

with $\varphi, \psi \in O_{X, p}^{\times}$and $a, b, c, d \geqslant 1$ since $E, F$ are contracted to $p$. Notice that $f_{*} \operatorname{ord}_{E}=v_{a, b}$ and $f_{*} \operatorname{ord}_{F}=v_{c, d}$. Consider the segment of monomial valuations $I$ centered at $p$ inside $\mathcal{V}_{X}\left(p ; \mathfrak{m}_{p}\right)$ we have that $f_{\bullet}: I \rightarrow I$ is injective, therefore $(a, b)$ is not proportional to $(c, d)$. Furthermore the open subset $U^{*}$ corresponding to the ball of radius $\varepsilon>0$ is $f$-invariant for $\varepsilon>0$ small enough and $f\left(U^{*}\right) \Subset U^{*}$. In that case, we show that $\lambda_{1}(f)$ is the spectral radius of the matrix $A=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$, hence an algebraic integer of degree 2. Indeed, $v_{*}=v_{s, t}$ where $(s, t)$ is an eigenvector of $A$ for the eigenvalue $\lambda_{1}$. Since $v_{*}$ is irrational, we have $s / t \notin \mathbf{Q}$ and therefore $\lambda_{1} \notin \mathbf{Q}$. Now, when we iterate $f$, we get that $f^{n}$ is pseudomonomial with monomials given by the matrix $A^{n}$, hence we get

$$
\begin{equation*}
\lambda_{1}^{n}\binom{v_{*}(z)}{v_{*}(w)}=A^{n}\binom{s}{t} \tag{4.88}
\end{equation*}
$$

If $\mathbf{k}=\mathbf{C}$, then $f$ is in the class 6 of Table 1 of [Fav00]. Hence it can be made monomial and there exists local analytic coordinates $x, y$ at $p$ such that

$$
\begin{equation*}
f(x, y)=\left(x^{a} y^{b}, x^{c} y^{d}\right) \tag{4.89}
\end{equation*}
$$

It is clear that $(x, y)$ is associated to $(E, F)$ since these are the only two germs of curves contracted by $f$.

Now finally, suppose that $v_{*}$ is divisorial. Take a completion $X$ as in Proposition 4.2.17. Let $p=E \cap E_{0}$ with $\nu_{*}=\operatorname{ord}_{E}$. The lift $f: X \rightarrow X$ is defined at $p$. Up to further blow-ups we can suppose that $\operatorname{Crit}(f) \cap X_{0}=\varnothing$. Therefore, $\operatorname{Crit}(f) \subset E \cup E_{0}$ which is totally invariant as $f_{*} \mathcal{V}_{X}(p) \Subset \mathcal{V}_{X}(p)$ so $f$ is rigid at $p$. There are no $f$-invariant germs of curves apart from $E$ at $p$ since for all $\mu \in \mathcal{V}_{X}(p ; E), f_{\bullet}^{n} \mu \rightarrow \operatorname{ord}_{E}$ by Proposition 4.2.17. Let $(x, y)$ be local coordinates at $p$ associated to $\left(E, E_{0}\right)$. Since $f_{*} \operatorname{ord}_{E}=\lambda_{1} \operatorname{ord}_{E}$ with $\lambda_{1} \geqslant 2$ we have $f^{*} x=x^{\lambda_{1}} \varphi$ with $\varphi \in O_{X, p}$. Since no germ of curve is sent to $E$ apart from $E_{0}$, we have that up to multiplying $x$ by a constant that $f^{*} x=x^{\lambda_{1}} y^{b}(1+\varphi)$ with $\varphi \in O_{X, p}$. Then, $E_{0}$ is contracted to $p$ so $f^{*} y=y^{c} \psi$ with $\psi \in O_{X, p}^{\times}$ and $c=1$ since $p$ is a noncritical fixed point of $f_{\mid E}$. Hence, in these coordinates the local normal form of $f$ is (3.6):

$$
\begin{equation*}
\widehat{f}(x, y)=\left(x^{a} y^{b}(1+\varphi), \lambda y(1+\psi)\right) \tag{4.90}
\end{equation*}
$$

with $a=\lambda_{1} \geqslant 2, b \geqslant 1, \lambda \in \mathbf{C}^{\times}$and $\varphi(0)=\psi(0)=0$.

### 4.3 General case

In this section, we extend Theorem A to the general case, without assuming $A^{\times}=\mathbf{k}^{\times}$or $\operatorname{Pic}^{0}\left(X_{0}\right)=0$. We rely on the universal property of the quasi-Albanese variety (see [Ser01]), as well as on the geometric properties of subvarieties of quasi-abelian varieties (see [Abr94]).

### 4.3.1 Quasi-Albanese variety and morphism

Let $G$ be an algebraic group over $\mathbf{k}$ with $\mathbf{k}$ algebraically closed. We say that $G$ is a quasi-abelian variety if there exists an algebraic torus $T=\mathbb{G}_{m}^{r}$, an abelian variety $A$, and an exact sequence of $\mathbf{k}$-algebraic groups

$$
\begin{equation*}
0 \rightarrow T \rightarrow G \rightarrow A \rightarrow 0 . \tag{4.91}
\end{equation*}
$$

Theorem 4.3.1 (see [Ser01], Théorème 7). Let $X$ be a variety over $\mathbf{k}$, then there exists a quasiabelian variety $G$ and a morphism $q: X \rightarrow G$ such that for any quasi-abelian variety $G^{\prime}$ and any morphism $\varphi: X \rightarrow G^{\prime}$ there exists a unique morphism $g: G \rightarrow G^{\prime}$ and a unique $b \in G^{\prime}$ such that

$$
\varphi=g \circ q .
$$

Moreover, $g$ is the composition of a homomorphism $L_{g}: G \rightarrow G^{\prime}$ of algebraic groups and a translation $T_{g}: G^{\prime} \rightarrow G^{\prime}$ by some element $b \in G^{\prime}$.

Such a $G$ is unique up to (a unique) isomorphism. It is called the quasi-Albanese variety of $X$ and it will be denoted by $\operatorname{QAlb}(X)$; the universal morphism $q: X \rightarrow \operatorname{QAlb}(X)$ is "the" quasi-Albanese morphism (it is unique up to post-composition with an isomorphism of $G$ ).

Proposition 4.3.2. Let $X_{0}$ be an affine variety. Then $\mathbf{k}\left[X_{0}\right]^{\times}=\mathbf{k}^{\times}$and $\operatorname{Pic}^{0}\left(X_{0}\right)=0$ if and only if $\mathrm{QAlb}\left(X_{0}\right)=0$.

Proof. Let $G=\operatorname{QAlb}\left(X_{0}\right)$ and $q: X_{0} \rightarrow G$ be a quasi-Albanese morphism. Let

$$
\begin{equation*}
0 \rightarrow T \rightarrow G \xrightarrow{\pi} A \rightarrow 0 \tag{4.92}
\end{equation*}
$$

be an exact sequence, as in Equation (4.91). Let $X$ be a completion of $X_{0}$ such that $\pi \circ q$ extends to a regular map $\pi \circ q: X \rightarrow A$.

Assume $\mathbf{k}\left[X_{0}\right]^{\times}=\mathbf{k}^{\times}$and $\operatorname{Pic}^{0}\left(X_{0}\right)=0$. Then, $\pi \circ q\left(X_{0}\right)$ is a point in $A$, and composing $q$ with a translation of $G$, we can assume that this point is the neutral element of $A$. Then,
$q\left(X_{0}\right) \subset T$, so $q$ is a regular map from $X_{0}$ to an algebraic torus, and $\mathbf{k}\left[X_{0}\right]^{\times}=\mathbf{k}^{\times}$implies that $q\left(X_{0}\right)$ is a point. This shows that $\mathrm{QAlb}\left(X_{0}\right)$ is a point.

Now, suppose that $\mathbf{k}\left[X_{0}\right]^{\times} \neq \mathbf{k}^{\times}$, then any non-constant invertible function $X_{0} \rightarrow \mathbf{k}^{\times}$provides a dominant morphism to a 1 -dimensional torus, $\operatorname{so} \operatorname{dim}\left(\operatorname{QAlb}\left(X_{0}\right)\right) \geqslant 1$ by the universal property. And if $\operatorname{Pic}^{0}\left(X_{0}\right) \neq 0$, the Albanese morphism also shows that $\operatorname{dim}\left(\operatorname{QAlb}\left(X_{0}\right)\right) \geqslant 1$. This concludes the proof.

In the following, we show that if $X_{0}$ is an irreducible normal affine surface with non-trivial quasi-Albanese variety and $f$ is a dominant endomorphism of $X_{0}$, then $\lambda_{1}(f)$ is a quadratic integer. See Proposition 4.3 .6 below. We will rely on the following result.

Theorem 4.3.3 (Theorem 3 of Abr94]). Let $Q$ be a quasi-abelian variety and let $V$ be a closed subvariety of $Q$. Let $K$ be the maximal closed subgroup of $Q$ such that $V+K=V$. Then, the variety $V / K$ is of general type.

### 4.3.2 Dynamical degree in presence of an invariant fibration

Proposition 4.3.4 (Stein Factorization). Let $X$, $S$ be projective varieties and let $f: X \rightarrow X$ be a rational transformation. Suppose that there exists $\varphi: X \rightarrow S$ and $g: S \rightarrow S$ such that the following diagram commutes,

Then there exists a variety $\widetilde{S}$ and morphisms $\psi: X \rightarrow \widetilde{S}, \pi: \widetilde{S} \rightarrow S$ such that

- $\varphi=\pi \circ \psi$,
- $\pi$ is finite and $\psi$ has connected fibers
- there exists a rational transformation $\tilde{g}: \widetilde{S} \rightarrow \widetilde{S}$ such that the diagram

## commutes.

Proof. The existence of $\widetilde{S}$ along with $\pi$ and $\psi$ is due to Stein Factorization theorem: It is known that one can take $\widetilde{S}=\operatorname{Spec}_{S} \varphi_{*} O_{X}$ where $\operatorname{Spec}_{S}$ is the relative Spec; that is for every affine open subset $U$ of $S$, one has

$$
\begin{equation*}
\pi^{-1}(U) \simeq \operatorname{Spec} O_{X}\left(\varphi^{-1}(U)\right) . \tag{4.93}
\end{equation*}
$$

Now to construct $\widetilde{g}$, take affine open subsets $U$ and $V$ of $S$ such that $U \subset g^{-1}(V)$. Suppose also that $\varphi^{-1}(U)$ and $\varphi^{-1}(V)$ do not contain any indeterminacy of $f$. To construct

$$
\begin{equation*}
\widetilde{g}_{\mid \pi^{-1}(U)}: \pi^{-1}(U) \rightarrow \pi^{-1}(V) \tag{4.94}
\end{equation*}
$$

we use the map $f^{*}: O_{X}\left(\varphi^{-1}(V)\right) \rightarrow O_{X}\left(\varphi^{-1}(U)\right)$ induced by $f$; this is well defined since $\varphi^{-1}(U) \subset f^{-1}\left(\varphi^{-1}(V)\right)$. It is clear that $\psi \circ f=\widetilde{g} \circ \psi$.

Proposition 4.3.5. Let $S$ be a quasiprojective surface and $f$ be a dominant endomorphism of S. Suppose there exists a quasiprojective curve $C$ with a dominant morphism $\pi: S \rightarrow C$ and an endomorphism $g: C \rightarrow C$ such that $\pi \circ f=g \circ \pi$. Then, the first dynamical degree of $f$ is an integer.

Proof. Let $X$ be a completion of $S ; f$ extends to a rational transformation of $X$. We can also suppose that $C$ is a projective curve, and then we apply Theorem4.3.4 to suppose also that $\pi$ has connected fibers.

Let $P$ be a general point of $C$ and $H$ an ample divisor of $X$. We have by [DN11, Tru15] that

$$
\begin{equation*}
\left.\lambda_{1}(f)=\max \left(\lambda_{1}(g), \lambda_{1}\left(f_{\mid \pi}\right)\right)\right) \tag{4.95}
\end{equation*}
$$

where $\lambda_{1}(g)$ is the integer given by the topological degree of $g$ and

$$
\begin{equation*}
\lambda_{1}\left(f_{\mid \pi}\right):=\lim _{n}\left(H \cdot\left(f^{n}\right)_{*} \pi^{-1}(P)\right)^{1 / n} \tag{4.96}
\end{equation*}
$$

Since $C$ is a curve and $\pi$ is dominant we have that $\pi$ is flat ([Har77] Proposition III.9.7) so for any point $P \in C$,

- $\pi^{-1}(P)$ is an irreducible curve $C_{P}$ and the topological degree of $f: C_{P} \rightarrow C_{g(P)}$ is an integer $d$ that does not depend on $P$
- $d \cdot d_{\mathrm{top}}(g)=\lambda_{2}(f)$.

Indeed, consider the following 0 -cycle in $S \times S$ :

$$
\begin{equation*}
\alpha(P)=\left(\pi_{1}^{*} C_{P}\right) \cdot\left(\pi_{2}^{*} H\right) \cdot \Gamma_{f} \tag{4.97}
\end{equation*}
$$

where $\pi_{1}, \pi_{2}: S \times S \rightarrow S$ are the two projections and $\Gamma_{f}$ is the graph of $f$. The degree of $\alpha(P)$ is

$$
\begin{equation*}
\operatorname{deg} \alpha=\left(H \cdot C_{g(P)}\right) \cdot \operatorname{deg}\left(f: C_{P} \rightarrow C_{g(p)}\right) . \tag{4.98}
\end{equation*}
$$

Now, since $C$ is a curve the morphism $\pi \circ \pi_{1}: S \times S \rightarrow C$ is flat, therefore $\operatorname{deg}(\alpha(P))$ does not depend on $P$ ([Ful98] §20.3) and since $\pi$ is flat, the intersection number $\left(H \cdot C_{P}\right)$ does not depend on $P$ either. Therefore, $\operatorname{deg}\left(f: C_{P} \rightarrow C_{g(P)}\right)$ is an integer $d$ independent of $P$. Hence, we infer

$$
\begin{equation*}
\lambda_{1}\left(f_{\mid \pi}\right)=\lim _{n}\left(H \cdot\left(f^{n}\right)_{*} \pi^{-1} P\right)=d \cdot \lim _{n}\left(H \cdot \pi^{-1} P\right)^{1 / n}=d \tag{4.99}
\end{equation*}
$$

and we get that $\lambda_{1}(f)$ is the integer $\max \left(d, \lambda_{1}(g)\right)$.

### 4.3.3 Dynamical degree when the quasi-Albanese variety is non-trivial

The goal of this section is to show the following proposition.
Proposition 4.3.6. Let $X_{0}$ be an irreducible normal affine surface and $f$ a dominant endomorphism of $X_{0}$. Suppose that $\operatorname{QAlb}\left(X_{0}\right)$ is non-trivial, then $\lambda_{1}(f)$ is an integer or a quadratic integer.

Set $Q_{0}=\operatorname{QAlb}\left(X_{0}\right)$ and let $q: X_{0} \rightarrow Q_{0}$ be a quasi-Albanese morphism. Let $V=\overline{q\left(X_{0}\right)}$ be the closure of the image of $X_{0}$ in $Q_{0}$. By the universal property, there exists an endomorphism $g$ of $Q_{0}$ such that

$$
\begin{align*}
q \circ f & =g \circ q  \tag{4.100}\\
g(z) & =L_{g}(z)+b_{g} \tag{4.101}
\end{align*}
$$

for some algebraic homomorphism $L_{g}: Q_{0} \rightarrow Q_{0}$ and some translation $z \mapsto z+b_{g}$ (here, we denote the group law by addition). In particular $g_{\mid V}$ defines a regular endomorphism of $q\left(X_{0}\right)$ and since $f$ is dominant, so is $g_{\mid V}$. As in Theorem 4.3.3. set $K=\left\{x \in Q_{0} ; x+V=V\right\}$. Then, denote by $\pi_{V}: V \rightarrow V / K$ the canonical projection onto the quotient.

Proposition 4.3.7. There exists an endomorphism $g^{\prime}: V / K \rightarrow V / K$ such that $g^{\prime} \circ \pi_{V}=\pi_{V} \circ g_{\mid V}$.

Proof. We have to show that $g_{\mid V}$ is compatible with the quotient map. Take $v \in V$ and $k \in K$. Since $v+k \in V, g(v+k) \in V$. Now,

$$
\begin{equation*}
g(v+k)=L_{g}(v+k)+b_{g}=L_{g}(v)+L_{g}(k)+b_{g}=g(v)+L_{g}(k) . \tag{4.102}
\end{equation*}
$$

Thus, $L_{g}(k)+g(V) \subset V$. Taking the closure and knowing that $g_{\mid V}$ is dominant, we have $L_{g}(k)+V=V$. Therefore, $L_{g}(k) \in K$ and $g_{\mid V}$ is compatible with the quotient modulo $K$.

Case $\operatorname{dim} V / K=2$ - In that case, the map $\pi_{V} \circ q: X \rightarrow V / K$ is generically finite. Since $V / K$ is of general type, $g^{\prime}$ has finite order: there is some positive integer $n$ such that $\left(g^{\prime}\right)^{n}=I d_{V / K}$. Thus, $f$ is also a finite order automorphism, and $\lambda_{1}(f)=1$.

Case $\operatorname{dim} V / K=1$ - In that case $\pi_{V} \circ q$ induces a fibration of $X_{0}$ over a curve of general type and we conclude that $\lambda_{1}(f)$ is an integer by Proposition 4.3.5.

Case $\operatorname{dim} V / K=0$ - This means that $V$ is equal to $K$ up to translation. Therefore, by the universal property of the quasi-Albanese variety, $K=V=Q_{0}$ and $q: X_{0} \rightarrow Q_{0}$ is dominant.

If $\operatorname{dim} Q_{0}=1$, then $f$ preserves a fibration over a curve and Proposition 4.3.5 implies again that $\lambda_{1}(f)$ is an integer.

Suppose now that $\operatorname{dim} Q_{0}=2$. Then $q$ is generically finite, so that $\lambda_{1}(f)=\lambda_{1}(g)$. A priori, there are three possibilities.

The first case is when $Q_{0}$ is a 2-dimensional multiplicative torus. In that case, $g$ is a monomial endomorphism: in coordinates, $g(x, y)=\left(\alpha x^{a} y^{b}, \beta x^{c} y^{d}\right)$ for some $\alpha, \beta$ in $\mathbf{k}^{\times}$and some integers $(a, b, c, d)$ with $a d-b c \neq 0$; then, $\lambda_{1}(g)$ is the spectral radius of the $2 \times 2$ matrix

$$
\left(\begin{array}{ll}
a & b  \tag{4.103}\\
c & d
\end{array}\right) .
$$

Thus, it is the maximum of the moduli $|\lambda|,\left|\lambda^{\prime}\right|$ of the eigenvalues of this matrix and, as such, it is an algebraic integer of degree $\leqslant 2$.

The second possibility is that $Q_{0}$ is an extension of an elliptic curve $A$ by a one dimensional torus $\mathbb{G}_{m}$; then, the projection $Q_{0} \rightarrow A$ is $g$-equivariant, and Proposition 4.3.5 implies that $\lambda_{1}(g)$ is an integer.

The third and last possibility is that $Q_{0}$ is an abelian surface. Let $X$ be a (good) completion of $X_{0}$ such that $q$ extends to a regular morphism $q_{X}: X \rightarrow Q_{0}$. Pulling back a regular 2-form by $q$, we see that the Kodaira dimension of $X$ is non-negative. If it is equal to 2, a positive iterate of $f$ is the identity, so $\lambda_{1}(f)=1$. If it is equal to 1 , the Kodaira-Iitaka fibration gives an $f$-invariant fibration and Proposition 4.3.5 implies that $\lambda_{1}(g)$ is an integer. Thus, we may assume that the Kodaira dimension of $X$ vanishes. Since the dimension of the Albanese variety of $X$ is 2 , the classification of surfaces implies that $X$ is a blow-up of its Albanese variety $Q_{0}$, and $q_{X}$ is the inverse of this blow-up. In particular, $q_{X}$ is a birational morphism, it is one-to-one on the complement of its exceptional locus $\operatorname{Exc}\left(q_{X}\right)$.

Set $B=q_{X}\left(\partial_{X} X_{0}\right)$. Since $\partial_{X} X_{0}$ supports an ample divisor, $B$ is a curve ( $\partial_{X} X_{0}$ cannot be contracted by $q_{X}$ ).

Let $p$ be an indeterminacy point of $f: X \rightarrow X$ and $C$ be the total transform of $p$ by $f$. Since $C$ is a union of rational curves and abelian surfaces do not contain rational curves, $q_{X}(C)$ is a point. Moreover, this point must be contained in $B$. Thus, $g(B)=q_{X}\left(f\left(\partial_{X} X_{0}\right)\right)$ is contained in $B$, and $B$ is $g$-invariant. Also, since $X_{0}$ does not contain any complete curve, each component of $\operatorname{Exc}\left(q_{X}\right)$ must intersect $\partial_{X} X_{0}$, and $q_{X}\left(\operatorname{Exc}\left(q_{X}\right)\right) \subset B$.

Composing $q$ by a translation we may assume that $B$ contains the neutral element $o$ of $Q_{0}$. Let $B_{0}$ be an irreducible component of $B$ containing $o$. Then, some positive iterate $g^{n}$ of $g$ preserves $B_{0}$. If the genus of $B_{0}$ is $\geqslant 2, g_{B_{0}}^{n}$ has finite order and $B_{0}$ generates the group $Q_{0}$, so $g$ has finite order, so does $f$, and $\lambda_{1}(f)=1$. Thus, we can now assume that the genus of each component of $B$ is 1 , each component being a translate of some elliptic curve.

If $B$ is irreducible, the quotient map $Q_{0} \rightarrow Q_{0} / B$ is $g$-equivariant and we conclude again by Proposition 4.3.5. If there is an irreducible component $B_{0}$ of $B$ with $g\left(B_{0}\right)=B_{0}+b$ for some $b \in Q_{0}$, we conclude in the same way.

Now, we can assume that $B$ is reducible and $g\left(B_{0}\right)$ is not a translate of $B_{0}$. There is an integer $n \geqslant 1$ such that the curve $B_{0}$ is periodic of period $n$, i.e. $B_{0}, B_{1}:=g\left(B_{0}\right), \ldots, B_{n-1}=g^{n-1}\left(B_{0}\right)$ are pairwise distinct, and $g^{n}\left(B_{0}\right)=B_{0}$. Taking some further iterate $g^{n m}$, and changing the position of the neutral element, we can suppose that $o$ is a point of intersection of $B_{0}$ and $B_{1}$ and that $g^{n m}(o)=o$. Let $d$ denote the degree of $g^{n}$ along $B_{0}$; since $g$ maps $B_{0}$ to $B_{1}, d$ is also the degree of $g^{n}$ along $B_{1}$. If $d=1$, then $f$ and $g$ have $\lambda_{1}=\lambda_{2}=1$.

Let us now assume $d \geqslant 2$ and derive a contradiction. On $B_{0}$, the pre-images $\left(g_{\mid B_{0}}^{n m}\right)^{-k}(z)$ form a dense subset of $B_{0}$; the same is true for $B_{1}$. The homomorphism $B_{0} \times B_{1} \rightarrow Q_{0}$ given by addition is an isogeny, so the preimages of any point of $Q_{0}$ under the action of $g$ form a dense subset of $Q_{0}$. Let $z$ be a point in $\operatorname{Exc}\left(q_{X}\right)$, then its preimages should be dense, but this would
imply that $f$ maps some point in the interior of $X_{0}$ into the boundary $\partial_{X} X_{0}$. This contraction concludes the proof.

### 4.4 The automorphism case

Here we suppose that $X_{0}$ is an irreducible normal affine surface that admits a loxodromic automorphism over a field of characteristic zero. In this situation, we can actually deduce a lot more from the result of Section 4.1. In particular one can first check that $X_{0}$ has to be rational, see [DF01] Table 1 Class 5. So the condition $\operatorname{Pic}^{0}\left(X_{0}\right)$ is automatically satisfied. We change the notation for this section, we will denote $\theta^{*}$ and $\theta_{*}$ by $\theta^{+}$and $\theta^{-}$respectively. So that $\left(f^{ \pm 1}\right)^{*} \theta^{ \pm}=\lambda_{1} \theta^{ \pm}$. By Proposition 4.1.15 and Theorem 4.1.16, we get that

- $\theta^{+}, \theta^{-} \in \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right) \cap \mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$ and they are both effective.
- $\theta^{+}=Z_{v_{-}}$and $\theta^{-}=Z_{v_{+}}$where $v_{+}$is the eigenvaluation of $f$ and $v_{-}$the eigenvaluation of $f^{-1}$.

Proposition 4.4.1. Let $X_{0}=\operatorname{Spec} A$ be a rational affine surface such that $A^{\times}=\mathbf{k}^{\times}$and let $f$ be a loxodromic automorphism of $X_{0}$, then

1. The eigenvaluations $v_{+}, v_{-}$of $f$ and $f^{-1}$ respectively are of the same type.
2. If $\lambda_{1} \in \mathbf{Z}_{\geqslant 0}$, then $\boldsymbol{v}_{+}$and $\boldsymbol{v}_{-}$are infinitely singular.
3. If $\lambda_{1} \in \mathbf{R} \backslash \mathbf{Z}_{\geqslant 0}$ then $v_{+}$and $v_{-}$are irrational.

Proof. If the eigenvaluation was divisorial, then we would get by Lemma 4.2.19 that $\lambda_{1} \leqslant \lambda_{2}$ and this is absurd because $\lambda_{1}>1, f$ being loxodromic. The dichotomy of the type of eigenvaluation follows from Theorem 4.2.1 and the fact that $\lambda_{1}(f)=\lambda_{1}\left(f^{-1}\right)$.

Corollary 4.4.2. In that case, the nef eigenclasses $\theta^{-}$and $\theta^{+}$verify

$$
\left(\theta^{-}\right)^{2}=\left(\theta^{+}\right)^{2}=0
$$

and in any completion $X$ of $X_{0}$ one has $\left(\theta_{\bar{X}}^{ \pm}\right)^{2}>0$.
Proof. The equalities $\left(\theta^{-}\right)^{2}=\left(\theta^{+}\right)^{2}=0$ come from Theorem 3.2.28 (3.71). Since the eigenvaluations are not divisorial, $\theta^{-}$and $\theta^{+}$are not Cartier divisors by Corollary 4.1.4 therefore for any completion $X$ of $X_{0},\left(\theta_{\bar{X}}^{ \pm}\right)^{2}>0$. Indeed, if $\left(\theta_{\bar{X}}^{ \pm}\right)^{2}=0$ then since $\theta^{ \pm}$is nef, we would get $\theta_{\bar{X}}^{ \pm}=\theta^{ \pm}$.

Let $X$ be a completion of $X_{0}$. We have a simple criterion to check whether a divisor at infinity is contracted thanks to Proposition 4.2.2.
Proposition 4.4.3. Let $E$ be a prime divisor at infinity in a completion $X$ of $X_{0}$. If $Z_{\operatorname{ord}_{E}} \cdot \theta^{-}>0$ then there exists $N>0$ such that $f^{N}$ contracts $E$ to the point $c_{X}\left(v_{+}\right)$.

### 4.4.1 Gizatullin's work on the boundary and applications

In [Giz71a], Gizatullin considers minimal completions of affine surface. That is a completion $X$ of $X_{0}$ minimal with respect to the following property:

- The boundary $\partial_{X} X_{0}$ does not have three prime divisors that intersect at the same point.
- If $\partial_{X} X_{0}$ has a singular irreducible component then $\partial_{X} X_{0}$ consists only of one irreducible curve with at most one nodal singularity.

For such a completion $1: X_{0} \hookrightarrow X$, Gizatullin defines the curve $E(\mathrm{l})$ as the union of the irreducible components $E$ of $\partial_{X} X_{0}$ that are contracted by an automorphism of $X_{0}$ (the automorphism depends on $E$ ).

We call a zigzag a chain of rational curves. That is a sequence $\left(E_{1}, \cdots, E_{r}\right)$ of rational curves such that $E_{i} \cdot E_{i+1}=1, i=1, \cdots, r-1$ and for all $i, j$ such that $|i-j| \geqslant 2, E_{i} \cdot E_{j}=0$. In particular the dual graph with respect to the $E_{i}$ 's is of the form

$$
\stackrel{\dot{E}_{1}}{ } \quad \dot{E}_{2} \quad \cdots \stackrel{\rightharpoonup}{E_{r-1}} \quad \dot{E}_{r}
$$

We will write $E_{1} \triangleright E_{2} \triangleright \cdots \triangleright E_{r}$ for the zigzag defined by $\left(E_{1}, \cdots, E_{r}\right)$.
A cycle of rational curves is a sequence $\left(E_{1}, \cdots, E_{r}\right)$ of rational curves such that $E_{i} \cdot E_{i+1}=1$ and $E_{1} \cdot E_{r}=1$. The dual graph with respect to the $E_{i}^{\prime}$ 's is of the form

Theorem 4.4.4. Let $X_{0}=\operatorname{Spec} A$ be an irreducible normal affine surface such that $A^{\times}=\mathbf{k}^{\times}$ and $\operatorname{Pic}^{0}\left(X_{0}\right)=0$. Suppose that $X_{0}$ admits an automorphism $f$ with $\lambda_{1}(f)>1$. If $X$ is a minimal completion of $X_{0}$, one has $E(\mathfrak{r})=\partial_{X} X_{0}$. Furthermore we have two mutually excluding cases

1. $\lambda_{1}(f)$ is an integer and in that case $E(\mathrm{l})$ is a zigzag.
2. $\lambda_{1}(f)$ is irrational and $E(\mathrm{l})$ is a cycle of rational curves.

Furthermore, there exists a completion $Y$ with two distinct points $p_{+}, p_{-} \in \partial_{Y} X_{0}$ and an integer $N>0$ such that

- $f^{ \pm 1}\left(p_{ \pm}\right)=p_{ \pm}$.
- $f^{ \pm N}$ contracts $\partial_{Y} X_{0}$ to $p_{ \pm}$.
- $f^{ \pm N}$ has a normal form at $p_{ \pm}$given by Theorem 4.2.1 it pseudomonomial or monomial in the cycle case and of type (3.2) or (3.3) in the zigzag case.
- In the cycle case, this set of properties remains true if we blow up $p_{+}$or $p_{-}$.
- In the zigzag case, the set of completions above $Y$ that satisfy these properties is cofinal in the set of all completions above $Y$.

The normal form of $f$ at $p_{ \pm}$is monomial in the cycle case and of the form of Theorem 4.2.1 case (3) in the zigzag case.

This shows Theorem C. We will prove Theorem 4.4 .4 in $\S 4.4 .2$ and 4.4.3. We end this section with some technical result that will be useful in the proof of Theorem 4.4.4.

Lemma 4.4.5. Let $X$ be a completion of $X_{0}$ and let $E$ be a prime divisor at infinity such that $Z_{\text {ord }_{E}} \cdot \theta^{+}=0$ and $E$ intersects some prime divisor in the support of $\theta_{X}^{+}$, then $c_{X}\left(v_{+}\right)$belongs to $E$.

Proof. Since $\theta^{+}$is effective and $\operatorname{ord}_{E}\left(\theta^{+}\right)=0$ we get $\theta^{+} \cdot E>0$ since $E$ intersects the support of $\theta^{+}$. This implies by Proposition 3.6.6 that $c_{X}\left(v_{+}\right)$belongs to $E$.

Lemma 4.4.6. Let $Y$ be a completion of $X_{0}$ and $E$ a prime divisor at infinity of $Y$ such that $Z_{\text {ord }_{E}} \cdot \theta^{+}>0$. If $p \in E \backslash\left\{c_{X}\left(v_{+}\right)\right\}$, then for any divisorial valuation $v$ such that $c_{X}(v)=p$, one has $Z_{v} \cdot \theta^{+}>0$.

Proof. Let $Z$ be the blow up of $Y$ at $p$. Then, $\theta_{Z}^{+}=\left(\pi^{*} \theta_{Y}^{+}\right)+c \widetilde{E}$ for some $c \in \mathbf{R}$. Since the center of $v_{+}$is not on $\widetilde{E}$, one has $\theta_{Z}^{+} \cdot \widetilde{E}=0$, hence $c=0$. Now whether $p$ is a free point on $E$ or a satellite point, we have $Z_{\text {ord }_{\tilde{E}}} \cdot \theta^{+} \geqslant Z_{\text {ord }_{E}} \cdot \theta^{+}>0$.

Lemma 4.4.7. Let $Y$ be a completion of $X_{0}$ such that the center of $\mathrm{v}_{+}$is the intersection of two prime divisors at infinity $F_{1}, F_{2}$. Then, $Z_{\text {ord }_{F_{1}}} \cdot \theta^{+}>0$ or $Z_{\operatorname{ord}_{F_{2}}} \cdot \theta^{+}>0$.

Proof. Recall that $\theta^{+}$is nef and effective. Suppose that $Z_{\text {ord }_{F_{i}}} \cdot \theta^{+}=0$ for $i=1,2$ and let $\widetilde{E}$ be the exceptional divisor above $p_{+}$. Let $\pi: Z \rightarrow Y$ be the blow-up at $p_{+}$. Then we have

$$
\theta_{Z}^{+}=\pi^{*}\left(\theta_{Y}^{+}\right)+c \widetilde{E}
$$

for some $c \in \mathbf{R}$. This implies $\theta^{+} \cdot \widetilde{E}=-c>0$ because $p_{+}$was the center of $v_{+}$on $Y$, therefore $c<0$. But $Z_{\operatorname{ord}_{\tilde{E}}} \cdot \theta_{Z}^{+}=\left(Z_{\operatorname{ord}_{F_{1}}}+Z_{\operatorname{ord}_{F_{2}}}\right) \theta_{Y}^{+}+c=c<0$ and this contradicts the fact that $\theta^{+}$is effective.

Proposition 4.4.8. For any completion $Y$ such that $c_{Y}\left(v_{+}\right)$is a free point, we have

$$
\begin{equation*}
\operatorname{Supp} \theta_{Y}^{+}=\partial_{Y} X_{0} . \tag{4.104}
\end{equation*}
$$

Hence, if $\mathrm{v}_{ \pm}$is an infinitely singular valuation, then for any completion $Z$, there exists an integer $N>0$ such that $f^{ \pm N}\left(\partial_{Z} X_{0}\right)=p_{ \pm}$.

Proof. Let $E$ be the unique prime divisor at infinity such that $c_{Y}\left(v_{+}\right) \in E$. If $\operatorname{Supp} \theta_{Y}^{+} \neq \partial_{Y} X_{0}$, there a prime divisor $F$ at infinity such that $Z_{\text {ord }_{F}} \cdot \theta^{+}=0$ and $F \cap \operatorname{Supp} \theta_{Y}^{+} \neq \varnothing$. By Lemma 4.4.5, we have $F=E$; therefore $Z_{\text {ord }_{E}} \cdot \theta^{+}=0$. But we have that $\theta_{Y}^{+}=\lambda Z_{\text {ord }_{E}}$ for some $\lambda>0$ by Proposition 4.1.5. So $\left(\theta_{Y}^{+}\right)^{2}=0$, but this is absurd by Corollary 4.4.2.

For the second assertion, assume that $\nu_{ \pm}$is an infinitely singular valuation. Let $Z$ be a completion of $X_{0}$. Then, by Proposition 3.3.16, there exists a completion $Y$ above $Z$ such that $c_{Y}\left(v_{ \pm}\right)$is a free point. The first assertion shows that $\operatorname{Supp} \theta_{Y}^{ \pm}=\partial_{Y} X_{0}$ and so the same is true for $\operatorname{Supp} \theta_{Z}^{ \pm}$. The fact that some iterate of $f^{ \pm 1}$ contracts the boundary on $p_{ \pm}$follows from Proposition 4.4.3.

### 4.4.2 Proof of Theorem 4.4.4, the cycle case

In that case it was already proven by Gizatullin that $\partial_{X} X_{0}=E(\mathfrak{\imath})$.
Proposition 4.4.9 ([ЀH74, CdC19]). Let $X$ be projective surface and $U$ an open subset of $X$ such that $X \backslash U$ is a cycle of rational curves. Assume that $X \backslash U$ is not an irreducible curve with one nodal singularity. Let $g$ be an automorphism of $U$, then the indeterminacy points of $g$ can only be intersection points of two components of the cycle.

Corollary 4.4.10. In the cycle case, the eigenvaluation of a loxodromic automorphism must be irrational and therefore $\lambda_{1}$ is an algebraic integer of degree 2, in particular it is irrational.

Proof. Proposition 4.4.9 shows that for any completion $X$ of $X_{0}, p_{+}=c_{X}\left(v_{+}\right)$is a satellite point at infinity. Indeed, since $\theta^{+}$is nef, its incarnation in $X$ cannot be 0 . Therefore, there exists a prime divisor $E$ at infinity such that $Z_{\text {ord }}^{E}$ $\cdot \theta^{+}>0$ because $\theta^{+}$is effective. Therefore, by Proposition 4.4.3, $E$ must be contracted by $f^{N}$ to $p_{+}$so it must be an indeterminacy point of $f^{-N}$. Proposition 3.3.16 shows that the eigenvaluations $v_{ \pm}$are irrational.

Proof of Theorem 4.4.4 Corollary 4.4.10 shows the first part of the theorem. We get the normal form at $p_{ \pm}$by blowing up the center of $v_{ \pm}$enough times. Since these are always intersection points of two prime divisors at infinity we can suppose that $\partial_{Y} X_{0}$ is still a cycle.

It remains to show that $\partial_{Y} X_{0}$ is contracted by some iterate of $f$ and $f^{-1}$. Suppose that there exists a prime divisor $E$ that is not contracted to $p_{+}$by any iterate of $f$. In particular $Z_{\text {ord }_{E}} \cdot \theta^{+}=0$ by Proposition 4.4.3. By Lemma 4.4.5, we have that $E$ contains $c_{Y}\left(v_{-}\right)$and $f^{-1}$ contracts $E$ to $p_{-}$. And by Lemma 4.4.7 and Corollary 4.4.10 we have that $E$ is the unique prime divisor at infinity that satisfy this property. Either $f$ contracts $E$ to a satellite point $p \neq p_{+}$ of the boundary or $f$ is sent to a prime divisor at infinity. Indeed, we cannot have $f(E)=E$, otherwise $E$ is $f$-invariant but this contradicts that $f^{-1}$ contracts $E$. If $E$ is contracted, it cannot be contracted to $p_{-}$because it is not an indeterminacy point of $f^{-1}$. Therefore, we have that the center of $f_{*} \operatorname{ord}_{E}$ is either another prime divisor at infinity or a satellite point at infinity that is not the center of $v_{+}$. In both case, we get $f_{*} Z_{\text {ord }_{E}} \cdot \theta^{+}>0$ by Lemma 4.4.6 and this is a contradiction.

### 4.4.3 Proof of Theorem 4.4.4, the zigzag case

### 4.4.3.1 Some technical lemmas about zigzags

We will say following [GD75, BD11b] that a zigzag $Z$ is standard if it is of the form

$$
\begin{equation*}
Z=F \triangleright E \triangleright Z^{\prime} \tag{4.105}
\end{equation*}
$$

where $F^{2}=0, E^{2} \leqslant-1$ and $Z$ is a negative zigzag meaning that every component of $Z^{\prime}$ has self-intersection $\leqslant-2$. Any zigzag can be put to a standard form via blow-up of points and contractions of (-1)-curves (see [GD75], §1.7)

Following [BD11b], an almost standard zigzag is a zigzag $Z=B_{1} \triangleright B_{2} \triangleright \cdots \triangleright B_{r}$ such that

1. There exists a unique irreducible component $B_{k}$ such that $\left(B_{k}\right)^{2} \geqslant 0$.
2. There exists at most one component $B_{l}$ such that $\left(B_{l}\right)^{2}=-1$ and in that case we must have $l=k \pm 1$.

We need to state some technical results for the proof of Theorem 4.4.4, we will need to apply them to a quasiprojective surface which is not necessarily affine. If $U$ is a quasiprojective surface, a completion of $U$ is defined in the same way as the completion of an affine surface. All the results in this Section rely heavily on Proposition 3.1.6 and the Castelnuovo criterion.

Lemma 4.4.11 (Proposition 3.1.3 of [BD11b]). Let $U$ be a quasiprojective surface and $X$ a completion of $U$ such that $X \backslash U$ is an almost standard zigzag that has no component of self intersection -1. Let $B_{k}$ be the unique irreducible component of nonnegative self-intersection of $X \backslash U$. Let $g$ be an automorphism of $U$, then

1. $g$ has at most one indeterminacy point $q$ on $X$.
2. $q$ has to be on $B_{k}$ (if it exists).
3. If $B_{k}$ is not on the boundary of the zigzag then $q$ must be the intersection point of $B_{k}$ with $B_{k+1}$ or $B_{k-1}$.

Proof. Suppose that $g$ has an indeterminacy point, then $g^{-1}$ also has one and $g$ has to contract a curve of the zigzag. Let $\pi: Y \rightarrow X$ be the minimal resolution of indeterminacies of $g$ and let $\tilde{g}$ be the lift of $g$. Then, the first curve contracted by $\widetilde{g}$ has to be the strict transform of $B_{k}$. So $g$ has at least one indeterminacy point on $B_{k}$.

There cannot be any indeterminacy point $q$ outside of $B_{k}$ because otherwise it belongs to components that have self-intersection $\leqslant-2$ and since the zigzag $X \backslash U$ contains no ( -1 )-curve any exceptional divisor above $q$ has to be contracted by $g$ so $q$ is not an indeterminacy point.

Suppose that $B_{k}$ is not on the boundary and that the indeterminacy point $p$ of $g$ is not an intersection point. Then, the map $\pi$ factorizes through the blow-up of $p$ and after contracting the strict transform of $B_{k}$, we get at infinity three prime divisors that intersect at the same point. But this is a contradiction because $\widetilde{g}$ consists only of blow ups of point at infinity and $X \backslash U$ does not have three divisors that intersects at the same point.

Finally, there cannot be more than one indeterminacy point on $X$. Suppose the contrary and let $p_{1}, p_{2}$ be two indeterminacy points, they both belong to $B_{k}$. Let $E_{1}, E_{2}$ be two exceptional divisor above $p_{1}$ and $p_{2}$ in $Y$ respectively. They cannot be contracted by $\tilde{g}$ because $Y$ is the minimal resolution of singularities of $g$. Therefore, their strict transform is either a $(-1)$-curve or a curve with nonnegative self intersection. But this is absurd because $X \backslash U$ does not contain any ( -1 )-curve and has only one curve of nonnegative self-intersection.

Corollary 4.4.12. Let $X$ be a completion of $U$ such that $X \backslash U$ is an almost standard zigzag $Z$ and let $f$ be an automorphism of $U$. Suppose that $f$ has an indeterminacy point that is a free point on $B_{k}$, then one of the two sides of $Z$ can be contracted so that $B_{k}$ becomes a boundary component of the zigzag.

Proof. Suppose that $B_{k}$ is not a boundary component of the zigzag and that $f$ has an indeterminacy point that is a free point on $B_{k}$. Then, by Lemma 4.4.11, $B_{k-1}$ or $B_{k+1}$ has to be a
$(-1)$-curve, suppose it is $B_{k+1}$. We contract it and we obtain an almost standard zigzag and $f$ still has an indeterminacy point that is a free point on $B_{k}$. If $B_{k}$ is on the boundary we are done, otherwise the only $(-1)$-curve is the strict transform of $B_{k+2}$ and we keep contracting until $B_{k}$ becomes a boundary component of the zigzag.

Lemma 4.4.13. Let $U$ be a quasiprojective variety and $X$ a completion of $U$ such that $X \backslash U$ is a zigzag of type $\left(-m_{1}, \cdots,-m_{k},-1,-1,-m_{k+1}, \cdots,-m_{r}\right)$ such that for all $i, m_{i} \geqslant 2$. Let $f$ be an automorphism of $U$. Then the intersection point of the two ( -1 )-curves cannot be an indeterminacy point of $f$.

If the zigzag is of type $(-1,-2, \ldots, \underbrace{-2}_{F}, \underbrace{-1}_{E},-m_{k+1}, \cdots,-m_{r})$ with $m_{i} \geqslant 2$, then $F \cap E$ cannot be an indeterminacy point of $f$.

Proof. Let $\pi: Z \rightarrow X$ be a minimal resolution of indeterminacy of $f: X \rightarrow X$ and let $\tilde{f}: Z \rightarrow X$ be the lift of $f$. The first curve contracted by $\tilde{f}$ must be the strict transform of one of the prime divisors at infinity of $X$. But if the intersection of the $(-1)$-curves is an indeterminacy point of $f$, then all the strict transforms of the prime divisors at infinity of $X$ have self-intersections $\leqslant-2$ and this is a contradiction.

If $X \backslash U$ is a zigzag $Z$ of type $\left(-1,-2, \cdots,-2,-1,-m_{k+1}, \cdots,-m_{r}\right)$, suppose that $F \cap E$ is an indeterminacy point of $f$, then the first curve contracted by $\tilde{f}$ must be the strict transform of the $(-1)$-curve on the left of the zigzag. So we can start by contracting it and we get a zigzag $Z^{\prime}$ of type $(-1,-2, \cdots, \underbrace{-2}_{F}, \underbrace{-1}_{E},-m_{k+1}, \cdots,-m_{r})$ and of size $\# Z-1$. We can repeat this process until we get a zigzag of the form $\left(-1,-1,-m_{k+1}, \cdots,-m_{r}\right)$ and we have that
 $F \cap E$ cannot be an indeterminacy point of $f$ by the previous case, this is a contradiction.

Lemma 4.4.14. Let $f$ be an automorphism of $X_{0}$ and let $X$ be a minimal completion of $X_{0}$ in the sense of Gizatullin. Then, $f$ defines an automorphism of $U=(E(\mathrm{l}))^{c} \subset X$, the complement of $E(\mathrm{l})$, i.e the birational map $f: X \rightarrow X$ does not have any indeterminacy point on $U$.

Proof. Suppose that $f$ admits an indeterminacy point $p$ on some component $E_{1}$ of $\partial_{X} X_{0}$ with $p \notin E(\mathrm{l})$. Let $\pi: Y \rightarrow X$ be a minimal resolution of indeterminacies for $f$ and let $F: Y \rightarrow X$ be the lift of $f$. The fiber $\pi^{-1}(p)$ contains at least one $(-1)$-curve and we claim that none of the irreducible components of $\pi^{-1}(p)$ can be contracted by $F$, indeed since $E_{1}$ is not contracted, one can only contract $(-1)$-curves of $\pi^{-1}(p)$ but that would contradict the minimality of $Y$. Therefore, the fiber $\pi^{-1}(p)$ is not affected by $F$ and neither are the self-intersections in the
fiber. This would imply that $\partial_{X} X_{0}$ contains some $(-1)$-curves that can be contracted and this contradicts the minimality of $X$.

Corollary 4.4.15. Let $X_{\min }$ be a minimal completion of the affine surface $X_{0}$. The centers $c_{X_{\min }}\left(\mathrm{v}_{ \pm}\right)$must belong to $E(\mathrm{l})$.

We will apply all the results of this section with $U=(E(\mathbf{l}))^{c} \subset X_{\text {min }}$ where $X_{\text {min }}$ is a minimal completion of $X_{0}$.

### 4.4.3.2 Elementary links between almost standard zigzags

From now on $U=(E(\mathrm{l}))^{c} \subset X_{\min }$ where $X_{\text {min }}$ is a minimal completion of the affine surface $X_{0}$. All the results of $\S 4.4 .3 .1$ will be applied to the following situation. If $X$ is a completion of $U$ (hence of $X_{0}$ ) and $f$ is a loxodromic automorphism of $X_{0}$, then some positive iterate of $f$ contracts a component of $X \backslash U$ to $c_{X}\left(\mathrm{v}_{+}\right)$. Thus, $c_{X}\left(\mathrm{v}_{+}\right)$is an indeterminacy point of some positive iterate of $f^{-1}$ on $X$.

Proposition 4.4.16. Let $X$ be a completion of $U$ such that $X \backslash U$ is an almost standard zigzag, then one can find a completion $Y$ of $U$ with a birational map $\varphi: X \rightarrow Y$ that is an isomorphism above $U$ such that

1. $Y \backslash U$ is also an almost standard zigzag.
2. Let $\widetilde{X}$ be the blow up of $X$ at $c_{X}\left(v_{+}\right)$, then the lift $\varphi: \widetilde{X} \rightarrow Y$ is defined at $c_{\widetilde{X}}\left(\boldsymbol{v}_{+}\right)$and is a local isomorphism there.

Proof. Let $B$ the unique irreducible component of $X \backslash U$ of nonnegative self intersection.

Case: $B$ is on the boundary $\quad X \backslash U$ is a zigzag of the form $B \triangleright E \triangleright Z$ where $B^{2} \geqslant 0, E^{2} \leqslant-1$ and $Z$ is a negative zigzag.

- $c_{X}\left(\nu_{+}\right)$is a free point on $B$ If $E^{2}=-1$, we blow up $c_{X}\left(v_{+}\right)$and then contract the strict transform of $E$. Let $Y$ be the new projective surface obtained, it satisfies the proposition. Suppose $E^{2}<-1$, If $B^{2}>0$ we blow up $B \cap E$ to obtain a new zigzag $B \triangleright E^{\prime} \triangleright Z^{\prime}$ which is still almost standard. We keep blowing up the strict transform of $B$ with the second component of the zigzag until $B^{2}=0$. After all these blowups, let $X^{\prime}$ be the newly obtained projective surface, we have that $X^{\prime} \backslash U$ is an almost standard zigzag of the form $B \triangleright E \triangleright Z$
where $B^{2}=0, E^{2}=-1$ and $Z$ is a negative zigzag. We blow up $c_{X^{\prime}}\left(\boldsymbol{v}_{+}\right)$and let $\widetilde{E}$ be the exceptional divisor, by Lemma 4.4.13, the center of $v_{+}$cannot be the intersection point of $\widetilde{E}$ and the strict transform of $B$, therefore it is a free point of $\widetilde{E}$ and we can contract the strict transform of $B$. We call $Y$ the new obtained surface it satisfies the proposition.
- $c_{X}\left(\mathrm{v}_{+}\right)$is the satellite point $B \cap E$ We blow up $B \cap E$ and call $\widetilde{E}$ the exceptional divisor. If $B^{2}>0$ in $X$, then we still have an almost standard zigzag and we call $Y$ the new obtained surface. If $B^{2}=0$ in $X$, then by Lemma 4.4.13 is a free point of $\widetilde{E}$ and we can contract the strict transform of $B$, we call $Y$ the newly obtained surface.

## Case: $B$ is not on the boundary

- $c_{X}\left(v_{+}\right)$is a free point of $B$ By Corollary 4.4.12, one of the two sides of $X \backslash U$ is contractible, so we contract it and call $X_{1}$ the newly obtained surface, we can now apply the proof of the boundary case to find $Y$.
- $c_{X}\left(v_{+}\right)$is the satellite point $B \cap E$ We can suppose up to contraction that if $X \backslash U$ contains a $(-1)$-component, it must be $E$. We start by blowing up $c_{X}\left(v_{+}\right)$and let $\widetilde{E}$ be the exceptional divisor.
- If $B^{2}>0$ in $X$, then we still have an almost standard zigzag and we call $Y$ the newly obtained surface.
- If $B^{2}=0$ in $X$, then by Lemma 4.4.13 the center of $v_{+}$cannot be the intersection of $\widetilde{E}$ and the strict transform of $B$ where $\widetilde{E}$ is the exceptional divisor. So we can contract the strict transform of $B$ and we get an almost standard zigzag and we call $Y$ the newly obtained surface.

Corollary 4.4.17. If $\partial_{X} X_{0}$ is a zigzag, the eigenvaluation $v_{+}$cannot be irrational, hence it is infinitely singular and $\lambda_{1}$ is an integer. Furthermore, $U=X_{0}$.

Proof. It suffices to show that the sequence of centers of $v_{+}$contains infinitely many free points. If not, we can apply Proposition 4.4.16finitely many times so that we get a completion $X$ of $X_{0}$ such that $X \backslash U$ is an almost standard zigzag and the center of $v_{+}$is always a satellite point. We show that this leads to a contradiction.

Case 1: $c_{X}\left(v_{+}\right)=B \cap E$ with $E$ a component of $X \backslash U \quad$ We can suppose after contractions and blow ups that $B^{2}=0$. We will show that we can suppose that $B$ is a boundary component of the zigzag. The zigzag $X \backslash U$ is of the form $Z_{1} \triangleleft B \triangleright E \triangleright Z$. Denote by ( $m_{1}, \cdots, m_{r}$ ) the type of $Z_{1}$.

- Case $m_{1} \geqslant 2$ Blow up $B \cap E$ and call $\widetilde{E}$ the exceptional divisor. The center of $v_{+}$has to be $B \cap \widetilde{E}$ or $\widetilde{E} \cap E$, but it cannot be $B \cap \widetilde{E}$ by Lemma 4.4.13. So we can contract the strict transform of $B$. We get a new zigzag of the form $Z_{1}^{\prime} \triangleleft B^{\prime} \triangleright Z^{\prime}$ with $m_{1}^{\prime}=m_{1}-1$ and $\# Z_{1}^{\prime}=\# Z_{1}$.
- Case $m_{1}=1$ call $E_{1}$ the first component of $Z_{1}$. Blow up $B \cap E$. The center of $v_{+}$is either $B \cap \widetilde{E}$ or $\widetilde{E} \cap E$. Either way, we can contract the strict transform of $E_{1}$. We get a zigzag of the form $Z_{1}^{\prime} \triangleleft B \triangleright \widetilde{E} \triangleright E \triangleright Z$ where $\# Z_{1}^{\prime}=\# Z_{1}-1$.

We can apply this procedure recursively, it stops because the sequence $\left(\# Z_{1}, m_{1}\right)$ is strictly decreasing for the lexicographical order. And we never blow down a curve that contains the center of $v_{+}$nor do we blow down a curve to the center of $v_{+}$.

Now that we have that $B$ is a boundary component, we can suppose that $X \backslash U$ is a 1 -standard zigzag. Call $E$ the (-1)-component of $X \backslash U$, we will show that $Z_{v_{+}} \cdot E=+\infty$. Indeed, blow up $B \cap E$ and let $\widetilde{E}$ be the exceptional divisor. By Lemma 4.4.13, the center of $v_{+}$has to be $\widetilde{E} \cap E$. If we blow up the center of $v_{+}$again we can still apply Lemma 4.4.13, so the center of $\nu_{+}$is always the intersection point of the strict transform of $E$ with the exceptional divisor. This implies that $v_{+}$is the curve valuation associated to the curve $E$ and this is absurd.

Case 2: $c_{X}\left(\mathrm{v}_{+}\right)=B \cap C$ with $C$ a component of $\partial_{X} X_{0}$ but $C \cap U \neq \varnothing$. This means that $c_{X}\left(v_{+}\right)$belongs to no other component of $X \backslash U$ than $B$. Using Lemma 4.4.11 we can contract one of the two sides of the zigzag so that $B$ is a boundary component of the zigzag $X \backslash U$, we can furthermore suppose that $X \backslash U$ has no ( -1 )-component. Call $m$ the self intersection of the component next to $B$ in the zigzag, we have by assumption $m \leqslant-2$.

- Case $B^{2}>0$ let $X^{\prime}$ be the blow up of $B \cap C$ and let $\widetilde{E}$ be the exceptional divisor. Then, since the strict transform of $B$ has nonnegative self intersection $X^{\prime} \backslash U$ is an almost standard zigzag. We must have that $c_{X^{\prime}}\left(v_{+}\right) \in \widetilde{E}$ and by Lemma 4.4.11 $c_{X^{\prime}}\left(v_{+}\right)$must be $B \cap \widetilde{E}$ and we are back in Case 1. This leads to a contradiction.
- Case $B^{2}=0$ Let $E$ be the component on $X \backslash U$ next to $B$ (if it exists). Let $X^{\prime}$ be the blow up of $B \cap C$ and let $\widetilde{E}$ be the exceptional divisor. By Lemma 4.4.13, $c_{X^{\prime}}\left(v_{+}\right)$cannot be $B \cap \widetilde{E}$
so it has to be $\widetilde{E} \cap C$. Let $X^{\prime \prime}$ be the blow down of the strict transform of $B$. The strict transform of $\widetilde{E}$ has nonnegative self-intersection and $X^{\prime \prime} \backslash U$ is an almost standard zigzag and $c_{X^{\prime \prime}}\left(v_{+}\right)=\widetilde{E} \cap C$. Rename $\widetilde{E}$ by $B$ in $X^{\prime \prime}$. If $E^{2}=m$ in $X$, then the strict transform of $E$ in $X^{\prime \prime}$ satisfies $E^{2}=m+1$. We repeat this procedure until $E^{2}=-1$. We then blow down $E$ and we end up back in the case $B^{2}>0$ and this leads to a contradiction.

The last case to treat is if $X \backslash U$ is a zigzag containing only $B$ with $B^{2}=0$. We will show in that case that $v_{+}(C)=+\infty$ which is a contradiction. Indeed, let $X^{\prime}$ be the blow up of $B \cap C$ and let $\widetilde{E}$ be the exceptional divisor. Then, by Lemma 4.4.13, $c_{X^{\prime}}$ cannot be $B \cap \widetilde{E}$ so it must be $\widetilde{E} \cap C$. Let $X^{\prime \prime}$ be the blow up of $\widetilde{E} \cap C$ and let $\widetilde{E}^{(2)}$ be the exceptional divisor. Again, by Lemma 4.4.13, $c_{X^{\prime \prime}}\left(v_{+}\right)=\widetilde{E}^{(2)} \cap C$. By induction, we see that the centers of $v_{+}$must always belong to the strict transform of $C$ in every blow up, this implies that $v_{+}$ is the curve valuation associated to $C$ and this is absurd.

Thus, $v_{+}$is not irrational. Hence, by Proposition 4.4.1 $v_{+}$is an infinitely singular valuation, so we get that $U=X_{0}$ by Proposition 4.4.8.

### 4.4.4 A summary and applications

We sum up the content of Theorem 4.4.18 in Figure 4.7 and 4.8

Figure 4.7: Dynamics at infinity of $f$ when $\lambda_{1}(f) \in \mathbf{Z}_{\geqslant 0}$

Theorem 4.4.18. Let $X_{0}=\operatorname{Sec} A$ be a normal affine surface defined over an algebraically closed complete field $\mathbf{C}_{v}$ such that $A^{\times}=\mathbf{C}_{v}^{\times}$and $\operatorname{Pic}^{0}\left(X_{0}\right)=0$. Let $f$ be a loxodromic automorphism of $X_{0}$. Then, there exists two unique (up to normalization) distinct valuations centered at $v_{+}, v_{-}$such that $f_{*}^{ \pm 1}\left(v_{ \pm}\right)=\lambda_{1} v_{ \pm}$. Let $\theta^{-}=Z_{v_{+}}$and $\theta^{+}=Z_{v_{-}}$. We have that $\theta^{+}, \theta^{-}$are nef, effective and satisfy the following relations

$$
\begin{align*}
& f^{*} \theta^{+}=\lambda_{1} \theta^{+},  \tag{4.106}\\
& f_{*} \theta^{+}=\frac{1}{\lambda_{1}} \theta^{+},  \tag{4.107}\\
& \theta^{-}=\frac{1}{\lambda_{1}} \theta^{-} \\
& \theta^{-}=\lambda_{1} \theta^{-}
\end{align*}
$$

Furthermore we have the following intersection relations: $\left(\theta^{+}\right)^{2}=\left(\theta^{-}\right)^{2}=0$ and $\theta^{+} \cdot \theta^{-}=1$.
We can find a completion $X$ of $X_{0}$ such that if $p_{+}:=c_{X}\left(v_{+}\right), p_{-}:=c_{X}\left(v_{-}\right)$, then

1. $p_{+} \neq p_{-}$.
2. some positive iterate of $f^{ \pm 1}$ contracts $\partial_{X} X_{0}$ to $p_{ \pm}$.
3. $f^{ \pm}$is defined at $p_{ \pm}, f^{ \pm}=p_{ \pm}$and $p_{\mp}$ is the unique indeterminacy point of $f^{ \pm}$.

$$
p_{+}=\operatorname{Ind}\left(f^{-1}\right)
$$

Figure 4.8: Dynamics at infinity of $f$ when $\lambda_{1}(f) \in \mathbf{R} \backslash \mathbf{Q}$
4. There exists an open neighbourhood $U^{ \pm}$of $p_{ \pm}$in $X\left(\mathbf{C}_{v}\right)$ and local coordinates at $p_{ \pm}$such that $f_{U^{ \pm}}^{ \pm}$has a local normal form of (pseudo)monomial type (3.4) or ( $(\underline{3.5)})$ if $\lambda_{1}(f) \notin \mathbf{Z}_{\geqslant 0}$ or of type (3.2) or (3.3) if $\lambda_{1}(f) \in \mathbf{Z}_{\geqslant 0}$.
5. For all prime divisor $E^{+}$of $X$ at infinity such that $p_{+} \in E^{+}$,

$$
\begin{equation*}
\operatorname{ord}_{E^{+}}\left(\theta^{+}\right)>\operatorname{ord}_{E^{+}}\left(\theta^{-}\right) \tag{4.108}
\end{equation*}
$$

6. For all prime divisor $E^{-}$of $X$ at infinity such that $p_{-} \in E^{-}$,

$$
\begin{equation*}
\operatorname{ord}_{E^{-}}\left(\theta^{-}\right)>\operatorname{ord}_{E^{-}}\left(\theta^{+}\right) \tag{4.109}
\end{equation*}
$$

7. If $\lambda_{1} \in \mathbf{Z}_{\geqslant 0}$, then $\left(\theta_{X}^{+}, \theta_{X}^{-}\right) \in \operatorname{Div}_{\infty}(X)_{\mathbf{Q}}$ is a well ordered pair (cf $\{3.2 .5$ ).

Proof. Any completion provided by Theorem 4.4.4 satisfies item (1)-(4). Fix $X$ such a comple-
tion, we show that there exists a completion above $X$ that satisfy (1)-(6) by successively blowing up the centers of $v_{+}$and $v_{-}$.

Lemma 4.4.19. There exists a completion $Y$ above $X$ such that for all completion $Y^{\prime}$ above $Y$, for all prime divisor $E^{+}$of $Y^{\prime}$ at infinity such that $c_{Y^{\prime}}\left(v_{+}\right) \in E^{+}$,

$$
\begin{equation*}
\operatorname{ord}_{E^{+}}\left(\theta^{+}\right)>\operatorname{ord}_{E^{+}}\left(\theta^{-}\right) \tag{4.110}
\end{equation*}
$$

Proof of Lemma 4.4.19. Recall that $\theta^{+}=Z_{v_{-}}$and $\theta^{-}=Z_{v_{+}}$. Let $p_{+}=c_{X}\left(v_{+}\right)$and replace $v_{+}\left(\right.$and $\left.\theta^{+}\right)$by their multiple such that $v_{+} \in \mathcal{V}_{X}\left(p_{+} ; \mathfrak{m}_{p_{+}}\right)$. Let $X_{n}$ be the sequence of completions defined by $X_{0}=X$ and $\pi_{n}: X_{n+1} \rightarrow X_{n}$ is the blow up of $X_{n}$ at $c_{X_{n}}\left(v_{+}\right)$. Define also the morphism of completions $\tau_{n}:=\pi_{0} \circ \pi_{1} \circ \cdots \circ \pi_{n}: X_{n+1} \rightarrow X$. Since $c_{X}\left(v_{+}\right) \neq c_{X}\left(v_{-}\right)$, we have that for all $n, c_{X_{n}}\left(\mathrm{v}_{+}\right) \neq c_{X_{n}}\left(\mathrm{v}_{-}\right)$. By Proposition 4.1.5 Equation (4.11), we have that for all $n, \theta_{X_{n+1}}^{+}=\pi_{n}^{*} \theta_{X_{n}}^{+}$since $c_{X_{n}}\left(v_{+}\right) \neq c_{X_{n}}\left(v_{-}\right)$, hence $\theta_{X_{n+1}}^{+}=\tau_{n}^{*} \theta_{X}^{+}$. Let $E_{n}$ be the exceptional divisor of $\pi_{n}: X_{n+1} \rightarrow X_{n}$. Notice that

$$
\begin{equation*}
\forall n \geqslant 0, \quad c_{X}\left(\left(\tau_{n}\right)_{*} \operatorname{ord}_{E_{n}}\right)=c_{X}\left(v_{+}\right) \tag{4.111}
\end{equation*}
$$

We have by Proposition 3.4 .26 that the sequence $v_{n}:=\frac{1}{b\left(E_{n}\right)} \operatorname{ord}_{E_{n}}$ converges strongly towards $v_{+}$. Therefore, by Corollary 4.1.8, we have

$$
\begin{equation*}
Z_{v_{n}} \rightarrow \lambda \theta^{-} \tag{4.112}
\end{equation*}
$$

where $\lambda>0$ such that $\lambda v_{+} \in V_{X}\left(p ; \mathfrak{m}_{p}\right)$. This convergence is with respect to the strong topology of $\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$, therefore we can intersect both sides with $\theta^{-}$, to get

$$
\begin{equation*}
Z_{v_{n}} \cdot \theta^{-} \rightarrow 0 \tag{4.113}
\end{equation*}
$$

This means that $\operatorname{ord}_{E_{n}}\left(\theta^{-}\right)=o\left(b\left(E_{n}\right)\right)$ when $n \rightarrow \infty$. Now, we evaluate $Z_{v_{n}} \cdot \theta^{+}$. Since for all $n, \theta_{X_{n+1}}^{+}=\tau_{n}^{*} \theta_{X}^{+}$, we get

$$
\begin{equation*}
Z_{v_{n}} \cdot \theta^{+}=Z_{v_{n}, X_{n+1}} \cdot \theta_{X_{n+1}}^{+}=\left(\tau_{n}\right)_{*} Z_{v_{n}, X_{n+1}} \cdot \theta_{X}^{+}=Z_{v_{n}, X} \cdot \theta_{X}^{+} . \tag{4.114}
\end{equation*}
$$

If $c_{X}\left(v_{+}\right) \in E$ is a free point, then by Equation (4.111) and Proposition 4.1.5

$$
\begin{equation*}
Z_{v_{n}, X}=\left(Z_{v_{n}} \cdot E\right) Z_{\text {ord }_{E}} \tag{4.115}
\end{equation*}
$$

By Proposition 3.6.20, we have that $L_{v_{n}}(E) \geqslant 1$. Hence, we get $\frac{1}{b\left(E_{n}\right)} \operatorname{ord}_{E_{n}}\left(\theta^{+}\right) \geqslant \operatorname{ord}_{E}\left(\theta^{+}\right)>0$. If $c_{X}\left(v_{+}\right)$is a satellite point, i.e $c_{X}\left(v_{+}\right)=E \cap F$ where $E, F$ are two prime divisors of $X$ at infinity, then we get by Equation (4.111), Proposition 4.1.5 and Proposition 3.6.20 that

$$
\begin{equation*}
\frac{1}{b\left(E_{n}\right)} \operatorname{ord}_{E_{n}}\left(\theta^{+}\right) \geqslant \operatorname{ord}_{E}\left(\theta^{+}\right)+\operatorname{ord}_{F}\left(\theta^{+}\right) \tag{4.116}
\end{equation*}
$$

and the lemma is proven.
Let $Y$ be a completion above $X$ given by Lemma 4.4.19. By the last assertion of Theorem 4.4.4, there exists a completion $Y^{\prime}$ above $Y$ that satisfy conditions (1)-(4) and Lemma 4.4.19 shows that $Y^{\prime}$ satisfies also conditions (5) and (6). Suppose now that $\lambda_{1} \in \mathbf{Z}_{\geqslant 0}$, then the eigenvaluations $v_{+}$and $v_{-}$are infinitely singular, therefore up to normalisation $\theta^{+}, \theta^{-} \in \operatorname{Weil}_{\infty}\left(\mathrm{X}_{0}\right)_{\mathbf{Q}}$ by Corollary 4.1.7 and $c_{X}\left(v_{+}\right), c_{X}\left(v_{-}\right)$are free points at infinity. Let $Y$ be a completion above $X$ such that $\theta_{X}^{+} \vee \theta_{X}^{-}$is defined in $Y$. By Proposition 3.6.25, the morphism of completions $\pi: Y \rightarrow X$ is a composition of blow ups of satellite points. Therefore, by Proposition 4.1.5, $\theta_{\bar{Y}}^{ \pm}=\pi^{*} \theta_{\bar{X}}^{ \pm}$and conditions (1)-(6) still holds in $Y$.

Proposition 4.4.20. Let $X_{0}$ be a normal affine surface defined over $\mathbf{C}_{v}$. If $f$ is a loxodromic automorphism of $X_{0}$, then, there are no $f$-invariant algebraic curves in $X_{0}$.

Proof. If $\operatorname{dim} \mathrm{QAlb}\left(X_{0}\right)=2$, then $X_{0}$ is a finite ramified cover of $\mathbb{G}_{m}^{2}$. It suffices to show the result for the loxodromic automorphisms of $\mathbb{G}_{m}^{2}$. Any monomial automorphism of $\mathbb{G}_{m}^{2}$ does not admit invariant curves, so the result follows.

If $\operatorname{dim} \operatorname{QAlb}\left(X_{0}\right)=1$, then every automorphism of $X_{0}$ preserves a fibration over a curve, hence it cannot be loxodromic.

Finally, if $\operatorname{dim} \operatorname{QAlb}\left(X_{0}\right)=0$, let $X$ be a completion of $X_{0}$ given by Theorem4.4.18. Suppose that $C \subset X_{0}$ is an algebraic curve invariant by $f$. Let $\bar{C}$ be the closure of $C$ in $X$. We must have $\left\{p_{+}, p_{-}\right\} \cap\left(\bar{C} \cap \partial_{X} X_{0}\right) \neq \varnothing$. Indeed, $\bar{C} \cap \partial_{X} X_{0}$ is not empty so let $p$ be a point in it. If $p \notin\left\{p_{+}, p_{-}\right\}$, then $f$ is defined at $p$ and $f(p)=p_{+}$. Since $\bar{C}$ is $f$-invariant, we get $p_{+} \in \bar{C}$. This means that $C$ defines a germ of an analytic curve at $p_{+}$that is invariant by $f$ but this is not possible by Theorem 4.2.1.

Corollary 4.4.21. If $X_{0}$ is a normal affine surface defined over a number field $K$ and $f$ is a loxodromic automorphism of $X_{0}$, then all periodic points of $f$ are defined over $\bar{K}$.

Proof. Suppose there exists $p \in X_{0}(\mathbf{C}) \backslash X_{0}(\bar{K})$ such that $f^{N}(p)=p$. Let $G:=\operatorname{Gal}(\mathbf{C} / \bar{Q})$, then for all $q \in G \cdot p$, we have $f^{N}(q)=q$. Since $p \notin X_{0}(\bar{K})$, the orbit $G \cdot p$ is infinite and its Zariski
closure $\overline{G \cdot p} \subset X_{0} \times \operatorname{Spec} \mathbf{C}$ has dimension $>0$. If $\operatorname{dim} \overline{G \cdot p}=2$, then $f^{N}=\mathrm{id}$ and this is impossible because $f$ is loxodromic. If $\operatorname{dim} \overline{G \cdot p}=1$, then $C=\overline{G \cdot p}$ is an $f^{N}$-invariant curve of $X_{0} \times \operatorname{Spec} \mathbf{C}$. This is impossible by Proposition 4.4.20.

Corollary 4.4.22. Let $X_{0}$ be a normal affine surface defined over $\mathbf{C}_{v}$ such that $\mathrm{QAlb}\left(X_{0}\right)=0$. Let $f$ be a loxodromic automorphism of $X_{0}$ and let $X$ be a completion of $X_{0}$ from Theorem 4.4.18 If $p \in X_{0}\left(\mathbf{C}_{v}\right)$, we have two possibilities.

1. The forward $f$-orbit of $p$ is bounded.
2. $\left(f^{n}(p)\right)_{n \geqslant 0}$ converges towards $p_{+}$.

Proof. Suppose that $\left(f^{n}(p)\right)_{n}$ is not bounded. Since $X\left(\mathbf{C}_{v}\right)$ is compact, $\left(f^{n}(p)\right)$ has an accumulation point $q \in \partial_{X} X_{0}$. Let $U_{+}$be the open neighbourhood of $p_{+}$given by Theorem4.4.18. We must have $q \in\left\{p_{+}, p_{-}\right\}$. Otherwise, since $f(q)=p_{+}$, if $f^{N_{0}}(p)$ is sufficiently close to $q$, then for all $N \geqslant N_{0}+1, f^{N}(p) \in U_{+}$and $q$ cannot be an accumulation point. Suppose that $q=p-$. Let $(x, y)$ be the local coordinates at $p_{-}$over $U^{-}$given by Theorem 4.4.18. Consider the norm $\max (|x|,|y|)$ over $U^{-}$. Looking at the normal form of $f$, for any $\varepsilon>0$ small enough, the ball $B\left(p_{-}, \varepsilon\right)$ of center $p_{-}$and radius $\varepsilon$, with respect to this norm, is $f^{-1}$-invariant and we have $f^{-1} B\left(p_{-}, \varepsilon\right) \Subset B\left(p_{-}, \varepsilon\right)$. Therefore if $f^{N_{0}}(p) \in B\left(p_{-}, \varepsilon\right)$, we have $p \in B\left(p_{-}, \varepsilon\right)$. Letting $\varepsilon \rightarrow 0$ we get $p=p_{-}$and this is a contradiction. Therefore, the only accumulation point of $\left(f^{N}(p)\right)_{N}$ is $p_{+}$and it is the limit of this sequence.

## Green functions and dynamics of LOXODROMIC AUTOMORPHISMS OF

## AFFINE SURFACES

### 5.1 Berkovich spaces, Adelic divisors and line bundles

### 5.1.1 Berkovich spaces

Let $\mathbf{k}$ be a complete field with a multiplicative norm $|\cdot|$. We recall the definition and main properties of Berkovich spaces, for a reference see [Ber12]. If $X$ is scheme over $\mathbf{k}$, we will write $X^{a n}$ or $(X / \mathbf{k})^{a n}$ the Berkovich analytification of $X$.

Definition 5.1.1. 1. If $X=\operatorname{Spec} A$ where $A$ is a $k$-algebra, then $X^{a n}$ is the set of multiplicative seminorms on $A$ extending the norm on $\mathbf{k}$. For every $x \in X^{a n}$ we have a seminorm $|\cdot|_{x}: A \rightarrow \mathbf{R}_{+}$. We will write $|P|_{x}$ as $|P(x)|$. The topology on $X^{a n}$ is the coarsest topology such that the evaluation maps $|f|: X^{a n} \rightarrow \mathbf{R}$ are continuous. This is the weak topology of simple convergence.
2. If $X$ is covered by an open affine cover $\left\{\operatorname{Spec} A_{i}\right\}$, then $X^{a n}$ is defined to be the union of the $\left(\operatorname{Spec} A_{i}\right)^{a n}$ glued in a canonical way. $X^{a n}$ has a locally ringed space structure.

If $X=\operatorname{Spec} A$, for any $x \in X^{a n}$, the seminorm $|\cdot|_{x}$ induces a norm over $A / \operatorname{ker}|\cdot|_{x}$. We can take the fraction field of $A / \operatorname{ker}|\cdot|_{x}$ and complete it with respect to the norm induced by $|\cdot|_{x}$. This defines the residue field of $x$ which we denote by $H_{x}$.

We have a functoriality property, If $f: X \rightarrow Y$ is a morphism of $\mathbf{k}$-schemes, then it induces a continuous map $f^{a n}: X^{a n} \rightarrow Y^{a n}$

Proposition 5.1.2 (Topological properties of the Berkovich space). 1. If $X$ is separated and of finite type over $\mathbf{k}$, then $X^{a n}$ is Hausdorff.

## Chapter 5 - Green functions and dynamics of loxodromic automorphisms of affine surfaces

2. If $X$ is of finite type over $\mathbf{k}$, then $X^{\text {an }}$ is locally compact.
3. If $X$ is projective over $\mathbf{k}$, then $X^{a n}$ is compact.

If $\mathbf{k}=\mathbf{C}$ equipped with the usual norm, then if $X$ is a scheme of finite type over $\mathbf{C}$, $X^{a n}=X(\mathbf{C})$.

Contraction map There is a natural contraction map $c: X^{a n} \rightarrow X$ defined as follows. Suppose $X=\operatorname{Spec} A$, then if $x \in X^{a n}$ the kernel of $|\cdot|_{x}: A \rightarrow H_{x} \rightarrow \mathbf{R}$ is a prime ideal of $A$, we let $c(x)$ be this prime ideal. If $p \in X$ is a closed point, then $c^{-1}(p)$ consists of a unique point and we have a natural embedding $X(\overline{\mathbf{k}}) \hookrightarrow X^{a n}$. Indeed, let $x \in c^{-1}(p)$, then $x$ induces a norm on the field $\kappa(p):=O_{X, p} / \mathfrak{m}_{p}$, but $\kappa(p)$ is a finite extension of $\mathbf{k}$ so there exists a unique extension of the norm of $\mathbf{k}$ to $\kappa(p)$.

The reduction map Suppose that $\mathbf{k}$ is a complete valued non-archimedean field. We write $\mathbf{k}^{\circ}$ for its valuation ring and $\mathbf{k}^{\circ 0}$ for the maximal ideal of $\mathbf{k}^{\circ}$. Let $X$ be a projective scheme over $\mathbf{k}$ and let $\mathscr{X}$ be a model of $X$. That is a projective $\mathbf{k}^{\circ}$-scheme $\mathscr{X}$ such that the generic fiber $\mathscr{X}_{\eta}$ is isomorphic to $X$. We denote by $\mathscr{X}_{o}$ the special fiber of $\mathscr{X}$. There exists a canonical reduction map $r_{\mathscr{X}}: X^{a n} \rightarrow \mathscr{X}_{o}$ defined as follows. Recall that we have the contraction map $c: X^{a n} \rightarrow X \simeq \mathscr{X}_{\eta}$. For every $x \in \mathbf{X}^{a n}$, let $\xi:=c(x)$, we have a non-archimedean norm on the residue field $\mathbf{k}(\xi)$ induced by $x$. Let $R_{\xi}$ be the valuation ring of $\mathbf{k}(\xi)$ with respect to the norm $x$. There is a map $\operatorname{Spec} R_{\xi} \rightarrow \operatorname{Spec} \mathbf{k}^{\circ}$ induced by $\mathbf{k}^{\circ} \rightarrow R_{\xi}$. By the valuative criterion for properness, there exists a unique lift in the following diagram

We define $r_{\mathscr{X}}(x)$ as the image of the closed point of $\operatorname{Spec} R_{\xi}$ in $\mathscr{X}_{\circ}$.

### 5.1.2 Green functions

Now until the end of this memoir, $\mathbf{C}_{v}$ will be an algebraically closed complete field. If $X$ is a scheme over $\mathbf{C}_{v}$, then $X^{a n}$ will be the Berkovich analytification of $\mathbf{C}_{v}$.

Definition 5.1.3. Let $X$ be a completion of $X_{0}$ and $D=\sum_{i} a_{i} E_{i} \in \operatorname{Div}(X)_{\mathbf{R}}$. A (continuous) Green function of $D$ is a continuous function $g: X^{a n} \backslash(\operatorname{Supp} D)^{a n} \rightarrow \mathbf{R}$ such that for any finite open affine cover $X=\bigcup_{j} U_{j}$ if $h_{i}^{j}$ is a local equation of $E_{i}$ over $U_{j}$, the function

$$
\begin{equation*}
g+\sum_{i} a_{i} \log \left|h_{i}^{j}\right| \tag{5.2}
\end{equation*}
$$

extends to a continuous function over $U_{j}^{a n}$.
Proposition 5.1.4. Two Green functions of the same $\mathbf{R}$-divisor $D$ differ by a bounded continuous function

Proof. If $g_{1}, g_{2}$ are two Green functions of $D, g_{1}-g_{2}$ can be extended to a continuous function over $X^{a n}$. Since $X$ is projective, $X^{a n}$ is compact and the function $g_{1}-g_{2}$ is bounded.

Proposition 5.1.5. Let $D \in \operatorname{Div}(X)_{\mathbf{R}}$ be an effective divisor, then any Green function of $D$ is bounded from below.

Proof. Let $g$ be any Green function of $D$. Write $D=\sum_{i} a_{i} E_{i}$ where $a_{i} \in \mathbf{R}$ and $E_{i}$ is a prime divisor. Let $x \in(\operatorname{Supp} D)^{a n}$ and let $h_{i}$ be a local equation of $E_{i}$ at $c(x)$. By definition, the function $g+\sum_{i} a_{i} \log |h|_{i}$ extends to a continuous function at $x$. Since $D$ is effective, $a_{i}>0 \forall i$ and $\sum_{i} a_{i} \log |h|_{i} \rightarrow-\infty$ at $x$. This means that there exists an open neighbourhood $U_{x} \subset X^{a n}$ of $x$ such that $g_{\mid U_{x} \backslash(\operatorname{Supp} D)^{a n}} \geqslant 0$. Since $\operatorname{Supp} D$ is a closed curve, $(\operatorname{Supp} D)^{a n}$ is compact so we can cover it by a finite number of such open subset $U_{x}$. We have therefore constructed an open neighbourhood $V$ of the curve $(\operatorname{Supp} D)^{a n}$ over which $g$ is $\geqslant 0$. Now, the complement of $V$ is a closed compact subset of $X^{a n} \backslash(\operatorname{Supp} D)^{a n}$, therefore $g$ is bounded over it. We get that $g$ is bounded from below over $X^{a n} \backslash(\operatorname{Supp} D)^{a n}$.

Proposition 5.1.6. Let $X, Y$ be two projective varieties and let $\varphi: Y \rightarrow X$ be a surjective morphism. Let $D \in \operatorname{Div}(X)_{\mathbf{R}}$, let $g_{D}$ be a Green function of $D$ and let $g_{\varphi^{* D}}$ be a Green function of $\varphi^{*} D$, then

$$
\begin{equation*}
g_{D} \circ \varphi^{a n}-g_{\varphi^{*} D} \tag{5.3}
\end{equation*}
$$

defines a continuous (bounded) function over $Y^{a n}$.

Proposition 5.1.7. Let $X$ be a completion of $X_{0}$. Let $D_{1}, D_{2} \in \operatorname{Div}_{\infty}(X)_{\mathbf{R}}$ and let $g_{1}, g_{2}$ be Green functions of $D_{1}$ and $D_{2}$ respectively. Suppose that $\left(D_{1}, D_{2}\right)$ is a well ordered pair. Then, $\max \left(g_{1}, g_{2}\right)$ is a Green function of $\max \left(D_{1}, D_{2}\right)$.

Proof. Let $D=\max \left(D_{1}, D_{2}\right)$ and $x \in \operatorname{Supp}(D)^{a n}$. We have that $c(x)$ is either a closed point on $\operatorname{Supp} D$ or the generic point of one of the irreducible components of Supp $D$.

If $c(x)=\eta_{E}$ is the generic point of an irreducible component of $\operatorname{Supp} D$ or if $c(x) \in E$ is a free point. Set $\alpha_{i}=\operatorname{ord}_{E}\left(D_{i}\right), i=1,2$. Then, if $z$ is a local equation of $E$ at $c(x)$ there exists a continuous function $\psi_{i}$ defined locally at $x$ such that $g_{i}+\alpha_{i} \log |z|=\psi_{i}$. If $\alpha_{1}=\alpha_{2}=\alpha$, then

$$
\begin{equation*}
\max \left(g_{1}, g_{2}\right)+\alpha \log |z|=\max \left(\psi_{1}, \psi_{2}\right) \tag{5.4}
\end{equation*}
$$

which is continuous. If $\alpha_{1}<\alpha_{2}$, then

$$
\begin{equation*}
\max \left(g_{1}, g_{2}\right)+\alpha_{1} \log |z|=\max \left(\psi_{1}, \psi_{2}+\left(\alpha_{1}-\alpha_{2}\right) \log |z|\right) . \tag{5.5}
\end{equation*}
$$

Since $\alpha_{1}-\alpha_{2}>0$, this is equal to $\psi_{1}$ on the open neighbourhood $\left\{\log |z|<\frac{\max \left|\psi_{2}\right|}{\alpha_{1}-\alpha_{2}}\right\}$ of $x$, so it extends to a continuous function at $x$.

If $c(x)=E \cap F$ is a satellite point where $E, F \in \operatorname{Supp} D$, set $\alpha_{i}=\operatorname{ord}_{E}\left(D_{i}\right), \beta_{i}=\operatorname{ord}_{F}\left(D_{i}\right)$. Let $z, w$ be local equations of $E, F$ at $c(x)$ respectively. There exist two continuous functions $\psi_{1}, \psi_{2}$ locally defined at $x$ such that $g_{i}+\alpha_{i} \log |z|+\beta_{i} \log |w|=\psi_{i}$. If $\alpha_{1}=\alpha_{2}=\alpha$ and $\beta_{1}=\beta_{2}=\beta$, then

$$
\begin{equation*}
\max \left(g_{1}, g_{2}\right)+\alpha \log |z|+\beta \log |w|=\max \left(\psi_{1}, \psi_{2}\right) \tag{5.6}
\end{equation*}
$$

which is continuous.
If $\alpha_{1}>\alpha_{2}$, since $\left(D_{1}, D_{2}\right)$ is a well ordered pair, we have $\beta_{1} \geqslant \beta_{2}$. Therefore,

$$
\begin{equation*}
\max \left(g_{1}, g_{2}\right)+\alpha_{1} \log |z|+\beta_{1} \log |w|=\max \left(\psi_{1}, \psi_{2}+\left(\alpha_{1}-\alpha_{2}\right) \log |z|+\left(\beta_{1}-\beta_{2}\right) \log |w|\right) \tag{5.7}
\end{equation*}
$$

Since $\alpha_{1}-\alpha_{2}>0$ and $\beta_{1}-\beta_{2} \geqslant 0$, the right hand side is equal to $\psi_{1}$ on the open neighbourhood $\left\{\left(\alpha_{1}-\alpha_{2}\right) \log |z|<\max \left|\psi_{2}\right|\right\}$ of $x$, so it extends to a continuous function at $x$.

Suppose $\mathbf{C}_{v}$ is non-archimedean. A model Green function of $D$ is any Green function of the following form. Let $\mathscr{X}$ be a projective variety over $\operatorname{Spec} O_{v}$ such that $X=\mathscr{X} \otimes_{O_{v}} \operatorname{Spec} \mathbf{C}_{v}$ and let $\mathscr{D}$ be a Cartier divisor of $\mathscr{X}$ such that $\mathscr{D} \otimes_{\mathcal{O}_{v}} \operatorname{Spec} \mathbf{C}_{v}=D$. We say that $(\mathscr{X}, \mathscr{D})$ is a model of $(X, D)$. We define the function $g_{(\mathscr{X}, \mathscr{D})}:(X \backslash \operatorname{Supp} D)^{a n}$ as follows. Let $r_{\mathscr{X}}: X^{a n} \rightarrow \mathscr{X}_{o}$ be the reduction map defined in Section 5.1. Let $x \in X^{a n} \backslash(\operatorname{Supp} D)^{a n}$. Let $h$ be a local equation of $\mathscr{D}$ at $r(x)$. By definition, we have a local ring homomorphism $O_{\mathscr{X}, r_{\mathscr{X}}(x)} \rightarrow R_{c(x)}$ where $R_{c(x)}$ is the valuation ring of the residue field $\kappa(c(x))$ equipped with the non-archimedean norm induced by $x$, in particular we can define $|h(x)|$. We define $g_{(\mathscr{X}, \mathscr{D})}(x)=-\log |h(x)|$. This does not depend
on the choice of $h$ because the quotient of two local equations of $\mathscr{D}$ is an invertible element of $O_{\mathscr{X}, r_{\mathscr{X}}(x)}$ hence it has norm 1. If $D=\sum_{i} a_{i} D_{i}$ is an $\mathbf{R}$-divisor of $X$ with $D_{i}$ Cartier divisors, then a model Green function is a function $g_{(\mathscr{X}, \mathscr{D})}=\sum_{i} a_{i} g_{\left(\mathscr{X}, \mathscr{V}_{i}\right)}$ where $\left(\mathscr{X}, \mathscr{D}_{i}\right)$ is a model of $\left(X, D_{i}\right)$.

A model Green function $g_{(\mathscr{X}, \mathscr{D})}$ is said to be semipositive if $\mathscr{D}$ is nef over $\mathscr{X}$.
Example 5.1.8. Let $h \in \mathbf{C}_{v}(X)^{\times}$be a rational function, then $\log |h|$ is a model Green function of $\operatorname{div}(h)$. Indeed, let $\mathscr{X}$ be a model of $X$ and consider the principal divisor $\operatorname{div}(h)$ on $\mathscr{X}$ as $h$ defines a rational function on $\mathscr{X}$.

Proposition 5.1.9. Let $X=\mathbf{P}_{\mathbf{C}_{v}}^{N}$ with homogeneous coordinates $T_{0}, \cdots, T_{N}$. Consider the affine chart $\left\{T_{0} \neq 0\right\}$ with affine coordinates $t_{1}, \cdots, t_{n}$. Then the function

$$
\begin{equation*}
g(x)=\log ^{+} \max \left(\left|t_{1}(x)\right|, \cdots,\left|t_{n}(x)\right|\right) \tag{5.8}
\end{equation*}
$$

If $\mathbf{C}_{v}$ is non-archimedean, $g$ is a semipositive model Green function for the divisor $\left\{T_{0}=0\right\}$. If $\mathbf{C}_{v}=\mathbf{C}$, then $g$ is a psh Green function of $\left\{T_{0}=0\right\}$.

Proof. Take $\mathscr{X}=\mathbf{P}_{O_{v}}^{N}$ with homogeneous coordinates $T_{0}, \cdots, T_{N}$ and set $\mathscr{D}=\left\{T_{0}=0\right\}$, then $(\mathscr{X}, \mathscr{D})$ is a model of $X, D$ where $D=\left\{T_{0}=0\right\} \in \operatorname{Div}(X)$.

Proposition 5.1.10. Let $X, Y$ be $\mathbf{C}_{v}$-projective scheme with a morphism $\varphi: Y \rightarrow X$. Let $D$ be a $\mathbf{R}$-divisor on $X$. Let $(\mathscr{X}, \mathscr{D})$ be a model of $(X, D)$ and suppose that there is a model $\mathscr{Y}$ of $Y$ and a morphism $\Phi: \mathscr{Y} \rightarrow \mathscr{X}$ extending $\varphi$. Then,

$$
\begin{equation*}
g_{\left(\mathscr{Y}, \Phi^{*} \mathscr{D}\right)}=g_{(\mathscr{X}, \mathscr{D})} \circ \varphi \tag{5.9}
\end{equation*}
$$

and it is a model Green function of $\varphi^{*} D$. Furthermore, $g_{(\mathscr{X}, \mathscr{D})}$ is semipositive, then $g_{\mathscr{X}, \mathscr{D}} \circ \varphi$ also is.

Corollary 5.1.11. Let $X$ be a projective variety and let $D$ be an integral effective divisor on $X$ such that $O_{X}(D)$ is generated by global sections. Let $s_{D}$ be the global section defining $D$ and let $s_{1}, \cdots, s_{n}$ be global sections of $O_{X}(D)$ such that $\left(s_{D}, s_{1}, \cdots, s_{n}\right)$ generates $O_{X}(D)$. Then, the function

$$
\begin{equation*}
\forall x \in(X \backslash \operatorname{Supp} D)^{a n}, \quad g_{s_{1}, \cdots, s_{n}}(x):=\log ^{+} \max \left(\left|\frac{s_{1}}{s_{D}}(x)\right|, \cdots,\left|\frac{s_{n}}{s_{D}}(x)\right|\right) \tag{5.10}
\end{equation*}
$$

is a semipositive model Green function of $D$, If $\mathbf{C}_{v}=\mathbf{C}$, then it is a psh Green function of D.

Proof. If $\mathbf{C}_{v}=\mathbf{C}$ the statement is clear, so we treat only the non-archimedean case. Consider the morphism $\varphi: X \rightarrow \mathbf{P}^{N}$ induced by the sections $s_{D}, s_{1}, \cdots, s_{n}$ such that $\varphi^{*} X_{0}=s_{D}$. Then, $g_{s_{1}, \cdots, s_{n}}$ is the pull back of the model Green function defined in 5.1 .9 which is semipositive. By Proposition 5.1.10 it is a semipositive model Green function of $D$.

Proposition 5.1.12. Every $\mathbf{R}$-divisor $D \in \operatorname{Div}(X)_{\mathbf{R}}$ admits a Green function.
Proof. We can suppose that $D$ is effective. Let $H$ be an ample divisor on $X$. Let $m$ be a large enough integer such that $O_{X}(m H+D)$ and $O_{X}(m H)$ are both generated by global sections. Let $g_{1}$ be a Green function of $m H+D$ and $g_{2}$ be a Green function of $m H$ both provided by Corollary 5.1.11. Then, $g_{1}-g_{2}$ is a Green function of $D$.

### 5.1.3 Adelic divisors

Definition 5.1.13. Let $X$ be a projective variety over a number field $\mathbf{K}$. An adelic $\mathbf{R}$-divisor over $X$ is the data $\left(D,\left(g_{v}\right)_{v \in \mathcal{M}(\mathbf{K})}\right)$ where $D$ is an $\mathbf{R}$-divisor over $X$ and for each place $v$ of $\mathbf{K}$, $g_{v}$ is a Green function of the divisor $D_{\mathbf{C}_{v}}:=D \otimes \operatorname{Spec} \mathbf{C}_{v}$ over $X_{\mathbf{C}_{v}}$ such that there exists an open subset $U$ of Spec $O_{\mathbf{K}}$ such that there is a model $\left(\mathscr{X}_{U}, \mathscr{D}_{U}\right)$ of $(X, D)$ over $U$ and for all $v \in U, g_{v}$ is the model Green function induced by

$$
\begin{equation*}
\left(\mathscr{X}_{U} \times \operatorname{Spec}_{U} O_{v}, \mathscr{D}_{U} \times{ }_{U} \operatorname{Spec} O_{v}\right) \quad \text { (coherence condition) } \tag{5.11}
\end{equation*}
$$

An adelic $\mathbf{R}$-divisor is semipositive if

- For every archimedean place, $g_{v}$ is a plurisubharmonic function and $c_{1}\left(D_{\mathbf{C}}, g_{v}\right)$ is a positive current.
- For every non-archimedean place $v,\left(D_{\mathbf{C}_{v}}, g_{v}\right)$ is semipositive.

To an adelic R-divisor $\bar{D}=\left(D,\left(g_{v}\right)_{v}\right)$ we can associate a height function defined as follows

$$
\begin{equation*}
\forall p \in(X \backslash \operatorname{Supp} D)(\overline{\mathbf{K}}), \quad h_{D}(p):=\frac{1}{\operatorname{deg} q} \sum_{v} \sum_{q \in \operatorname{Gal}(\overline{\mathbf{K}} / \mathbf{K}) \cdot p} n_{v} g_{v}(q) \tag{5.12}
\end{equation*}
$$

where $n_{v}$ is an integer that depend only on the place $v$.

### 5.1.4 Metrics over line bundles

Let $X$ be a projective variety over $\mathbf{C}_{v}$ and let $X^{a n}$ be its Berkovich analytification. Since $X^{a n}$ is a locally ringed space, we can define line bundles on $X^{a n}$. If $L$ is a line bundle over $X$ we define
$L^{a n}:=c^{*} L$ the analytification of $L$ where $c: X^{a n} \rightarrow X$ is the contraction map. Let $L$ be a line bundle over $X^{a n}$ a metric over $L$ is the data for every $x \in X^{a n}$ of a $\mathbf{C}_{v}$-norm over the stalk $L_{x}$ of $L$ at $x$.

Let $L$ be a line bundle over $X$. A model metric of $L^{a n}$ is a metric defined as follows. Let $(\mathscr{X}, \mathscr{L})$ be a model of $(X, L)$ over $\mathbf{C}_{v}$. That is $\mathscr{X}$ is a model of $X$ and $\mathscr{L}$ is a line bundle over $\mathscr{X}$ such that $\mathscr{L} \otimes \operatorname{Spec} \mathbf{C}_{v} \simeq L^{n}$ for some integer $n \geqslant 1$. Let $x \in X^{a n}$ and let $s \in L_{x}^{a n}$. Then, there exists $s^{\prime} \in L_{c(x)}$ such that $s=c^{*} s^{\prime}$. Now, let $\widetilde{s}$ be a local generator of $\mathscr{L}$ at $c(x) \in X \subset \mathscr{X}$. We have that there exists a germ of regular function $\varphi$ at $c(x)$ such that $\left(s^{\prime}\right)^{n}=\varphi \widetilde{s}$. We set

$$
\begin{equation*}
\|s(x)\|=|\varphi(x)|^{1 / n} . \tag{5.13}
\end{equation*}
$$

Example 5.1.14. Let $X=\mathbf{P}_{\mathbf{C}_{v}}^{N}$ with homogeneous coordinates $T_{0}, \cdots, T_{N}$ and let $L=O(1)$. Consider the model $\mathscr{X}=\mathbf{P}_{O_{v}}^{N}$ with the same homogeneous and the line bundle $\mathscr{L}=O(1)_{\mathscr{X}}$ over $\mathscr{X}$. The line bundle $L$ (and $\mathscr{L}$ ) is generated by the global sections induced by the $T_{i}^{\prime} s$. Let $x \in X^{a n}$, suppose that $r_{\mathscr{X}}(x) \in\left\{T_{i} \neq 0\right\}$ this means that $c(x) \in\left\{T_{i} \neq 0\right\}$ and $\max _{j \neq i}\left|\frac{T_{j}}{T_{i}}(x)\right| \leqslant 1$ (indeed, $\frac{T_{j}}{T_{i}}$ defines a germ of regular function at $r_{\mathscr{X}}(x)$ ). Consider $s_{i}$ the global section of $L$ induced by $T_{i}$. Then, it is also a section of $\mathscr{L}$, therefore

$$
\begin{align*}
\left\|T_{i}(x)\right\| & =1  \tag{5.14}\\
& =\frac{1}{\max \left(\left|\frac{T_{0}}{T_{i}}(x)\right|, \cdots,\left|\frac{T_{i-1}}{T_{i}(x)}\right|, 1,\left|\frac{T_{i+1}}{T_{i}}(x)\right|, \cdots,\left|\frac{T_{n}}{T_{i}}(x)\right|\right)}  \tag{5.15}\\
& =\frac{\left|T_{i}(x)\right|}{\max \left(\left|T_{0}(x)\right|, \cdots,\left|T_{n}(x)\right|\right)} \tag{5.16}
\end{align*}
$$

In particular, consider the global section $T_{0}$ and consider the affine space $\left\{T_{0} \neq 0\right\} \simeq \mathfrak{a}^{n}$ with homogeneous coordinates $t_{1}, \cdots, t_{n}$. Then, we have the Green function of $\left\{T_{0}=0\right\}$ given by

$$
\begin{equation*}
g(x)=-\log \left\|T_{0}(x)\right\|=\log ^{+} \max \left(\left|t_{1}(x)\right|, \cdots,\left|t_{n}(x)\right|\right) \tag{5.17}
\end{equation*}
$$

Which is the model Green function from Proposition 5.1.9.

A model metric is said to be semipositive if for every vertical curve $\mathscr{C}$ in $\mathscr{X}, \operatorname{deg}_{\mathscr{C}} \mathscr{L} \geqslant 0$.

Proposition 5.1.15. Let $L$ be a line bundle over $X$ and let $s \in H^{0}(X, L)$. Then, the function $\left.x \mapsto-\log \|\left(c^{*} s\right)(x)\right) \|$ is a Green function of $\operatorname{div}(s)$. Conversely, if $D \in \operatorname{Div}(X)$ and $g$ is a Green

## Chapter 5 - Green functions and dynamics of loxodromic automorphisms of affine surfaces

function of $D$. Then, we can define a metric on $O_{X}(D)^{\text {an }}$ by setting

$$
\begin{equation*}
\forall x \in X^{a n} \backslash(\operatorname{Supp} D)^{a n}, \quad\left\|\left(c^{*} s_{D}\right)(x)\right\|=e^{-g(x)} \tag{5.18}
\end{equation*}
$$

### 5.1.5 Adelic line bundles

Let $X$ be a projective variety over a number field $\mathbf{K}$, an adelic line bundle $\bar{L}$ is the data of a line bundle $L$ over $X$ and a collection of metrics $\left\{\|\cdot\|_{v}\right\} v \in \mathscr{M}(\mathbf{K})$ such that there exists an open subset $U \subset \operatorname{Spec} O_{\mathbf{K}}$ and a model $\left(\mathscr{X}_{U}, \mathscr{L}_{U}\right)$ of $(X, L)$ over $U$ such that for every place $v \in U$, the metric $\|\cdot\|_{v}$ is the metric induced by the model $\left(\mathscr{X}_{U} \times \operatorname{Spec} O_{v}, \mathscr{L}_{U} \times \operatorname{Spec} O_{v}\right)$.

An adelic line bundle is semipositive if

- For every archimedean place $v, c_{1}\left(L_{\mathbf{C}},\|\cdot\|_{v}\right)$ is a positive current.
- For every non archimedean place $v$, the metric $\|\cdot\|_{v}$ on $L_{v}$ is a uniform limit of semipositive model metric on $L_{v}$.

It is integrable if it is the difference of two semipositive adelic line bundles.
To an adelic line bundle $\bar{L}$, we can associate a height function $h_{\bar{L}}$ defined for all closed subvarieties of $X$ defined by the following formula

$$
\begin{equation*}
h_{\bar{L}}(Z)=\frac{\left(\bar{L}_{Z}\right)^{\operatorname{dim} Z+1}}{\operatorname{deg}_{Z}\left(L_{\mid Z}\right)} . \tag{5.19}
\end{equation*}
$$

In particular, if $s \in H^{0}(X, L)$ is a global section of $L$, then for all $p \in(X \backslash \operatorname{Supp} \operatorname{div}(s))(\overline{\mathbf{K}})$,

$$
\begin{equation*}
h_{\bar{L}}(x)=\frac{1}{\operatorname{deg} x} \sum_{v} \sum_{y \in \operatorname{Gal}(\overline{\mathbf{K}} / \mathbf{K}) \cdot x}-n_{v} \log \|s(y)\|_{\bar{L}_{v}} \tag{5.20}
\end{equation*}
$$

which is exactly the height function associated to the adelic divisor $\left(\operatorname{div}(s),-\log \|s\|_{\bar{L}_{v}}\right)$ (see (5.12)).

### 5.1.6 Chambert-Loir measure

Let $X$ be a projective variety over $\mathbf{C}_{v}$ of dimension $d$, let $\overline{L_{1}}, \cdots, \overline{L_{d}}$ be integrable metrized line bundles, then Chambert-Loir constructed in [Cha03] a measure

$$
\begin{equation*}
c_{1}\left(\overline{L_{1}}\right) \cdots c_{1}\left(\overline{L_{d}}\right) \tag{5.21}
\end{equation*}
$$

defined over $X^{a n}$. Here are the main properties of this measure:
Proposition 5.1.16. If for every $i$, there exists $e_{i}$ such that ${\overline{L_{i}}}^{e_{i}}$ is induced by a model $\left(\mathscr{X}, \mathscr{L}_{i}\right)$. Then, let $\mathrm{X}_{1}, \cdots, \mathrm{X}_{l}$ be the irreducible components of the special fiber X of $\mathscr{X}$ and let $\mathrm{L}_{i}$ be the restriction of $\mathscr{L}_{i}$ to the special fiber of $\mathscr{X}$. For each $j$, there exists a unique point $\xi_{j} \in X^{\text {an }}$ such that $r\left(\xi_{j}\right)$ is the generic point of $X_{j}$, we have

$$
\begin{equation*}
c_{1}\left(\overline{L_{1}}\right) \cdots c_{1}\left(\overline{L_{d}}\right)=\frac{1}{e_{1} \cdots e_{d}} \sum_{j}\left(c_{1}\left(\mathrm{~L}_{1}\right) \cdots c_{1}\left(\mathrm{~L}_{d}\right) \mid \mathrm{X}_{j}\right) \delta_{\xi_{j}} \tag{5.22}
\end{equation*}
$$

This is in fact how the measure is defined for the model case.
Proposition 5.1.17 ([Cha03]]). Let $X$ be a projective variety over $\mathbf{C}_{v}$ of dimension d. Let $\overline{L_{1}}, \cdots, \overline{L_{d}}$ be semipositive metrized line bundles, then for any sequences $\left(\overline{L_{i, n}}\right)_{n}$ of semipositive model metrics of $L_{i}$ converging to $\overline{L_{i}}$ one has that the measures

$$
\begin{equation*}
c_{1}\left(\overline{L_{1, n}}\right) \cdots c_{1}\left(\overline{L_{n, d}}\right) \tag{5.23}
\end{equation*}
$$

converges to a measure independent of the choices of the sequences. We denote this measure $c_{1}\left(\overline{L_{1}}\right) \cdots c_{d}\left(\overline{L_{d}}\right)$. Furthermore, it has total mass

$$
\begin{equation*}
\int_{X^{a n}} c_{1}\left(\overline{L_{1}}\right) \cdots c_{d}\left(\overline{L_{d}}\right)=c_{1}\left(L_{1}\right) \cdots c_{1}\left(L_{d}\right) \tag{5.24}
\end{equation*}
$$

In particular, we write $\mu_{\bar{L}}:=\frac{1}{c_{1}(L)^{d}} c_{1}(\bar{L}) \cdots c_{1}(\bar{L})$, we call it the equilibrium measure of $\bar{L}$, it is a probability measure by Proposition 5.1.17. If $\bar{L}$ is an adelic line bundle over a projective variety $X$ over a number field $\mathbf{K}$, we write $\mu_{\bar{L}, v}$ for the equilibrium measure of $\bar{L}_{v}$.

### 5.1.7 Equidistribution

Let $\left(x_{n}\right)$ be a sequence of $X(\bar{K}) \subset X\left(\overline{\mathbf{C}}_{v}\right)$ and let $\mu_{v}$ be a measure on $\left(X_{\mathbf{C}_{v}}\right)^{\text {an }}$. We say that the Galois orbit of $\left(x_{n}\right)$ is equidistributed with respect to $\mu_{v}$ if the sequence of measures

$$
\begin{equation*}
\delta\left(x_{n}\right):=\frac{1}{\operatorname{deg}\left(x_{n}\right)} \sum_{x \in \operatorname{Gal}(\overline{\mathbf{K}} / \mathbf{K}) \cdot x_{n}} \delta_{x} \tag{5.25}
\end{equation*}
$$

weakly converges towards $\mu$, where $\delta_{x}$ is the Dirac measure at $x$.
We say that a sequence of points $\left(x_{n}\right)$ of $X(\overline{\mathbf{K}})$ is generic if no subsequence of $\left(x_{n}\right)$ is contained in a strict subvariety of $X$. In particular, a generic sequence is Zariski dense.

## Chapter 5 - Green functions and dynamics of loxodromic automorphisms of affine surfaces

Lemma 5.1.18. Let $X$ be a projective variety over a number field $\mathbf{K}$ and let $\left(x_{n}\right)$ be a Zariski dense sequence of $X(\bar{K})$, then one can extract a generic subsequence of $\left(x_{n}\right)$.

Proof. The set of strict irreducible subvarieties of $X$ is countable because $\mathbf{K}$ is a number field. Let $\left(Y_{q}\right)_{q \in \mathbf{N}}$ be the set of strict irreducible subvarieties of $X$. We construct a generic subsequence $\left(x_{q}^{\prime}\right)_{q \in \mathbf{N}}$ as follows. Set $Y_{q}^{\prime}=\bigcup_{k \leqslant q} Y_{k}$. This is a strict subvariety of $X$, since $\left(x_{n}\right)$ is Zariski dense, there exists an integer $n(q)$ such that $x_{n(q)} \notin Y_{q}^{\prime}$. We set $x_{q}^{\prime}=x_{n(q)}$. The sequence $\left(x_{q}^{\prime}\right)$ is a subsequence of $\left(x_{n}\right)$ which is clearly generic.

Theorem 5.1.19 (Yuan-Zhang equidistribution theorem, [YZ22]). Let $X$ be a projective variety and let $\bar{L}$ be a semipositive adelic line bundle over $X$ such that $\operatorname{deg}_{X}(L)>0$. Let $\left(x_{n}\right) \in X(\overline{\mathbf{K}})$ be a generic sequence such that $\lim _{n} h_{\bar{L}}\left(x_{n}\right) \rightarrow h_{\bar{L}}(X)$, then at every place $v$ the Galois orbit of the sequence $\left(x_{n}\right)$ is equidistributed with respect to the equilibrium measure $\mu_{\bar{L}, v}$.

### 5.1.8 Intersection of line bundles

Let $X$ be a projective variety over $\mathbf{C}_{v}$ of dimension $d$ and let $\bar{L}_{0}, \cdots, \bar{L}_{d}$ be integrable line bundles over $X$. Then, there exists an intersection number

$$
\begin{equation*}
\bar{L}_{0} \cdots \bar{L}_{d} \tag{5.26}
\end{equation*}
$$

with the following properties:

1. It is multilinear.
2. If $s$ is a global rational section of $L_{0}$, then

$$
\begin{equation*}
\bar{L}_{0} \cdots \bar{L}_{d}=\left(\bar{L}_{1} \cdots \bar{L}_{d} \mid \operatorname{div}(s)\right)-\int_{X^{a n}} \log \|s\| c_{1}\left(\bar{L}_{1}\right) \cdots c_{1}\left(\bar{L}_{d}\right) \tag{5.27}
\end{equation*}
$$

Theorem 5.1.2 (Arithmetic Hodge index theorem, [YZ17]). Let X be a projective surface over some complete algebraically closed field $\mathbf{C}_{v}$. Let D be a big, nef and effective divisor on $X$ and let $\bar{L}$ be a semipositive metrized line bundle such that $L=O_{X}(D)$. If $(M,\|\cdot\|)$ is an integrable metrized line bundle such that $M=O_{X}$, then

$$
\begin{equation*}
\bar{M}^{2} \cdot \bar{L} \leqslant 0 \tag{5.28}
\end{equation*}
$$

Furthermore, if $\bar{M}$ is $\bar{L}$ bounded, we have equality if and only if $\|\cdot\|$ is constant.

As in [YZ17], we get the following corollary

Corollary 5.1.21 (Calabi Theorem). Let $D$ be a big, nef and effective divisor over a projective surface $X$ over $\mathbf{C}_{v}$. Let $g_{1}, g_{2}$ be two semipositive Green functions of $D$ such that $c_{1}\left(D, g_{1}\right)^{2}=c_{1}\left(D, g_{2}\right)^{2}$, then $g_{1}-g_{2}$ is constant over $X$.

Proof. Let $\overline{L_{i}}$ be the metrized line bundle such that $L_{i}=O_{X}(D)$ and the metric on $\overline{L_{i}}$ is induced by $g_{i}$. Consider $\bar{M}=\overline{L_{1}}-\overline{L_{2}}$. Let $f=g_{1}-g_{2}$, then

$$
\begin{equation*}
\bar{M} \cdot{\overline{L_{1}}}^{2}=-\int_{X^{a n}} f c_{1}\left(\overline{L_{1}}\right)^{2}=-\int_{X^{a n}} f c_{1}\left(\overline{L_{2}}\right)^{2}=\bar{M} \cdot{\overline{L_{2}}}^{2} . \tag{5.29}
\end{equation*}
$$

Hence we get

$$
\begin{equation*}
\bar{M}^{2} \cdot\left(\overline{L_{1}}+\overline{L_{2}}\right)=0 \tag{5.30}
\end{equation*}
$$

Now, $\bar{M}$ is $\left(\overline{L_{1}}+\overline{L_{2}}\right)$-bounded so by the equality case in the Arithmetic hodge index theorem we get that $g_{1}-g_{2}$ is constant.

Proof of Arithmetic Hodge index theorem. The only part not shown by Yuan and Zhang is the equality part in the case where we only suppose that $D$ is big, nef and effective and not ample. So we prove only the second assertion. Suppose that $\bar{M}^{2} \cdot \bar{L}=0$. Following the proof of [YZ17], We have the following result

Lemma 5.1.22 ([YZ17], Lemma 2.5). For any integrable line bundle $\overline{M^{\prime}}$ such that $M^{\prime}=O_{X}$, we have

$$
\begin{equation*}
\bar{M}^{2} \cdot \overline{M^{\prime}}=0 \tag{5.31}
\end{equation*}
$$

In particular, it implies that $c_{1}(\bar{M})^{2}=0$. Indeed, since $\bar{M}^{2} \cdot \bar{M}^{\prime}=0$, this means that

$$
\begin{equation*}
\int_{X^{a n}} g^{\prime} c_{1}(\bar{M})^{2}=0 \tag{5.32}
\end{equation*}
$$

where $g^{\prime}=\log \|1\|_{\overline{M^{\prime}}}$. So this holds for any model metric of the trivial line bundle. Now, by a result of Gubler or [Mor16] Theorem 3.3.3, the set of model metric of the trivial line bundle is dense in the set of all real-valued continuous function over $X^{a n}$ for the topology of uniform convergence so we get $c_{1}(\bar{M})^{2}=0$.

Lemma 5.1.23. For all curve $C \subset X$,

$$
\begin{equation*}
\bar{M}_{\mid C}^{2}=0 \tag{5.33}
\end{equation*}
$$

Proof. We first show that there exists an integer $m \geqslant 1$ such that $O_{X}(m D)$ has a section that vanishes along $C$. Indeed, if $C$ is not in the support of $D$, since $D$ is big, by [Laz04] Proposition 2.2.6, there exists an integer $m \geqslant 1$ such that $H^{0}\left(X, O_{X}(m D-C) \neq \varnothing\right.$. Therefore, we can find a section $s \in H^{0}(X, m D)$ such that $s$ vanishes along $C$. If $C$ is in the support of $D$, there is a global section $s \in H^{0}\left(X, O_{X}(D)\right)$ such that $\operatorname{div}(s)=D$, in particular it vanishes along $C$.

Write $\operatorname{div}(s)=\sum_{i} a_{i} C_{i}$ with $a_{i}>0$. We get

$$
\begin{equation*}
0=\bar{M}^{2} \cdot \bar{D}=\sum_{i} a_{i} \bar{M}_{\mid C_{i}}^{2}-\int_{X^{a n}} \log \|s\|_{\bar{L}} c_{1}(\bar{M})^{2} \tag{5.34}
\end{equation*}
$$

By Lemma 5.1 .22 , we get $0=\sum_{i} a_{i}\left(\bar{M}_{\mid C_{i}}\right)^{2}$. By the arithmetic Hodge index theorem in the case of curves, every term in the sum is nonpositive, hence there are all equal to 0 . Since $C$ is one of the $C_{i}$ we get the result.

Now, the equality case when $X$ is a curve is shown in [YZ17] and therefore we get that for every curve $C \subset X, g_{\mid C^{a n}}$ is constant where $g=\log \|1\|_{\bar{M}}$. We are going to show that $g$ is constant. The set of rational points $X\left(\mathbf{C}_{v}\right)$ is Zariski dense in $X^{a n}$ so it suffices to show that $g$ is constant on this subset. Let $p, q \in X\left(\mathbf{C}_{v}\right)$ be two closed point, it suffices to show that there exists a connected curve of $X$ containing $p$ and $q$. If we embed $X$ in some projective space $\mathbf{P}^{N}$ we get by [Har77] Chapter III Corollary 7.9 that for every hyperplane $H, H \cap X$ is connected. Therefore, if $H$ is a hyperplane containing $p$ and $q, H \cap X$ is connected curve $C$ that contains $p$ and $q$ and we get the result.

### 5.2 Definition of the Green functions

Definition 5.2.1. Fix a completion $X$ of $X_{0}$ that satisfy Theorem4.4.18. Let $D \in \operatorname{Div}_{\infty}(X)_{\mathbf{R}}$ and let $G(D)$ be a Green function of $D$. Recall that $f$ is a fixed loxodromic automorphism of $X_{0}$. We define the sequence of continuous functions over $X_{0}^{a n}$

$$
\begin{align*}
G_{n, D}^{+} & :=\frac{1}{\lambda_{1}^{n}} G(D) \circ\left(f^{a n}\right)^{n}  \tag{5.35}\\
G_{n, D}^{-} & :=\frac{1}{\lambda_{1}^{n}} G(D) \circ\left(f^{a n}\right)^{-n} \tag{5.36}
\end{align*}
$$

In the following we are going to state all the results for the sequence $G_{n, \bullet}^{+}$, as everything is analogous for $G_{n, \bullet}^{-}$.

Remark 5.2.2. The choice of the Green function $G(D)$ is not canonical but by Proposition 5.1.4, the limit process we are going to apply will not depend on this choice.

Proposition 5.2.3. For any effective $\mathbf{R}$-divisor $R \in \operatorname{Div}_{\infty}(X)_{\mathbf{R}}$. The function

$$
\begin{equation*}
G(R) \circ f^{a n}-G\left(f_{X}^{*} R\right) \tag{5.37}
\end{equation*}
$$

extends to a continuous function over $X^{a n} \backslash p_{-}$.
Proof. Let $\pi: Y \rightarrow X$ be a completion above $p_{-} \in X$ such that the lift $F: Y \rightarrow X$ is regular. By definition, $f_{X}^{*} R=\pi_{*} F^{*} R$. Now, by Proposition 5.1.6, we have that $G(R) \circ F^{a n}$ is a Green function of $F^{*} R$ over $Y^{a n}$. Now, $\pi$ induces an isomorphism $\pi: Y \backslash \operatorname{Exc}(\pi) \rightarrow X \backslash p_{-}$. Let $q \in \partial_{X} X_{0} \backslash p_{-}$, let $\psi$ be a local equation of $f_{X}^{*} R$ at $q$. By definition, $F^{*} R-\pi^{*} f_{X}^{*} R$ is $\pi$-exceptional, therefore $\pi^{*} \psi$ is a local equation of $F^{*} R$ at $\pi^{-1} q$. Thus, the function

$$
\begin{equation*}
G(R) \circ F+\log \left|\pi^{*} \psi\right| \tag{5.38}
\end{equation*}
$$

extends to a continuous function at $\pi^{-1}(q)$ and therefore $G(R) \circ f+\log |\psi|$ extends to a continuous function at $q$.

### 5.2.1 The Green function of $\theta_{X}^{+}$

Start with the following lemma

## Chapter 5 - Green functions and dynamics of loxodromic automorphisms of affine surfaces

Lemma 5.2.4. Let $\pi: Y \rightarrow X$ be a birational morphism between smooth projective surfaces. Let $D \in \operatorname{Div}(Y)_{\mathbf{R}}$, suppose that $D$ is effective and nef, then

$$
\begin{equation*}
\pi^{*} \pi_{*} D \geqslant D \tag{5.39}
\end{equation*}
$$

Proof. If $\pi=$ id then the lemma is true. Suppose $\pi=\pi^{\prime} \circ \tau$ where $\tau: Y \rightarrow X^{\prime}$ is the blow up of a point. Let $D \in \operatorname{Div}(Y)_{\mathbf{R}}$ be nef and effective, then

$$
\begin{equation*}
\pi^{*} \pi_{*} D=\tau^{*}\left(\pi^{\prime}\right)^{*} \pi_{*}^{\prime} \tau_{*} D . \tag{5.40}
\end{equation*}
$$

By induction, we get $\left(\pi^{\prime}\right)^{*} \pi_{*}^{\prime}\left(\tau_{*} D\right) \geqslant \tau_{*} D$ because $\tau_{*} D$ is nef and effective. Therefore, it suffices to show that $\tau^{*} \tau_{*} D \geqslant D$. Let $p \in X^{\prime}$ be the center of $\tau$, write $D^{\prime}=\tau_{*} D=\sum_{i} a_{i} C_{i}+R$ with $p \in C_{i}$ and $p \notin \operatorname{Supp} R$. Let $\widetilde{E}$ be the exceptional divisor above $p$, then

$$
\begin{equation*}
\tau^{*} D^{\prime}=\tau^{\prime} R+\sum_{i} a_{i} \tau^{\prime}\left(C_{i}\right)+\left(\sum_{i} a_{i} m_{i}\right) \widetilde{E} \tag{5.41}
\end{equation*}
$$

where $m_{i}$ is the multiplicity of $C_{i}$ at $p$ and

$$
\begin{equation*}
D=\tau^{\prime} R+\sum_{i} a_{i} \tau^{\prime}\left(C_{i}\right)+\delta \widetilde{E} . \tag{5.42}
\end{equation*}
$$

Since $D$ is nef, we have $D \cdot \widetilde{E} \geqslant 0$. Hence,

$$
\begin{equation*}
D \cdot \widetilde{E}=-\delta+\sum_{i} a_{i} m_{i} \geqslant 0 \tag{5.43}
\end{equation*}
$$

and $\delta \leqslant \sum_{i} a_{i} m_{i}$ which shows the result.
Proposition 5.2.5. The sequence $\left(G_{n, \theta_{X}^{+}}^{+}\right)$converges uniformly over any compact of $X_{0}^{\text {an }}$ to a continuous function $G_{\theta_{X}^{+}}^{+}$that satisfy the following properties

1. $G_{\theta_{X}^{+}}^{+} \circ f=\lambda_{1} G_{\theta_{X}^{+}}^{+}$.
2. $\left\{G_{\theta_{X}^{+}}^{+}>0\right\}=\bigcup_{n \geqslant 0} f^{-n}\left(U_{+} \backslash \partial_{X} X_{0}\right)$.
3. $\forall p \in X_{0}^{a n}, G_{\theta_{X}^{+}}^{+}(p) \geqslant 0$ and $G_{\theta_{X}^{+}}^{+}(p)=0$ if and only if the forward $f$-orbit of $p$ is bounded.
4. If $\mathbf{C}_{v}=\mathbf{C}$, then $G_{+}$is a plurisubharmonic function over $X_{0}(\mathbf{C})$, it is pluriharmonic on the set $\left\{G_{+}>0\right\}$.
5. The function $G^{+}-G\left(\theta_{X}^{+}\right)$extends to a continuous function $h$ over $\left(X^{a n} \backslash p_{-}\right)$which is bounded from above.
6. The sequence $\left(G_{n, \theta_{X}^{+}}^{+}-G\left(\theta_{X}^{+}\right)\right)$converges uniformly to $h$ over any compact subset of $X^{a n} \backslash p_{-}$.

Proof. By Proposition 5.2.3, the function

$$
\begin{equation*}
\Psi:=\frac{1}{\lambda_{1}} G\left(\theta_{X}^{+}\right) \circ f-G\left(\theta_{X}^{+}\right) \tag{5.44}
\end{equation*}
$$

extends to a continuous function over $X\left(C_{v}\right) \backslash p_{-}$. We first show that $\Psi$ is bounded from above. Let $\pi: Y \rightarrow X$ be a morphism of completions such that the lift $F: Y \rightarrow X$ is regular. We have $\lambda_{1} \theta_{X}^{+}=f_{X}^{*} \theta_{X}^{+}=\pi_{*} F^{*} \theta_{X}^{+}$. By Lemma 5.2.4, we get that there exists an effective divisor $R \in \operatorname{Div}_{\infty}(Y)$ such that $\lambda_{1} \pi^{*} \theta_{X}^{+}=F^{*} \theta_{X}^{+}+R$. By Proposition 5.1.6, we get that

$$
\begin{equation*}
\Psi=-G(R)+O(1) \tag{5.45}
\end{equation*}
$$

And by Proposition 5.1.5, we get that $\Psi$ is bounded from above. Set $G:=G\left(\theta_{X}^{+}\right), G_{n}^{+}:=G_{n, \theta_{X}^{+}}^{+}$ In particular, $G_{0}^{+}=\bar{G}$. We have

$$
\begin{align*}
G_{n}^{+} & =\frac{1}{\lambda_{1}^{n}} G \circ f^{n}=\frac{1}{\lambda_{1}^{n-1}}\left(\frac{1}{\lambda_{1}} G \circ f\right) \circ f^{n-1}  \tag{5.46}\\
& =\frac{1}{\lambda_{1}^{n-1}}(\Psi+G) \circ f^{n-1}  \tag{5.47}\\
& =\frac{1}{\lambda_{1}^{n-1}} \Psi \circ f^{n-1}+G_{n-1}^{+} \tag{5.48}
\end{align*}
$$

By induction we get

$$
\begin{equation*}
G_{n}^{+}=G_{0}^{+}+\sum_{k=0}^{n-1} \frac{1}{\lambda_{1}^{k}} \Psi \circ f^{k} \tag{5.49}
\end{equation*}
$$

So, for all $n \geqslant 0, G_{n}^{+}-G_{0}^{+}=G_{n}^{+}-G$ extends to a continuous function over $X^{a n} \backslash p_{-}$which is bounded from above since $\psi$ is. Now, let $U_{-}$be a small open neighbourhood of $p_{-}$. Since $p_{-}$ is a super attracting fixed point of $f^{-1}$ we can suppose that $f^{-1} U_{-} \subset U_{-}$so that $W:=X^{a n} \backslash U_{-}$ is $f$-invariant. The function $|\psi|$ is bounded by a constant $M$ and therefore

$$
\begin{equation*}
\sup _{W} \frac{1}{\lambda^{n}} \psi \circ f^{n} \leqslant \frac{M}{\lambda_{1}^{n}} \tag{5.50}
\end{equation*}
$$

In particular, $G_{n}^{+}$converges uniformly over $W \cap X_{0}^{a n}$ to a continuous function $G_{\theta_{X}^{+}}^{+}$and $G_{\theta_{X}^{+}}^{+}-G_{0}^{+}=G_{\theta_{X}^{+}}^{+}-G$ extends to continuous bounded from above function over $X^{a n} \backslash p_{-}$. This shows (5) and (6).

Proof of (1): This follows from $G_{n, \theta_{X}^{+}}^{+} \circ f=\lambda_{1} G_{n+1, \theta_{X}^{+}}$.
Proof of (2) and (3): Since $G\left(\theta_{X}^{+}\right)(p) \rightarrow+\infty$ when $p \rightarrow p_{+}$we can replace $U^{+}$by a smaller $f$-invariant subset such that $\left(G_{\theta_{X}^{+}}^{+}\right)_{\mid U^{+} \cap \partial_{X} X_{0}}>0$. By (1), we get

$$
\begin{equation*}
\bigcup_{n \geqslant 0} f^{-n}\left(U^{+} \backslash \partial_{X} X_{0}\right) \subset\left\{G_{\theta_{X}^{+}}^{+}>0\right\} \tag{5.51}
\end{equation*}
$$

. To get the other inclusion, we use Corollary 4.4.22. Let $p \in X_{0}^{a n}$. If $\left(f^{n}(p)\right)_{n \geqslant 0}$ is bounded, then $G_{\theta_{X}^{+}}^{+}(p)=0$. If not, then by Corollary 4.4.22 we have that $f^{n}(p) \xrightarrow[n \rightarrow+\infty]{ } p_{+}$so for $n$ large enough $f^{n}(p) \in U^{+}$and by (1), $G^{+}(p)=\frac{1}{\lambda_{1}^{n}} G^{+}\left(f^{n}(p)\right)>0$.

Proof of (4): We will show in Proposition 5.2.12 that $G^{+}$is locally the uniform limit of a sequence of psh functions, so $G^{+}$is plurisubharmonic. We show the pluriharmonicity over $\left\{G_{\theta_{X}^{+}}^{+}>0\right\}$ we only need to show by (1) and (2) that $G_{\theta_{X}^{+}}^{+}$is pluriharmonic over $U^{+} \cap \partial_{X} X_{0}$. We have that $U^{+}$is $f$-invariant. Let $(u, v)$ be local analytic coordinates at $p_{-}$such that if $p_{+} \in E$ is a free point, then $u=0$ is a local equation of the $E$; and if $p_{+}=E \cap F$ is a satellite point then $u v=0$ is a local equation of $E \cup F$ at $p_{+}$.

In the free case, we have that $G\left(\theta_{X}^{+}\right)=\alpha \log |u|+\log |\varphi|$ where $\varphi$ is an invertible holomorphic function over $U^{+}$, then $\left(f^{n}\right)^{*} u=u^{\lambda_{1}^{n}} \psi_{n}$ where $\psi_{n}$ is an invertible holomorphic function over $U^{+}$and $\left(f^{n}\right)^{*} \circ \varphi$ is still an invertible holomorphic function over $U^{+}$, therefore

$$
\begin{equation*}
\frac{1}{\lambda_{1}^{n}} G\left(\theta_{X}^{+}\right) \circ f^{n}=\alpha \log |u|+\frac{\alpha}{\lambda_{1}^{n}} \log \left|\psi_{n}\right|+\frac{1}{\lambda_{1}^{n}} \log \left|\left(f^{n}\right)^{*} \varphi\right| \tag{5.52}
\end{equation*}
$$

over $U^{+} \cap X_{0}$. Since $u$ does not vanish on $U^{+} \cap X_{0}$ we have that $G^{+}$is a uniform limit of pluriharmonic functions over $U^{+} \cap X_{0}$ so it is pluriharmonic.

### 5.2.2 The Green function for any divisor not supported on $E_{+}$and $F_{+}$

Let $R \in \operatorname{Div}_{\infty}(X)_{\mathbf{R}}$ be an effective divisor such that $\operatorname{Supp} R \cap\left\{E^{+}, F^{+}\right\}=\varnothing$ where $E_{+}, F_{+}$are the prime divisor at infinity on which $c_{X}\left(\mathrm{v}_{+}\right)$lies. If it is a free point, we use the convention that $E_{+}=F_{+}$.

Proposition 5.2.6. For any such $\mathbf{R}$-divisor $R$, the function

$$
\begin{equation*}
G(R) \circ f \tag{5.53}
\end{equation*}
$$

extends to a continuous function over $X\left(C_{v}\right) \backslash p_{-}$.

Proof. For any $E$ in the support of $R$, we have $f_{X}^{*}(E)=0$, therefore by Proposition 5.2.3, we have that $G(E) \circ f$ extends to a continuous function over $X\left(C_{v}\right) \backslash p_{-}$.

Corollary 5.2.7. For any such $\mathbf{R}$-divisor, the sequence $G_{n, R}^{+}$converges uniformly to the zero function over any compact subset of $X^{a n} \backslash p_{-}$.

Proof. Any compact subspace of $X_{0}$ is a subset of $X^{a n} \backslash U^{-}$for some open neighbourhood $U^{-}$ of $p_{-}$. We can shrink $U^{-}$such that $f^{-1}\left(U^{-}\right) \Subset U^{-}$. Therefore, $W:=X^{a n} \backslash U^{-}$is $f$-invariant. The function $G(R) \circ f$ is continuous over $W$ by Proposition5.2.6. Now $W$ is compact, therefore $|G(R) \circ f|$ is bounded over $W$. We get

$$
\begin{equation*}
\sup _{W}\left|\frac{1}{\lambda_{1}^{n}} G(R) \circ f^{n}\right| \leqslant \frac{1}{\lambda_{1}^{n}} \sup _{W}|G(R) \circ f| \rightarrow 0 \tag{5.54}
\end{equation*}
$$

### 5.2.3 The Green function for $D^{-}$

Proposition 5.2.8. If we are in the cycle case, there exists $D^{-} \in \operatorname{Div}_{\infty}(X)_{\mathbf{R}}$ such that

$$
\begin{equation*}
f_{X}^{*} D^{-}=\frac{1}{\lambda_{1}} D^{-} \tag{5.55}
\end{equation*}
$$

Proof. Write $\theta_{X}^{+}=\alpha^{+} E_{+}+\beta^{+} F_{+}+\cdots$. Let $M=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$ be the matrix associated to the normal form of $f$ at $p_{+}$. From $f_{X}^{*} \theta_{X}^{+}=\lambda_{1} \theta_{X}^{+}$we get that the vector $\left(\alpha^{+}, \beta^{+}\right)$is an eigenvector of ${ }^{t} M$ for the eigenvalue $\lambda_{1}$. Since $\operatorname{det} M=\lambda_{2}(f)=1$ there exists $\alpha^{-}, \beta^{-} \in \mathbf{R}$ such that $\left(\alpha^{-}, \beta^{-}\right)$ is an eigenvector of ${ }^{t} M$ for the eigenvalue $1 / \lambda_{1}$. Define $D:=\alpha^{-} E_{+}+\beta^{-} F_{+}$. We have

$$
\begin{equation*}
f_{X}^{*} D=\frac{1}{\lambda_{1}} D+R \tag{5.56}
\end{equation*}
$$

## Chapter 5 - Green functions and dynamics of loxodromic automorphisms of affine surfaces

with $E_{+}, F_{+} \notin \operatorname{Supp} R$, therefore $f_{X}^{*} R=0$. Set $D^{-}:=D+\lambda_{1} R$, then

$$
\begin{equation*}
f_{X}^{*} D^{-}=f_{X}^{*} D=\frac{1}{\lambda_{1}} D+R=\frac{1}{\lambda_{1}}\left(D+\lambda_{1} R\right)=\frac{1}{\lambda_{1}} D^{-} \tag{5.57}
\end{equation*}
$$

Lemma 5.2.9. One has $\theta^{-} \cdot D^{-}=0$.

Proof. We have $\theta^{-} \cdot f_{X}^{*} D^{-}=\lambda_{1} \theta^{-} \cdot D^{-}$because $\theta^{-}$is associated to the eigenvaluation of $f$. On the other hand,

$$
\begin{equation*}
\theta^{-} \cdot f_{X}^{*} D^{-}=\frac{1}{\lambda_{1}} \theta^{-} \cdot D^{-} . \tag{5.58}
\end{equation*}
$$

Since $\lambda_{1}>1$, we get $\theta^{-} \cdot D^{-}=0$.

Lemma 5.2.10. The family $\left(\theta_{X}^{+}, D^{-}\right) \cup\left(E ; E \notin\left\{E_{+}, F_{+}\right\}\right)$is a basis of $\operatorname{Div}_{\infty}(X)_{\mathbf{R}}$.

Proof. Since the length of the family is the dimension of $\operatorname{Div}_{\infty}(X)$, we only need to show that the family is free. Suppose that

$$
\begin{equation*}
\lambda \theta_{X}^{+}+\mu D^{-}+R=0 \tag{5.59}
\end{equation*}
$$

with $\lambda, \mu \in \mathbf{R}$ and $R \in \operatorname{Div}_{\infty}(X)_{\mathbf{R}}, E_{+}, F_{+} \notin \operatorname{Supp} R$. Since $\theta_{X}^{-} \cdot \theta_{X}^{+}=\theta^{+} \cdot \theta^{-}=1$ and $\theta^{-} \cdot R=0$, by intersecting Equation (5.59) with $\theta_{X}^{-}$we get

$$
\begin{equation*}
\lambda=0 \tag{5.60}
\end{equation*}
$$

Now, write $D^{-}=\alpha^{-} E_{+}+\beta^{-} F_{+}$. From the proof of Proposition 5.2.8, we have either $\alpha^{-} \neq 0$ or $\beta^{-} \neq 0$ since the vector $\left(\alpha^{-}, \beta^{-}\right)$is an eigenvector for an invertible $2 \times 2$ matrix. Suppose for example that $\alpha^{-} \neq 0$, then intersecting Equation (5.59) with $Z_{\text {ord }_{E_{+}}}$, we get

$$
\begin{equation*}
\mu \alpha^{-}=0 \tag{5.61}
\end{equation*}
$$

and therefore $\mu=0$. It remains that $R=0$ and the result is proven.
Proposition 5.2.11. The sequence $\left(G_{n, D^{-}}^{+}\right)$converges uniformly to zero over any compact subset of $X_{0}^{a n}$. Moreover the sequence $\left(G_{n, D_{-}}^{+}-\frac{1}{\lambda_{1}^{2 n}} G\left(D^{-}\right)\right)$converges uniformly to the zero function over any compact subspace of $X\left(C_{v}\right) \backslash p_{-}$.

Proof. Set $G:=G\left(D^{-}\right)$and $G_{n}^{+}:=G_{n, D^{-}}^{+}$. From $f_{X}^{*} D^{-}=\frac{1}{\lambda_{1}} D^{-}$and Proposition 5.2.3 we get that the function

$$
\begin{equation*}
\Psi=G\left(D^{-}\right) \circ f-\frac{1}{\lambda_{1}} G\left(D^{-}\right) \tag{5.62}
\end{equation*}
$$

extends to a continuous function over $X^{a n} \backslash p_{-}$. By an analogous computation as before we get

$$
\begin{align*}
G_{n}^{+} & =\frac{1}{\lambda_{1}^{n}}\left(G\left(D^{-}\right) \circ f\right) \circ f^{n-1}  \tag{5.63}\\
& =\frac{1}{\lambda_{1}^{n}}\left(\Psi+\frac{1}{\lambda_{1}} G\left(D^{-}\right)\right) \circ f^{n-1}  \tag{5.64}\\
& =\frac{1}{\lambda_{1}^{n}} \Psi \circ f^{n-1}+\frac{1}{\lambda_{1}^{2}} G_{n-1}^{+} \tag{5.65}
\end{align*}
$$

By induction, we get

$$
\begin{equation*}
G_{n}^{+}=\sum_{k=0}^{n}\left(\frac{1}{\lambda_{1}^{n+k}} \Psi \circ f^{n-k+1}\right)+\frac{1}{\lambda_{1}^{2 n}} G\left(D^{-}\right) \tag{5.66}
\end{equation*}
$$

Take a small open neighbourhood $U_{-}$of $p_{-}$such that $W:=X^{a n} \backslash U_{-}$is $f$-invariant. For any compact subset $K \subset X_{0}^{a n} \cap W$, we get

$$
\begin{equation*}
\sup _{K}\left|G_{n}^{+}\right| \leqslant \frac{1}{\lambda_{1}^{n}} \cdot \sup _{W}|\Psi| \cdot\left(\frac{\lambda_{1}}{\lambda_{1}-1}\right)+\frac{1}{\lambda_{1}^{2 n}} \sup _{K}\left|G\left(D^{-}\right)\right| \rightarrow 0 \tag{5.67}
\end{equation*}
$$

### 5.2.4 The Green function for any divisor

Proposition 5.2.12. Let $H$ be an $\mathbf{R}$-divisor supported at infinity, then the sequence $\left(G_{n, H}^{+}\right)$of continuous function over $X_{0}^{a n}$ converges uniformly locally to the function $\left(H \cdot \theta^{-}\right) G_{\theta_{X}^{+}}^{+}$. Moreover, there exists a real number t such that the sequence

$$
\begin{equation*}
\left(G_{n, H}^{+}-\left(H \cdot \theta^{-}\right) G\left(\theta_{X}^{+}\right)+\frac{t}{\lambda_{1}^{2 n}} G\left(D^{-}\right)\right)_{n} \tag{5.68}
\end{equation*}
$$

converges to a continuous function over ( $X^{a n} \backslash p_{-}$) uniformly over any compact subspace of $X\left(C_{v}\right) \backslash p_{-}$.

Proof. If we are in the cycle case, let $D^{-}$be the divisor from Proposition 5.2.8. If we are in the

## Chapter 5 - Green functions and dynamics of loxodromic automorphisms of affine surfaces

zigzag case, set $D^{-}=0$. By Lemma 5.2.10, we can write

$$
\begin{equation*}
H=\left(H \cdot \theta^{-}\right) \theta_{X}^{+}+\mu D^{-}+R . \tag{5.69}
\end{equation*}
$$

with $E_{+}, F_{+} \notin \operatorname{Supp} R$. Therefore, we get that for all $n \geqslant 0$

$$
\begin{equation*}
G_{n, H}^{+}=\left(H \cdot \theta^{-}\right) G_{n, \theta_{X}^{+}}^{+}+\mu G_{n, D^{-}}^{+}+G_{n, R_{X}}^{+} \tag{5.70}
\end{equation*}
$$

By Propositions 5.2.5 5.2.7 and 5.2.11, $G_{n, H}^{+}$converges uniformly locally to $\left(H \cdot \theta^{-}\right) G_{\theta_{X}^{+}}^{+}$and we also get the result on the uniform convergence over any compact subset of $X^{a n} \backslash p_{-}$

Corollary 5.2.13. The function $G_{\theta_{X}^{+}}$is plurisubharmonic over $X_{0}(\mathbf{C})$.
Proof. Let $H$ be a very ample divisor supported at infinity, then $H \cdot \theta^{-}>0$ and by Proposition 5.2.12 $\left(H \cdot \theta^{-}\right) G_{\theta_{X}^{+}}$is uniformly locally the limit of $\frac{1}{\lambda_{1}^{n}} G(H) \circ f^{n}$, now since $H$ is very ample, it is globally generated so by Corollary 5.1.11 we can suppose that $G(H)$ is plurisubharmonic over $X_{0}(\mathbf{C})$. Then, for all $n \geqslant 0, \frac{1}{\lambda_{1}^{n}} G(H) \circ f^{n}$ is plurisubharmonic, so $G_{\theta_{X}^{+}}$also is.

### 5.2.5 An invariant adelic divisor

Lemma 5.2.14. The $\mathbf{R}$-divisor $D=\max \left(\theta_{X}^{+}, \theta_{X}^{-}\right)$is big, nef and effective.
Proof. It is obvious that $D$ is effective since $\theta_{X}^{+}$and $\theta_{X}^{-}$both are. For every prime divisor $E$ at infinity, set $a_{ \pm}(E)=\operatorname{ord}_{E}\left(\theta_{X}^{ \pm}\right)$. Let $E$ be a prime divisor at infinity, then since $X$ is a good completion

$$
\begin{equation*}
\theta_{\bar{X}}^{ \pm} \cdot E=a_{ \pm}(E) E^{2}+\sum_{|F \cap E|=1} a_{ \pm}(F) . \tag{5.71}
\end{equation*}
$$

And,

$$
\begin{equation*}
D \cdot E=\max \left(a_{+}(E), a_{-}(E)\right) E^{2}+\sum_{F \neq E} \max \left(a_{+}(F), a_{-}(F)\right) \tag{5.72}
\end{equation*}
$$

If for example $a_{+}(E) \geqslant a_{-}(E)$, we get

$$
\begin{equation*}
D \cdot E \geqslant a_{+}(E) E^{2}+\sum_{F \neq E} a_{+}(F) \geqslant \theta_{X}^{+} \cdot E \geqslant 0 \tag{5.73}
\end{equation*}
$$

Therefore, $D$ is nef. Since the intersection form is non-degenerate over $\operatorname{Div}_{\infty}(X)$ there must exist a prime divisor $E$ at infinity such that $D \cdot E>0$, therefore $D^{2}>0$ and $D$ is big.

Set $G^{+}:=G_{\theta_{X}^{+}}^{+}$and $G^{-}:=G_{\theta_{X}^{-}}^{-}$.

Proposition 5.2.15. Suppose that $\lambda_{1}(f)$ is an integer. Let $G:=\max \left(G^{+}, G^{-}\right)$, then

1. $G$ is a continuous function over $X_{0}^{a n}$.
2. If $\mathbf{k}=\mathbf{C}$, then $G$ is plurisubharmonic on $X_{0}(\mathbf{C})$, it is pluriharmonic on $\{G>0\}$.
3. $G(p)=0$ if and only if the orbit of $p$ under $f^{\mathbf{Z}}$ is bounded. In particular, $\{G=0\}$ is a compact subset of $X_{0}^{a n}$.
4. The function $G-G\left(\max \left(\theta_{X}^{+}, \theta_{X}^{-}\right)\right)$extends to a continuous function $\Psi$ over $X$.
5. Set $G_{n}=\max \left(G_{n, \theta_{X}^{+}}^{+}, G_{n, \theta_{X}^{-}}^{-}\right)$, then the sequence of continuous functions

$$
\begin{equation*}
\left(G_{n}-\max \left(G\left(\theta_{X}^{+}\right), G\left(\theta_{X}^{-}\right)\right)\right)_{n} \tag{5.74}
\end{equation*}
$$

converges uniformly to $\Psi$ over $X^{a n}$.
Proof. (1) is immediate as both $G^{+}$and $G^{-}$are continuous over $\mathbf{X}_{0}^{a n}$.
(2) is also direct as the maximum of two plurisubharmonic (resp. pluriharmonic) is plurisubharmonic (resp. pluriharmonic)
(3): $G(p)=0 \Leftrightarrow G^{+}(p)=G^{-}(p)=0$ so the forward and backward orbit of $p$ under $f$ has to be bounded.
(4)-(5): On a small open neighbourhood $U^{-}$of $p_{-}$we have $G\left(\theta_{X}^{+}\right) \leqslant G\left(\theta_{X}^{-}\right)$because, by our assumption, if $c_{X}\left(v_{-}\right) \in E$, then $\operatorname{ord}_{E}\left(\theta^{-}\right)>\operatorname{ord}_{E}\left(\theta^{+}\right)$. Now, by Proposition 5.2.5, there exists a constant $M>0$ such that over $U^{-} \cap X_{0}$,

$$
\begin{align*}
& G^{+}(p) \leqslant G\left(\theta_{X}^{+}\right)(p)+M  \tag{5.75}\\
& G^{-}(p) \geqslant G\left(\theta_{X}^{-}\right)(p)-M . \tag{5.76}
\end{align*}
$$

We can shrink $U^{-}$even more such that on $U^{-}, G\left(\theta_{X}^{-}\right)>G\left(\theta_{X}^{+}\right)+10 M$ because of the weights of $\theta_{X}^{+}, \theta_{X}^{-}$at the prime divisor at infinity on which $p_{-}$lies. Therefore, $G^{-}>G^{+}$over $U^{-} \cap X_{0}$ and $G=G^{-}$on $U^{-} \cap X_{0}$. Therefore, $G-G\left(\max \left(\theta_{X}^{+}, \theta_{X}^{-}\right)\right)$extends to a continuous function at $p_{-}$. The same assertion holds at $p_{+}$. This shows (4). Now to show (5), set $W=X^{a n} \backslash\left(U^{+} \cup U^{-}\right)$. We have by Proposition 5.2 .5 that $G_{n, \theta_{X}^{+}}^{+}-G\left(\theta_{X}^{+}\right)$converges uniformly to $G^{+}-G\left(\theta_{X}^{+}\right)$over $W \cup U^{+}$and that $G^{-} n, \theta_{X}^{-}-G\left(\theta_{X}^{-}\right)$converges uniformly to $G^{-}-G\left(\theta_{X}^{-}\right)$over $W \cup U^{-}$. We therefore get that $\max \left(G_{n, \theta_{X}^{+}}^{+}, G_{n, \theta_{X}^{-}}^{-}\right)$converges uniformly towards $G$ over $W$. Now since $G^{+}>G^{-}$ over $U_{+} \cap X_{0}$ and $G^{-}>G^{+}$over $U^{-} \cap X_{0}$ the convergence is uniform over $X^{a n}=W \cup U^{+} \cup U^{-}$. This shows (5).

Proposition 5.2.16. Let $X_{0}$ be an affine surface over a number field $\mathbf{K}$, let $f$ be a loxodromic automorphism of $X_{0}$ with $\lambda_{1}(f) \in \mathbf{Z}_{\geqslant 0}$ and let $X$ be as in Theorem 4.4.18 If $G_{v}=\max \left(G_{v}^{+}, G_{v}^{-}\right)$, then $\left(\max \left(\theta_{X}^{+}, \theta_{X}^{-}\right),\left(G_{v}\right)_{v \in \mathscr{M}(\mathbf{K})}\right)$ is a semipositive $\mathbf{Q}$-adelic divisor over $X$. In particular, the corresponding adelic line bundle $\bar{L}$ satisfies the hypothesis of Theorem 5.1.19.

Proof. We show the semipositivity. Let $v$ be a place of $K$, replace $X$ by $X_{v}$ and set $D^{ \pm}=\theta_{\bar{X}}^{ \pm}$ and $D:=\max \left(D^{+}, D^{-}\right)$. Since $\theta_{X}^{+}$and $\theta_{X}^{-}$are both big and nef and their support supports an ample divisor there exists an integer $m$ such that $O_{X}\left(m \theta_{X}^{+}\right)$and $O_{X}\left(m \theta_{X}^{-}\right)$are generated by global sections. Set $s_{m D^{+}}, s_{1}^{+}, \cdots, s_{r}^{+}$and $s_{m D^{-}}, s_{1}^{-}, \cdots, s_{t}^{-}$be a set of global sections generating $O_{X}\left(m D^{+}\right), O_{X}\left(m D^{-}\right)$and let $P_{i}=\frac{s_{i}^{+}}{s_{D^{+}}}, Q_{i}=\frac{s_{i}^{-}}{s_{D^{-}}}$be the induced regular functions over $X_{0}$. Then by Corollary 5.1.11, the function

$$
\begin{equation*}
G\left(D_{\mathbf{C}_{v}}^{+}\right):=\frac{1}{m} \log ^{+} \max \left(\left|P_{1}\right|_{v}, \cdots,\left|P_{r}\right|_{v}\right) \tag{5.77}
\end{equation*}
$$

is a semipositive model Green function of $D_{\mathbf{C}_{v}}^{+}$. The same holds for $D_{\mathbf{C}_{v}}^{-}$with the $Q_{i}$ 's instead of the $P_{i}$ 's.

Claim 5.2.17. For every $n \geqslant 0$, the line bundle $O_{X}\left(m \lambda_{1}^{n} \max \left(D^{+}, D^{-}\right)\right)$is globally generated by

$$
\begin{equation*}
\left(\left(f^{n}\right)^{*} P_{1}, \cdots,\left(f^{n}\right)^{*} P_{r},\left(f^{-n}\right)^{*} Q_{1}, \cdots,\left(f^{-n}\right)^{*} Q_{s}\right) \tag{5.78}
\end{equation*}
$$

viewed as elements of $\Gamma\left(X, O_{X}\left(m \lambda_{1}^{n} D\right)\right)$.
The claim along with Corollary 5.1.11 shows that for every $n \geqslant 0$,

$$
\begin{equation*}
\max \left(G\left(D_{\mathbf{C}_{v}}^{+}\right)_{v} \circ\left(f^{a n}\right)^{n}, G\left(D_{\mathbf{C}_{v}}^{-}\right)_{v} \circ\left(f^{a n}\right)^{-n}\right) \tag{5.79}
\end{equation*}
$$

is a semipositive model Green function of $D_{\mathbf{C}_{v}}$ which converges uniformly to $G_{v}$, so $G_{v}$ is semipositive.

Proof. Proof of the Claim First of all, since $O_{X}\left(D^{+}\right)_{\mid X_{0}}=O_{X_{0}}$ we have that $\cap_{i} P_{i}^{-1}(0)=\varnothing$ and this remains true for $P_{i} \circ f^{n}$ since $f$ is an automorphism. So it is clear that this set of global sections generate $O_{X}\left(m \lambda_{1}^{n} D\right)_{\mid X_{0}}$. Now, take a point at infinity $q \in \partial_{X} X_{0}$, we want to show that this set of global sections generates $O_{X}\left(m \lambda_{1}^{n} D\right)$ at $q$. First suppose that $q \neq c_{X}\left(v_{+}\right), c_{X}\left(v_{-}\right)$. We are going to suppose that $q$ is a satellite point because this is the harder case. So, suppose $q=E \cap F$ with $E, F$ two prime divisors at infinity. Let $(z, w)$ be local coordinates at $p$ associated to $E$ and $F$. Both $f$ and $f^{-1}$ are defined at $q$. Since $\left(f_{X}^{n}\right)^{*} \theta_{X}^{+}=\lambda_{1} \theta_{X}^{+}$, the fractional ideal
$\left\langle\left(f^{n}\right)^{*} P_{1}, \ldots,\left(f^{n}\right)^{*} P_{r}\right\rangle$ is locally generated at $q$ by

$$
\begin{equation*}
z^{-m \lambda_{1}^{n} \operatorname{ord}_{E}\left(D^{+}\right)} \cdot w^{-m \lambda_{1}^{n} \operatorname{ord}_{F}\left(D^{+}\right)} . \tag{5.80}
\end{equation*}
$$

In the same way, $\left.\left\langle\left(f^{-n}\right)^{*} Q_{1}, \cdots,\left(f^{-n}\right)^{*} Q_{s}\right)\right\rangle$ is locally generated at $q$ by

$$
\begin{equation*}
z^{-m \lambda_{1}^{n} \operatorname{ord}_{E}\left(D^{-}\right)} \cdot w^{-m \lambda_{1}^{n} \operatorname{ord}_{F}\left(D^{-}\right)} . \tag{5.81}
\end{equation*}
$$

Now, $O_{X}\left(m \lambda_{1}^{n} D\right)$ is locally generated at $q$ by

$$
\begin{equation*}
z^{-m \lambda_{1}^{n} \max \left(\operatorname{ord}_{E}\left(D^{+}\right), \operatorname{ord}_{F}\left(D^{+}\right)\right)} \cdot w^{-m \lambda_{1}^{n} \max \left(\operatorname{ord}_{F}\left(D^{+}\right), \operatorname{ord}_{F}\left(D^{-}\right)\right)} \tag{5.82}
\end{equation*}
$$

Since $D^{+}, D^{-}$is a well ordered pair we have that

$$
\begin{equation*}
\left(\left(f^{n}\right)^{*} P_{1}, \cdots,\left(f^{n}\right)^{*} P_{r},\left(f^{-} n\right)^{*} Q_{1}, \cdots,\left(f^{-n}\right)^{*} Q_{s}\right) \tag{5.83}
\end{equation*}
$$

generates $O_{X}\left(m \lambda_{1}^{n} D\right)$ at $q$.
Now suppose for example that $q=c_{X}\left(v_{-}\right)=p_{-}$the indeterminacy point of $f$. Since we have supposed that $\lambda_{1}(f) \in \mathbf{Z}$, we have that $p_{-}$is a free point at infinity. Let $E$ be the unique prime divisor at infinity over which $p_{-}$lies and let $z$ be a local equation of $E$. Then for every $i$, we have locally at $p_{-}\left(f^{n}\right)^{*} P_{i}=z^{-m \lambda_{1}^{n} \operatorname{ord}_{E}\left(D^{+}\right)} \varphi_{i}$ where $\varphi_{i}$ is a regular non invertible function because $f$ is not defined at $p_{-}$. However, $f^{-1}$ is defined at $p_{-}$, therefore the fractional ideal $\left(\left(f^{-n}\right)^{*} Q_{1}, \cdots,\left(f^{-n}\right)^{*} Q_{r}\right)$ is locally generated by $z^{-m \lambda^{n} \operatorname{ord}_{E}\left(D^{-}\right)}$. Since we have $\operatorname{ord}_{E}\left(D^{-}\right)>\operatorname{ord}_{E}\left(D^{+}\right)$we get that the fractional ideal

$$
\begin{equation*}
\left\langle\left(f^{n}\right)^{*} P_{1}, \cdots\left(f^{n}\right)^{*} P_{r},\left(f^{-n}\right)^{*} Q_{1}, \cdots,\left(f^{-n}\right)^{*} Q_{s}\right\rangle \tag{5.84}
\end{equation*}
$$

is locally generated by $z^{-m \lambda_{1}^{n} \operatorname{ord}_{E}\left(D^{-}\right)}$so it is equal to $O_{X}\left(m \lambda_{1}^{n} D\right)_{p_{-}}$at $p_{-}$.
We show that the coherence condition is satisfied. Let $\mathscr{X}$ be a model of $X$ over $\operatorname{Spec} O_{\mathbf{K}}$, $f$ and $f^{-1}$ induce birational transformations on $\mathscr{X}$. There exists an open subset $U$ of $\operatorname{Spec} O_{\mathbf{K}}$ such that if we set $\mathscr{X}_{U}=\mathscr{X} \times{ }_{O_{K}} U$.

1. The indeterminacy locus of $f_{U}: \mathscr{X}_{U} \rightarrow \mathscr{X}_{U}$ does not contain vertical components.
2. We have ${\overline{\left\{p_{+}\right\}}}_{\mid U} \cap{\overline{\left\{p_{-}\right\}}}_{\mid U}=\varnothing$.
3. The horizontal divisors $D_{U}^{+}$and $D_{U}^{-}$induced by $D^{+}$and $D^{-}$over $\mathscr{X}_{U}$ are big and nef.

For every $v \in U$ set $\mathscr{X}_{v}=X_{U} \times_{U} \operatorname{Spec} O_{v}, \mathscr{D}_{v}^{ \pm}=D_{U}^{ \pm}$and $f_{v}^{ \pm}=f_{U} \times \operatorname{Spec} O_{v}$.
Claim 5.2.18. For every $v \in U$, we have $\forall x \in\left(X_{\mathbf{C}_{v}}\right)^{\text {an }} \backslash\left(\operatorname{Supp} D_{v}^{ \pm}\right)$, if $r_{\mathscr{X}_{v}}(x) \neq r_{X_{v}}\left(p_{\mp}\right)$, then

$$
\begin{equation*}
\frac{1}{\lambda_{1}} g_{\left(\mathscr{X}_{v}, \mathscr{D}_{v}^{ \pm}\right)}\left(\left(f_{v}^{ \pm}\right)^{a n}(x)\right)=g_{\left(\mathscr{X}_{v}, \mathscr{D}_{v}^{ \pm}\right)}(x) \tag{5.85}
\end{equation*}
$$

Proof of the claim. We have that $f_{v}^{ \pm}$defines a regular endomorphism of $\mathscr{X}_{v} \backslash\left\{p_{\mp}, r_{\mathscr{X}_{v}}\left(p_{\mp}\right)\right\}$ by condition (1) and (2). Recall that $r_{\mathscr{X}_{v}}$ is anti continuous so the set $V^{-}:=\left\{r_{\mathscr{X}_{v}}=r_{\mathscr{X}_{v}}\left(p_{-}\right)\right\}$is an open subset of $\left(X_{\mathbf{C}_{v}}\right)^{a n}$. Since $p_{-}$is fixed by $f_{v}^{-1}, r_{\mathscr{X}_{v}}\left(p_{-}\right)$also is and therefore $V^{-}$is $\left(f_{v}^{-1}\right)^{a n}{ }_{-}$ invariant. Therefore, the complement of $V^{-}$is $f_{v}^{a n}$-invariant. Let $x \in X^{a n} \backslash V^{-}$, Let $\xi$ be a local equation of $\mathscr{D}_{v}^{+}$at $r_{\mathscr{V}_{v}}\left(f_{v}^{a n}(x)\right)$ and $\psi$ a local equation of $\mathscr{D}_{v}^{+}$at $r_{\mathscr{X}}(x)$. From $f_{v}^{*} \mathscr{D}_{v}^{+}=\lambda_{1} \mathscr{D}_{v}^{+}$ over $\mathscr{X}_{v} \backslash\left\{p_{-}, r_{\mathscr{X}_{v}}\left(p_{-}\right)\right\}$we get that there exists an invertible regular function at $r_{\mathscr{X}_{v}}(x)$ such that

$$
\begin{equation*}
f_{v}^{*} \xi=u \cdot \psi^{\lambda_{1}} \tag{5.86}
\end{equation*}
$$

Since $u$ is invertible, we have $|u(x)|=1$ and the claim is shown.
To show the coherence condition we show that on the open subset $V^{-}, g_{\left(\mathscr{X}_{v}, \mathscr{O}_{v}^{+}\right)} \leqslant g_{\left(\mathscr{X}_{v}, \mathscr{P}_{v}^{-}\right)}$ and this is immediate as $p_{-} \in E_{-}$is a free point and therefore the only irreducible component of $\mathscr{D}_{v}^{ \pm}$on which $r_{\mathscr{X}_{v}}\left(p_{-}\right)$lies is the closure of $E_{-}$in $\mathscr{X}_{V}$, since $\operatorname{ord}_{E_{-}}\left(\theta_{X}^{-}\right)>\operatorname{ord}_{E_{-}}\left(\theta_{X}^{+}\right)$the result is proven.

Finally, let $\bar{L}$ be the associated semipositive adelic line bundle. To show that $\bar{L}$ satisfies the hypothesis of Theorem 5.1.19 it suffices to show that $\operatorname{deg}_{X}(L)>0$ but this is equal to $D^{2}$ with $D=\max \left(\theta_{X}^{+}, \theta_{X}^{-}\right)$. By Lemma 5.2.14. $D$ is big and nef therefore $D^{2}>0$ (see [Laz04] Theorem 2.2.16).

Remark 5.2.19. If $\lambda_{1}(f) \in \mathbf{R} \backslash \mathbf{Q}$, then we can still define $G=\max \left(G^{+}, G^{-}\right)$, however since $\theta_{X}^{+}$ and $\theta_{X}^{-}$are $\mathbf{R}$-divisors, in general they are not a well ordered pair and $G$ is not the Green function of any $\mathbf{R}$-divisor. In fact, the right way to look at $G^{+}$and $G^{-}$is to consider adelic line bundles over the quasi-projective variety $X_{0}$ (see [YZ22]). Roughly speaking an adelic line bundle over a quasi-projective variety $U$ is a limit of model adelic line bundles over completions $X$ of $U$ that satisfy a compatibility condition over $U$. The process is very similar to the construction of Weil ${ }_{\infty}\left(\mathrm{X}_{0}\right)$ or $\mathrm{L}^{2}\left(\mathrm{X}_{0}\right)$. In particular, Yuan and Zhang showed the equidistribution theorem for this generalized class of adelic line bundles. We conjecture the following result.

Conjecture 5.2.20. Suppose $f$ is a loxodromic automorphism of $X_{0}$ and $\lambda_{1}(f) \notin \mathbf{Z} \geqslant 0$. The Green functions $G^{+}$and $G^{-}$induce two nef adelic line bundles $\bar{L}^{+}$and $\bar{L}^{-}$on the quasiprojective variety $X_{0}$ in the sense of [YZ22]] such that

1. $f^{*} \overline{L^{+}}=\lambda_{1} \overline{L^{+}}$
2. $\left(f^{-1}\right)^{*} \overline{L^{-}}=\lambda_{1} \overline{L^{-}}$
3. If $\bar{L}:=\frac{1}{2}\left(\overline{L^{+}}+\overline{L^{-}}\right)$, then $\bar{L}$ satisfies the hypothesis of Theorem 5.1.19
4. At the archimedean places, the equilibrium measure of $\frac{1}{2}\left(\overline{L^{+}}+\overline{L^{-}}\right)$is $d d^{c} G^{+} \wedge d d^{c} G^{-}$.

As explained in the previous remark, I believe that the work done in this memoir and the work of Yuan and Zhang will be sufficient to prove this Conjecture, with a construction similar to [YZ17] Section 4.

Using Proposition 5.2 .16 or assuming Conjecture 5.2 .20 we can consider the canonical height $h_{\bar{L}}$ associated to $f$. From Proposition 5.2.15 (3) and Proposition 5.2.5 (3) it follows that if $p \in X_{0}(\bar{K})$ is periodic, then $h_{\bar{L}}(p)=0$.

For the last two propositions of this section, we assume $\lambda_{1}(f) \in \mathbf{Z}$. We assume that they will be true for $\lambda_{1}(f) \notin \mathbf{Z}_{\geqslant 0}$ once Conjecture 5.2 .20 is established.

Proposition 5.2.21 (Northcott property for heights for affine surfaces). Let $d, B>0$, the set

$$
\begin{equation*}
\left\{p \in X_{0}(\bar{K}) \mid \operatorname{deg} p \leqslant d, h_{\overline{L_{f}}}(p) \leqslant B\right\} \tag{5.87}
\end{equation*}
$$

is finite.
Proof. Let $D=\max \left(\theta_{X}^{+}, \theta_{X}^{-}\right)$, then $D$ is big, nef and effective by Lemma 5.2.14 and we know that $\operatorname{Supp} D=\partial_{X} X_{0}$. Let $H \in \operatorname{Div}_{\infty}(X)$ be an ample divisor such that $\operatorname{Supp} H=\partial_{X} X_{0}$. Then, for $m \geqslant 1$ large enough, there exists an effective $\mathbf{Q}$-divisor $N$ such that

$$
\begin{equation*}
D=\frac{1}{m} H+N . \tag{5.88}
\end{equation*}
$$

Now we have by the well known properties of heights [Sil86] that

$$
\begin{equation*}
h_{D}=h_{\overline{L_{f}}}=(1 / m) h_{H}+h_{N}+O(1) \tag{5.89}
\end{equation*}
$$

and since $N$ is effective, we have $h_{N} \geqslant O(1)$ over $X_{0}(\overline{\mathbf{K}})$ (see [Sil86]), therefore

$$
\begin{equation*}
h_{\overline{L_{f}}} \geqslant(1 / m) h_{H}+O(1) \tag{5.90}
\end{equation*}
$$

and the result follows from Northcott Theorem [Sil86] which states that since $H$ is ample, for
all $d, B>0$ the set

$$
\begin{equation*}
\left\{p \in X(\overline{\mathbf{K}}) \mid \operatorname{deg} p \leqslant d, h_{H}(p) \leqslant B\right\} \tag{5.91}
\end{equation*}
$$

is finite.
Proposition 5.2.22. For any $p \in X_{0}(\bar{K})$ we have

$$
\begin{equation*}
h_{\overline{L_{f}}}(p)=0 \Leftrightarrow p \text { is periodic } \tag{5.92}
\end{equation*}
$$

Proof. We look at the sequence $\left(h_{\overline{L_{f}}}\left(f^{n}(p)\right)\right)$. We have $h_{\overline{L_{f}}}(p)=0$ if and only if for every place $v, G_{v}(q)=0$ for all points $q$ in the Galois orbit of $p$, this is equivalent to saying that $f^{\mathbf{Z}}(q)$ is bounded for all places $v$. This means that $h_{\overline{L_{f}}}\left(f^{n}(p)\right)=0$ for all $n$, since the points $\left(f^{n}\right)(p)$ all have the same degree, we get that this sequence is finite by Proposition5.2.21

### 5.3 Periodic points and equilibrium measure

### 5.3.1 Equidistribution of periodic points

Let $X_{0}$ be a normal affine surface defined over a number field $\mathbf{K}$ and let $f \in \operatorname{Aut}\left(X_{0}\right)$ be a loxodromic automorphism. Let $X$ be a completion as in Theorem4.4.18. For any place $v \in \mathscr{M}(\mathbf{K})$, let $G_{v}^{+}, G_{v}^{-}, G_{v}$ be the Green functions of $f$ defined in Section 5.2. Let $\bar{L}_{f}$ be the adelic line bundle induced by these Green functions. If $\lambda_{1}(f) \in \mathbf{Z}_{\geqslant 0}$, then this comes from Proposition 5.2 .16 and if $\lambda_{1}(f) \notin Z$, then we use Conjecture 5.2.20. We have for every place the equilibrium measure $\mu_{\bar{L}_{f, v}}$.

If $v$ is archimedean, then we can apply the $d d^{c}$ operator to our plurisubharmonic functions. Namely the equilibrium measure is proportional to

$$
\begin{equation*}
\left(d d^{c} G\right)^{2}=d d^{c} G_{+} \wedge d d^{c} G_{-} \tag{5.93}
\end{equation*}
$$

which is well-defined via the work of Bedford and Diller in [BD05], indeed the condition of Bedford and Diller is satisfied because every iterate of $f$ has indeterminacy point either $p_{+}$or $p_{-}$. The measure $\mu$ is $f$-invariant thanks to Proposition 5.2.5. In addition, Dujardin showed in [Duj04] that over $X_{0}(\mathbf{C})$ the periodic points of $f$ equidistributes with respect to $\mu$.

Theorem 5.3.1. If $\left(p_{n}\right)$ is a generic sequence of $X_{0}(\overline{\mathbf{K}})$ of periodic points of $f$, then for every place $v$ of $\mathbf{K}$ the Galois orbit of $\left(p_{n}\right)$ is equidistributed with respect to the measure $\mu_{\overline{L_{f}}, v}$.

Proof. We apply Yuan-Zhang's equidistribution theorem to the adelic line bundle $\overline{L_{f}}$. We need to show that the sequence $h_{\overline{L_{f}}}\left(p_{n}\right)$ converges to $h_{\overline{L_{f}}}(X)$. Since the points $p_{n}$ are periodic, this bounds to show that $h_{\bar{L}_{f}}(X)=0$. To do that we apply Theorem 5.3.3 of [YZ22]. Namely, let

$$
\begin{equation*}
e(X,(D, G)):=\sup _{U \subset X} \inf _{p \in U} h_{\overline{L_{f}}}(p) \tag{5.94}
\end{equation*}
$$

this quantity is called the essential minimum of $(D, G)$. Here, since we suppose that we have a generic sequence of periodic points, we get $e(X,(D, G))=0$. Theorem 5.3.3 of [YZ22] states that

$$
\begin{equation*}
e(X,(D, G)) \geqslant h_{f}(X) \tag{5.95}
\end{equation*}
$$

Therefore we get $h_{f}(X)=0$ and Yuan's equidistribution theorem gives the desired result.

## Chapter 5 - Green functions and dynamics of loxodromic automorphisms of affine surfaces

For any place $v$ (archimedean or not), we have that

$$
\begin{equation*}
\operatorname{Supp} \mu_{f, v} \subset\left\{G_{v}=0\right\}=K_{v} \tag{5.96}
\end{equation*}
$$

If $\lambda_{1}(f) \in \mathbf{Z}$, we characterize the set $\left\{G_{v}=0\right\}$ with the measure $\mu_{v}$.
Theorem 5.3.2 (Extension of [DF17] Lemma 6.3). If $\lambda_{1}(f) \in \mathbf{Z}$, then for any $P \in O\left(X_{0}\right)$, one has

$$
\begin{equation*}
\sup _{\operatorname{Supp} \mu_{v}}|P|_{v}=\sup _{K_{v}}|P|_{v} \tag{5.97}
\end{equation*}
$$

In analogy with the case of the affine plane, we can say that $K_{v}$ is the polynomial convex hull of $\operatorname{Supp} \mu_{v}$.

Proof. Let $D=\max \left(\theta_{X}^{+}, \theta_{X}^{-}\right)$, let $a$ be an integer such that $a D \geqslant \operatorname{div}_{\infty, X}(P)$ and let $C_{0}$ be a constant such that $\log \frac{|P|_{v}}{C_{0}} \leqslant 0$ over $\operatorname{Supp} \mu_{v}$. Then, the functions $a G_{v}$ and $\widetilde{G}_{v}=\max \left(a G_{v}, \log \frac{|P|_{v}}{C_{0}+\varepsilon}\right)$ are both semipositive (or psh if $v$ is archimedean) Green functions of the divisor $a D$. Now, on an open neighbourhood $V$ of $\operatorname{Supp} \mu_{v}$ we have $\widetilde{G}_{v}=a G_{v}$ and we get that

$$
\begin{equation*}
\left(c_{1}\left(a D, \widetilde{G}_{v}\right)_{\mid V}\right)^{2}=\left(c_{1}\left(a D, a G_{v}\right)_{\mid V}\right)^{2} \tag{5.98}
\end{equation*}
$$

by [DF17] Appendix A. 2 (in loc. cit. the result is stated for ample divisors but the proof works for big and nef divisors). Since the two measures $c_{1}(a D, \widetilde{G})^{2}$ and $c_{1}\left(a D, a G_{v}\right)^{2}$ are positive and have total mass $a^{2} D^{2}>0$ we conclude that they are equal. Therefore, by the arithmetic Hodge index theorem we get that $a G_{v}-\widetilde{G}$ is a constant, since they coincide on Supp $\mu_{v}$ we get $\widetilde{G}=a G$ and therefore $\log \frac{|P|_{v}}{C_{0}+\varepsilon} \leqslant 0$ over $K_{v}$. Letting $\varepsilon \rightarrow 0$ yields the result.

### 5.3.2 A rigidity theorem

Theorem 5.3.3. Let $X_{0}$ be a normal affine surface over a number field $\mathbf{K}$ such that $\mathbf{K}\left[X_{0}\right]^{\times}=\mathbf{K}^{\times}$ and let $f, g$ be two loxodromic automorphisms of $X_{0}$ such that $\lambda_{1}(f) \in \mathbf{Z}_{\geqslant 1}$, then the following assertions are equivalent

1. $\operatorname{Per}(f) \cap \operatorname{Per}(g)$ is Zariski dense.
2. $\mu_{f, v}=\mu_{g, v}, \forall v \in \mathscr{M}(\mathbf{K})$.
3. $K_{f, v}=K_{g, v}, \forall v \in \mathcal{M}(\mathbf{K})$.
4. $\operatorname{Per}(f)=\operatorname{Per}(g)$.

If $\lambda_{1}(f) \notin \mathbf{Z}$, assuming Conjecture 5.2.20 we have that if $\operatorname{Per}(f) \cap \operatorname{Per}(g)$ is Zariski dense, then for every place $v \in \mathcal{M}(\mathbf{K}), \mu_{f, v}=\mu_{g, v}$.

Proof. We apply the results of Section 5.3.1. Let $\mu_{f, v}, \mu_{g, v}$ be the equilibrium measure of $f$ and $g$ at every place. Let $\left(p_{n}\right)$ be a Zariski dense sequence of $\operatorname{Per}(f) \cap \operatorname{Per}(g)$. By Lemma 5.1.18 We can suppose that $\left(p_{n}\right)$ is generic. We can apply Theorem5.3.1 to $f$ and $g$ with the sequence $\left(p_{n}\right)$. Therefore, we get for all places $v \in \mathscr{M}(\mathbf{K})$ that $\mu_{f, v}=\mu_{g, v}$. If $\boldsymbol{\lambda}_{1}(f) \notin \mathbf{Z}$ we are done.

Otherwise, let $G_{v, f}$ and $G_{v, g}$ be the Green functions of $f$ and $g$ respectively at every place $v$ of $\mathbf{K}, K_{v, f}:=\left\{G_{v, f}=0\right\}, K_{v, g}:=\left\{G_{v, g}=0\right\}$ and let $h_{f}, h_{g}$ be the respective canonical height of $f$ and $g$. by Theorem 5.3 .2 we get that $K_{v, f}=K_{v, g}$ for any place $v$. Therefore, the canonical heights $h_{f}, h_{g}$ have the same set of points of height 0 . By Proposition 5.2.22, we get that $\operatorname{Per}(f)=\operatorname{Per}(g)$.

### 5.3.3 A stronger rigidity result for the Markov Surface

Assuming Conjecture 5.2.20 we show the following result.
Theorem 5.3.4. Let $M_{D}$ be the Markov surface of parameter $D$. Suppose that $D=0$ or $D=-2+2 \cos \left(\frac{2 \pi}{q}\right)$ with $q \in \mathbf{Z}_{\geqslant 1}$. Let $f, g$ be two loxodromic automorphism of $M_{D}$ defined over a number field $\mathbf{K}$. Then, the following assertions are equivalent

1. $\operatorname{Per}(f) \cap \operatorname{Per}(g)$ is Zariski dense.
2. $\exists N, M \in \mathbf{Z}, f^{N}=g^{M}$.

The proof relies on the following proposition.
Proposition 5.3.5. Suppose $D=0$ or $D=-2+2 \cos \left(\frac{2 \pi}{q}\right)$ and let $f \in \operatorname{Aut}\left(\mathcal{M}_{D}\right)$ be a loxodromic automorphism. If $v$ is an archimedean place, then $f$ admits a periodic saddle fixed point $q(f) \in \mathcal{M}_{D}(\mathbf{C})$ such that

1. $q(f) \in \operatorname{Supp}\left(\mu_{f, v}\right)$
2. If $g \in \operatorname{Aut}\left(\mathcal{M}_{D}\right)$ is loxodromic such that $f$ and $g$ do not share a common iterate, then ( $\left.g^{n}(q(f))\right)$ is unbounded.

Assuming the proposition, suppose that $f, g$ share a Zariski dense subset of periodic points, then by Theorem 5.3.3 we have equality of the equilibrium measures of $f$ and $g$ at every place so in particular at every archimedean place. Fix $v$ one of them. Suppose that $f$ and $g$ do not share a common iterate, then $\left(g^{n}(q(f))\right)_{n}$ is unbounded. Let $\mu=\mu_{f, v}=\mu_{g, v}$. Since $\operatorname{Supp} \mu=\operatorname{Supp} \mu_{f, v}=\operatorname{Supp}_{g, v}$, we have that $\operatorname{Supp} \mu$ is a compact subset of $\mathcal{M}_{D}(\mathbf{C})$ invariant by $f$ and $g$. Since $q(f) \in \operatorname{Supp} \mu_{f, v}=\operatorname{Supp} \mu$ we get that $\left(g^{n}(q(f))\right) \subset \operatorname{Supp} \mu$ which is a contradiction.

To construct $q(f)$ we use Quasi-Fuchsian representation theory.

### 5.3.4 Character varieties and the Markov surface

Let $\mathbb{T}_{1}$ be the once punctured torus. The fundamental group $\pi_{1}\left(\mathbb{T}_{1}\right)$ is a free group generated by two elements $a$ and $b$. The commutator $[a, b]:=a b a^{-1} b^{-1}$ is represented by a simple loop around the puncture that follows the orientation of the surface. One can study the representation of $\pi_{1}\left(\mathbb{T}_{1}\right)$ into $\mathrm{SL}_{2}(\mathbf{C})$. It is clear that

$$
\begin{equation*}
\operatorname{Hom}\left(\pi_{1}\left(\mathbb{T}_{1}\right), \mathrm{SL}_{2}(\mathbf{C})\right) \simeq \mathrm{SL}_{2}(\mathbf{C}) \times \mathrm{SL}_{2}(\mathbf{C}) \tag{5.99}
\end{equation*}
$$

as $\pi_{1}\left(\mathbb{T}_{1}\right)$ is a free group on two generators, therefore it is an algebraic variety. We are interested in the Character variety,

$$
\begin{equation*}
x:=\operatorname{Hom}\left(\pi_{1}\left(\mathbb{T}_{1}\right), \mathrm{SL}_{2}(\mathbf{C})\right) / / \mathrm{SL}_{2}(\mathbf{C}) \tag{5.100}
\end{equation*}
$$

where the action of $\mathrm{SL}_{2}(\mathbf{C})$ is diagonal and given by conjugation and // is the Geometric Invariant Theory (GIT) quotient. This is also an algebraic variety and we have the following result of Fricke and Klein.

Theorem 5.3.6 (Fricke, Klein, [Gol09]). The algebraic variety $X$ is isomorphic to $\mathfrak{a}_{\mathbf{C}}^{3}$. The isomorphism is given by

$$
\begin{equation*}
[\rho] \in X \mapsto(\operatorname{Tr}(\rho(a)), \operatorname{Tr}(\rho(b)), \operatorname{Tr}(\rho(a b))) \tag{5.101}
\end{equation*}
$$

We will denote by $(x, y, z)=(\operatorname{Tr}(\rho(a)), \operatorname{Tr}(\rho(b)), \operatorname{Tr}(\rho(a b)))$ these are the Frick-Klein coordinates.

Let $K=[a, b]$ and let $\kappa: X \rightarrow \mathbf{C}$ be the regular function

$$
\begin{equation*}
\kappa(\rho)=\operatorname{Tr}(\rho(K)) . \tag{5.102}
\end{equation*}
$$

One can show that

$$
\begin{equation*}
\kappa=x^{2}+y^{2}+z^{2}-x y z-2 \tag{5.103}
\end{equation*}
$$

Therefore, if $X_{t}=\kappa^{-1}(t)$ is the relative character variety, we have

$$
\begin{equation*}
X_{t}=\mathcal{M}_{t+2} \tag{5.104}
\end{equation*}
$$

where $\mathcal{M}_{D}$ is the Markov surface of parameter $D$.
The generalized mapping class group $\operatorname{MCG}^{*}\left(\mathbb{T}_{1}\right)$ is the group of homotopy class of homeomorphism of $T_{1}$ not necessarily orientation preserving. It contains $\operatorname{MCG}\left(\mathbb{T}_{1}\right)$ as an index 2 subgroup and it acts on $\pi_{1}\left(\mathbb{T}_{1}\right)$, we have the following isomorphism:

$$
\begin{equation*}
\mathrm{MCG}^{*} \simeq \operatorname{Out}\left(\pi_{1}\left(\mathbb{T}_{1}\right)\right) \tag{5.105}
\end{equation*}
$$

Furthermore,

$$
\begin{equation*}
\operatorname{Out}\left(\pi_{1}\left(\mathbb{T}_{1}\right)\right) \simeq \mathrm{GL}_{2}(\mathbf{Z}) \tag{5.106}
\end{equation*}
$$

and the action on $F_{2}$ is as follows, if $M=\left(\begin{array}{ll}m_{11} & m_{12} \\ m_{21} & m_{22}\end{array}\right)$, then

$$
\begin{align*}
M \cdot a & =a^{m_{11}} b^{m_{12}}  \tag{5.107}\\
M \cdot b & =a^{m_{21}} b^{m_{22}} \tag{5.108}
\end{align*}
$$

For any element $\varphi \in \operatorname{Out}\left(\pi_{1}\left(\mathbb{T}_{1}\right)\right), \varphi([a, b])$ is conjugated to $[a, b]^{ \pm}$. This implies, that the action of $\operatorname{MCG}^{*}\left(\mathbb{T}_{1}\right)$ on $X$ preserves every $X_{t}$. Now, the matrix id acts trivially, because in $\mathrm{SL}_{2}(\mathbf{C})$ we have that $\operatorname{Tr} A=\operatorname{Tr} A^{-1}$, so for all $D \in \mathbf{C}$ we get a group homomorphism

$$
\begin{equation*}
\operatorname{PGL}_{2}(\mathbf{Z}) \rightarrow \operatorname{Aut}\left(\mathscr{M}_{D}\right) \tag{5.109}
\end{equation*}
$$

Theorem 5.3.7 ([CL07] Theorem A, [ЕЕН74]). Let $\Gamma^{*} \subset \mathrm{PGL}_{2}(\mathbf{Z})$ be the subgroup of element congruent to id $\bmod 2$, then for any $D \in \mathbf{C}$,

$$
\begin{equation*}
\Gamma^{*} \rightarrow \operatorname{Aut}\left(\mathcal{M}_{D}\right) \tag{5.110}
\end{equation*}
$$

is injective and its image is of index at most 8.

## Chapter 5 - Green functions and dynamics of loxodromic automorphisms of affine surfaces

We can describe the group homomorphism. Let $\sigma_{x} \in \operatorname{Aut}\left(\mathcal{M}_{D}\right)$ be the automorphism

$$
\begin{equation*}
\sigma_{x}(x, y, z)=(y z-x, y, z), \tag{5.111}
\end{equation*}
$$

If we fix the coordinates $y, z$, then the equation defining $\mathcal{M}_{D}$ becomes a polynomial equation of degree 2 with respect to $x, \sigma_{x}$ permutes the 2 roots of this equation. We can define $\sigma_{y}, \sigma_{z}$ in the same way. Then, $\sigma_{x}, \sigma_{y}, \sigma_{z}$ generate a free group isomorphic to $(\mathbf{Z} / \mathbf{2 Z}) *(\mathbf{Z} / \mathbf{2 Z}) *(\mathbf{Z} / \mathbf{2} \mathbf{Z})$ which is of finite index in $\operatorname{Aut}\left(\mathcal{M}_{D}\right)$ (see [仓̀H74]). The subgroup $\Gamma *$ is the free group on the three generators

$$
\left(\begin{array}{cc}
-1 & -2  \tag{5.112}\\
0 & 1
\end{array}\right), \quad\left(\begin{array}{cc}
1 & 0 \\
-2 & -1
\end{array}\right), \quad\left(\begin{array}{cc}
1 & 0 \\
0 & -1
\end{array}\right)
$$

which correspond respectively to $\sigma_{x}, \sigma_{y}, \sigma_{z}$.

### 5.3.5 Fuchsian and Quasi-Fuchsian representation

A Fuchsian group is a discrete subgroup $\Gamma$ of $\mathrm{PSL}_{2}(\mathbf{R})$. A Quasi-Fuchsian group is a discrete subgroup $\Gamma$ of $\mathrm{PSL}_{2}(\mathbf{C})$ such that its limit set in $\widehat{\mathbf{C}}:=\mathbf{P}^{1}(\mathbf{C})$ is a Jordan curve. Let $S$ be a compact surface of negative Euler characteristic. We say that a representation $\rho: \pi_{1}(S) \rightarrow \mathrm{SL}_{2}(\mathbf{C})$ is Fuchsian (resp, Quasi-Fuchsian) if $\bar{\rho}(S) \subset \mathrm{PSL}_{2}(\mathbf{C})$ is Fuchsian (resp. Quasi-Fuchsian).

Let $\operatorname{Teich}(S)$ be the Teichmuller space of $S$, that is the set of complete finite hyperbolic metrics over $S$. Every point of Teich $(S)$ induces a Fuchsian representation of $S$. We can actually parametrize the set of Quasi-Fuchsian representations of $S$ using Teich $(S)$ by the double uniformization theorem of Bers.

Theorem 5.3.8 ([|]er60]). There is a biholomorphic map

$$
\begin{equation*}
\text { Bers : } \operatorname{Teich}(S) \times \overline{\operatorname{Teich}(S)} \rightarrow \mathrm{QF}(S) \tag{5.113}
\end{equation*}
$$

where $\overline{\operatorname{Teich}(S)}$ is the Teichmuller space with its reversed orientation.
Using this theorem, one can apply an iterative process to find a fixed point in the character variety of $S$.

Theorem 5.3.9 ([|McM96]). Let $S$ be a compact surface of negative Euler characteristic. Let $(X, Y) \in \operatorname{Teich}(S) \times \overline{\operatorname{Teich}(S)}$, let $\varphi \in \operatorname{Mod}(S)$ be pseudo-Anosov, then the sequence

$$
\begin{equation*}
\operatorname{Bers}\left(\varphi^{n}(X), \varphi^{-n}(Y)\right) \tag{5.114}
\end{equation*}
$$

has an accumulation point $\rho_{\infty}: \pi_{1}(S) \rightarrow \operatorname{PSL}_{2}(\mathbf{C})$. Furthermore,

1. $\rho_{\infty}$ is discrete and faithful.
2. The limit set of $\rho_{\infty}\left(\pi_{1}(S)\right)$ is the whole boundary $\mathbb{S}^{2}$ of $\mathbb{H}^{3}$.
3. $\rho_{\infty}$ is a fixed point of $\varphi$ and $\varphi$ is conjugated to an isometry $\alpha$ of $\tilde{M}_{\varphi}=\mathbb{H}^{3} / \rho_{\infty}\left(\pi_{1}(S)\right)$.
4. The group of isometries of $M_{\infty}$ is discrete and $\alpha$ is of infinite order.
5. The mapping torus $M_{\varphi}$ is isomorphic as an hyperbolic manifold to $\left.\tilde{M}_{\varphi} /<\alpha\right\rangle$.
6. The subgroup generated by $\alpha$ of the group of isometries of $\tilde{M}_{\varphi}$ is of finite index.

### 5.3.6 The surface $\mathscr{M}_{0}$ and a Theorem of Minsky

We are interested in this section with the Markov surface $\mathcal{M}_{0}$ that is when $\operatorname{Tr}(K)=-2$, therefore $\rho(K)$ is a parabolic Möbius transformation. The real points $\mathcal{M}_{0}(\mathbf{R})$ consist of an isolated point $(0,0,0)$ and four diffeomorphic connected components that are given by the signs of $x$ and $y$. We will denote by $\mathcal{M}_{0}(\mathbf{R})^{+}$the connected component such that $x, y>0$. It is known that Teich $\left(\mathbb{T}_{1}\right)\left(\mathbb{T}_{1}\right.$ the punctured torus) is isomorphic to the upper half plane $\mathbb{H}^{+}$and we make this identification from now on. The action of $\operatorname{Mod}\left(\mathbb{T}_{1}\right)$ on $\operatorname{Teich}\left(\mathbb{T}_{1}\right)$ is conjugated to the usual action of $\mathrm{PSL}_{2}(\mathbf{Z})$ by isometries on $\mathbb{D}$.

Any point in Teich $\left(\mathbb{T}_{1}\right)$ gives rise to a representation $\bar{\rho}: \pi_{1}\left(\mathbb{T}_{1}\right) \rightarrow \operatorname{PSL}_{2}(\mathbf{R})$ which can be lifted to four distinct representations $\rho: \pi_{1}\left(\mathbb{T}_{1}\right) \rightarrow \mathrm{SL}_{2}(\mathbf{R})$. The cusp condition gives the condition $\operatorname{Tr}(\rho(a, b))=-2$ (because $\operatorname{Tr}=2$ corresponds to reducible representations). Therefore, we get an embedding of $\operatorname{Teich}\left(\mathbb{T}_{1}\right)$ into the 4 different connected component of $\mathcal{M}_{0}(\mathbf{R}) \backslash(0,0,0)$. We will restrict our attention to the embedding $\operatorname{Teich}\left(\mathcal{T}_{1}\right) \hookrightarrow \mathcal{M}_{0}(\mathbf{R})^{+}$. The set $\mathcal{M}_{0}(\mathbf{R})^{+}$is made of (conjugacy class of) Fuchsian representations. Let $\mathrm{DF}_{0} \subset \mathcal{M}_{0}(\mathbf{C})$ be the subset of discrete and faithful representation of $\pi_{1}\left(\mathbb{T}_{1}\right)$. Then $\mathrm{DF}_{0}$ has four different connected components, one of them contains $\mathcal{M}_{0}(\mathbf{R})^{+}$. We denote it by $\mathrm{DF}_{0}^{+}$and we denote by $\mathrm{QF}_{0}^{+}$the set of QuasiFuchsian representation inside $\mathrm{DF}_{0}^{+}$. In fact, $\mathrm{QF}_{0}^{+}$is the interior of $\mathrm{DF}_{0}^{+}$(see [Min02]). We can identify Teich $\left(T_{1}\right)$ with the upper half plane $\mathbb{H}^{+}$and $\operatorname{Teich}\left(\mathbb{T}_{1}\right)$ with the lower half plane $\mathbb{H}^{-}$. The group $\mathrm{PSL}_{2}(\mathbf{Z})$ acts on $\mathbf{P}^{1}(\mathbf{C})$ via Möbius transformation. It preserves $\mathbb{H}^{+}, \mathbb{H}^{-}$and $\mathbf{P}^{1}(\mathbf{R})$. In particular, the mapping class group $\operatorname{MCG}\left(\mathbb{T}_{1}\right)=\mathrm{SL}_{2}(\mathbf{Z})$ acts on $\mathbf{P}^{1}(\mathbf{C})$ and we can conjugate this action to the action on $\mathscr{M}_{0}(\mathbf{R})^{+}$via the Bers mapping. Namely, let $\Phi \in \operatorname{MCG}\left(\mathbb{T}_{1}\right)$ and let
$f_{\Phi} \in \operatorname{Aut}\left(\mathcal{M}_{0}\right)$ induced by the map from Equation (5.109). We have for every $(s, t) \in \mathbb{H}^{+} \times \mathbb{H}^{-}$,

$$
\begin{equation*}
\operatorname{Bers}(\Phi(s, t))=f_{\Phi}(\operatorname{Bers}(s, t)) \tag{5.115}
\end{equation*}
$$

Theorem 5.3 .9 is not applicable directly as $\mathbb{T}_{1}$ is not compact. However, Minsky showed that the Bers mapping can be extended to almost all the boundary of $\operatorname{Teich}\left(\mathbb{T}_{1}\right) \times \operatorname{Teich}\left(\overline{\mathbb{T}}_{1}\right)$. The boundary of $\mathbb{H}^{+}$is $\mathbf{P}^{1}(\mathbf{R})$. We denote by $\Delta$ the diagonal in $\partial \operatorname{Teich}\left(\mathbb{T}_{1}\right) \times \partial \operatorname{Teich}\left(\overline{\mathbb{T}}_{1}\right)$.

Theorem 5.3.10 ([Min99]). The Bers mapping extend to a continuous bijection

$$
\begin{equation*}
\text { Bers }: \overline{\operatorname{Teich}\left(\mathbb{T}_{1}\right) \times \operatorname{Teich}\left(\overline{\mathbb{T}}_{1}\right)} \backslash \Delta \rightarrow \mathrm{DF}^{+} \tag{5.116}
\end{equation*}
$$

In particular, let $\Phi \in \mathrm{SL}_{2}(\mathbf{Z})=\operatorname{MCG}\left(\mathbb{T}_{1}\right)$ be a loxodromic element and let $f_{\Phi}$ be its associated automorphism over $\mathcal{M}_{0}$. The isometry $\Phi$ has a repulsive fixed point $\alpha(\Phi)$ on $\mathbf{P}^{1}(\mathbf{R})$ and an attractive one $\omega(\Phi)$. By Minsky's theorem, this gives two unique fixed point

$$
\begin{equation*}
p(\Phi)=\operatorname{Bers}((\alpha(\Phi), \omega(\Phi))), \quad q(\Phi)=\operatorname{Bers}((\omega(\Phi), \alpha(\Phi))) \tag{5.117}
\end{equation*}
$$

of $f_{\Phi}$ in $\mathrm{DF}^{+} \backslash \mathrm{QF}^{+}$.

### 5.3.7 Construction of the saddle fixed point $q(f)$

Suppose first that $D=0$. Up to taking an iterate of $f$ we can suppose that there exists a loxodromic element $\Phi_{f} \in \mathrm{SL}_{2}(\mathbf{Z})$ such that $f=f_{\Phi_{f}}$. Denote by $p(f)=p\left(f_{\Phi_{f}}\right)$ and $q(f)=q\left(f_{\Phi_{f}}\right)$ the fixed point constructed using Minsky theorem. These two fixed point are saddle fixed points by [McM96] Corollary 3.19. The fixed point $q(f)$ corresponds to a representation $\rho_{\infty}: F_{2} \rightarrow \operatorname{PSL}_{2}(\mathbf{C})$, one can show that $\rho_{\infty}$ also satisfies Theorem 5.3.9 even though the punctured torus is not compact.

Suppose now that $D=2-2 \cos \frac{2 \pi}{q}$. Following [McM96] §3.7, let $S$ be the orbifold obtained from a genus 1 torus with a singular point of index $q$. The fundamental group of $S$ is

$$
\begin{equation*}
\pi_{1}(S)=\left\langle a, b \mid[a, b]^{q}=1\right\rangle \tag{5.118}
\end{equation*}
$$

The modular class group $\operatorname{Mod}(S)$ of $S$ is also $\mathrm{SL}_{2}(\mathbf{Z})$. Let $\Phi_{f} \in \mathrm{SL}_{2}(\mathbf{Z})$ be an element of $\operatorname{Mod}(S)$ associated to $f$.

There exists a smooth (real) surface $\widetilde{S}$ with a map $\widetilde{S} \rightarrow S$ which is a finite characteristic covering. In particular, $\Phi_{f}$ lifts to $\widetilde{S}$ and defines an element of $\operatorname{Mod}(\widetilde{S})$ that we denote
by $\widetilde{\Phi}_{f}$. Apply Theorem 5.3 .9 to ( $\left.\widetilde{S}, \widetilde{\Phi}_{f}\right)$, there exists a faithful and discrete representation $\widetilde{\rho}_{\infty}: \pi_{1}(\widetilde{S}) \rightarrow \operatorname{PSL}_{2}(\mathbf{C})$. Let $\widetilde{M}_{\infty}=\mathbb{H}^{3} / \widetilde{\rho}_{\infty}\left(\pi_{1}(\widetilde{S})\right)$, the group of isometries of $\widetilde{M}_{\infty}$ contains the subgroup generated by $\widetilde{\Phi}_{f}$. The quotient $\widetilde{M}_{\infty} /<\widetilde{\Phi}_{f}>$ is the mapping torus $M_{\widetilde{\Phi}_{f}}$ of $\widetilde{\Phi}_{f}$ which is a finite cover of the mapping torus $M_{\Phi_{f}}$. By Mostow rigidity theorem, the covering group can be realized by isometries, therefore the hyperbolic structure on $M_{\widetilde{\Phi}_{f}}$ descends to a hyperbolic structure on the mapping torus $M_{\Phi_{f}}$, which yields a fixed point $\rho_{\infty}$ of $f$ in $\mathcal{M}_{D}$ that we denote by $q(f)$. By [McM96] Corollary 3.19, $q(f)$ is a saddle fixed point.

### 5.3.8 Saddle periodic points are in the support of the equilibrium measure

Theorem 5.3.11. Let $f$ be a loxodromic automorphism of the Markov surface. Every periodic saddle point of $f$ is in the support of the measure $\mu_{f}$.

This shows item (1) of Proposition 5.3.5. This theorem, stated in [Can01], follows directly from the work of Dinh and Sibony in [DS13], which extends [BS91b], and an argument of [BLS93] for Hénon type automorphisms of the complex affine plane. We do not provide a detailed proof, our goal in this section is only to describe the type of techniques and arguments used in [BLS93, DS13].

### 5.3.8.1 Green functions and bounded orbits

First, let us summarize some of the properties of the function $G_{f}^{+}: X_{0}(\mathbf{C}) \rightarrow \mathbf{R} \geqslant 0$
(a) $\left\{G_{f}^{+}=0\right\}$ coincides with the set $K^{+}(f)$ of points with a bounded forward orbit;
(b) $G_{f}^{+}$is plurisubharmonic, and is pluriharmonic on the set $\left\{G_{f}^{+}>0\right\}$;
(c) the set $K^{+}(f)$ is closed in $X_{0}(\mathbf{C})$, its closure in $X(\mathbf{C})$ coincides with $K^{+}(f) \cup p_{-}$;
(d) locally, near every point $q \neq p_{-}$of $\partial_{X} X_{0}$,

$$
\begin{equation*}
G_{f}^{+}(x)=-\sum_{i} a_{i} \log \left(\left|s_{i}(x)\right|\right)+u(x) \tag{5.119}
\end{equation*}
$$

where the functions $s_{i}(x)$ are holomorphic equations of the boundary components containing $q$, the real numbers $a_{i} \geqslant 0$ are the weight of $\theta_{X}^{+}$, and $u(x)$ is a continuous (pluriharmonic) function.
(e) there is an open neighborhood $U^{-}$of $p_{-}$in $X(\mathbf{C})$ such that $f^{-1}\left(U^{-}\right) \Subset U^{-}$and $U^{-}$is contained in the basin of attraction of $p_{-}$for the backward dynamics; there is an open neighborhood $U^{+}$of $p_{+}$with similar properties for $f$ instead of $f^{-1}$;
(f) If $q$ is a saddle periodic point, its stable manifold $W^{s}(q)$ is contained in $K^{+}(f)$; in fact, the proof of Proposition 5.1 in [BS91a] shows that $W^{s}(q)$ is contained in the boundary of $K^{+}(f)$;
(g) $f$ does not preserve any algebraic curve $C_{0} \subset X_{0}(\mathbf{C})$.

In particular, if $S$ is a closed positive current supported by $\overline{K(f)}=\overline{K^{+}(f) \cap K^{-}(f)}$, then its support does not intersect the open set $U^{-}$.

### 5.3.8.2 Rigidity of $\overline{K^{+}(f)}$ and equidistribution of stable manifolds

The properties (a) to (g) are sufficient to apply the arguments of Sections 4, 5, 6 of [DS13]. More precisely, one first obtains Theorem 6.6 of [DS13], because its proof relies only on the above properties and general results concerning closed positive currents (in particular Corollary 3.13 of [DS13]). ${ }^{1}$

Then, one gets directly the following fact (which corresponds to a weak version of Theorem 6.5 of [DS13], with the same proof):

Theorem 5.3.12. The set $\overline{K^{+}(f)}$ (resp. $\overline{K^{-}(f)}$ ) supports a unique closed positive current, namely $T_{f}^{+}=d d^{c} G_{f}^{+}$(resp. $T_{f}^{-}$) up to multiplication by a positive constant.

This rigidity results provides automatic equidistribution theorems for $(1,1)$ positive currents. We shall need the following specific application.

If $q$ is a saddle periodic point of $f$, then its stable manifold $W^{s}(q)$ is biholomorphic to the complex line ${ }^{2}$. Denote by $\xi: \mathbf{C} \rightarrow W^{s}(q) \subset X_{0}(\mathbf{C})$ a one to one holomorphic parametrization of $W^{s}(q) ; \xi$ is an entire holomorphic curve. To such a curve, one can associate a family of currents of mass 1, constructed as follows. One fixes a Kähler form $\kappa$ on $X(\mathbf{C})$ and one measures lengths, areas and volumes with respect to this form. For instance, if $\mathbb{D}_{r} \subset \mathbf{C}$ is the disk of

[^4]radius $r$ centered at the origin, then
\[

$$
\begin{equation*}
\operatorname{Area}\left(\xi\left(\mathbb{D}_{r}\right)\right)=\int_{\xi\left(\mathbb{D}_{r}\right)} \kappa=\int_{\mathbb{D}_{r}} \xi^{*} \kappa \tag{5.120}
\end{equation*}
$$

\]

is the area of the image of $\mathbb{D}_{r}$ by $\xi$. Averaging with respect to $d r / r$, one introduces the function

$$
\begin{equation*}
N(R)=\int_{t=0}^{R} \operatorname{Area}\left(\xi\left(\mathbb{D}_{t}\right)\right) \frac{d t}{t} \tag{5.121}
\end{equation*}
$$

Now, for each disk $\mathbb{D}_{r}$, one can consider the current of integration over $\xi\left(\mathbb{D}_{r}\right)$ : to a smooth form $\alpha$ of type $(1,1)$, this current $\left\{\xi\left(\mathbb{D}_{r}\right)\right\}$ associates the number

$$
\begin{equation*}
\left\langle\left\{\xi\left(\mathbb{D}_{r}\right)\right\} \mid \alpha\right\rangle=\int_{\xi\left(\mathbb{D}_{r}\right)} \alpha=\int_{\mathbb{D}_{r}} \xi^{*} \alpha . \tag{5.122}
\end{equation*}
$$

Taking averages with respect to the weight $d r / r$ one obtains the following family of currents, parametrized by a radius $R>0$ :

$$
\begin{align*}
\left\langle N_{\xi}(R) \mid \alpha\right\rangle & =\frac{1}{N(R)} \int_{t=0}^{R}\left\langle\left\{\xi\left(\mathbb{D}_{r}\right)\right\} \mid \alpha\right\rangle \frac{d t}{t}  \tag{5.123}\\
& =\frac{1}{N(R)} \int_{t=0}^{R} \int_{\xi\left(\mathbb{D}_{R}\right)} \alpha \frac{d t}{t} . \tag{5.124}
\end{align*}
$$

The normalization by $1 / N(R)$ assures that the mass $\left\langle N_{\xi}(R) \mid \kappa\right\rangle$ is equal to 1 for every $R>0$. From an inequality of Ahlfors, and from the compactness of the space of positive currents of mass 1, there are sequences of radii $\left(R_{n}\right)$ such that $N_{\xi}\left(R_{n}\right)$ converges to a closed positive current $S$. A priori, such a closed positive current $S$ depends on the choice of the sequence $R_{n}$; if there is a unique closed positive current $S$ that can be obtained as such a limit, one says that there is a unique Ahlfors-Nevanlinna current (namely $S$ ) associated to $\xi$.

Corollary 5.3.13 (Proposition 4.10, Corollary 4.11 [DS13]). Let $q$ be a saddle periodic point of $f$. Let $\xi: \mathbf{C} \rightarrow X_{0}(\mathbf{C})$ be a holomorphic parametrization of the stable manifold of $f$. Then, there is a unique Ahlfors-Nevanlinna current associated to $\xi$, and this current is equal to $T_{f}^{+}$.

Here is another similar consequence of [DS13]: Given any algebraic curve $C_{0} \subset X_{0}$, the sequence of currents $\lambda(f)^{-n}\left\{\left(f^{n}\right)^{*} C_{0}\right\}$ converges towards a positive multiple of $T_{f}^{+}$as $n$ goes to $+\infty$ (see Corollary 6.7 of [DS13]). Thus, $T_{f}^{+}$can be approximated by a sequence of currents of integration on algebraic curves of a fixed genus (properly renormalized); in this context,
one can apply the theory of strongly approximable laminar currents, as developed by Dujardin (see [Can14, Duj04] for an introduction).

### 5.3.8.3 Laminarity, Pesin theory and consequence

The measure $\mu_{f}=T_{f}^{+} \wedge T_{f}^{-}$is an ergodic measure of positive (and maximal) entropy for $f$, and tools from Pesin theory can be used to describe the dynamics of $f$ with respect to this measure. In particular, in our setting, one can apply the work of Bedford, Lyubich, and Smillie in [BLS93] or the work of Dujardin in [Duj04].

First, the laminar structure of $T_{f}^{+}$is compatible with Pesin theory; the second one is that $\mu_{f}$ has a local product structure. Taken together, these facts imply that one can find holomorphic bi-disks $V \simeq \mathbb{D} \times \mathbb{D}$ in $X_{0}(\mathbf{C})$ and transverse laminations $\mathcal{L}^{s}$ and $\mathcal{L}^{u}$ of $V$, the leaves of $\mathcal{L}^{s}$ being horizontal graphs, the leaves of $\mathcal{L}^{u}$ being vertical graphs, such that
(a) it makes sense to restrict $T_{f}^{+}$(resp. $T_{f}^{-}$) to the support $\operatorname{Supp}\left(\mathcal{L}^{s}\right)$ of $\mathcal{L}^{s}$ (resp. on $\operatorname{Supp}\left(\mathcal{L}^{u}\right)$ );
(b) the restriction is given by the current of integration on the leaves of $\mathcal{L}^{s}$ (resp. $\mathcal{L}^{u}$ ) averaged by a transversal measure $\mu_{V}^{+}$(resp. $\mu_{V}^{-}$); in other words, if $\mathcal{L}^{u}(w)$ is a leaf of $\mathcal{L}^{u}, \mu_{V}^{+}$ induces a positive measure on $\operatorname{Supp}\left(\mathcal{L}^{s}\right) \cap \mathcal{L}^{u}(w)$ and if $\alpha$ is a smooth form supported by a compact subset of $V$, then

$$
\left\langle T_{f}^{+} \mid \alpha\right\rangle=\int_{z \in \mathcal{L}^{u}(w)}\left\langle\left\{\mathcal{L}^{s}(z)\right\} \mid \alpha\right\rangle d \mu_{V}^{+}(z) .
$$

(c) in restriction to $\operatorname{Supp}\left(L^{+}\right) \cap \operatorname{Supp}\left(L^{-}\right)$, the measure $\mu_{f}$ is given by the product of the currents, i.e. by the Dirac masses at the points of intersection of the leaves, weighted by $d \mu_{V}^{+} \otimes d \mu_{V}^{+} ;$
(d) for $\mu_{f}$ almost every point $x \in \operatorname{Supp}\left(L^{+}\right) \cap \operatorname{Supp}\left(L^{-}\right)$, the leaf $\mathcal{L}^{s}(x)$ is a piece of stable manifold, and $\mathcal{L}^{u}(x)$ is a piece of unstable manifold.

Then, one can apply the following argument, taken from Section 9 of [BLS93]. Pick a saddle periodic point $q$ of $f$, take a small neighborhood $W$ of $q$, and consider its stable manifold, parametrized by $\xi: \mathbf{C} \rightarrow W^{s}(q)$. Since the Ahlfors-Nevanlinna current of $\xi$ coincides with $T_{f}^{+}$, each disk of $\mathcal{L}^{s}$ is a limit of disks $\xi\left(D_{i}\right)$, for some topological disks $D_{i} \subset \mathbf{C}$. Since the laminations $\mathcal{L}^{u}$ and $\mathcal{L}^{s}$ intersect transversally, one finds a disk $\xi\left(D_{i}\right)$ that intersects $\mathcal{L}^{u}$ transversally. Then, if one applies $f^{N}$ with $N$ large, the preimages of $\xi\left(D_{i}\right) \cap \mathcal{L}^{u}$ approach the point $q$, and
the inclination lemma implies that the images of the leaves of $\mathcal{L}^{u}$ are (very large) disks which, in the neighborhood $W$ of $q$, converge towards $W^{u}(q)$ (in the $C^{1}$ topology). Doing the same with the unstable manifold $W^{u}(q)$ and the dynamics of $f^{-N}$, one pull back $\mathcal{L}^{s}$ near $q$. On the other hand, $T_{f}^{+}$and $T_{f}^{-}$are eigencurrents for $f$. Thus, one sees that $T_{f}^{+}$and $T_{f}^{-}$give mass to two transversal laminations of $W$. And this implies that $\mu_{f}$ gives a positive mass to $W$. Since this work for any neighborhood of $q$, this point is in the support of $\mu_{f}$. Thus, Theorem 5.3 .11 is proven.

### 5.3.9 The sequence $\left(g^{n}(q(f))\right)$ is unbounded

Suppose $D=0$ we can consider $S$ as the flat torus $T=\mathbf{R}^{2} / \mathbf{Z}^{2}$ with a puncture at the origin, i.e. $S=T \backslash\{o\}$, or as a complete hyperbolic surface $X$ of finite area (we fix such a hyperbolic structure, it corresponds to some point $X$ in the Teichmuller space $\operatorname{Teich}(S) \simeq \mathbb{D}$ ).

An element $f$ of $\mathrm{Out}^{+}\left(F_{2}\right)$ is pseudo-Anosov if the corresponding matrix $A_{f} \in \mathrm{SL}_{2}(\mathbf{Z})$ has $\operatorname{Tr}\left(A_{f}\right)^{2} \geqslant 4$. In that case, the matrix has two eigenvalues $\lambda(f)>1$ and $1 / \lambda(f)<1$ and the mapping class is represented by a linear automorphism of the torus $T$ (fixing the origin $o$ ) with stable and unstable linear foliations. In the hyperbolic surface $X$, these foliations give rise to two measured laminations $F_{-}$and $F_{+}$(by geodesic lines). If $C \subset S$ is a closed curve (represented by some geodesic in $X$ ), one can define two intersection numbers $i\left(C, F_{+}\right)$and $i\left(C, F_{-}\right)$; they depend only on the free homotopy class of $C$. The product $j(C)=i\left(C, F_{+}\right) i\left(C, F_{-}\right)$is $f$ invariant, because $f$ stretches $F_{+}$by a dilatation factor $\lambda(f)>1$, and contracts $F_{-}$by $1 / \lambda(f)$; if $C$ is not homotopic to a loop around the puncture $j(C)$ is strictly positive (any closed geodesic is transverse to $F_{+}$and $F_{-}$).

If $D=2-2 \cos (2 \pi / q)$, let $S$ be the genus one torus with an orbifold singularity of order $q$. We have seen that there exists a characteristic finite covering $\widetilde{S} \rightarrow S$ with $\widetilde{S}$ a compact surface of negative Euler characteristic. We let $X=\mathbb{H}^{2} / \Gamma$ be a hyperbolic surface homeomorphic to $\widetilde{S}$ (i.e $X \in \operatorname{Teich}(\widetilde{S})$ ). If $f \in \operatorname{Out}^{+}\left(F_{2}\right)$ is pseudo-Anosov then it lifts to a pseudo-Anosov $\tilde{f} \in \operatorname{Mod}(X)=\operatorname{Out}^{+}\left(F_{2}\right)$ pseudo-Anosov also. In that case, there exist two measured laminations $F_{+}$and $F_{-}$over $\widetilde{S}$ (the stable and the unstable one) and by Proposition 1.5.1 of [Ota96]. We have that for any geodesic $\gamma \in \widetilde{S}$,

$$
\begin{equation*}
\frac{(\tilde{f})^{ \pm i}(\gamma)}{\ell(\tilde{f})^{ \pm i}(\gamma)} \underset{i \rightarrow+\infty}{ } F_{ \pm} \tag{5.125}
\end{equation*}
$$

in the sense of measured laminations. (This also holds in the case $D=0$ ). Here $\ell$ is the length
induced by the hyperbolic structure from the quotient $\mathbb{H}^{2} / \Gamma$ so $\ell(\widetilde{f})_{*}^{ \pm i}(\gamma)$ grows like $\lambda(\widetilde{f})^{i}$. We also have that $j(\gamma)=i\left(\gamma, F_{+}\right) i\left(\gamma, F_{-}\right)$is $f$-invariant as $i\left(\tilde{f}_{*}(\gamma), F_{ \pm}\right)=\lambda(\widetilde{f})^{\mp 1} i\left(\gamma, F_{ \pm}\right)$and if $\gamma$ is a geodesic, then $j(\gamma)>0$. To unify the notations we will still denote by $f$ the lift $\tilde{f}$ of $f$ to $X$.

Lemma 5.3.14. If $f$ and $g$ are two loxodromic elements of $\operatorname{Out}^{+}\left(F_{2}\right) \simeq S L_{2}(\mathbf{Z})$ generating $a$ non-elementary subgroup of $S L_{2}(\mathbf{Z})$, then given any geodesic $\gamma \subset X, j\left(g^{n}(\gamma)\right)$ goes to $+\infty$ as $n$ goes to $+\infty$.

Proof. Let $G_{+}$and $G_{-}$be the unstable and stable laminations associated to $g$ in $X$. Since $f$ and $g$ generate a non-elementary subgroup of $G L_{2}(\mathbf{Z}), G_{+}$is transverse to both $F_{+}$and $F_{-}$(equivalently, the four fixed points of $A_{f}$ and $A_{g}$ on $\mathbf{P}^{1}(\mathbf{R})$ are distinct). Thus, by Equation (5.125) $j\left(g^{n}(C)\right) \simeq \lambda(g)^{n} i\left(G_{+}, F_{+}\right) i\left(G_{-}, F_{-}\right)$by continuity of the intersection number (see [Ota96] p.151).

Lemma 5.3.15. Let $f$ and $g$ be two loxodromic elements of $\operatorname{Out}^{+}\left(F_{2}\right) \simeq S L_{2}(\mathbf{Z})$ generating $a$ non-elementary subgroup of $\operatorname{SL}_{2}(\mathbf{Z})$. Let $\gamma \subset X$ be a geodesic, and let $[\gamma]$ be its free homotopy class. Then the sequence $g^{n}[\gamma]$ intersects each orbit of $f$ only finitely many times.

Proof. This follows from the previous lemma and the fact that $j(\cdot)$ is $f$-invariant so it is constant in each orbit of $f$.

Recall the definition of $M_{\Phi_{f}}, \widetilde{M}_{\Phi_{f}}, \rho_{\infty}$ and $\alpha_{f}$ from Theorem 5.3.9 (here we consider $f \in \operatorname{Mod}(\widetilde{S})$ if we are in the orbifold case). In $M_{\Phi_{f}}$, the number of simple closed geodesics of length $\leqslant L$ is finite (for every $L>0$ ); thus, in $\widetilde{M}_{\Phi_{f}}$, given any upper bound $L$, there are only finitely many homotopy classes of simple closed curves up to the action of $f^{\mathbf{Z}}$ (Note that, since $\alpha_{f}$ acts by isometry, each closed geodesic $C \subset \widetilde{M}_{f}$ gives rise to infinitely many geodesics $\alpha_{f}^{n}(C)$ with the exact same length).

Proof of Proposition 5.3.5 item (2) Fix a generator $a$ in $\pi_{1}(S)$ where $S$ is either the punctured torus or the genus 1 torus with an orbifold singularity of index $q$. Set $k$ to be the degree of the finite cover $\widetilde{S} \rightarrow S$ in the orbifold case and $k=1$ otherwise. The element $a^{k}$ gives rise to a closed geodesic $A$ in $\widetilde{M}_{\Phi_{f}}$. From these preliminaries and the previous lemma, the sequence of homotopy classes $g^{n}\left(a^{k}\right)$ correspond to a sequence of closed geodesics in $\widetilde{M}_{\Phi_{f}}$, with length going to infinity because $f$ acts by isometry on $\widetilde{M}_{\Phi_{f}}$.

Now, $g^{n}\left(a^{k}\right)$ corresponds to a (conjugacy class of a) matrix $\rho_{\infty}\left(g^{n}\left(a^{k}\right)\right) \in S L_{2}(\mathbf{C})$, and the trace of this matrix is related to the length of the geodesic by a simple formula; in particular, the fact that the length goes to infinity implies that the modulus of the trace goes to $+\infty$. Since for
any matrix $A \in \operatorname{SL}_{2}(\mathbf{C}), \operatorname{Tr} A^{k}$ is a polynomial in $\operatorname{Tr} A$ we get that $\operatorname{Tr}\left(\rho_{\infty}\left(g^{n}(a)\right)\right)$ goes to infinity. This implies that the orbit of $q(f)$ under the action of $g$ on $\mathcal{M}_{D}(\mathbf{C})$ is discrete, going to infinity.

Titre : Sur la dynamique des endomorphismes des surfaces affines
Mot clés : Système dynamique, dynamique arithmétique, valuations, géométrie algébrique

Résumé : Une variété affine $X_{0}$ sur un corps algébriquement clos $\mathbf{k}$ est un sousespace de $\mathbf{k}^{N}$ défini par des équations polynomiales. Un endomorphisme polynomial $f$ de $X_{0}$ est alors une transformation polynomiale de $\mathbf{k}^{N}$ qui préserve $X_{0}$ au sens où $f\left(X_{0}\right) \subset X_{0}$. Lorsque la dimension de $X_{0}$ vaut 2 , on dira que $X_{0}$ est une surface affine. Le but de ma thèse est d'étudier le système dynamique donné par $X_{0}$ une surface affine et $f: X_{0} \rightarrow X_{0}$ un endomorphisme polynomial de $X_{0}$. Les différentes questions que j'aborderai sont les suivantes: y'a-t-il des orbites
denses ou Zariski-denses? Si l'orbite d'un point part à l'infini, peut-on contrôler sa vitesse de fuite? Y'a-t-il beaucoup d'orbites périodiques? Comment construire des mesures invariantes qui sont dynamiquement intéressantes? Pour répondre à ces questions, j'utilise des techniques valuatives. Le système dynamique ( $X_{0}, f$ ) induit un système dynamique ( $\mathcal{V}_{\infty}, f_{*}$ ) où $\mathcal{V}_{\infty}$ est l'espace des valuations centrées à l'infini de $X_{0}$. C'est l'étude de cette action qui sera au coeur de ce mémoire et permettra d'aborder ensuite les questions évoquées ci-dessus.

Title: On the dynamics of endomorphisms of affine surfaces
Keywords: Dynamical systems, arithmetic dynamics, valuations, algebraic geometry

#### Abstract

An affine variety $X_{0}$ over an algebraically closed field $\mathbf{k}$ is a subspace of $\mathbf{k}^{N}$ defined by polynomial equations. A polynomial endomorphism of $X_{0}$ is a polynomial transformation of $\mathbf{k}^{N}$ that preservers $X_{0}$ in the sense that $f\left(X_{0}\right) \subset X_{0}$. When the dimension of $X_{0}$ is 2 , we say that $X_{0}$ is an affine surface. The goal of my thesis is to study the dynamical system given by an affine surface $X_{0}$ and $f: X_{0} \rightarrow X_{0}$ a polynomial endomorphism of $X_{0}$. The different questions one can ask are: are there dense orbits or Zariski-dense orbits ? If the orbit of a

point goes to infinity, can we control the speed of divergence ? Is there a lot of periodic orbits ? Can we construct interesting invariant probability measures? To answer these questions, I use valuative techniques. The yynamical system ( $X_{0}, f$ ) induces a dynamical system ( $\mathcal{V}_{\infty}, f_{*}$ ) where $\mathcal{V}_{\infty}$ is the space of valuations centered at infinity of $X_{0}$. The study of this dynamical system is the main goal of this memoir and it will allow to answer the questions mentionned above.

[^0]:    1. Une variété quasi-abélienne est un groupe algébrique $X$ tel qu'il existe un tore algébrique $T$ et une variété abélienne $A$ satisfaisant la suite exacte $0 \rightarrow T \rightarrow X \rightarrow A \rightarrow 0$ de groupes algébriques.
[^1]:    2. Une suite est générique si aucune sous suite n'est contenue dans une sous variété fermée stricte
[^2]:    2. A sequence is generic if no subsequence is contained in strict closed subvariety.
[^3]:    2. isomorphic here means that there exists an order preserving bijection.
[^4]:    1. The only changes in this proof are that (1) $\mathbf{P}^{2}(\mathbf{C})$ should be replaced by $X(\mathbf{C})$ and the line at infinity by $\partial_{X} X_{0}$; and (2) the function $\log \left(1+\|z\|^{2}\right)^{1 / 2}$ should be replaced by a smooth Green function associated to the R-divisor $\theta_{X}^{+}$, as in Definition 5.1.3
    2. Indeed, it is a Riemann surface, it is homeomorphic to $\mathbf{R}^{2}$, and $f$ acts on it as a contraction fixing $q$, so $W^{s}(q)$ cannot be a disk and Riemann uniformization theorem says that it is a copy of $\mathbf{C}$
